The solution to the reference device problem was to change the explanatory reference device. Instead of describing the evolution of organisms relative to natural selection pressures in independent external environments, F. J. Odling-Smee and colleagues (2003) describe evolution relative to the "niches," or organism–environment *interactive* relationships. Because niches are defined by *two-way* interactions between organisms and their environments, this step allowed an "interactionist" theory of evolution to be substituted for the standard externalist account. The niche is a neutral explanatory reference device for evolutionary theory that can capture reciprocal causation without imposing any bias in favor of natural selection and against niche construction, or vice versa.

On the basis of this revised explanatory reference device, all developmental processes that modify the organism–environment relationship are potentially evolutionarily causal. NCT replaces proximate and ultimate causation with "reciprocal causation" and regards the characteristics of organisms as caused by interacting cascades of selection and construction, described elsewhere as "cycles of contingency." From the beginning of life, all organisms have always, in part, modified their selective environments by niche construction, and their ability to do so has always, in part, been a consequence of natural selection.

This recognition of reciprocal causation in evolution also goes a long way toward addressing Lewontin's concerns regarding the misleading metaphors of unfolding developmental programs and the externalism of natural selection. The organism is viewed as both a cause of its own development and a cause of its own selective environment. The key task for any developing organism is the active *regulation* of its inherited "niche," both by responding to its environment and by altering its environment, in ways that keep its personal organism–environment relationship continuously adaptive, for the rest of its life.

Human Cultural Niche Construction and Sociocultural Change

Humans are, of course, one of the species that actively modify their environment; in fact, human beings are the most energetic and wide-ranging species in this respect, continuously affecting their environment through cultural changes that, in turn, modify the selection pressures on their genes. Cultural niche construction refers to evolving sociocultural traits (e.g., dairy farming, cooking, weapons, property rights, discriminate sociality, or educational patterns linked to preferences in family sizes) shaping specific cultural niches that impinge upon the evolution of genetic as well as other cultural traits.

NCT has recently moved into human niche construction that results from cultural (social, economical, etc.) practices that are shown to precipitate the creation of niches. In doing so, NCT has tried to show, both by empirical research and by mathematical modeling, that its theoretical insights and methodological precepts can have an impact on the human and social sciences, from archaeology to sociology. Conversely, support for NCT has very recently come from other quarters, namely the

extended-mind hypothesis and distributed-cognition thesis in the philosophy of mind.

By engaging with the biological role of cultural practices—not themselves biological adaptations—NCT has also corrected and developed further the thesis of gene–culture coevolution. By applying itself to humans, NCT has been able, unlike alternative paradigms like sociobiology, to give to culture (or economic, social, symbolic, etc., practices) its accurate causal role in evolution, explaining correctly how acquired traits can be transmitted. NCT provides a conceptual framework appropriate to the social sciences that is both biologically and culturally based, recognizing the role of human agency whereby humans are, in addition to natural selection, themselves part causes of their own evolution and history. In fact, it has been argued that niche construction as a result of human cultural practices can sometimes be even more effective than gene-based niche construction in directing evolutionary processes and affecting human genes (the human mind, in particular). It is also more rapid. Like biological evolution, cultural processes can be seen as functional solutions to problems posed by the environment, but unlike the former, the latter can be seen to be shortcuts to acquiring adaptive information: This is because human individuals can quickly copy (learn rapidly from) more knowledgeable or experienced others (e.g., when told what to eat or how to avoid danger), "allowing naive individuals to shortcut the many iterations of ontogenetic selection necessary to learn for themselves behavioral patterns appropriate to their environment and thus leapfrog to the functional and already-tested solutions established by others" (Laland, 2011, pp. 196–197). In other words, rapid cultural responses to a culturally modified niche can render genetic reactions redundant.

There are two interesting examples of how NCT may be significant to social-scientific inquiry. One study (Gintis) shows the impact of gene–culture coevolution on the internalization of norms and character virtues and argues that cultural features of the social environment directed the genetic evolution of predispositions, for example, moral cognition. Another study (Shennan) reverses the order of explanation of an important economic phenomenon, wealth inequality, challenging standard social-scientific explanation as well as orthodox evolutionary models.

Finally, one important implication of NCT epistemological proposals is interdisciplinarity: More than one discipline seems to be required since no discipline on its own is adequate to establish cause and effect in cases of gene–culture interaction.

Human Geography, Social Science of

When first confronted with the literature on how geographers construct their world philosophically, the reader is faced with a bewildering set of ostensible alternatives. As a named discipline, geography is an ancient form of intellectual inquiry, predating Greek classicism and its notions of rational thinking. While its Greek meaning—*earth writing*—hints at the importance of geography as a disciplinary practice and its central concern for how humans and earth interact, what is thought of as philosophy in geography has changed radically since the early 20th century, with the last half-century, in particular, resulting in an increasingly conflicted and contradictory set of arguments for how a geographic way of knowing is (and, indeed, should be) constituted and practiced.

Philosophy and Geography

For the most part, philosophy in human geography (or how human geography is thought about) is approached with a keen eye on how people, places, and spaces intersect, interact, and interrelate. Because it is important to capture contemporary geography as an intellectual as well as practiced discipline that is internally differentiated and contested, while at the same time we should understand that knowledge is always partial and practice is often infused with passion, this entry does not attempt to elaborate the entire corpus of knowledge that constitutes contemporary human geographic thought. Rather, it points to what is central from the standpoint of the philosophy of social sciences: the contested and hotly debated nature of diverse ways of knowing within the discipline.

One way of approaching philosophy in human geography is to provide a linear and historical appraisal of how knowledge is built and transformed. There is a commonly accepted narrative of what might be thought of as a patterned sequence to how geographers have come to know the world. In this formulation, the discipline's so-called paradigms—or "isms"—stretch back over time and help define what follows. This way of structuring knowledge is essentially about lumping philosophies into categories that may begin, for example, with environmental determinism in the early 20th century and then flow through possibilism, regionalism, the quantitative revolution, structuralism, realism, humanism, Marxism, feminism, queer geographies, postmodernism, and postcolonialism, to end perhaps with poststructuralist and relational perspectives today.

Earlier Issues and Tendencies

The notion in the early 20th century that the *environment* determines human behavior, resulting in the suggestion that certain peoples and cultures at lower latitudes are enervated by torrid conditions while those in temperate climates rise to become great civilizations, is quickly criticized. This way of thinking was succeeded by the idea that environments are limiting at worst, while many things are possible (i.e., possibilism). In the 1920s, geographers in France and California focused on the importance of *Le Pays*—or the region—as a unifying motif for how we practice living, but this idiographic approach with its focus on the uniqueness of place was challenged by a push for explanation, generalizability, and scientific objectivity as positivism swept through the social sciences from the 1950s onward.

Very quickly, the notion of scientific objectivity was challenged by humanism and feminism, joining a strand of anarchism and Marxism that was present in human geography since the mid 19th century with the work of Peter Kropotkin. By the 1970s, postcolonialism refocused intellectual narratives from the center of colonial power to the so-called geographic margins (former colonial spaces). Humanism, feminism, queer studies, and postcolonialism also contributed to a growing discussion of political identities that changed the focus of the geographical imaginary toward subaltern, psycho-, and corporeal geographies. Poststructuralism in geography pushes the study of the politics of identity and subjectivity

to include the study of representations and representational and nonrepresentational politics.

The "isms" suggest abstract knowledge that is extracted and simplified from a very complex set of interactions between people, places, and intellectual movements. It is common with this kind of delineation for commentators to smooth out and generalize the connections between different philosophical approaches or sensibilities. Too often, the contested nature of the world and our knowledge of it are neglected by supplying a relatively linear set of approaches melding into each other and ending with a particular writer's preferred way of knowing. Readers often fail to grasp the contested nature of the discipline and regard the approaches as "pick-and-mix" alternatives rather than recognizing the tensions between those who adopt different philosophical positions. Tensions often revolve around what a set of philosophies and theories proposes as a basis for geographic knowledge and how practical those philosophies and theories are in delivering that knowledge. Indeed, the debates between the particular (idiographic) and the general (nomothetic) that populated the pages of academic geography in the 1950s return in different forms throughout the last half-century with critiques of metanarratives, arguments between materialist and idealist approaches, local and global perspectives, discussions about the merits of humanistic, poststructural, and relativistic approaches, and so on. Because the context of discussions changes at different times and in different places, the point is not just about what is contested and resolved but that contestation is creatively adopted and used to philosophically propel geographical ways of knowing and understanding.

Current Approaches

Today, human geographers are taking on very interesting philosophical questions of how contestation does not have to necessarily be understood negatively. Instead, drawing on the "immanent" and "affirmative" philosophies of thinkers such as Baruch Spinoza and, more recently, Gilles Deleuze and Antonio Negri and intersecting them with the insights, concerns, and critiques of more traditional intellectual streams in geography—such as feminism, ecology, and Marxism—geographers have begun challenging how staple geographical unifying concepts, such as scale, environment, landscape, time, and place and space, and wider social concepts such as class, race, gender, and politics are approached, thought about, communicated, and consumed. "Immanence" muddies the connections between things internal, external, outside, part of, and beyond while simultaneously mandating connections with the material and corporeal. "Affirmative" philosophies are about disambiguation and creating contexts for positive and constructive practices for people as well as the nonhuman and the more than human. We are deeply embedded in our very particular geographies, and those geographies are variously connected to larger communities and economies to the extent that a complex web of different relations circumscribes our daily embodiments, practices, and politics. Human geography today grapples with some of the pithy philosophical questions that arise from these relations in fluid and uncompromising ways and pays keen attention to how their material and intellectual intersections and entanglements continually affect and produce different people, places, and spaces.

Human–Machine Interaction

Philosophy has always sought to pose the larger questions in life and provide answers. Two of the most important of these questions are (1) What, if anything, differentiates human beings from all other

forms of life? and (2) What does it mean to be human? The latter question has recently been extended to include concerns regarding the distinction between humans and machines, especially when these two interact. These questions are addressed in this entry. Its primary frame of reference is the consideration of humans and their interaction with machines.

Human Beings as Differentiated From All Other Forms of Life

Many differing characteristics have been championed as key elements that differentiate human beings from all other orders of life. In itself, the fact that this question is posed so often indicates how desperately humans have sought to distinguish and divorce themselves from the rest of the animal world. Among the candidates offered are the utilization of language, the capabilities rendered by the opposable thumb, the capacity for an upright gait, and even the form of face-to-face sexual intercourse, which is very rarely practiced outside the human species. Such characteristics are certainly attractive as potential causal explanations, but whether they are, individually or collectively, open to empirical resolution is itself an interesting conundrum. What is offered in this entry is an account founded on the use of advanced forms of tools, specifically machines. As will become evident, we seek also to distinguish "mere" tools from externally powered machine systems.

Evolution is typically associated with Charles Darwin's theory, in which each individual organism adapts to its ambient environment and certain associated and subsequently transmittable advantages are "selected" as a function of experienced, contextually contingent pressures. But what of the process of selection in our contemporary human species? What are the pressures exerted by our environment that currently surrounds us? Most likely, you are reading this tract in book form or via some technological appendage in a designed and "artificial" environment that has been created by human beings who have preceded you. What are the "natural" constraints you are now experiencing? Our answer is that such constraints are now predominantly self-determined. That is, humans have conceived, created, and constructed the main fabric of the modern world in which we live. Thus, although we acknowledge and recognize that there is quite a spectrum of tool use in the animal kingdom and indeed that most living systems look to optimize their own living conditions as far as it is within their control, it is only we humans who occupy a dominantly self-manufactured environment. More formally, specific, species-produced *orthotics,* which then themselves co-adapt, are confined solely to human beings. That co-adaptation occurs at a frequency that is derived from the integration of the respective timescales of change as represented by variation rate in the organism (human) and the orthotic (machine) themselves. Peter A. Hancock and Gabriella Hancock have termed this characteristic *the self-symbiotic species*. This is perhaps *the* dimension that makes human beings unique.

Now one of the great conflicts of the late 19th century can be reconciled. Humans are indeed animals in that they possess the fundamental structure and functions common to all animal life. Thus, Darwin was correct. Yet we are not *only* animals. We have been involved, sui generis, in the creation of a new form of hybrid species in which we are ever more progressively conjoining with the product of our own minds. We are certainly not gods, but we have used what the English mathematician and occultist John Dee (1581) called *thaumaturgike* (he referred to it as a low form of magic) to elevate ourselves beyond any other living system (at least any that is currently known to us).

What It Is and What It Will Be to Be Human

Although we must be careful to distinguish between tools and machines, we can, as a general statement, propose that tools created humans as much as humans created tools. (As Peter Hancock explains, our primary differentiation here is that a machine derives its motive power from a source beyond its immediate user, as compared with a tool, which is directly powered by the individual who wields it.) Furthermore, from a topical examination of brain architecture, we can sequentially conclude that a tool (and its evolutionary offspring, the machine) can be thought of as both a cause and an effect of the imagination. We are *self-symbiotic,* first with tools but now with the machines that we create. In case one doubts this assertion, it is quite possible to induce significant distress in any of our modern

generation simply by parting them from their handheld computational and communication devices for even just one day! But this process of coevolution is far from finished, and indeed one can reasonably argue that it has barely begun. In light of this development, we now have to ask rather difficult philosophical questions such as "What are the boundaries of the human condition?" It is very evident that we cannot abandon our technology and remain the current incarnation of the present species. Yet technological evolution progresses at a dissociatingly fast rate of development compared with intrinsic human change. Thus, our coevolutionary path seems disproportionately driven by profit-driven, technical advances.

Our linkage with our machines is also becoming physically as well as cognitively more intimate. Many people now have in-dwelling medical diagnostic and therapeutic devices. It will not be long before such implants are primarily elective rather than medically obligatory. What will it mean to be human when we are progressively more machine in composition? At this juncture, the questions of science fiction and philosophical contemplation become intimately and indeed alarmingly related. The issues of ownership, privacy, responsibility, and legal culpability are all immediately brought into play when hardware and software physically enter humanware. And with our viral capitalistic structure, the violent shadow of profit is also sure to enter the equation associated with such deliberations. However, we have been instructed that the purpose of philosophy is not simply to study the world but to change it. Thus, we have to conclude here by asking questions not of what is and what may well be but rather what *should* be. Thus, our conclusion is certainly a value judgment, but in such times, statements of value are mandated.

We are in particular danger of associating, attaching, embedding, and enabling an insufficiently capable biological system (the human being) to an ever more powerful and evidently destructive capacity (the ascendingly complex and interrelated systems of global technology). Our media are decorated with the failures that accrue when the fallible human is overwhelmed by the demands of the voracious machine. If human error is an expression of passive malevolence, we also live with the specter of actively malevolent humans let loose with portable and awesomely destructive weapons. How then can we regulate this emerging symbiosis? Can we inculcate morality (e.g., safety) into technology by steps of pure design? It seems evident that we are in a race to establish the next state of punctuated equilibrium in this symbiotic evolution before we destroy the very fabric of the environment that sustains us. Some observers find reason to believe that we shall fail in this endeavor.

Human–Machine Interaction: Approaches

Approaches for research (and the theories that drive such science) should therefore understand this unique relationship between humans and the technology they use, so that future design efforts and training methods foster more effective human–machine interaction (HMI) rather than promote discord. To this end, research in this domain has been often multidisciplinary in nature; most commonly, a two-pronged approach combining both behavioral and computer science. Design and industrial engineering provide insight into the mechanical perspective of the human–machine dyad, while cognitive psychology and ergonomics attempt to explain and predict the physical and psychological reactions and performance of the human operator. Human factors psychologists (i.e., those working in the multidisciplinary Human Factors Science or ergonomics), however, merge each of these respective disciplines to work on the HMI as its own complete system, investigating its effectiveness, usability, interface structure, and the like.

Current Trends

Some of the major areas of interest in HMI today are augmented reality, individuation/customization, and embodied cognitive agents. Augmented reality research looks to create an interface whereby the human is able to perceive an environment with overlaid information that would normally be available to the senses. For example, in the Google Glasses project a person wears a set of transparent glasses to successfully interact with the world in front of her; projected onto the glasses themselves, however, is information about the person's surroundings (i.e., a GPS screen provides her with directions on where to walk, pop-ups alert her that there is a coffee shop near her current location, etc.). But, to come

to the second major area mentioned above, all such technologies are rapidly becoming more attuned to the individual and less designed for inflexible mass consumption. In particular, with the overwhelming number of personal devices now available, users are able to choose a number of personalized settings: backgrounds, schemes, ringtones, covers, and so on. Moreover, some devices have been programmed to respond only to the sound of an authorized user's voice. We anticipate that such individual customization or individuation will burgeon greatly in the near future.

Other contemporary thrusts have featured embodied cognitive agents through which some machines are now able to reciprocate individuated types of communication. An embodied cognitive agent is a machine or program displaying a limited amount of artificial intelligence (AI), which is anthropomorphized to an extent so as to give the human user a sense of social interaction with the technology. For example, Siri is an application for the iPhone that works as an intelligent personal assistant; "she" is able to vocalize and talk with the user, ensuring that "her" findings are indeed what the user wanted.

Major Players: Past and Present

Throughout the 20th century, scientists from a number of disciplines contributed significantly to the theories and research underlying HMI. For example, Alphonse Chapanis of Johns Hopkins University is generally considered the father of this area, in particular ergonomics, at least in the United States. Another early luminary was Paul M. Fitts Jr., whose most preeminent contributions concern his law of motor performance and his study of piloting error. As one of the founding fathers of aviation psychology, he was also interested in maximizing the efficiency of human movement necessary to interface with machine (airplane) controls. In respect to decision making as related to HMI, Herbert Simon, educated at the University of Chicago and a Nobel Prize winner in economics, made a significant contribution to HMI research with his work on AI. His work with Allen Newell on the Logic Theory Machine and the General Problem Solver helped further the capabilities of machines to perform more complex, decision-making tasks. Donald Norman, a graduate of MIT and the University of Pennsylvania, has advanced HMI research with his concept of "user-centered design," which dictates that engineers and designers primarily focus on designing a machine based on the human user's needs rather than on convenient engineering or aesthetics. Last, Ivan Sutherland (who was educated at CalTech and MIT) was one of the pioneering scientists at the forefront of the development of the graphical user interface. His invention, Sketchpad, was the prototype for software on which most modern-day personal computer systems are now based. Sutherland was also one of the computer scientists who contributed to the development of the Internet, arguably the invention that has most radically altered HMI since the advent of technology.

Hypothetico-Deductivism

Hypothetico-deductivism (H-D) is an account of the confirmation or testing of (scientific) theories, typically by empirical (observational) evidence. Some philosophers, most notably Karl Popper, have offered H-D as an alternative to inductive accounts of confirmation. H-D's core claim is that a theory or a hypothesis is confirmed or tested by testing its deductive observational consequences. Arguably, it is the version of confirmation that is still most prevalent among working scientists. However, attempts to provide a rigorous formulation of H-D have led to a series of technical problems that have led most leading philosophers of science to reject H-D. Recently, it has been argued that these formal problems are not fatal but that H-D suffers serious philosophical shortcomings, namely, that it does not sufficiently account for inductive support and does not provide an account of the confirmation of statistical theories. This suggests that H-D can at best give a partial account of confirmation.

The Formal Accounts of H-D

Although H-D has been attributed to the 19th-century scientist and philosopher of science William Whewell, this attribution, and especially the related attribution to Whewell of a wholesale rejection of induction, is questionable. Rather, it is with 20th-century writers such as Ernest Nagel, Karl Popper, and Carl Hempel, coming after the development of modern logic, that the distinction between H-D and induction and the attempt to formulate formal accounts of H-D come into sharp focus.

At its simplest, H-D is the claim that (observational) evidence E confirms hypothesis H if and only if H logically entails E. A key objection to this simple version is that many hypotheses deal with unobservable entities and hence have no direct bearing on observation. Consider, for instance, the claim that all electrons are negatively charged. Rather, such hypotheses when supplemented with various background auxiliary assumptions and statements of initial conditions entail observational consequences. This leads to more complicated versions of H-D: For instance, evidence E confirms hypothesis H relative to background information B if the conjunction of H and B entails E, but B alone does not entail E. This needed complication brings additional worries of its own. It may be argued that knowing that some H is confirmed relative to some B by observational evidence E does not tell us if H has itself been confirmed. Some critics want an account of how we get from relative confirmation to simple confirmation, their worry presumably being that for any hypotheses H there will always be some observational evidence E that will confirm H relative to some totally crazy and/or ad hoc background assumption B. Others, pressing what has come to be known as holistic accounts of confirmation, have questioned thus: If it is B and H that together entail E, why should we take the confirmation to accrue to H rather than to B? Alternatively, why not simply say that E confirms the combination of H and B? Analogously, some have raised similar questions about disconfirmation: Where H and B together entail E, but we find that E is false, why should we say that it is H rather than B—or, alternatively, the combination of H and B—that has been disconfirmed?

For the time being, we can put aside these questions and concentrate on the simplest version of H-D so as to appreciate the formal problems that have led philosophers of science to reject H-D.

Two Formal Problems

Rather than survey all the formal problems, we shall briefly consider the two main ones.

Tacking by Conjunction

If H entails E, then for arbitrary H′ the conjunction of H′ and H entails E. So if deductive entailment is sufficient for confirmation, then where E confirms H it also confirms the conjunction of H and arbitrary H′. So finding that the first planet of the solar system travels in an elliptical orbit around the sun confirms not simply that all the planets of the solar system travel in elliptical orbits around the sun but also the conjunctive hypothesis that all the planets of the solar system travel in elliptical orbits around the sun and all the planets of the solar system are made of rubber.

Tacking by Disjunction

If hypothesis H entails E and E′ is some arbitrary true observational claim that has nothing to do with H, then H entails the true observational claim E or E′.

So for any hypothesis H there will always be some true observational claim that confirms H. Thus, "All the planets of the solar system are made of rubber" is confirmed by the true observation claim "The first planet of the solar system is made of rubber, or the first planet of the solar system travels in an elliptical orbit around the sun."

Recently, it has been argued that these and other formal problems may be avoided by recasting H-D in terms of natural axiomatizations of theories. The idea is that a theory has certain canonical (natural) representations, and only those axioms of a canonical representation that are needed in the derivation of E are confirmed by E. So where H entails E, it is true that the conjunction of H and H′ also entails E, but only H is needed in the derivation of E, so only H is confirmed by E. That disposes of the tacking-by-conjunction objection.

To get rid of the tacking-by-disjunction objection, we can demand that for hypothetico-deductive confirmation the relevant E should not simply be a logical consequence of the relevant H but should be part of its content. The idea here is to say that while "All the planets of the solar system are made of rubber" logically entails both "The first planet of the solar system is made of rubber" and "The first planet of the solar system is made of rubber, or the first planet of the solar system travels in an elliptical orbit around the sun," only the former counts as part of the content of "All the planets of the solar system are made of rubber." Thus, we might claim that E only hypothetico-deductively confirms axiom H of a theory if E is part of the content of H.

Philosophical Problems

Leaving aside these formal problems, there are a number of deep philosophical problems that suggest that even if there is something to H-D it should not be presented as providing a necessary condition for confirmation.

The first philosophical problem is that canonical formulations of H-D do not allow for inductive support. Consider that of the two claims "All the planets of the solar system travel in elliptical orbits around the sun" and "The seventh planet of the solar system travels in elliptical orbits around the sun," only the former entails "The first six planets of the solar system travel in elliptical orbits around the sun." So where H-D provides *necessary* and sufficient conditions for confirmation, it has the consequence that the true claim "The first six planets of the solar system travel in elliptical orbits around the sun" confirms "All the planets of the solar system travel in elliptical orbits around the sun" but does not confirm "The seventh planet of the solar system travels in elliptical orbits around the sun." In other words, H-D taken as providing necessary and sufficient conditions for confirmation actually precludes inductive support. While Popper may have taken this as a virtue of H-D, most would take the view that if confirmation of a theory gives no reason to think that the theory will work in the next case, then we have little reason for caring whether or not our theories are confirmed.

The second major philosophical problem is that a statistical hypothesis, for instance, that the probability of a birth in England being of a male child is 50% or that the half-life of radon isotope 222 is 3.8 days, has no *deductive* observational consequences, and hence, if H-D is correct, there is no observational evidence that can confirm the hypothesis.

In light of these objections, H-D should be recast as giving only sufficient and not necessary conditions for confirmation. This would allow that H-D could be combined with a Hempelian transmission condition, such as "If E confirms H and H′ is part of the content of H, then E confirms H′." This would allow for inductive confirmation.

Bayesian Confirmation

To allow for confirmation of probabilistic hypotheses, one might relax the required relationship between E and H. Thus, instead of demanding that H entail E, we might simply demand that H make E more likely. So while "The half-life of radon isotope 222 is 3.8 days" does not logically entail that "Any large ensemble of radon isotope 222 will show radioactive decay when measured with a Geiger counter," it does make that claim highly likely. Put in terms of probability theory, the condition that H makes E more likely amounts to the requirement that $P(E/H) > (E)$; in other words, the probability of E given H is higher than the probability of E by itself. Bayesians, following the lead of Carnap, have long claimed that E confirms H if and only if $P(H/E) > P(H)$. What has often gone unrecognized is that that claim is equivalent to the claim that E confirms H if and only if $P(E/H) > (E)$, and hence, Bayesian

confirmation is simply a weakening of the core demand for confirmation laid done by H-D.

It is tempting, and now very common among philosophers of science, to conclude that H-D should be simply abandoned in favor of Bayesian accounts of confirmation. This suggestion itself meets with both formal and philosophical objections. One formal objection is that Bayesianism in its current forms is actually subject to both the tacking objections mentioned above that have been promoted against H-D. The main philosophical objection is that Bayesian accounts rely on the arguably suspect notion of prior probabilities. Given a coin, before any observations, I may have a prior probability of its coming up heads on a given throw of .5. But what is my prior probability, separate from any observation or, for that matter, separate from any theoretical knowledge, for the claim that the first planet of the solar system has an elliptical orbit?

Conclusion

Because of its failure to account for the confirmation of probabilistic hypotheses, H-D, even when supplemented with a Hempelian transmission condition allowing for inductive support, cannot be taken as the whole account of confirmation. However, it should be recognized as giving a sufficient account of confirmation, one not encumbered by fanciful assumptions about wholesale distributions of prior probabilities. Moreover, it should be recognized that it is in practice the way most scientists actually seek to confirm their theories. That is to say, scientists will recognize as good practice the process of (a) giving clear, nonarbitrary formulations of their theories; (b) teasing out observational consequences from those theory formulations; (c) checking those consequences for truth; and (d) raising their confidence in the truth of the parts of the theory involved in teasing out those observational consequences if those observational consequences are in fact borne out.

IDEALISM

The concept of *idealism* has a long and complex history. The first half of this entry traces the outline of this history. The second half of the entry focuses on idealism in the social sciences.

Definition

Idealism is a family of philosophical theories according to which ultimate reality is ideal and transcendent or a function of consciousness or reason. Idealism is also the view that human beings should strive to live under the influence of self-chosen ideals. Finally, idealism can be a view of historical change as being the result of mainly ideas, plans, visions, or interpretations. In general, idealists tend to emphasize activity and freedom while being opposed to materialism and determinism. Many idealists are therefore interested in human subjectivity and its status. In discussions of art, idealists valorize creativity and imagination over faithful copying of nature (or realism).

History of Idealism

Ontological Idealism

The word *idealism* is derived from the Greek words *idea* (ἰδέα) and *eidos* (εἶδος), which appear as early as in the works of Homer. The term *eidos/idea* (a derivative of the verb *to see* or *to look*) can mean "image," "shape," "look," "kind," or "species." In Plato, who is the first to employ this term for philosophical purposes, "idea" designates the unchanging, transcendent, and supersensible forms of things—a world of pure essences in relation to which the sensible world is ontologically inferior and no more than a reflection or imitation.

In dialogues such as *Phaedo, Phaedrus,* and *Politeia*, Plato arrives at this view, which by focusing on what constitutes reality as such can be called ontological idealism, from many different directions. In order to tell that a thing is of a certain nature, it is necessary to know something that cannot be derived from contemplating the particular thing itself. In order to know that *this* is a horse, one must have knowledge of what being a horse is, for otherwise one would not be able to identify *this* as a horse. One must know something about what all horses in the world have in common—the conditions under which something may be said to be a horse. Once one arrives at the thought that these conditions cannot be arbitrary and changing and destructible (since, if all horses disappeared, what it is to be a horse must not be possible to touch), then the conclusion at hand is that every way a thing might be must be determined by essences that exist beyond the empirical world, in a world of perfection that will never change.

In Plato and in the Platonic tradition, idealism is the view that reality is supersensible, composed of essences or immaterial (and hence indestructible) forms that human beings can only cognize through thinking, in particular the kind of reflective thinking that Plato calls dialectics. As Platonism started to influence Christianity via Plotinus, Augustine,

Origen, and others, idealism became a crucial component in the attempt to distinguish between good and evil, which was often associated with the distinction between the transcendent and the immanent or between intelligible form and sensible matter. In many Neo-Platonist schools (and already in Plato), idealism also involved distinguishing sharply between the immaterial soul and the material body and thinking that the world is essentially One, a world soul, chained to matter but capable of liberating itself to its original source in pure light, *nous,* or the Good. In Plotinus, in particular, idealism formed the basis of a type of mysticism that called for the fusion of the human soul with the One or the absolute. Thus, idealism was sharply opposed to all views, Epicureanism in particular, that emphasized the material dimension of existence and argued for its ontological priority.

Epistemological Idealism

In the 17th and 18th centuries, with the rise of empiricism and a renewed interest in questions of epistemology, the term *idealism* attained new meanings. Idealism could now mean, as in Bishop Berkeley, that only mental content is real, or it could, as in David Hume, take a more skeptical form and imply that, whereas one must conjecture that a mind-independent reality exists, humans can only be aware of their (internal) impressions and ideas. With Berkeley's *esse est percipi,* the world becomes identical with the thought or representation we have of it. With Hume's skepticism, on the other hand, we can never know with certainty that our representations match any mind-independent reality. The best we can do is to continue acting as though they do. Idealism, if taken to its extreme in Berkeley, may offer a complete ontology and even a new, anti-materialistic worldview. In Hume, however, it threatens to enclose the perceiving and thinking subject inside the circle of its own representations. Idealism, on these views, is contrasted with realism, the belief (ontologically) that mind-independent entities exist and (epistemologically) that we can know them.

Later, Immanuel Kant's transcendental idealism aims to overcome Hume's skepticism while at the same time avoiding Berkeley's equation of mental content with reality. According to Kant, we need to distinguish between the order of things as they exist independently of any possible human cognition and the order of things as they exist for human beings endowed with certain objectivating capacities. We can know whichever entities can be presented to us in accordance with the necessary and universal conditions for representing them. According to Kant, such conditions are space and time as well as certain functions of unity in judgment called categories. The fact that we cannot know things as they are in themselves (qua "*noumena*") but only as they appear to us (qua "*phenomena*") via our schemata is not tantamount to a disastrous epistemological defeat. On the contrary, since it would make no sense to claim to know anything outside of the conditions whereby it can be known, we have reason to be perfectly satisfied with knowledge of appearances. On Kant's view, objective knowledge arises as the result of the correct interplay between conceptual structuring capacities and the constraining impact the world exerts on our senses.

Absolute Idealism

In subsequent phases of German Idealism and, in particular, G. W. F. Hegel's absolute idealism, the Kantian distinction between the order of appearances and the order of things in themselves is vigorously attacked. According to Hegel, it makes no sense to postulate the existence of anything outside the conceptual understanding we already possess. Rather, such understanding is an element of spirit (*Geist*), which for Hegel is a totality without any outside. In Hegel's system, spirit's conceptual self-understanding, including the self-alienation and self-appropriation of spirit, forms the basis for conceiving of human life and history as partaking in a rational structure that develops teleologically. Thus, history itself becomes the unfolding of spirit—the long and arduous process whereby spirit comes to know itself in full freedom.

On a traditional interpretation of Hegel, spirit is God, and everything belongs to and becomes intelligible in light of God's own presence and development in the world. On more recent interpretations, however, spirit is essentially communal, a collective form of self-reflection expressed in art, religion, and philosophy and embodied in the institutions of the modern state. While different in most respects, both interpretations take Hegel's absolute idealism to entail that human history develops along rational lines and that the categories determining the logic of

this development as well as the shape of the modern state can be reconstructed in a speculative philosophy of right. Thus, as Hegel puts it in the preface to the *Elements of the Philosophy of Right,* "What is rational is actual; and what is actual is rational." Idealism in Hegel's account affirms the status quo. It demonstrates that whatever exists is rational, thereby making it possible to reconcile oneself to reality.

In the first half of the 19th century, idealism takes many forms, ranging from Hegel's pan-rationalism to F. W. J. Schelling's system of absolute identity and Arthur Schopenhauer's philosophy of the will. In all of these systems, the material world is ontologically downgraded and seen either as an expression of the absolute (Hegel, Schelling) or as an illusion (Schopenhauer).

In the latter half of the 19th century, the rise to cultural prominence of natural and social science conspired with secularization and modernization to undermine the credibility of absolute idealism. Karl Marx's critique of Hegel is a case in point. According to Marx, Hegel wrongly sought to derive the structure of the modern state from the pure categories of dialectical philosophy. On Marx's view, a materialist account, which refers to the actual social relations between agents in a particular social formation with its specific mode of production, is better able to understand the nature of the modern state than any a priori reconstruction. Rather than Hegel's theoretical approach, which considers social life from the vantage point of the philosophical system, one needs to take into consideration the ways in which agents actively and collectively engage with social reality—what Marx called *praxis*.

British Idealism

Reacting to a long-standing British tradition of empiricism, in the second half of the 19th century and well into the early decades of the 20th, philosophers such as T. H. Green (1836–1882), F. H. Bradley (1846–1924), B. Bosanquet (1848–1923), J. M. E. McTaggart (1866–1925), and H. H. Joachim (1868–1938) developed a species of absolute idealism that has come to be known as British idealism. Thinkers associated with this movement viewed the notion that philosophy should concentrate on the epistemological question of how the mind is able to represent a mind-independent reality as a recipe for skepticism. In the interest of developing a nonskeptical understanding of reality, they rejected the subject–object duality and formulated a *coherence theory of truth* according to which truth arises from a coherent system of beliefs rather than some relation between belief and external reality.

Ultimately, the British idealists believed in the ontological primacy of a self-organizing, self-sufficient sphere of absolute or ideal being. Drawing on Hegel (yet without his peculiar form of dialectical logic), on their account the highest task of reason consisted in conceptually articulating what they thought of as the structure of the absolute.

In contributions to social philosophy and ethics, the British idealists typically emphasized collectivity and social unity over individualism and social atomism. While far from espousing reactionary forms of authoritarianism, they criticized liberalism and tended to lament what they saw as the fragmentation of modern society.

While dominant for some decades and a rare example of the extended Continental influence on British philosophy, mainly at Oxford, British idealism was vehemently attacked and discarded by the subsequent generation of logical positivists and linguistically oriented philosophers. The rise of analytic philosophy dealt a death blow to British idealism (despite some unsuccessful rearguard battles fought by Collingwood and later on by the Hegelian G. R. G. Mure). In the hands of thinkers like Bertrand Russell and G. E. Moore, the British idealists had to be left behind for a new and purportedly more rigorous philosophy to emerge. Since the late 1930s, British idealism has had little impact on contemporary philosophy. Recently, there is some renewed, if somewhat isolated, interest in their thought on metaphysics but quite a burgeoning research activity as far as their political philosophy is concerned.

Idealism in the 20th Century

Idealism continued to play an important role in 20th-century philosophy. In Edmund Husserl's transcendental phenomenology, the immediate givenness of intentional (mental) content is appealed to in order to explore the essential features of reality. Since what we can call real must be possible to present for consciousness, it can be studied from within the immanence of what Husserl calls "pure consciousness"—that is, content as it presents itself

for consciousness without any reference to actual existence.

Phenomenology explores the meaning of the phenomenon as it presents itself to consciousness. In the hands of Martin Heidegger, Jean-Paul Sartre, and many other prominent theorists, it becomes a powerful and nonreductive approach to the study of both subjective and intersubjective phenomena. A crucial part of the attraction of phenomenology is its apparent ability to refute relativism and ground science in an account of rationality.

Much of 20th-century philosophy has rejected the idea that human beings have unmediated access to an objective reality. In phenomenology, and also in pragmatism, poststructuralism, hermeneutics, critical theory, and much of post-Wittgensteinian philosophy of language, the fundamental claim has been that knowledge and understanding are mediated by essentially public structures like language, practices, horizons of pregiven meaning, or ideology. Similarly, in analytic philosophy, so-called anti-realists have held that truth must be a function of warranted assertibility. As opposed to realists, who argue that meaningful propositions have an objective truth-value independently of any possible verification or justification, anti-realists claim that what we can call truth must always be possible to justify. Truth is therefore relative to our actual language-games. Although not everyone has concluded from considerations such as these that knowledge or understanding is therefore restricted, or that it cannot attain objectivity, the emphasis on mediation means that idealism has played a major role in recent philosophical endeavors.

Idealism in Aesthetics

There are several reasons why the term *idealism* has been important in thinking about art. In classicism, and also in rationalism, a beautiful work of art instantiates certain ideal or formal properties that the theoretician seeks to disclose. The successful work of art thus strives to approximate an idea of formal perfection.

Another strain of idealist aesthetics, influenced by Plato, emphasizes transcendence. The successful work of art intimates the eternal ideas existing behind phenomena. The work of art does this either by presenting these ideas directly or by alluding to them. In both cases, aesthetic experience is supposed to lift the beholder out of everyday empirical existence. In the most Platonic accounts, such experiences are supposed to liberate the soul from enslavement in the body.

A third strain of idealist aesthetics, often but not necessarily associated with Romanticism, points to expressive freedom, creativity, originality, and imagination as sources of art. As opposed to realist views of art, which explore the senses in which a work of art can be said to be *about* something, such theories view art as affirming an account of the human subject as free and autonomous. Art becomes a privileged vehicle for manifesting freedom. In Kant's theory of genius, the Romantics found reason to celebrate the artist as an exceptional being, sometimes exempt from bourgeois conventions and everyday morality.

Idealism in the Social Sciences

Idealism in the social sciences is generally the view that ideas and self-interpretations can play an explanatory role when accounting for social phenomena and change. Opposed to this view is materialism, which for explanatory purposes emphasizes the economy, power, material structure, or psychological hardwiring. Max Weber's study of the rise of capitalism is a good example of an idealist approach to social explanation. According to Weber in *The Protestant Ethic and the Spirit of Capitalism,* Calvinism, with its deeply felt need to prove oneself worthy of salvation in the eyes of God, created a mind-set focused on investment and frugality. Although other factors had to be in place, capitalism was largely the result of the implementation of this mind-set. Weber's argument entails that what agents think, feel, and say about themselves influence and often cause their actions. Indeed, radical social change, such as the rise of capitalism, may come about as the direct result of agents having certain beliefs and desires; thus, what people believe and desire can be enormously consequential. Weber bolsters this view by developing a theory of intentional action. Actions, Weber argues, are the result of intentions; their aim is to actualize the specific purposes sought by the agent.

Other idealist accounts of social life include those of Peter Winch and certain versions of discourse analysis. According to Winch, who was deeply influenced by the later Wittgenstein, social behavior is essentially rule governed. To act is to follow a rule that is shared among all members of a particular

community or life form. Discourse analysis, by contrast, is based on the view that people's actions, identities, and self-interpretation are constituted via discourse. Following structuralism, which can also be said to represent an idealist orientation, discourse analysts, like the contemporary social theorist Ernesto Laclau, argue that discourse is structured around an underlying set of oppositions and something is what it is only through its differential relations to something else.

The most obvious objection to idealisms of these sorts is that they underestimate the causal and explanatory power of events and occurrences in the materially existing world and that they are blind to power, class, and other factors external to the self-understanding of agents. As Marx famously summarizes this objection in *The German Ideology,* "It is not consciousness that determines life, but life that determines consciousness."

Idealism is not only juxtaposed to materialism. In debates in political science, one sometimes hears of idealist versus realist approaches to international relations. While realist approaches see power as the underlying factor in understanding how nations come to set and implement national and international priorities and think of international politics as an essentially anarchistic realm of struggle for security and power, idealists see the existence of a self-contained world of laws and rules as essential. The idea behind idealism is that successful relations between nations do not rest exclusively on a balance of power but on the explicit rejection of force grounded in self-enforced rules of behavior. Idealism in this regard is often associated with the political views of Kant, who argued that relations between states should ideally be governed by laws reflecting the general will of all states. Realism, by contrast, tends to be associated with Hobbes, who in the *Leviathan* argued that, rather than legitimacy grounded in law, the fundamental task of all political arrangements is stability, the provision of order and security.

Idealism, Personhood, and the Good

An idealist is sometimes characterized as a person who acts on the basis of ideals—that is, on some conception of the good. Unlike realists, who tend to be pessimistic or stoically detached, idealists in this sense are *optimistic,* believing that their goals will be achieved or at least that it is worth striving to achieve them even when the outcome of doing so is uncertain. The idealist can have this faith because he or she thinks that being committed to certain ideals is good independently of what their actualization may lead to. Idealism in this sense is related to a vision of moral personhood according to which our identity, our sense of selfhood, is a function of the kinds of commitments we make and the clarity and seriousness with which they are articulated. To know who one is requires to be oriented in moral space, a space in which questions can arise about what matters and what is good.

Idealism in the sense of actively committing oneself to ideals also plays a role in thinking about the formation of social policy and about politics in general. While the idealist will tend to seek social change in the form of reform or revolution, and therefore be progressive, the realist will tend toward more conservative policies. As in most idealisms (with the exception of the metaphysical idealism we find in Plato), the dignity of the human subject consists in its freedom.

Idealization in Social-Scientific Theories

Since the 17th-century scientific revolution, the role of theory in science has been the principal preoccupation of philosophy of science. The naive realist view, defended by some sophisticated realists, is that the central function of scientific theory is to explain, by reference to hidden unobservable mechanisms, the observable events of the real world. Idealizations within theory range from the use of abstraction to drastic simplifications of the subject matter being studied. Particularly with the rise of logical positivism, the realist view of theory was challenged by focusing on the role of idealization in scientific theory.

In this entry, the role of idealizations in the philosophy of the social sciences in general and the philosophy of economics in particular is examined.

Idealization and the Philosophy of Science

In Newtonian mechanics, for example, one represents physical bodies as point masses, even though it is self-evident that in reality the three-dimensional mass of a body is not located in a geometrical point. Since a premise known to be false cannot be used in any acceptable explanation, clearly scientific theories with idealizations known to be false fail to explain. An alternative account to that of naive realism is thereby required. This is furnished by instrumentalism. Instrumentalists, by focusing on the actual use of theories with idealizations, reject the realist notion of explanatory power. For instrumentalists, the realist question of the truth or falsehood of a theory is of no concern because a theory is basically a heuristic instrument or device for discovering more information about the world. Just as physical instruments/tools, such as a hammer, have specific, limited uses, a successful theory is a conceptual device used for the limited purpose of predicting or discovering new facts in a systematic way. Also, just as some physical instruments become obsolete and are replaced by more efficient ones, some theories become obsolete as heuristic-predictive instruments and are replaced by more efficient ones. Finally, just as physical instruments tell us little or nothing about the objects that result from their use, neither do scientific theories tell us anything about the observable world.

Idealization, Social Theorizing, and Economics

In the social sciences, neoclassical economics is frequently identified as the exemplar of successful theorizing. Within the domain of economics, especially for those committed to orthodox economics, there is no comparable successful rival: Neoclassical economics dominates the theoretical field. However, as the American economist Milton Friedman emphasized in the 1950s, neoclassical theory is akin to Newtonian mechanics, with its own specific range of idealizations. The idealizations embedded, for instance, in the notion of homo economicus—rational economic man—are evident in its assumptions, such as perfect foresight. Since these assumptions are patently false, any naive realist reading of neoclassical theory as a genuine explanation is without justification. What is required is an instrumentalist approach to the success of neoclassical economics. The criterion of success of neoclassical economic theory does not lie in the realism (truth or falsehood) of its assumptions; rather, it lies in whether or not neoclassical theory delivers correct predictions. According to Friedman, in this respect, neoclassical theory is eminently successful.

Friedman, however, gives a specific twist to this standard instrumentalist defense of the idealizations of neoclassical economics. This twist is related to the issue of the survival of firms in the marketplace. He maintains that, just as a billiard player will not survive in a billiard competition unless he behaves *as if* he were calculating his shots using the principles of Newtonian mechanics—which clearly he is not—a firm will not survive in the marketplace unless it behaves *as if* it were acting according to the principles of neoclassical theory—that is, profit maximization. Friedman's *as if* defense has been a major source of debate among both economists and philosophers of economics. The Cambridge

economist Frank Hahn rejects Friedmanite idealizations. For Hahn, Friedman's *as if* defense might be plausible if economic predictions attained the same level of success as quantum physics. Compared with quantum physics, however, neoclassical predictions are not impressive. Thus Hahn, contrary to Friedman and many others, insists that economics is *not* a predictive science á la physics. Rather, the aim of neoclassical theory is to gain an objective understanding of highly complex economic systems. To achieve this, one must avoid ambiguity, subjectivity, and vagueness, and hence the theoretical economist has recourse to logic and mathematics. This in turn means that idealizations based on the grounds of mathematical tractability are indispensable to economic theorizing. However, Friedmanite idealizations based on patent falsehoods are not acceptable because they hinder the fulfillment of the central task of gaining an objective understanding of an economy. A Hahn-like understanding, moreover, is quite different from hermeneutical approaches to understanding in the human sciences, emphasized in continental philosophy from Hans-Georg Gadamer to Paul Ricoeur.

Friedman's intriguing 1953 piece, "The Methodology of Positive Economics," remains a *locus classicus* for contemporary debates on idealizations in economics. Critical realists, like Tony Lawson, criticize Friedmanite idealizations because such assumptions hinder the discovery of the hidden generative mechanisms operating in real economies. On the other hand, realists, like Uskali Mäki, reconstruct scientific realism as minimal scientific realism and argue that in the end Friedman is a realist. Other equally interesting approaches have been developed. Alan Nelson, by recourse to a Cartesian model of idealization, as distinct from the standard idealization of physics, illuminates idealizations in economic theorizing.

Nelson attempts to retrieve a concept of idealization that he attributes to René Descartes, the 17th-century philosopher, mathematician, and scientist, which he terms *Cartesian idealization*. Descartes's ideas on idealization have received little attention, a neglect that is unwarranted for Nelson. He argues that Descartes's contribution on this topic could prove illuminating for economics, and by extension perhaps for social science in general. Cartesian idealization is embedded in a mechanistic view of science, whose laws are derived from fundamental metaphysical principles and are known to be true of the world, given their deduction from divinely underwritten innate ideas of God and matter. These ideal laws, which in a later terminology would be described as *a priori,* are true but for a variety of reasons as advanced by Descartes may be quite inadequate in providing accurate predictions of the behavior of physical objects. This was not a source of concern for Descartes, however, since he was satisfied that the provision of a possible mechanistic account based on unassailable metaphysical principles sufficed. In Nelson's interpretation of Descartes's conception of idealization, the Cartesian laws are true, even if seriously defective in providing accurate predictions, but they do provide schematic qualitative accounts of the mechanisms that may underlie the phenomena under study, which are not inconsistent with the ideal laws.

The task of understanding economics through Cartesian idealization is, for Nelson, neither disingenuous nor as outlandish as it might seem on first acquaintance. In fact, Nelson finds in the writings of Lionel Robbins, the distinguished economics methodologist, a position not incompatible with Nelson's own interpretation of Cartesian idealization. Robbins's methodological doctrine maintained that economics was a deductive system, based on a set of assumptions that are so integral to everyday experience that, once stated, they are deemed self-evidently obvious. If these assumptions relate to reality, as Robbins accepted they did, then the deductions had a similar point of reference in reality. However, in economics, there are acute problems arising from whether the deductions from the assumptions refer to reality, given the abysmal performance of economics in quantitative prediction. This particular concern has been at the center of a major methodological debate that dominated a large part of the 20th century. Milton Friedman reoriented this question by insisting that predictive accuracy was the central task of economic theory, as we saw above, and that the theory, complete with its set of assumptions, that produced the best set of predictions was the best theory; and its assumptions were then retrospectively or instrumentally justified, regardless of whether they were "realistic" or not, where "realistic" has the connotation of empirical accuracy. Consequently, economists committed to Friedman's instrumentalism and invoking standard idealization, as interpreted by Nelson, would argue

that the assumptions of economic theory are false, while those advocating Cartesian idealization, as interpreted by Nelson, would require the assumptions of economic theory to be true even if neither realistic nor empirically accurate. Nelson provides an interesting contrast between the concepts of standard idealization, derived from physics and adhered to by numerous economists, and Cartesian idealization, which provides an alternative view of idealization that arguably requires more reflection than it has received to date.

Rationality and the Social Sciences

Homo economicus of neoclassical economics is an idealized account of rationality in the pursuit of wealth. This idealization has been increasingly extended to the other sociohistorical sciences. According to Popperians, the aim of the social sciences is to understand/explain social events, and to this end, social scientists construct models. These models are idealizations in the sense that a model reconstructs the actual situation in terms of a *typical* social situation. These idealized models on their own, however, are not sufficient to explain social events: Recourse to the rationality principle is also required. In this connection, Popperians use the homo economicus idealization as a benchmark against which the rationality of a human action is measured. This homo economicus idealization subsists in Karl Popper's autonomous, quasi-Platonistic World 3. In this Popperian approach, the homo economicus model is not part of the description of social actions. Rather, it is the prescriptive benchmark for deciding the rationality, the degree of rationality, or the irrationality of actual actions. Thus, homo economicus becomes the logic of rational choice.

According to other philosophers, however, it is very evident that the idealized model of homo economicus does not apply across the broad range of human interactions. Rather, as Philip Pettit suggests, people's actions are culturally framed in a vast network connecting their commitments to ideals, fair play, friendship, honesty, integrity, kindness, membership of certain groups, politeness, and so on. Rationality in this extensive and thick cultural setting is very far from the model of the self-interested homo economicus. Pettit, however, argues that the acknowledgment of the cultural framing of rationality does not imply the rejection of the homo economicus model. He proposes a conciliationist thesis in which both are reconcilable. Clearly, while the principles of homo economicus are not actually present in culturally framed decisions and choices, they are virtually present—they hover on the edge of realization. This virtual presence becomes evident when an agent's decisions made in his or her cultural frame are liable to cost him or her dearly in self-regarding terms. In such situations, the alarm bells of homo economicus begin to ring, and the agent begins to calculate à la homo economicus.

Clearly, idealizations in both economics and the other sociohistorical sciences raise intriguing methodological and philosophical issues and debates, which continue to exercise philosophers of the social sciences.

Identity, Personal (Philosophy of)

The entry explains what the philosophical problem of personal identity is, presents the main solutions offered as well as some recent developments, and highlights the relation between philosophy and the social sciences with respect to this problem.

The philosophical problem of *personal identity* is most commonly understood as a special case of a more general metaphysical puzzle about the persistence of complex objects. The general puzzle is expressed in the famous case of the Ship of Theseus, whose planks are replaced one by one over several years until the ship that remains has no wood in common with the original. The question is *whether a single object persists throughout these changes* and, if so, in virtue of what it remains selfsame despite the replacement of all of its parts. The problem of personal identity applies this question to persons. Persons too change drastically over time, and philosophers of personal identity seek a systematic account of the kinds of vicissitudes they can and cannot survive.

The standard philosophical question of personal identity is thus different from the question of personal identity as it is construed in most other contexts. Often, worries about identity involve questions about someone's fundamental psychological or social makeup rather than what makes her a single persisting entity. An adolescent trying to find her identity, for instance, is not uncertain about which individual object she is but about what she truly believes and desires. There are, however, important points of contact between the two questions, and understanding this overlap leads to many fruitful interactions between philosophy and the social sciences.

Psychological Continuity

One powerful strand of thought in the philosophy of personal identity, found, for instance, in the work of Derek Parfit, John Perry, Sydney Shoemaker, and David Lewis, is the view that personal identity over time should be defined in terms of *psychological continuity.* This approach is an updated version of John Locke's claim that the identity of persons resides in "sameness of consciousness" rather than sameness of substance. To defend this view, Locke asks us to imagine the consciousness of a prince entering the body of a cobbler and replacing the cobbler's own. The result is someone with the cobbler's physical appearance but with the memories, intentions, beliefs, and desires of the prince. Clearly, Locke says, this individual is the prince and not the cobbler, which shows that the *person* goes where the psychological life goes. Present-day psychological theorists take up and develop this general insight, broadening Locke's notion of sameness of consciousness into a more general notion of psychological continuity and defending the suggestion that it can define the literal persistence of persons. This approach does not claim that the metaphysical identity question raised by philosophers is the same as the more common psycho/social identity question, but it does see the two as importantly related.

A central task for psychological theorists is to provide a viable understanding of what is involved in identity-constituting psychological continuity. One element usually taken to be an important part of such continuity is *memory.* Locke is typically taken to hold that what makes a person at one time a person at an earlier time is that the later person has an autobiographical memory of an experience of the earlier person's experiences. There are several difficulties with this position as stated, and some question about why only memory should count as an identity-constituting connection, but psychological continuity theorists generally agree that memory is an important part of what constitutes personal identity. To understand this claim and make it plausible, it is necessary to explore a variety of questions about the nature of memory—what kinds of memory there are, how different sorts of memory connect to our sense of self and psychological functioning, what it means for a memory to be accurate, and the extent to which memory is possible without other kinds of psychological continuity being in place. All these questions require close attention to empirical work.

Some psychological theorists suggest that the best way to think about identity-constituting psychological continuity is in terms of a *self-narrative*. The distinctive psychological lives of persons, these theorists argue, take the form of a narrative, and it is because we have narrative self-understanding that we are able to have the kinds of experiences and take the kinds of actions that make us persons. The unity of an individual person, on this view, is the unity of a *life-narrative*.

The narrative conception of persons has also been an object of investigation in psychology, for instance, in the work of Jerome Bruner, Ulrich Neisser, and Katherine Nelson. Nelson's work emphasizes the development of narrative self-understanding in children and its connection to the emergence of the peculiar kind of self-consciousness humans possess. This kind of self-awareness is very like the consciousness in terms of which Locke defines personhood and personal identity, and a more complete understanding of its origins and structures is invaluable in defining the kind of narrative unity that potentially constitutes the metaphysical unity of persons.

The Role of Social Context

Another central set of issues in the philosophy of personal identity involves the question as to what extent and in what ways social environments and interactions can play a role in constituting the metaphysical identity of a person. Some philosophers hold that relational properties can in no way define the true identity of any entity, since the entity must first exist as a well-defined whole before it can stand in a relation to anything else. Others, however, insist that a person as subject and agent can exist only in a social context within which she or he relates to and distinguishes herself or himself from others. In exploring this question, the burgeoning and wide-ranging body of empirical work on the ways in which social embeddedness scaffolds cognitive development and affects self-understanding and self-consciousness offers important insights. It is only with a detailed picture of the various ways in which social relations affect our inner lives that we are in a position to assess whether these might be constitutive of metaphysical identity.

Unity of Consciousness

Finally, there are questions about whether the unity of consciousness in terms of which Lockeans define the unity of a person is a real phenomenon. Philosophers like Daniel Dennett have used findings from psychology to argue that the unified subject is an illusion and should be considered a useful fiction rather than a metaphysical fact in need of explanation.

Philosophy and Social Science

Philosophers of personal identity seek to answer a metaphysical question about the persistence of an object. Many wish to couch this answer in social or psychological terms, and this means appreciating and respecting empirical findings from the social sciences. At the same time, philosophical distinctions among different kinds of identity questions and their connections to one another provide a framework that is helpful in interpreting empirical results and understanding their broader significance. Philosophy and the social sciences thus have a great deal to offer one another in exploring these issues.

Identity, Social

According to identity theory, identities define who a person is in terms of the groups or categories to which they belong (*social identities*), the roles they occupy (*role identities*), and the personal characteristics they claim (*person identities*). For example,

an individual's social identity as an American or a Hispanic is what it *means* to him or her to be an American or a Hispanic, an individual's role identity as a truck driver or a student is what it *means* to that individual to be a truck driver or a student, and an individual's person identity as a dominant person or a moral person is what it *means* to that individual to be dominant or moral. The focus on *meaning* comes from identity theory's origins in *symbolic interactionism*.

"Social," "person," and "role" are three different bases for identities, though each functions in the same way. This entry will discuss these identity bases in turn after having first outlined the identity components and the so-called identity verification process whereby identities are maintained and protected in social contexts. Such a verification process is further explained, and its pivotal role in building these identity bases in social contexts is stressed.

Introduction

The *meanings* of identities are derived from the culture that is shared among persons so that the understanding of the meanings is shared and communicated. People act to create and maintain meanings in interaction with others that identify and reflect who they are. They do this through their words, actions, dress, and appearance. Truck drivers act and dress like truck drivers. They have and maintain the tools, equipment, licenses, skills, and language that are necessary to be truck drivers. In this way, they identify themselves as truck drivers, and others can identify them as truck drivers and interact appropriately with them, whether those others are other truck drivers, dispatchers, truck-stop personnel, or loaders. In addition to *displaying* their identities, people also *protect* and *maintain* their identities (this is the "identity verification process") when the meanings in the situation are changed by circumstances or by others verifying their own identities.

Identity Components

To understand the identity-verification process, let us begin with an outline of the component parts of an identity, which are the same for role, person, and social identities.

The first part is the *identity standard,* which is the set of meanings defining the identity. These are the meanings that the person displays and maintains while in the identity. Second are the meanings of the *output* or *behaviors* enacted in the situation. In identity theory, it is not the behavior as such that matters but how that behavior is interpreted—what it means. People act to reproduce in the situation the meanings held in the identity standard. The third part is the *perceptual input* of identity-relevant meanings from the situation. People perceive how they are coming across to others, either directly (direct appraisals) or indirectly through what are called *reflected appraisals*. Reflected appraisals are what each person thinks others think of him or her. For example, if I act in such a way as to make myself understood as a dominant person but the reaction of others indicates that they think I am meek (i.e., I think they see me as meek—the reflected appraisal), then I am not getting my message across, and I will act in an even more dominant manner.

The fourth part is the *comparator,* which functions to compare the perceived meanings with the identity standard meanings. This comparison is a simple difference. When the difference is zero, the person perceives that the meanings she is portraying in the situation match those held in her identity standard. When they match, her identity is being verified. Others see her the way she sees herself. According to identity theory, people control their perceptions of identity-relevant meanings to have them match the meanings in their identity standard. They allow their behavior to vary in order to keep the perceived meanings constant, matching the identity standard that defines them.

Verification Process

In identity theory, people are motivated to verify their identities—to make sure the meanings in the situation reflect the meanings held in the identity standard. One could view this as a goal, to make the situational meanings match the identity standard meanings. This is true for all identity bases: social identities based on group or category memberships, role identities based on the roles one occupies, and person identities that make one a unique individual. When verification does not occur for any of these identities, when the reflected appraisals do not match the identity standard, there are several outcomes. First, there is a negative emotional response to nonverification. The strength of the negative emotion is a function of the squared amount of difference between the reflected appraisal meanings and the identity standard meanings. When a person has a certain level of dominance as an important meaning

in their person identity standard, she becomes upset if others see her either as more dominant or as less dominant than defined in the identity standard.

At the same time a person is feeling an emotional response, she also begins to act in ways that change the displayed meanings in the interaction situation. The behavior is a function of the plain (not squared) difference between the reflected appraisal meanings and the identity standard meanings. If a person is seen, for example, as less dominant than the identity standard, that person will increase the dominance meanings in her behavior. The person may act gruffer, more abrupt, more commanding, more forceful, or some combination of these or other behaviors that convey the appropriate meanings to impress upon others who she is. By perceiving others' reactions that convey impressions, the reflected appraisals come to match the identity standard. Similarly, if the person is seen as aggressive and authoritarian, that impression is more dominant than what is defined in the identity standard, and the person will act in ways that convey less dominance until the reflected appraisals are brought into agreement with the identity standard.

In addition to the immediate emotional response and the adjusted behavior to achieve identity verification, there is a longer-term consequence of maintaining or not maintaining verification over time. This longer-term effect influences the self-esteem of the person. A person who continues to have difficulty verifying an identity, especially an important identity, will lose self-esteem. Being able to achieve verification of important identities over time will increase feelings of self-esteem. In this way, self-esteem is earned or lost by one's achievements with respect to identity verification. Self-esteem cannot be given to a person; rather it is earned by a person in his own mind by his own successes or failures at verification. Identity theory sees self-esteem as made up of three parts or bases: self-worth or feeling of value, self-efficacy or feeling competent and able to accomplish things, and authenticity or feeling that you can be your true self.

Identity Bases

There are three different bases for the identities that persons have. *Social* identities are based on group or category membership, *role* identities are based on the roles a person occupies within a group or organization, and *person* identities denote the meanings each person claims as defining and describing him- or herself as a distinct person. While identities from each basis have the same component parts and each operates in the same manner for verification, they differ in the nature of the meanings they contain and the consequences of verification or nonverification.

Social Identities

The meanings in a social identity define a person to be *similar to* others in their group or category and to be *different from* persons in other contrasting groups or categories. All the persons in a fraternity, for example, define themselves in terms of upholding the principles of the fraternity and being different from other fraternities, perhaps emphasizing academics over sports. By verifying this social identity, persons help maintain the principles and distinctions of the fraternity, and they maintain the distinctions and separations from other fraternities. By being like others, they are accepted by others in the fraternity for who they are; they belong and their self-worth, one of the bases of self-esteem, is maintained or enhanced.

Role Identities

The meanings in a role identity do not make persons like others with whom they interact (as in the case of social identities), but they make them *complementary* to role partners, that is, persons occupying counter-roles. The role of a student is complementary to the counter-role of a professor. The role of a daughter is complementary to that of the mother. The role of fraternity president is complementary to the counter-roles of the other officers in the fraternity. Verifying a role identity means carrying out the expectations and standards of the role, and this in turn allows the occupants of counter-roles to carry out their duties and obligations—that is, verify their role identities. Verification of a role identity is an accomplishment, and as a consequence, it leads to an increase or maintenance of feelings of self-efficacy or competence, the second basis of self-esteem.

Person Identities

The meanings in a person identity are those that make that person a *unique* individual. These meanings, like dominance or sincerity or morality, are always with the person, in all situations, in all groups, and in all roles. In that way, these meanings

are very central or core to the person, and verification of these meanings allows the person to be who he or she is truly as an individual. Verification of a person identity leads to an increase or maintenance of feelings of authenticity, the third basis of self-esteem.

Mutual Verification

Because identity verification takes effort to maintain meanings in the face of disturbances or events in the situation that change meanings away from the identity standard, it is advantageous to interact with others who, in being themselves, allow us to be ourselves. When husbands and wives, for example, verify their partner's identity in the process of verifying their own identity, we have a situation of mutual verification; they are supporting each other's identity meanings. Mutual verification has been found to raise the self-esteem of the partners, increase their love and trust, and strengthen their bonds as a couple or group. They become a "we" rather than two "I"s. Mutual nonverification, on the other hand, has been found to lead to separation and divorce.

Identity and Society

Because society is made up of groups and organizations with their roles and divisions of labor, as well as categories of persons who may or may not be granted access to these groups, roles, and organizations, it is clear that identity verification by maintaining the categories, groups, roles, and organizations also maintains society. This is the link between individuals and society. Individuals hold identities that link them to positions in society (roles and groups) that are defined by the shared culture. Because these identities are self-defining, they are enacted and protected. It is who we are. But by enacting and protecting identities, people enact the roles, maintain the groups, and keep the divisions and separations between social categories. It is clearly a circular process. Societies and cultures define the roles, groups, and categories. Individuals take these roles, groups, categories, and organizations on as identities and reproduce the meanings that define themselves, their roles, their groups, and their organizations, that is, their society. In the process, they feel good and gain self-esteem.

However, this is not always possible. Sometimes (perhaps often) people have trouble verifying their identities because others who are more powerful maintain meanings in situations that do not fit their identity standard. This, of course, leads to negative emotions and, over time, an erosion in self-esteem. Conflict can arise as people compete for particular meanings in the interaction that fit with their identities. People may leave situations and others who do not verify their identities, they may abandon identities that are not verified, and identities may change over time so that they fit the meanings being provided by more powerful persons. Indeed, according to identity theory, all of these things happen. Identity theory also tells us some of the conditions under which these happen, alone or in combination.

IDEOLOGY

Ideology is one of the—if not *the*—most complex concepts in the social sciences. It is what has been called an "essentially contested" concept; that is, one whose definition (and therefore application) is a subject of acute and unavoidable controversy.

This is not surprising since the concept of ideology deals with the bases, if any, of our most fundamental values. This entry gives an account of the origins of the term, goes on to introduce the main Marxist conception of ideology, and concludes with an account of recent and current developments.

Origins

The term *ideology,* unlike many other similarly controversial terms, such as *democracy* or *liberty,* is relatively new. It was coined in the immediate aftermath of the French Revolution by the French philosopher Destutt de Tracy (member of the "Société des idéologues") in his *Elements d'Ideologie,* written between the years 1801 and 1815. Here, he proposed a new *science of ideas* and *idealogy,* which would be the ground of all other sciences. Rejecting the concept of innate ideas, de Tracy explained how all our ideas are based on physical sensations (and hence ideology is a branch of zoology). A rational investigation of the origin of these ideas, free from religious or metaphysical prejudice, would be the foundation of a just and happy society. For the investigation of individual ideas would show their common origin in universal needs and desires. These needs would form the framework of laws regulating society on a natural basis and promoting the harmonious fulfillment of the relevant desires. For the natural and the social worlds coincided. And this coincidence would be laid bare by the rational assessment of the origin of ideas, by ideology. Clearly, here the notion of ideology was positive and progressive (vide Napoleon Bonaparte's reaction to it).

In the German tradition, by contrast, the Romantic movement laid emphasis on the way we invest the world with our own meanings. Unlike de Tracy, for whom the natural and the social worlds were pellucid to the rational mind, the German romantics considered that human beings collectively and individually created their own reality in response to changing circumstances. For the German Idealist philosopher G. W. F. Hegel, who tried to give these ideas a systematic intellectual basis, the ideas of a particular age (*Zeitgeist*) could not claim absolute validity in themselves for they were evidently relative to changing historical situations. If there *were* a rationality, a meaning to history, it would have to be found in the whole process rather than in the partial aims of particular individuals and epochs.

Marx and His Followers

These Hegelian ideas strongly influenced Karl Marx, and it was Marxism, mixing both the French and the German trends, that put the concept of ideology in the forefront of political discourse. Marx himself did not (most of the time) think that all ideas were ideology and did not wish simply to produce a more dynamic version of de Tracy's science of ideas. For him, it was their connection with the class struggle and its social and economic basis that gave certain ideas their ideological force. Society was in fact driven by conflicts of interest, but for it not to fall apart, these oppositions were *covered up* by ideas that represented attempts to portray society as cohesive rather than conflictual by justifying the asymmetrical distribution of social and economic power (i.e., an "ideological distortion"). Hence, Marx's famous statement that "the ideas of the ruling class are in every epoch the ruling ideas," since those who controlled economic production and distribution could also regulate the production and distribution of ideas. In his late writings, Marx added a further dimension. Here, ideology still served, as in the earlier conception, to conceal and invert real relationships between people. But in addition, Marx now concentrated on the way in which ideology was produced by the form in which people related together in the ordinary everyday transactions of capitalist society. There was also less emphasis on illusion, since ideology was seen here as reflecting something real, if decidedly partial, and also as being itself a real force.

During the first half of the 20th century, particularly under the influence of Marx's close collaborator, Friedrich Engels, the positivist tradition of de Tracy, with its attempt at an objective science of society, was prominent. Lenin was happy to talk of "socialist ideology," with no pejorative connotation. Perhaps the subtlest Marxist thinker was the Italian Antonio Gramsci, who drew a close parallel between ideology and his concept of *hegemony,* which he inherited from Lenin and Lukacs. For Gramsci, the worldview of the ruling class was so thoroughly diffused by its intellectuals as to become the "common sense" of the whole of society, the "structure of feeling" in which it lived. This conception was Gramsci's answer to the puzzle of how capitalism had managed to survive in the bourgeois democracies of the West.

Outside the Marxist tradition, Marx's two fellow-founders of sociology, Max Weber and Émile Durkheim, produced discussions about the genesis

and validity of ideas that contributed substantially to subsequent treatments of ideology—Weber as the inspirer of much of the later empirical investigation in the Anglo-Saxon world and Durkheim as the forerunner of structuralist analyses. But it was the German sociologist Karl Mannheim who produced a comprehensive theory of ideology that is still a reference point for today's discussions. Mannheim, in his 1929 book *Ideology and Utopia,* evolved a sociology of knowledge that investigated, through description and structural analysis, the ways in which social relationships influence thought. Avoiding relativism, Mannheim attached a privileged role to intellectuals due to their constituting a relatively classless stratum that was not too firmly situated in the social order.

The End of Ideology?

In the last half of the 20th century, discussion has been dominated by the "end of ideology" thesis. This positivist and restrictive definition of ideology, combined with a discussion of ideology that, itself, claimed not to be ideological, flourished mainly in the United States. This reflected the predominance of behavioralism in postwar American political science and the stress on ordinary language and linguistic analysis in British philosophy. Its main proponents were Seymour Martin Lipset, in his influential 1960 book *Political Man,* and Daniel Bell, whose *End of Ideology,* published the same year, claimed that ideology, which was once a road to action, has become a dead end. Their approach was supported by Hannah Arendt's *Origins of Totalitarianism,* which saw all ideological thinking as suffused with totalitarian elements.

More recently, some have seen postmodernism as a recycling of the end-of-ideology thesis: Critical and mockingly destructive, it rejects even broad and tentative attempts to establish foundations for our thought, foundations that are swept away in a spiral of endless metaphor. An accessible form of this approach is found in the work of the contemporary American philosopher Richard Rorty, whose playful and "ironic" liberalism (as he called it) springs from a postmodernism that expresses the continental tradition of Friedrich Nietzsche and Martin Heidegger through an analytical Anglo-Saxon pragmatism. The most well-known proponent of the end of ideology, and indeed of history itself, is Francis Fukuyama, whose book *The End of History and the Last Man* elaborated many of its themes.

The beginning of the 21st century, however, has shown these views to be premature. The resurgence of religion and the challenges provided by environmental change show that ideology, under almost any of its manifold definitions, is with us for a good time to come. And it is difficult to avoid the useful conclusion that all views about ideology are themselves in some sense ideological. But if we are indeed all implicated in ideologies that are both real and powerful, an understanding of this fact can at least prevent us from becoming their unconscious victims.

Implicit Bias and Social Cognition

Recent decades have seen large advances in the understanding of social cognition. One set of unsettling findings is about what have come to be called *implicit biases,* unconscious negative evaluative tendencies about individuals based on their membership in a social group. The existence and character of implicit biases raise a variety of interesting

issues for different areas of philosophy, including many relevant to the social sciences. Getting into a position to address those issues requires becoming familiar with implicit biases themselves, the sorts of tools psychologists have developed to investigate them, and some of their more noteworthy features. This entry addresses the aforementioned issues first. The final section briefly describes some of the initial implications of implicit biases that have been drawn for philosophy and the social sciences.

Useful Distinctions

Implicit biases may not fit easily with an intuitive picture of the mind, so social psychologists have made a number of clarifying distinctions to characterize them. A mental state or process is *automatic* if it is typically outside a person's conscious control and can influence a person's behavior and judgment without deliberation, attention, or effort. Many, though not all, automatic mental states or processes are also *implicit*; they are outside the person's conscious awareness. To study automatic and implicit mental states, social psychologists have developed a number of sophisticated experimental techniques, often called indirect measures. Much of what is known about implicit biases has been inferred from people's performance on tasks that use such techniques. The measures are said to be *indirect* in that they do not directly rely on subjects' powers of introspection or self-report and are able to avoid the problems associated with both. In these tasks, people who harbor implicit biases show a slight but consistent negative evaluation of members of whatever social group they are implicitly biased against, relative to members of other social groups. For instance, those with implicit biases against the elderly will be more likely to show a slight preference for young and middle-aged people, those with implicit biases against women will show a preference for men, those with implicit biases against Blacks will show a preference for Whites or Latinos, and so on. Implicit biases directed toward social groups defined along a number of dimensions have been found, including race, gender, sexual orientation, age, weight, and religion. Details about implicit biases (the social groups they are directed at, their strength, and even their presence) can vary from person to person as well as from culture to culture (though little cross-cultural research has been done).

Features of Implicit Social Cognition

One consistent and striking finding of this research is that within a single person, implicit biases against a particular social group are distinct from, and can coexist with, consciously endorsed attitudes to the contrary. For example, when directly asked, a person might sincerely state about herself that she is not racist and holds tolerant, egalitarian views toward all races, thus expressing her *explicit* attitudes. Nevertheless, indirect testing can reveal that she also harbors *implicit* biases against members of certain races. Indeed, research has shown that it is possible to harbor implicit biases against social groups that one is a member of oneself—that is, one's own race, gender, and so on.

Initial studies into development suggest that though implicit biases are not easy to uproot, they are fairly easy to acquire. Certain types, implicit racial biases, appear to be widespread, at least in the United States. The influence of implicit biases on behavior, especially behavior in the real world, outside controlled laboratory experiments, is difficult to measure with precision, but mounting evidence indicates that implicit biases toward a particular social group can subtly shape a person's evaluations of and interactions with members of the social group to which they apply.

Another area of research explores the ways in which implicit biases might be managed or controlled. For instance, once a person becomes aware that she harbors implicit biases toward a certain social group, she might make an effort to explicitly suppress the expression of those biases, in both judgment and behavior. This has been shown to work to some extent but requires vigilance, is mentally fatiguing, and can backfire in a number of ways. Other forms of self-control not based on suppression, such as making an active attempt to see others as individuals rather than as members of a category or social group, appear to fare better. Moreover, taking less direct steps, such as exposing oneself to positive images of, or having positive interactions with, members of the social group in question, has also been shown to lessen the influence of implicit biases.

Philosophical Issues

Philosophers have just begun to take note of implicit biases and to examine their implications. The work of those who have can be divided into two broad groups. First, those interested in the epistemology

and conceptual foundations of the social sciences, especially those who think that many of the central concepts (races, genders, classes, etc.) pick out kinds that are *socially constructed,* have begun exploring how features of social cognition affect the construction and stability of those concepts and kinds. They have emphasized how full explanations of the sorts of regularities studied by social scientists can incorporate, and sometimes may require, appeal to features of individual psychologies, including elements of social cognition like implicit biases.

Second, those interested in social justice have seen implicit biases as relevant to a number of issues. Some have attempted to understand how they contribute to social inequalities like persistent gender and racial disparities, emphasizing that the moral problems raised by such cases are intertwined with the epistemic burdens imposed by the implicit biases involved. Philosophers are also beginning to investigate how social and legal institutions might best take implicit biases into account and assign responsibility for individual behaviors and institutional outcomes that are influenced by them. Another preliminary line of inquiry has attempted to evaluate various proposals for social reform in light of what is known about social cognition and implicit biases.

In sum, research on implicit biases, into the psychology of the biases themselves, their influence on the behavior of institutions, and their implications for understanding groups and population-level social dynamics, is barely out of its infancy; there remains much fertile and exciting territory to explore.

Individualism, Methodological

Methodological individualism is a principle, or rule, for the analysis of social phenomena, which says that they should invariably be understood and explained in terms of individual human beings: their motives, actions, interaction, and situation. At least, this is the main version of this much-debated doctrine. As this entry will show, methodological individualism is not one but many, and its various versions are united by family resemblance rather than by the invariable common features found in all versions. What they do share in common is a focus on individuals. They all assign pride of place to individuals in their approach to society.

Methodological individualism originates with the Austrian School of Economics at the end of the 19th century. The height of the debate about it was in the middle of the 20th century, when the philosopher Karl Popper and his followers made it a central part of their methodology.

Methodological individualism was advanced very much against its opposite: *methodological holism,* or *collectivism,* which says that social phenomena should be understood and explained in terms of social wholes and/or collectives, such as social structures and social institutions.

Among the social sciences, economics is, by far, the most and anthropology probably the least individualistic in the methodological sense of the term. Political science and sociology fall somewhere in between. The main reason for this is that methodological individualism is part of rational choice theorizing, which is the approach of mainstream economics. The prevalence of methodological individualism in the other social sciences is largely a function of the extent to which they use rational choice.

Methodological Individualism *Avant la Lettre*

Methodological individualism was used long before it was explicitly stated. Already in Greek antiquity, we find it in the theories of society suggested by the Sophists and by Epicurus. This is the archetype of methodological individualism, and it reappeared in the modern theory of the social contract, which dominated thinking about society from the Renaissance to the 18th century. Most well-known are the theories of Thomas Hobbes and John Locke. The former, in particular, is recognized as the prototypical methodological individualist *avant la lettre*. He explained social institutions as the intended results of the actions of rational and self-interested individuals in a state of nature.

A second paradigm of methodological individualism appeared with the rise of economics. Adam Smith analyzed market phenomena as the unintended consequences of the actions of individuals, and this analysis eventually developed into the theory of general equilibrium. The aim of this theory is to do away with all social institutions and relations in models of the market. According to its founder, the French mathematical economist Léon Walras, pure economics is a natural science of things, recognizing only isolated individuals and impersonal prices.

Of the classical economists, only John Stuart Mill was much interested in methodology, and his methodology was individualistic. In *A System of Logic* (1843), he argued that all social laws are based on psychological laws of the mind. Only psychological laws are causal. Social laws, therefore, can and should be reduced to psychological laws. This methodological individualist view was adopted by neoclassical economics, in the form of a belief that macroeconomics should be provided with microfoundations.

Austrian Methodological Individualism

As an explicitly stated principle of social analysis, methodological individualism probably goes back to the Austrian economist Carl Menger (*Problems of Economics and Sociology,* 1883). He suggested that complex phenomena should be reduced to their simplest element, the actions of individual human beings, and called it "the atomistic method." Complex social phenomena were analyzed, by Menger, as the unintended consequences of the actions of individuals. The term *methodological individualism* was coined by the eminent economist and political scientist Joseph Schumpeter, who used it to make a distinction between methodological and political individualism.

Max Weber brought methodological individualism from economics to sociology. According to him, sociology too should use a strictly individualist method and treat the single individual as its basic unit, or atom. Weber's individualism follows from his interpretive sociology, which takes its point of departure in the interpretive understanding of social action. Understanding is achieved when we know the subjective meaning individuals attach to their actions. This includes an understanding of their motives, which are the immediate causes of their actions and the ultimate causes of all social phenomena.

Weber's interpretive sociology exerted a strong influence on the Austrian economist Ludwig von Mises, who turned it into a nominalist and subjectivist ontology of the social world (nominalist in the sense that it does not assign ontological status to social wholes, it does not admit them as irreducibly real). According to him, only individuals exist, and society, therefore, exists only in the minds of individuals. From this view, he derived the epistemological thesis that all knowledge about society is based on knowledge about individuals.

Austrian methodological individualism achieved its most developed form in the writings of Friedrich von Hayek. His version is a synthesis of elements taken from Menger, Weber, and Mises. Like the

former, he suggests an atomistic method to study unintended consequences, but the terminology is different. For Hayek, it is a matter of using a "composite," or "synthetic," method to study "spontaneous orders." The influence from Weber and Mises is most clearly visible in his subjectivist view of social institutions and artifacts. Money, for instance, is constituted by the beliefs people entertain about the pieces of metal and paper used as money and not just by money itself. All social phenomena are subjective, and society as a whole is constituted by the beliefs of individuals.

Popperian Methodological Individualism

The philosopher Karl Popper is probably the single most influential advocate of methodological individualism: It puts forward the postulate that we must understand and explain all social phenomena in terms of the aims and beliefs of individuals, their action and interaction with one another, and the situation they are in. Popper takes exception to the psychologism of John Stuart Mill and supplements his own individualism with situational logic, which is a version of rational choice, and with institutionalism, which claims that the actions of individuals usually cannot be explained without reference to social institutions. So far, there is little to distinguish Popper's methodological individualism from that of the Austrians. They too make reference to social institutions in their models of social phenomena. There is one important difference, however. While the Austrians tended to treat institutions as phenomena to be explained, Popper sees them as part of the explanation. The difference becomes even greater in conjunction with the objectivism of Popper's philosophy. For Popper, institutions do not reside only in the minds of individuals but are also part of their environment, or situation.

Popper was particularly concerned to combat the Marxist and historicist kinds of holism. His methodological individualism gave rise to an intense debate in the 1950s, and it fell upon his pupils to clarify and defend it, but in different ways. J. W. N. Watkins, who wrote most about it, kept to the strictly individualistic principle, while Joseph Agassi and Ian C. Jarvie developed Popper's institutionalism and objectivism.

According to Watkins, the principle of methodological individualism states that social phenomena should be explained in terms of the principles governing the behavior of individuals together with a description of their situations. Unlike Popper, however, Watkins excluded institutions from the description of the situation. If they nevertheless pop up, they should be reduced to the attitudes of individuals toward things and other people. This is closer to the Austrians than to Popper, but Watkins shared the Popperian view that methodological individualism is about the explanation of social phenomena but not about the definition of collective concepts.

At first, Watkins did not distinguish methodology from ontology and epistemology, but eventually, he reached the conclusion that methodological individualism, strictly speaking, is a rule for social analysis, based on the ontological thesis that social phenomena are caused and constituted by individuals and the epistemological thesis that only individuals are observable. While we have direct access to facts about individuals, knowledge about social wholes is always derivative.

It may, finally, be noticed that Watkins does recognize the existence of holistic generalizations about large-scale social phenomena and comes to accept them as a legitimate part of social science. He still believes, however, that they are "in principle" reducible to psychological laws. These generalizations provide "half-way" explanations in terms of large-scale social phenomena, as distinguished from the "rock-bottom" explanations in terms of individuals and their interrelations, which are the ultimate goal of social science. With the recognition of half-way explanations, the status of methodological individualism changes from a rule to an aspiration.

With Agassi, we get an explicit statement of a new version of methodological individualism, which was only implicit in the writings of Popper. It is called "institutional individualism," and it derives from Popper's institutionalism and situational logic, rather than from his methodological individualism. The important point about institutional individualism is that it includes social institutions as objective elements in the situation of individuals. According to institutional individualism, social phenomena should be explained in terms of both individuals *and* social institutions.

The difference between the original versions of methodological individualism and institutional individualism was clarified by Jarvie, who suggested that methodological individualists typically put social wholes in the explanandum, while holists put

them in the explanans. Institutional individualists put both individuals and social institutions in the explanans.

Recent Developments

The debate about methodological individualism has waned somewhat since the 1960s but has never ended. In economics, confidence in methodological individualism seems less today than it used to be, and it is possible to see a shift from the original version to institutional individualism. In sociology, a new version, called "structural individualism," has emerged. It is akin to institutional individualism, but the main idea is that the explanation of social phenomena often requires reference to the positions occupied by individuals in social structures. In philosophy, methodological individualism is usually discussed as a form of reductionism and, recently, most often in light of the notion of supervenience.

Varieties of Methodological Individualism

Austrian methodological individualism was a principle about both the explanation of social phenomena and the definition of collective concepts. With Popper and his followers, it ends up as a rule only for the explanation of social phenomena. At times, methodological individualism has also been conceived as a doctrine suggesting the reducibility of social laws to (psychological) laws about individuals.

Of these three versions, the second has been the most common and also appears the most viable. Explanation is a more incontestable aim of science than is definition. It has also proved more difficult to define collective concepts than to explain social phenomena in terms of individuals. Considering the well-attested paucity of laws in social science, the reductionist thesis, too, seems problematic. If there are no laws, there is nothing to reduce.

In addition, the explanatory version of methodological individualism has the advantage of being closely associated with the plausible ontogenetic thesis that social phenomena are caused by the action of human beings.

Speaking literally, *methodological* individualism is a principle, or rule, telling social scientists how to proceed. Methodology is normative. Many advocates of methodological individualism, however, state it as a thesis about the nature and cause of social phenomena. Most common, however, is to use ontological individualism to support methodological individualism. Since ontological individualism is considered trivially true, methodological individualism follows as a matter of course.

Sometimes, methodological individualism is also stated as an epistemological thesis about knowledge. Since only individuals are directly observable in society, it is suggested that all knowledge about social phenomena can, at least in principle, be stated in terms of individuals.

On closer scrutiny, it is possible to identify a number of more or less radical versions of methodological individualism. They range from versions requiring a full explanation of social phenomena in terms of individuals to versions requiring only that individuals are part of the explanation, while assigning virtually all explanatory power to social institutions and social structure.

The main divide is between those versions that admit only individuals and their interaction in the explanans and versions that allow social institutions and social structure to be part of the explanation. In the former, social institutions and structures always appear as the results of interacting individuals. In the latter, the actions and interaction of individuals can be seen as the result of social institutions and structures. The former may be called *strong* and the latter *weak* versions of methodological individualism.

Induction and Confirmation

The Problem of Induction

As David Hume observed, first in his *Treatise on Human Nature* (1739) and then, more succinctly, in the *Enquiry Concerning Human Understanding* (1748), there is no contradiction in thinking that the future will be unlike the past in any way one cares to specify or in thinking that unobserved features of the world may behave very differently than those observed. But what philosophers call "the problem of induction" runs, as Hume himself made clear, much deeper than the mere failure of past history to logically entail any consequence about the future and the unobserved. Rather, past experience, exactly because it is experience of the past and the experienced, cannot tell us what features of our experience to date are so much as *relevant* to founding correct expectations about the future and the unobserved. No matter how well our plans and projections have worked in the past, no matter how much we may argue, in the modern vein, that without a huge amount of stability and continuity in the way things are and work, a species such as ours, able to reason and to use language, could not have evolved, all that concerns what we take ourselves to know about what has been the case up to now. We need, it seems, a principle that the future will resemble the past, a principle of *the uniformity of nature,* but we cannot hope to ground rational acceptance of the principle save by appeal to that very principle.

Hume's aim is not to impugn our everyday habits of thought, the more so, as we certainly do not have good grounds on which to believe, say, that the sun will *not* rise tomorrow, but rather to show us that they are no more than *habits* of thought, thoroughly well entrenched, psychologically inescapable habits, no doubt, but habits and nothing more. This "sceptical solution," as Hume called it, has been thought scandalous. Surely, it is said, some expectations about the future course of events, some projections from observed behavior to the behavior of things unobserved, are more reasonable than others (and in an everyday sense, some are, but reason in the narrower sense in which Hume uses it in setting up the problem does not, he says, make them so). From Immanuel Kant, roused, as he said, from his dogmatic slumbers by reading Hume, onward, much of philosophy—in part spurred by the success of (mostly natural) science—has aimed to explain how some beliefs about the future and the unobserved are justified, or at least better justified than others; but even if, with Peter Strawson, we say that our inductive practices are in part constitutive of rationality (and hence require no justification), we must recognize, as Strawson did, that they are not guaranteed success.

Varieties of Inductive Practices

Hume does not decry our inductive practices (how could he, since he thought that we cannot but employ them?), but what are they? The simplest is *enumerative induction,* reasoning from observed cases to unobserved ones (a process identified by Aristotle and criticized by Sextus Empiricus, ca. second to third century BCE, for reasons very like Hume's). The traditional example, which argued from all observed swans being white to all swans being white, came to grief when de Vlamingh sailed up the Swan in Western Australia and named it for its black swans. A similar pattern of reasoning involves statistical extrapolation from samples, projecting percentages in the sample to the population in general. Another involves curve fitting—why should we draw the smoothest line through plotted data points? Each requires care in use so that what is observed/sampled must be representative, to which end there are heuristics governing variety and randomness.

Nelson Goodman's "New Riddle of Induction" in 1946 showed matters to be more complex. Let *t* be some time in the future, and let *grue* mean "examined before *t* and green or not examined before *t* and blue." Let us suppose that all emeralds examined thus far have been green. Then all are, equally, grue. But the generalizations "All emeralds are green" and "All emeralds are grue," both obtained by the pattern of enumerative induction, disagree on emeralds not examined before *t* and so are inconsistent should there be any such. Clearly, we cannot reasonably accept the conclusions of both inferences. Goodman called those predicates that can be used in inductive inferences *projectible* and suggested that what makes "green" projectible, and "grue" not, is its use (and the use of cognate terms in other languages) in past actual projections (inductive inferences); "green" is *entrenched,* he says, whereas "grue" is not. Some have preferred to take the projectible predicates to be those that pick out *natural kinds,* objective kinds found in the natural world, not artificial or owing anything to our classificatory endeavors—the kinds that, to borrow from Plato, "carve nature at its joints." Theories in the natural sciences have as one of their aims, it is said, the determination of natural kinds—chemical elements provide the standard example. But if induction is used in the development or assessment of scientific theories, then circularity threatens.

Enumerative induction is often pictured as a means of arriving at a generalization and thus has a close connection with individual psychology and learning. As such, it has been modeled and has undergone refinement and prodigious development in artificial intelligence, wherein, in the subdisciplines of inductive learning, computational learning, algorithmic learning, and formal learning theory, we find notions such as the Vapnik-Chervonenkis dimension, Leslie Valiant's Probably Approximately Correct learning, and questions of computational tractability (computation in polynomial time). Two commonalities in this work are that (1) a means for encoding the data is given *ab initio* (circumventing "grue"/green issues) and (2) the hypothesis space is constrained; there is no modeling of *unbiased* learning, no computational *tabula rasa.*

For the American pragmatist Charles Sanders Peirce (1839–1914), *abduction* is the process by which we arrive at hypotheses. From available explanations, we choose that which best explains the phenomena in question. Brought to prominence in our times by Gilbert Harman in 1965 as a better account of what we do, even in cases of apparent enumerative induction, this has subsequently been turned into a very general account of the *confirmation* of theory by evidence: That theory is most likely to be true that scores highest on a balancing of various theoretical virtues, such as simplicity, explanatory power, consistency with the evidence, and coherence, both internal and with accepted theories. (There's a subtlety here: If "bestness" helps us arrive at the hypothesis/theory, then the initial plausibility may be a feature included in determining the best; if "bestness" is what is involved in confirming the hypothesis, its being the best explanation is what makes it the most plausible, given the available evidence.)

Confirmation

In the 19th century, John Herschel drew a distinction subsequently important for the philosophy of science, that between the *context of discovery* and the *context of justification* (in now standard terminology taken from Hans Reichenbach's *The Rise of Scientific Philosophy,* 1951). According to Herschel, how we come to a generalization or, indeed, any scientific hypothesis or theory (context of discovery) matters little for science and matters less the better and more plentiful the agreement with observation and experiment (context of justification). The idea that one should not just observe Nature at work but contrive tests goes back at least to the Middle Ages, to Roger Bacon (ca. 1214–1292). Three centuries later we find Francis Bacon (1561–1626) advocating the experimental method that was to be central to the foundation of the Royal Society in 1660. (Hume, it should be noted, conceived of his *Treatise* as "an attempt to introduce the experimental method of reasoning into moral subjects.")

Having drawn Herschel's distinction, inductive reasoning takes on a broader guise, that of the *confirmation* of generalizations, hypotheses, and theories by evidence. Enumerative induction can still play a role, but it now features in the support given to a generalization, say "All emeralds are green," by the observation of increasingly large numbers of green emeralds and no emeralds of any other color. The simplest and perhaps most obvious suggestion is *Nicod's criterion,* named for Jean Nicod

(1893–1924): that in the absence of an *A* that is not a *B*, the generalization "All *A*s are *B*s" is confirmed (supported) by the observation of *A*s that are also *B*s and by nothing else—confirmation by positive instances. By support or confirmation, we mean being positive evidence, evidence for, evidence in favor of a generalization or hypothesis. Doubt was cast on Nicod's criterion by Carl Hempel's *Raven Paradox*. Take the generalization "All ravens are black." By Nicod's criterion, this is confirmed/supported by the observation of black ravens. But logically speaking, "All ravens are black" says no more and no less than the generalization "All nonblack things are nonravens"—the two are logically equivalent (at least in classical logic, which is accepted without question in most methodological studies). By Nicod's criterion, this generalization is confirmed by the observation of anything that is neither a raven nor black. But, the thinking goes, logical equivalents should be confirmed/supported by the same evidence (for they are true and false in exactly the same circumstances), so the observation of a green emerald, say (i.e., a green emerald being a nonblack nonraven) confirms the generalization "All ravens are black." This conclusion is counterintuitive, hence the epithet "paradox." (Odder still, logically speaking, "All ravens are black" says the same as "All nonblack ravens are nonravens," which has *no* positive instances.)

Responses to Hempel's Paradox

There are two ways to respond to a paradox: (1) reject one of the premises on which it depends or (2) accept the conclusion and try to mitigate its counterintuitiveness. As there are two premises, this gives us three responses to Hempel's paradox, all three of which have had their advocates. Accepting the conclusion, one can say that a black raven provides better evidence/more support than a green emerald, and one can defend this by contrasting the small number of ravens with the large number of things that are not black. Rejecting one premise, one can deny that logical equivalents are supported by the same evidence; the difficulty here is explaining why how one expresses the generalization should matter to what counts as evidence in its favor, logical equivalents in effect making the same claim about the way things are. The third possibility is to deny Nicod's criterion (a course suggested by the lack of positive instances of "All nonblack ravens are nonravens" and by various less contrived examples in the literature).

Alternatives: Falsifiability and Probability

Can science do without induction? Karl Popper (*The Logic of Scientific Discovery,* 1959; first published in German in 1934) claimed so. The hallmark of the scientific is, for Popper, falsifiability. Science progresses by subjecting bold hypotheses to the test; we learn from our mistakes. We should use well-corroborated theories, for they have survived severe tests, but there is, says Popper, no inference to their likely future success. Just this absence of an inference strikes many as problematic for the technological application of scientific theories: It is not sufficient that we use a theory not (yet) known to be in error; we want to base applications on a theory most likely to be sufficiently accurate in the intended domain of application. (The so-called Duhem-Quine problem shows that falsificationism is less straightforward than this quick sketch may suggest. No sophisticated theory is tested in isolation; if nothing else, there is theory involved in the construction of experimental apparatus, the hypothesis that the equipment is performing as it should, and, perhaps, assumptions about the reliability of lab technicians or field workers. Thus, one is never obliged to lay a failed prediction at the door of the theory notionally under test.)

According to the *hypothetico-deductive* account of scientific theories, predictions of unknown occurrences and explanations of known ones are deduced from hypotheses and known "initial conditions." Hempel laid down various seemingly plausible criteria for confirmation of hypotheses by evidence in this setting, but as he himself noted, unless one finds a way to rule out logical gerrymandering, intuition is in error. For example, it may seem that a hypothesis is confirmed by a successful prediction and that when a hypothesis is confirmed so are its consequences, but these two claims lead to the consequence that any evidence confirms any statement whatever, for *e* is entailed by the conjunction *e* & *s*, as is *s*.

Well aware that enumerative inductions have gone awry in the past, one might think that in place of the bold "All *A*s are *B*s" we should posit the more cautious "Probably, all *A*s are *B*s" in the conclusion of an inference employing enumerative induction. That's one way to go: qualify the conclusion of

inductive inferences. Another is to qualify the inference itself. By this it is meant that, holding that some hypotheses are better supported by available evidence than others, one qualifies the inference from evidence to hypothesis. The standard framework for this latter practice is the orthodox theory of probability that we have from Blaise Pascal, Pierre Fermat, and Christiaan Huygens, which gained formal perfection in the 1930s in Andrey Kolmogorov's axiomatization (standard but not universal: L. Jonathan Cohen [1923–2006] championed a conception of probability he found in Francis Bacon's works). Assuming that $P(e)$, the prior probability of the evidence *e,* is nonzero, the conditional probability of the hypothesis h in light of that evidence, $P(h|e)$, is given by

$$P(h|e) = P(h \,\&\, e)/P(e).$$

$P(h|e)$ is the posterior probability of h, the probability of h in light of the evidence. The probabilities are often read epistemically, as the degrees of belief of a (idealized) rational agent. Under the rubric of *updating by Bayesian conditionalization,* $P(h|e)$ represents the degree of belief in h that the agent comes to have on learning that e (and learning nothing more). The stock-in-trade of Bayesian methodologists is to use this framework to explicate methodological insights (often made by those who have little time for the Bayesian/probabilistic approach). With that in view, we arrive at the *positive relevance* model of confirmation:

- e confirms h when $P(h|e) > P(h)$.
- e disconfirms h when $P(h|e) < P(h)$.
- e is evidentially irrelevant to/neutral with respect to h when $P(h|e) = P(h)$.

(An older terminology would have "infirms" for "disconfirms.")

This conception is not only found in much contemporary philosophy of science; in the theory of legal reasoning, we find the same conception of probative evidence, a conception enshrined in U.S. Federal Rule of Evidence 401.

Applying probability to inductive reasoning is not new. In the late 18th century, Pierre-Simon Laplace, taking the world to be 5,000 years old and modeling the rising of the sun as an unbroken sequence of heads obtained with a coin of unknown bias, arrived by means of his *Rule of Succession* at odds of 1,826,214 to 1 of its rising on the morrow.

Of course, we not only have the idea of evidence confirming and disconfirming, we can make comparisons: One piece of evidence may provide more support, may have, as they say in legal circles, more *probative value,* than another. Especially as we start from quantified values, the prior and posterior probabilities, this leads naturally to the project of measuring the amount of confirmation. If there is either confirmation or disconfirmation, there is a difference between the posterior and prior probabilities of the hypothesis. For any quantity, there are three common ways to represent differences in value: (1) the difference, as in, say, *three meters longer*; (2) the ratio, as in *twice as long*; and (3) the proportional difference, as in *30% longer.* In the case of confirmation, numerous measures have been proposed, of which the difference measure, the ratio measure (and its logarithm), and the "odds ratio" measure, $P(e|h)/P(e|\text{not-}h)$ (and its logarithm), have featured prominently in the literature. Debate as to their merits focuses on both their formal properties and how well they accord with intuitive judgments. (The odds ratio gets its name because it is equal to the ratio of posterior to prior odds; the logarithm of the odds ratio was used by Alan Turing [1912–1954] in his cryptographic work at Bletchley Park during World War II.)

While read epistemically, there is room for disagreement on the exact nature of the probabilities involved. Rudolf Carnap favored a logical interpretation of probability and developed a formal inductive logic in which the sentences of a formal, logical language, of the kind that served well in the development of formal and mathematical logic in the 20th century, are assigned values determined by the structure of the language. In his *Tractatus Logico-philosophicus,* Ludwig Wittgenstein had assigned a probability of ½ to elementary propositions and treated them as probabilistically independent, a formulation that allows no learning from experience (as with tosses of a fair coin). Initially, Carnap assigned probabilities on the model of ascribing equal probabilities to the different numbers of heads possible in a sequence of tosses.

Concluding Remarks

As Carnap and his coworkers labored on this project through the 1950s and 1960s, he drew back from fixing on one particular assignment of probabilities; this, Goodman's paradox, and, most important, the recognition that theories in sophisticated sciences are rarely couched in the terms applied in

the description of the phenomena that support them persuaded the majority of philosophers of science that there is no formal inductive logic, akin to formal deductive logic, underlying the confirmation of scientific theories. Philosophers of science reached this conclusion regarding (inductive) *confirmation* around the same time artificial intelligencers began to tackle computational implementation of inductive *learning and hypothesis generation.*

INFERENTIALISM

This entry delineates the core elements of inferentialism. Recent inferentialist accounts of language and thought emphasize the importance of social practices of language users in terms of giving and asking for reasons, the essential normativity involved in inferences, the presence of commitments in all such activities, and the indispensability of others and of intersubjective ascriptions of entitlements in making inferences or ascribing them. Inferentialism underlines the sociality of language and thought rather than truth or representation, as in orthodox accounts, and recent versions of it prioritize language over thought.

Inferentialism is a theory concerning what constitutes the meaning of an expression or the conceptual content of a thought and authorized inferential relations between linguistic and between mental items, respectively. Drawing on themes from the contemporary analytic philosophers Wilfrid Sellars and Michael Dummett and from the earlier philosophical logician Gottlob Frege, the American philosopher Robert Brandom has recently given this theory its most explicit formulation and defense in his *Making It Explicit: Reasoning, Representing, and Discursive Commitment,* in *Articulating Reasons: An Introduction to Inferentialism* and in subsequent work. In this latter version, inferentialism has been drawn by Brandom close to some Hegelian themes.

Language, Thought, and Inference

Inferentialism explains meaning in terms of use, where *use* is specified in terms of the social practices of giving and asking for reasons. These practices institute the norms constitutive of language as a public possession. The meaning of a linguistic expression or the conceptual content of a thought is determined by its role in reasoning, the inferences that would authorize using that expression or having that thought, and the inferences that it, in turn, authorizes or commits one to. There is room for disagreement about the relative priority (epistemological

or metaphysical) of language and thought, but most current inferentialists prioritize language over thought.

Inference is fundamentally a form of speech activity involving sentences. Strictly, an inference is something we *do*—a transition from a (set of) uttered sentence(s) to another sentence or set thereof—though it would be a mistake to think that inferences must be actions. Utilizing Sellars's view that our concepts of intentional states are modeled on semantic concepts applied to utterances, a generalized notion of inference can then be extended to episodes of internal cognitive activity. Inferentialism thus appeals to pragmatists, who emphasize that thought and language must be understood as activities that enable us *to cope with the world*. Inferentialists take the functional notion of sentences providing rational support for other sentences to be the most basic notion in the semantic arena, more basic even than truth, which they tend to treat in a deflationary way. Note that an inferential role is not a purely causal role—it is normatively assessable as contributing to a good or a bad inference; it operates in "the logical space of reasons"—to use Sellars's famous formulation (i.e., in giving and accepting reasons, an operation fundamentally unlike causal action in physical space).

Inferentialism's Attack on Semantic Orthodoxy and Representationalism

Inferentialism takes seriously Frege's claim that sentences are the basic units of meaning. The meaning of subsentential expressions depends on the contribution those expressions make to inferences involving the sentences using them. A clear example of this approach is the definition of the truth-functional connectives ("and," "or," "not," "if . . . then," etc.) by means of introduction and elimination rules for each connective in "natural deduction" systems. The truth-functional "&" simply *is* the expression such that premises "A" and "B" license the conclusion "A & B" and the premise "A & B" licenses the conclusions "A" and "B."

This distinguishes inferentialism from current semantic orthodoxy, which takes a relation between terms and (sets of) objects; calls it "reference" or "satisfaction," to be the primitive factor in a meaning; and then constructs a definition of truth for the language Tarski-style (which arguably accounts for any remaining aspect of meaning). Inferentialists also reject the parallel "representationalist" paradigm in the philosophy of mind, which assumes the existence of a primitive *representation* relation between mental states and objects in the world. Inferentialists deny that there is any single particular, privileged relation of representation or correspondence between our concepts and objects in the world; we can speak and think about the world in virtue of our complex interactions with the world. These include *language-entry transitions,* such as observation reports in response to an irradiation of our sensory surfaces; *language-exit transitions,* such as announcing one's intention to shut the window followed by one's shutting it; and *intralinguistic transitions,* such as inferring from "smoke here" to "fire nearby." Strictly, only intralinguistic transitions are inferences, but inferentialists tend to see roles in entry and exit transitions as significant in constituting the meaning of numerous expressions.

Justificatory Relations and Commitment

Justificatory relations is a broad category; it certainly includes more than those inferences recognized by formal logic. Consider, for instance, the inference from "*x* is red" to "*x* is colored." This is obviously a good inference but is not valid in any formal logical system. Traditionally, logicians treat it as an enthymeme, an inference in which a premise is left out. The inferentialist denies that every good inference must be squeezed into the Procrustean bed of formal logic. Thus, inferentialists recognize a category of good *material* inferences beyond the class of formally valid inferences. Brandom argues at great length that formal logic must itself be seen as the discipline of *making explicit* (by allowing us to formulate in a distinctive vocabulary) a particularly significant subset of inferences without which language and conceptual thought would themselves not be possible. Brandom also accepts Sellars's suggestion that modalities express our endorsement of and *commitment* to certain inferences.

Thus, Sellars speaks of natural *laws* as "inference tickets"; the law of reflection, for instance, offers us a license to infer (ceteris paribus) from "The light impinged on the mirror at xB" to "The light was reflected from the mirror at xB." This accounts for the fact that laws support counterfactuals, whereas empirical generalizations do not. *Moral* laws are practical inference tickets.

Brandom, recently, has distinguished *weak inferentialism,* according to which "inferential articulation is a *necessary* element in the demarcation of the conceptual" (2000, p. 28); *strong inferentialism,* according to which "inferential articulation *broadly construed* is *sufficient* to account for conceptual content" (p. 28); and *hyperinferentialism*—"the view that inferential articulation *narrowly* construed is *sufficient* to account for conceptual content" (p. 28). The "inferential articulation" of a sentence concerns not just the inferences to and from that sentence made by a single subject but the inference licenses it gives *others* and those that *others* give it. Language is a distinctly *social* practice. The commitments, entitlements, and endorsements in terms of which language use is explicated are *intersubjective,* and language users are responsible to their linguistic community in what they say and what they thereby do. Brandom argues that holding a normative status is a matter of being held accountable to the inferences endorsed.

The Importance of Language

Inferentialists tend to draw a significant line between the cognitive states of those with and those without language. There may be some language-*like* internal processing in nonlinguistic beings, but there is clearly no actual inferential behavior strictly so-called in infralinguals. Furthermore, without language, the reflection that enables one to make explicit what one is doing in using language or in having thoughts seems unavailable.

Information Ethics

This entry presents the historical background and conceptual development of moral questions as well as of methodological and scientific issues comprising the ethics of information, viewing information and communication especially in its technological form.

Historical Background

Information ethics, understood as a philosophical discipline dealing with good and bad practices of human communication, has a long history going back, in the Western tradition, to the question of freedom of speech (*parrhesia*) in the Greek polis, dealing particularly with the Sophists' and Socrates's criticisms of the mores, principles, and concepts underlying communication in all its practical and theoretical dimensions. Plato's questioning of the written *logos* as well as Aristotle's careful analyses of the uses of language and his theory of rhetoric are forerunners of ethical thinking on the pervasive biases and power structures of communication. The invention of the printing press by Johannes Gutenberg around 1450 and the Reformation that profited from it challenged the legitimization of practices of interpretation and application of the Bible by the Roman Catholic Church, but implicitly it also challenged any kind of monopolization of knowledge and its production, storage, retrieval, distribution, and criticism by any human agent based on power. The questioning of

customary premodern communication practices culminated in the Enlightenment and its criticisms of political and religious censorship. Freedom of the press, the transformation of private libraries owned by the nobility and the Catholic Church into public property, and several encyclopedic projects aiming at critical and broad public access to knowledge were some practical corollaries of information ethics in the modern era.

Information ethics became a matter of concern particularly with the invention of the computer and the widespread use of the Internet since the last decade of the 20th century. Terms like *computer ethics* and *cyberethics* became popular. The term *information ethics* has been used particularly in relation to the information society by international agencies such as UNESCO since the end of the 1990s. This process culminated in the World Summit on the Information Society in 2003 and 2005.

Information Ethics as an Academic Discipline

The terms *information ethics* and *computer ethics* have been used since the early 1980s in the context of library and information science as well as computer science. In the mid 20th century, computer scientists such as Norbert Wiener (1894–1964) and Joseph Weizenbaum (1923–2008) raised ethical questions about the impact of computers on society, focusing on the responsibility of computer scientists. Computer ethics courses were introduced into academic curricula in the 1990s in schools of computer science in the United States. In the first decade of the new century, professional societies and networks such as the International Society for Ethics and Information Technology, the Centre for Computing and Social Responsibility (De Montfort University, United Kingdom), and the International Center for Information Ethics were set up. There is a large bibliography in the field, including specialized journals and handbooks as well as several international and regional conferences.

There are divergent views concerning the intention and extension of the concept of "information ethics"—that is, both its meaning and its reference. Some philosophers criticize the focus on human communication and plead for an extension to include all kinds of beings. This view turns eventually into informational metaphysics: questions of ontology and what to include in it. At the other end of the spectrum, there is the view of information ethics as dealing only with human communication as shaped particularly by information technology. In this case, the concept of information ethics excludes nondigital communication media still used today or prevalent in other epochs and cultures. The concept of information ethics might be extended to cover all kinds of information technology applications beyond the sphere of human communication. From a digital perspective that addresses all beings insofar as they can be digitized in order to be understood, information ethics is grounded in information ontology and concerns good practices of being-in-the-world in the digital age.

Key Topics in Information Ethics

The relation between information technology and ethical practices is twofold. On the one hand, it deals with the impact of information technology on good practices and their principles, while on the other hand, it has to do with the ethical reflection on information technology, which could be less reactive and more proactive with regard to the new societal challenges arising from new information and communication technologies. In both cases, information ethics has the task of discussing good practices and their principles with regard to either digital information technology or other media.

Information ethics deals with descriptive and critical issues in different cultures and epochs, giving rise to intercultural information ethics. This includes, but is not restricted to, the question of universal practices and principles. There might be agreement on universal declarations, but their interpretation and application might be different according to cultural traditions. An example of intercultural dialogue in information ethics is the discussion on the concept of privacy from a Western versus from a Buddhist perspective. Practical consensus might involve different reasons that are the object of analysis and criticism by information ethics. Deontological and utilitarian theories play a major role in information ethics, no less than do theories grounded in hermeneutics, analytical philosophy, critical theory, social theory, Marxism, postmodernism, and critical rationalism, to mention just a few.

Classical topics in information ethics are privacy, identity, trust, justice, intellectual property, cyberwar, the surveillance society, plagiarism, censorship, gender issues, and information overload.

Information ethics addresses the effects of the materiality of information technology on the environment caused by electronic waste and especially by its export to Third World countries. It also deals with the economic and political impact of information technology. Ethical analysis and critical evaluation of the global digital economy concern the relation between transparency, privacy, and secrecy, no less than issues of justice regarding access to and use of the Internet. Information technology in general, and in social networks in particular, plays a major role in the political development of societies. They might strengthen liberation movements and enable new forms of democratic participation, but they can be misused for oppression and exploitation as well. The vision of a people-centered, inclusive, and development-oriented information society, as proclaimed by the World Summit on the Information Society, outlines the object of ethical scrutiny and evaluation in order to develop reliable social conditions for trust, security, and transparency.

New technological developments such as ambient intelligence, human–machine symbiosis, neuroelectronics, affective computing, augmented reality, bioelectronics, the future of the Internet, cloud computing, and quantum computing are among the most relevant challenges for information ethics in the foreseeable future. The underlying philosophical debate concerns theoretical and practical prospects for human freedom and self-understanding in the digital age. Both issues cannot be divorced from the relation between humankind and the world, as well as between human and nonhuman life, taking into consideration the dangers and opportunities arising from their manipulation and transformation based on the uses and abuses of digital technology.

Information Society

The term *information society* has become a common phrase, but it is used differently and sometimes vaguely by different people, especially those from different disciplinary or professional backgrounds. In its widest sense, it implies a society or culture in which information is a fundamental component of life. It could be argued that this is a condition of all human societies, even the least developed. In practice, however, this broad definition is usually narrowed to mean cultures in which organized knowledge (i.e., information) is consciously used to inform actions and decisions. Such information may be transmitted orally but is more often recorded in some retrievable form that might be graphic, but it is more often linguistic and numerical.

Since the 1990s—when the phrase became more common—it has usually been assumed that the information storage and retrieval systems are electronic. Consequently, the information society is often understood as meaning one in which networked computers and other electronic devices are essential instruments in all aspects of personal, professional, and public life. By extension, some then assume that the phrase also encompasses information technology

(i.e., computation and associated communications systems) rather than, or as well as, the social, economic, and political dimensions of information capture, storage, retrieval, and use. Given this lack of agreement about the phrase itself, it is better to perpetuate the vagueness and to emphasize that the focal point is information itself.

Information

In the social sciences (including for this purpose library and information sciences), information is normally understood to mean knowledge that has been organized. The organizational process is essentially intellectual, although it has a physical manifestation. Thus, to take a relatively simple example, the complex ontologies that underpin the classification systems (e.g., Dewey or Library of Congress) that have been used in libraries since the late 19th century are manifested as alphanumeric codes, which are then used to determine the order in which books are placed on the shelves. An even simpler example is this present encyclopedia, arranged in the order of the letters of the Latin alphabet, following certain conventions that are almost universally understood. At a deeper level, however, individual pieces of information (what computer scientists would call *bits*) are brought together in a way that adds value so that the whole is greater than the sum of its parts. Even a simple piece of information—that Columbus crossed the Atlantic Ocean in 1492—is actually derived from multiple individual pieces or bits; if the statement about Columbus is deconstructed, it will soon be recognized that understanding it requires a range of knowledge (e.g., about geography and chronology), which is shared between the originator and the user of the information. The construction of knowledge from information is perhaps most explicit in computing, where the bits represent the smallest reduction of the sum total of the information that is being recorded and processed.

The gap between information understood at this theoretical level and its societal application may seem to be very great. Indeed it is, and it is precisely for this reason that pragmatic and empirical approaches to the study of the information society are perhaps the most fruitful.

The Development of the Information Society

The formal history of information recording and retrieval begins with the invention of writing some 5,000 years ago and the development of media on which written matter could be stored and preserved. In Asia and Europe, at various times and in different ways, these innovations evolved into books and documents of the kind with which we are still familiar. Mechanical means of reproduction were developed independently in East Asia and Western Europe, but it was in the latter—by using pieces of metal that printed individual letters and symbols—that it was finally developed into the craft of printing in the 15th century. Within a relatively brief period of time (less than 100 years in some of the more sophisticated parts of Europe), printing had become an indispensable element in the organization of the state, of religion, of education, and of many aspects of private as well as public life. By the middle of the 19th century, when the printing processes themselves had been mechanized and industrialized, there was an ever-increasing flow of information in cultures that were approaching universal levels of literacy, benefiting from unprecedented prosperity, and developing complex technologies of communication. Some of these technologies were physical—the railroads, for example—but others were based on relatively recent scientific developments, such as the use of electricity for telegraphs and telephones. These wired networks provided a conceptual precedent for the Internet in the later 20th century.

By the time of the outbreak of World War I in Europe (1914), information was already being stored and retrieved through managed systems. While these seem crude 100 years later, the use of devices such as the "3 × 5" index card revolutionized the systematic storage and retrieval of information. In both business and government, information came to be seen as a vital commodity to be protected from competitors and to be made available only for the benefit of its owners. The extreme example was state secrecy, leading to the wartime development of espionage. But the same awareness of both the value and the use of information lay behind the development of mechanical devices such as adding machines and cash registers, which came to be widely used. Telephone networks—underdeveloped in Europe, although not in the United States, before 1914—were another beneficiary of war, and in the 1920s and 1930s, the broadcast media—radio followed by television—brought new sources of information into people's very homes. Social change followed quickly on the development of these systems and media. Businesses could be more tightly managed, and innovative systems of management

evolved, exemplified in the so-called Fordist production line in the rapidly growing automobile industry. Governments needed, and could both gather and store, vastly more information about citizens to support the social security systems that were developing in Europe and, by the late 1930s, in the United States. New forms of entertainment, some of them social (e.g., the movie theaters) and others domestic (e.g., broadcasting) began to change people's use of their leisure time and disposable income. And all the while, more people were better informed—and perhaps better able to exercise economic and political choice—than at any time in history.

Computers: The Information Machines

The computer was a wartime product. Building on work in theoretical physics and pure mathematics in the 1920s and 1930s, as well as experimentation in electromechanical engineering, a team of British scientists co-opted into the war effort produced the first true electronic computer. The commercial initiative in the development of computation crossed the Atlantic in the immediate postwar period, but not before the first machines had been installed in a handful of businesses. Early predictions that the world would need the power of two or three machines are easy to mock, but it was perhaps a decade before anyone outside the inner circles of the mathematicians, scientists, and engineers who were most closely involved really began to appreciate the potential of these new machines. The concept of a thinking machine—an electronic brain in the jargon of science fiction movies of the 1950s—came close to reality in machines that, even if they could not think, could certainly process data and information on a scale that the human brain could not. Although the earliest applications were almost entirely numerical, by the late 1960s, computers were in use for storing and sorting alphanumeric data, and input and output devices were being developed that made their use relatively easy. The period from 1970 to 1990 saw innovations that brought computing both economically and technically within the capacity of tens of millions of people; between them, the silicon chip and the mouse transformed an esoteric science into a tool in daily use.

The same two decades saw another advance: academic experiments in whether computers could be electrically linked—whether they could "talk" to each other in the popular language of the 1970s—were transformed into the infinitely complex and yet extremely simple-to-use Internet. Like computers themselves, the Internet had its origins in the military and intelligence communities. Like them, its civilian applications were transformative of whole societies. By the late 1990s, networked computing was commonplace in the academic world, was becoming normal in the U.S. government and was spreading into the wider world. The development of a simple interface, using the highly sophisticated concept of hypertext, was all that was needed to propel the final stage of takeoff. The World Wide Web, emerging from the civilian scientific community among theoretical physicists in Europe, became the platform for the near-universalization of the Internet and in the eyes and minds of billions of ordinary men and women (and above all children and young people), became the Internet itself. By the turn of the millennium, the Internet was on the verge of becoming mobile. Cellular telephones presaged the independence of devices from wired networks, and as devices became both cheaper and more powerful, the mobile telephone became ubiquitous; indeed, in some parts of the world, where telephone services had always been unreliable, mobile telephony is probably the most important single development in the history of communication. By the end of the first decade of the 21st century, the cell phone had become a mobile computer providing access to the Internet, and hence to e-mail, as well as to voiced telephony and text messaging systems, the latter the preferred medium of the coming generation. Superimposed on all of this—and to some extent driving it—were the search engines that actually provided more or less systematic access to the ever-increasing information content of the Internet.

A New Society?

It is these two and a half decades of change that are argued by some to have made the information society a reality. But others take the view that we should not fall into the trap of technological determinism. It is certainly the case that cheap and mobile access to networks and all the content they can carry, as well as the interpersonal communication systems that they facilitate, has changed how people live and work. There is a far greater consciousness of information, and perhaps a greater understanding of it. On the other hand, the roots of this information society lie deep in Western culture, with its

tradition of literacy and text, which goes back more than 2,000 years, and a 1,000-year-old system of education, beginning with the acquisition of literacy. Governments have been seeking, collecting, and protecting information for centuries in surveys, mapmaking, and population censuses. Business owners have kept financial records for at least as long, even if it was only relatively recently (say in the past 150 years) that such record keeping has been standardized. Information and computing technologies have made all of this easier and indeed have made a practical reality of systems that could previously only be conceptualized. Some social scientists have argued that all that has happened is that there are new and infinitely faster and generally more effective tools for doing old things. Others prefer the view that the change is as profound as it has been rapid. Certainly it is radical. By the middle of the 21st century, the world will be led by men and women who have never known any other society than the one we have now, people to whom the mobile information and communication devices are as normal as automobiles (and perhaps by then more socially acceptable) and people to whom the transmitted word is a manifestation of an electronic file, not the physical product of a printing press.

The social and economic benefits of the information society are clear enough, but even many of those who accept that concede that there is another side to the coin. Ease of electronic communication, whether by voice, text, or e-mail, can be cogently argued to have changed human interaction and diminished the importance of face-to-face meetings and conversations. Colleagues who once visited each other's offices or used the telephone now work by text messages or e-mail. Social networking systems allow members to have scores or hundreds of "friends" whom they have never met, and about whom they actually know nothing or may "know" only the deliberate falsehoods that the "friend" has posted. This may be thought to be socially or psychologically disturbing. Even more disturbing perhaps, is that the information society can be readily transmuted into a surveillance society. Governments, even in democracies, have had some powers to tap telephones or open mail, but such powers were carefully regulated by legislation and usually required the specific permission of a court of law. Electronic communications are easier to tap into—which journalists know well and exploit to their advantage—and it can be done without either sender or recipient being aware of the fact. The use of closed-circuit television systems in streets, in buildings, and on public transportation systems is redefining the very concept of public space and indeed of privacy itself. Legislation has, generally, lagged behind the rapid technical change, and politicians have shown a tendency either to be ignorant of the issues or to consciously ignore them. The regulation of the information society—striking the democratic balance between the rights and obligations of the citizen and those of the state—is an issue that urgently needs to be addressed.

Institutional Economics

Institutional economics was a term originally used to describe the works of a prominent group of American economists including Thorstein Veblen, Wesley C. Mitchell, John R. Commons, and many others. Although its influence declined, even after World War II the original institutionalism retained some prominence. Simon Kuznets and Gunnar Myrdal declared an affinity with the original institutionalism and won Nobel Prizes in 1971 and 1974,

respectively. In 1975, Oliver Williamson coined the term *new institutional economics* to apply to work by him and others, including Ronald Coase, Mancur Olson, and Douglass North. These authors were reviving interest in the role of institutions in the economy, and much of their work used the concept of *transaction costs*. Since then, Ronald Coase, Douglass North, Elinor Ostrom, and Oliver Williamson have all been awarded Nobel Prizes for their work in institutional economics.

This entry gives an overview of ideas in the original and new traditions of institutional economics.

A Prominent Feature of the Original Institutional Economics

The original institutionalism was highly diverse, but it did exhibit some common themes. Among these was the emphasis placed on the role of institutions in both understanding the economy and developing policies for social reform. Another common theme pervades institutionalism, from the writings of Veblen in the 1890s to those of John Kenneth Galbraith, who died in 2006—the notion that the individual is not given but can be reconstituted by institutions. By contrast, much of mainstream economics during the 20th century, including much (but not all) of the new institutional economics, takes individual preferences as given.

The assumption of malleable preferences is often criticized as leading to some kind of structural or cultural determinism or to methodological collectivism. The individual, it is said, is made a puppet of institutional or cultural circumstances. But in the writings of Veblen and Commons, there are both upward and downward effects; individuals create and change institutions, just as institutions mold and constrain individuals. The old institutionalism is not necessarily confined to the "top-down" cultural and institutional determinism or methodological collectivism with which it is sometimes associated.

A merit of the idea that institutions shape individual dispositions is that it admits an enhanced concept of *power* into economic analysis. Power is exercised not only by forceful coercion. Power is often exercised more cleverly—and often without overt conflict. Supreme power is exercised by subtly influencing the thoughts and desires of others. These considerations are almost entirely absent from mainstream economics.

Preference malleability is also important in regard to *learning*, which typically takes place through and within social structures. Mainstream economics has difficulty accommodating a full notion of learning because the very idea of "rational learning" is problematic. It also assumes that our preference function is at birth fully primed to evaluate options about which we are not yet aware and that may not have emerged. But instead of the mere informational input of "facts" to given individuals, learning in practice is a developmental and reconstitutive process. Learning involves adaptation to changing circumstances, and such adaptations mean the reconstitution of the individuals involved. Institutions and cultures play a vital role in establishing the concepts and norms of the learning process.

Because conceptions of social power and learning are placed at the center of economic analysis, the original institutionalism is arguably more suited to address questions of structural change and long-term economic development, including the problems of less-developed economies and the transformation processes in the former communist countries. On the other hand, the analysis becomes much more complicated and less open to formal modeling. In normative terms, the individual is no longer taken as the best judge of his or her welfare. A different type of welfare analysis is required, but such alternatives are so far underdeveloped in institutional economics.

The Evolving New Institutionalism

Since its development by Coase and Williamson, the concept of *transaction costs*—defined as the costs of formulating, monitoring, and enforcing contracts—has generated a vast theoretical and empirical literature and helped us understand the nature and operation of firms and markets. But comparisons of different institutional structures in most transaction cost analyses do not consider the possibility that individual preferences are molded by different institutional circumstances.

The "new institutional economics" originally set out to explain the existence of political, legal, or social institutions by reference to a model of given, individual behavior, tracing out its consequences in terms of human interactions. The explanatory movement is from individuals to institutions, taking individuals as primary and given.

But the reception of information by individuals requires cognitive norms and frames to process and make sense of that information. Furthermore, our interaction with others requires the use of the institution of language. Original institutionalists argued that the transmission of information from institution to individual is impossible without a coextensive process of *enculturation*, in which the individual learns the meaning and value of the sense-data that are communicated.

Institutions constrain, enable, and influence individuals. Accordingly, if there are institutional influences on individuals and their goals, then these are worthy of explanation. At the very minimum, analysis of the development of institutions depends upon interpersonal communication of information. And the communication of information itself requires shared conventions, rules, routines, and norms.

This does not mean that new institutionalist research is without value, but it suggests that the starting point of explanations cannot be institution-free: The main project has to be reformulated as just a part of a wider theoretical analysis. The reformulated project would stress the evolution of institutions, in part from other institutions rather than from a hypothetical, institution-free "state of nature." It also means that the existence of the firm may not be explained by transaction costs alone; other causal factors may also be relevant.

Some "new" institutionalists have taken these points on board. Douglass North has insisted on the general importance of understanding the context and processes of cognition. He has cautioned on the limits of the rational choice framework, emphasizing the way institutionalized ideologies influence individual cognitions and goals. This places North's recent writing close to the original institutionalist tradition.

Other contemporary institutionalists have abandoned the idea of starting from given individuals alone. For example, Jack Knight criticizes much of the new institutionalist literature for neglecting the importance of distributional and power considerations in the emergence and development of institutions. Elinor Ostrom emphasizes the role of culture and norms in establishing and molding both perceptions and interactions. Masahiko Aoki identifies the problem of infinite explanatory regress in much of the former literature and develops a novel approach. Using game theory, he explores the evolution of one set of institutions from another. These developments reveal some convergence between elements of the "new" institutional economics and ideas that can trace their origin to the original institutionalism.

The Future Development of Institutional Economics

Once we move in the direction of a more open-ended evolutionary approach, another question is raised. If in principle every component in the system can evolve, then so too can individual preferences. Institutions involve rules, constraints, practices, and ideas that can—through psychological and social mechanisms that need to be revealed—sometimes mold individual purposes and preferences in some way.

Such intuitions can be found in the original institutionalism. But what is lacking in some of this literature is a clear exposition of the causal processes involved. One of the most fertile explanations of the processes is found in the writings of Veblen, where he describes the influence of selective competition between institutions on individual *habits*. Veblen took the concept of habit from American pragmatist authors including Charles Sanders Peirce and William James. Habits are acquired psychological dispositions to respond in particular ways to specific triggers. Insofar as individuals are constrained or motivated to follow particular institutional norms or rules, they tend to strengthen habits that are consistent with this behavior. Individuals may then rationalize these outcomes in terms of preference or choice. That is, conscious preferences are the outcome of habits, rather than the other way round. Our habits help make up our preferences and dispositions. When new habits are acquired or existing habits change, then our preferences alter. The framing, shifting, and constraining capacities of social institutions give rise to new perceptions and dispositions within individuals. Once habits become established, they become a potential basis for new intentions or beliefs. As a result, shared habits are the constitutive material of institutions, providing them with enhanced durability, power, and normative authority.

Alongside Veblen, the contribution of Commons to the interface of economics and law is still relevant. Veblen was theoretically weak on the nature and analysis of market institutions, and here we must learn from others. A number of institutionalists have taken up Keynesian ideas, but so far only limited progress has been made in developing robust

theoretical links between the theoretical analysis of institutions and macroeconomic theory. Finally, all institutional approaches so far lack a developed alternative grounding for economic policy to rival the patently limited neoclassical welfare approach, where the individual is assumed to be always the best judge of his or her interests.

Much work in the New Institutionalism is oriented toward practical policy design. Those influenced by the original institutionalism are also interested in policy, but they are also disposed to be more reflective about the philosophical foundations of their approach. These concerns have become prominent in recent discussions about the nature of institutions. Although there is widespread agreement that institutions are systems of rules, there is ongoing discussion concerning the nuances of this definition and how broadly the term *institution* may apply. Such discussions involve social ontology as well as other philosophical issues, as exhibited in the work of John Searle, among others.

Conclusion

There is now much overlap, and the possibility of fruitful dialogue, between original and New Institutionalism. There has also been an "institutional turn"—recognizing the importance of institutions—in other social sciences, including politics, sociology, history, and geography. What emerges as institutional economics in the next few decades may turn out to be very different from what was prominent in the 1980s and 1990s, and it may trace its genealogy from the original as well as the New Institutionalism.

Institutionalism and Institutional Theory

This entry gives an extended overview of an area that, in its recent rich revival, has brought back the study of institutional structures and organizations to the center of social sciences and, in particular, of political science. Institutionalism poses significant questions of epistemological and, more generally, philosophical import for the study of the social world, not least of which is the core antithesis between holism and individualism.

Origins

The study of institutions was the foundation of political science. Theorists going back to the greats such as Aristotle, Baron de Montesquieu, Thomas Hobbes, and John Locke (among others) sought to understand how institutions function and how to

design better institutions. More recently, much of comparative politics was based on the study of public-sector institutions and constitutions, with the fundamental assumption that formal structures would determine what governments actually did as they attempted to govern.

As political science moved away from its organizational and institutional foundations toward assumptions about the centrality of individual behavior, then much of that central role for institutions was lost. First with "behavioralism" and then with rational choice theory, methodological individualism came to dominate political science, and institutions were at best merely structures within which individuals interacted. Beginning in the 1980s, however, there was a significant revival of interest in institutions and institutional theory, usually discussed as the "New Institutionalism."

The New Institutionalism

The New Institutionalism in political science differed from the older versions of this basic approach in several important ways. The most important is that the New Institutionalism is explicitly theoretical, attempting to develop more or less comprehensive explanations for political behavior on the basis of institutions. Furthermore, the New Institutionalism has been informed by the understandings about individual political behavior that have emerged from other parts of political science. Therefore, one of the central questions in contemporary institutional theory is how institutions shape individuals while at the same time individuals shape institutions. Finally, the New Institutionalism has extended its analytic reach from just issues of comparative politics to influence a wide range of topics such as international relations, political parties, and interest groups.

One Institutionalism or Many?

Although the revival of institutional theory has been successful in returning the concern for political structures and organizations to the center of political science, it was perhaps too successful in that it has spawned a wide range of alternative versions of institutional theory. Each of these alternative approaches provides important perspectives on the behavior of institutions and on politics more broadly, but each also has important limitations. Although a brief discussion of each approach cannot do them justice, it is important to at least identify the more important characteristics of each.

Normative Institutionalism

The first major version of institutionalism to emerge was normative institutionalism. It is here referred to in this manner because it assumes that the behavior of individuals within an institution is shaped by a "logic of appropriateness," meaning the norms, values, symbols, and myths within that institution. This perspective is in contrast to a "logic of consequentiality" in which individuals choose their actions based on their predictions and evaluations of the outcomes. In the normative perspective on institutions, individual preferences are endogenous to the institution, being created as individuals join the institution, and the process of socialization of new members is crucial for maintaining appropriate behavior within the institution.

The normative institutionalism is closely allied with strands of institutionalism in sociology, as well as closely connected to organization theory. Its emphasis on the norms and values defining institutions is similar to the approach of sociologists such as Philip Selznick, who have also emphasized the importance of values in institutions. This work also is in the tradition of the "bounded rationality" of Herbert Simon, who has argued that individuals cannot be comprehensively rational but rather operate within a set of boundaries on that rationality, notably those imposed by organizational memberships. The "logic of appropriateness" establishes a clear set of bounds on the rationality of individuals and provides the individual with a set of boundaries for behavior.

Rational Choice Institutionalism

Rational choice institutionalism is the second widely used approach to institutionalism, but it is almost diametrically opposed to the logic of normative institutionalism. Rational choice institutionalism assumes that individuals within institutions still attempt to maximize their personal utility, but they do so within the context of the incentives and rules that can be used to characterize institutions. In this perspective, institutions are defined by individual reactions to those rules and incentives so that the institution constitutes in essence an ecology of action for the individual participants.

In short, in rational choice institutionalism, individuals make their decisions according to a logic of consequentiality.

Even more than in most other approaches to institutions, in the rational choice perspective, institutional designs are undertaken explicitly to overcome certain fundamental social problems. One is the need to overcome collective action problems and to create equilibrium under conditions that otherwise would produce instability. Somewhat similarly, this approach to institutions is concerned with the capacity to overcome collective action problems, such as the tragedy of the commons, and problems of common pool resources. Finally, rational choice institutionalism focuses on the designs of institutions that facilitate or hinder action in government in general.

Historical Institutionalism

The simplest prediction for any social or political setting is the persistence of the status quo. In the historical institutionalism, this basic observation has become central to a theoretical approach to political science. The assumption behind the historical institutionalism is that the decisions about policies and organization made at the "formative moment" of an institution are likely to persist until they are transformed by some force sufficient to overcome the inertia in the system. This "path dependence" would persist until some "punctuated equilibrium," meaning major departures from the established patterns based on some fundamental transformation of the environment or of the ideas governing the policy domain.

Although historical institutionalism has been widely used within political science, it has clear roots in economics. Economists have been interested in why suboptimal solutions to problems persist, even in the presence of better options. The fundamental answer offered by economists has been the transaction costs of moving to superior solutions. Political scientists, on the other hand, have tended to focus on the reinforcements offered for continuing the existing solutions, especially the benefits that may be offered to political and administrative elites responsible for the programs. In this perspective, significant change in an institution will not occur without conflict over the nature and the mission of the institution.

Discursive Institutionalism

Most versions of institutionalism are concerned directly with structures and their interaction with the members of those institutions. Scholars have, however, developed an approach to institutions that depends more on the ideas of the members of those institutions. The logic of this approach is that members of an institution have alternative discourses about the nature of the institution and about its programs. These discourses may be coordinative, linking the members of the institution, or they may be communicative, linking the institution with its environment. In either case, however, the argument is that the best means of understanding the institution is to understand its discourses.

This discursive version of institutionalism is in many ways closely related to the normative institutionalism discussed above. Both of these approaches are based on ideas, with the assumption that those ideas rather than formal hierarchical structures are central in controlling the behavior of the members of the organization. One principal difference between the two approaches is that the normative version tends to assume that the institution strives toward one common set of ideas and that those ideas will be relatively stable. The discursive model, on the other hand, assumes more competition among competing discourses, so that any set of ideas will generally be in competition with alternative discourses.

Central Theoretical Questions

As well as the numerous differences existing among the several approaches to institutionalism, there are some important theoretical questions that cut across the approaches. The various approaches all provide somewhat different answers to these questions, but all must address these points if they are to function as effective theoretical approaches to institutions and to political life more generally.

Institutional Change

Perhaps the most difficult question for any institutional theory is how it integrates change into its framework for analysis. The basic logic of institutions is to create predictability and stability for individual behavior and within the structures themselves. In general, therefore, institutional theories tend to be better at explaining and predicting stability than they are at explaining change. Indeed, for historical

institutionalism, the principal focus of the approach is demonstrating the difficulties of change actually occurring in institutions, except in the most extreme circumstances. Although institutional theory does emphasize stability, we do know that institutions change, and we need to bring change into the theoretical apparatus.

Even the historical institutionalism that places stability at the center of its analysis of institutions must somehow find the means for understanding and coping with change. As noted earlier, the original presentations of the approach depended upon major changes—punctuations—as descriptions of changes, although there was little means of explaining those major shifts. More recent theorizing has retained the underlying logic of historical institutionalism while also admitting a number of more gradual mechanisms for change, such as layering or displacement.

At the other end of the spectrum of mutability, rational choice institutionalism implies the greatest facility for change. Since the preferences of individuals are unchanged by their involvement with the institution, all institutional change requires is to alter the rules and/or incentives for change to occur. If the incentives are designed properly then those who would alter institutional behavior can produce the types of behaviors that are desired. That said, scholars working in this tradition have also begun to consider less rationalistic mechanisms such as learning as sources of change.

The models of institutions based on values pose particular problems for change. While the internal control of individuals within an institution is facilitated by their normative commitment to the institution, producing change requires undoing efforts at having those members accept the "logic of appropriateness." If the leadership of the institution seeks to alter those beliefs, then resocialization and recommitment become necessary. This is not only difficult and time-consuming but may over time breed cynicism among members when they are given seemingly mixed signals over what constitutes "good" behavior within the institution.

Institutionalization and Deinstitutionalization

As well as being concerned about the way in which institutions change, institutional theorists must be concerned about how institutions form and how they disintegrate. The process of creating institutions, or institutionalization, is crucial for the success of an institution, but the conceptualization of this process is closely allied with the various approaches to institutionalism: Normative institutionalists, for example, tend to see institutionalization as infusing a structure with values, while historical institutionalists tend to assume that institutionalization occurs virtually automatically during the "formative moment" of the program.

Most institutional theory tends to consider institutions in a rather dichotomous manner—they either exist or they do not. In reality, however, institutions are always becoming more or less institutionalized. For example, from a normative perspective, if the dominant values of an institution are challenged, or are not being sufficiently followed by the members of the institution, then the institution will be to some extent deinstitutionalized. If the processes of deinstitutionalization go too far, then the institution will fail or perhaps be replaced by a new one in some process of "punctuated equilibrium."

Individuals and Institutions

Finally, the interactions of institutions and individuals are important for defining the manner in which institutions perform their tasks. A fundamental paradox dwells within this relationship in institutional theory. Institutions are human creations, but once created, they are meant (at least in some models of institutions) to shape human behavior and to be virtually immutable. Although seemingly paradoxical, this points to a crucial characteristic of institutional theory: Individuals shape institutions, but institutions also shape individuals.

Again, the manner in which this fundamental characteristic of institutional theory is actually manifested depends upon the nature of the particular approach to institutions. The normative approach, for example, emphasizes the way in which institutions shape the preferences and values of its members. Although less explicit, the historical institutionalism also assumes that being within an institution tends to shape the perspectives of individuals so that they will maintain the policy approach of the institution.

Individuals not only shape institutions at their inception, but they may have continuing influence over those institutions. Individuals are the raw material of public institutions—both as employees and

as the clients of their programs. If either of these two groups change in any fundamental way, then too the institution will have to adapt. For example, the changes in the recruits coming into the U.S. military during the Vietnam War required fundamental changes in military management, and those changes persisted in the institutions.

Conclusion

The preceding discussion has considered institutionalism in terms of the various alternative versions, all of which have something to say about institutions. Each of these approaches has something interesting to say, but the question that remains is whether there is enough in common among them to argue that there is an institutional approach, rather than just a collection of rather disparate approaches. While the alternative approaches are useful in their own right, and can illuminate many aspects of political behavior, if institutionalism is to be an alternative paradigm for political science, then there should be some greater integration of the ideas within these various versions.

At a minimum, all these approaches are concerned with creating regularities of behavior, especially in situations in which one would expect more diverse patterns. The approaches may generate that regularity in rather different ways, but they all still create greater regularities and greater predictability than would be found in social systems. Furthermore, the degree of regularity expected in the several approaches may differ significantly—with the discursive model requiring rather little—while some regularity is central to all the approaches.

Institutional theory is an important contribution to our collective understanding of social and political questions, but it is certainly not without its shortcomings. The most obvious problem is the lack of uniformity and common definitions of even basic points such as what constitutes an institution. But emphasizing that politics occurs largely within institutions, and that indeed a good deal of politics is the interaction of institutions, these approaches taken together have helped alter the perspective of the social sciences. The extreme individualism of some approaches to political life has been challenged, and the need to understand institutions has been returned to a central place in the social sciences.

Institutions as Moral Persons

This entry presents an important issue in social ontology: whether formal institutions, such as organizations or corporations, can be considered as bona fide moral persons. The entry discusses the principal theories' pros and cons.

The Issue

It is difficult to ignore the fact that institutions—formal organizations that evidence corporate managerial structures and decision making (unlike constructs of social order such as the family or marriage)—play dominant roles in the social, political, and economic spheres and that they are often targets of moral evaluation in ordinary discourse.

Nonetheless, since at least as early as the 17th century, it was fashionable in the philosophical literature to regard the actions and interests of institutions, for moral purposes, as reducible to the actions and interests of those humans who function within them. Only humans, it was held, can be moral persons and morally appraisable. "Moral persons," on that traditional account, are solely humans who are capable of intentional action, of conforming to rules, of understanding the moral significance of what they do and how they are perceived by others, and, in some measure, of being receptive and reactive to moral reasons to do one thing rather than another. That is, moral persons must be functionally intentional, responsive to moral reasons, and capable of affectivity. Opponents of treating institutions as moral persons maintain that institutions qua institutions cannot meet all or some of those criteria and so must not be admitted into the moral community.

Denying That Institutions Can Be Moral Persons

Two theories, one metaphysical (ontological) and the other meta-ethical, typically are intertwined in the position held by opponents of treating institutions as moral persons. The metaphysical one is usually referred to as *methodological individualism*. The other might be called *moral individualism*.

Methodological individualism holds that the behavior of an institution is always *reducible* to the behavior of the individuals who make up the institution (without remainder). Methodological individualists maintain that apparent institutional actions always can be reduced to a set of facts about individuals, which can then be arranged to provide a complete description of the behavior of institutions. For them, it might be said, the names of institutions are collective, not singular, nouns, and an institution is little more than a contractual nexus of humans. Many sociologists have rejected that theory because it does not adequately explain a significant number of social facts concerning organizational/institutional behavior.

Moral individualists, who may or may not reject methodological individualism, maintain that the well-being of individual human persons is the primary (maybe the sole) consideration of ethics and that from the moral point of view only individual humans who satisfy certain criteria (as stated above) can be proper subjects of moral responsibility ascriptions and objects of moral assessment and reactive attitudes such as moral indignation and resentment.

Defending the View That Institutions Can Be Moral Persons

With the publication of "The Corporation as a Moral Person" in the *American Philosophical Quarterly* in 1979, Peter A. French attacked the individualist tradition regarding institutions, organizations, and corporations by offering a functionalist conception of what it is to be a moral person and an analysis of how formal institutions can qualify as moral persons. French defended the view that corporations exhibit intentionality, are capable of rationality regarding their intentions, and are able to alter their intentions and behavior to respond to reasons, including moral reasons. He concluded that corporations and corporate-like institutions are full-fledged moral persons. Central to this argument is his depiction of the *internal decision structures* (he dubbed them CID structures) that make institutional decisions and actions possible. By coordinating, subordinating, and synthesizing the actions and intentions of individual human members of a formal organization (and often its machines), a CID structure transforms them into an institutional action taken for institutional reasons, such as promoting institutional interests. CID structures are composed of two elements: (1) an organizational chart that delineates stations and levels within the institution and (2) rules that reveal how to recognize decisions that are institutional ones and not simply personal decisions of the humans who occupy positions on the chart. Those rules are typically embedded, whether explicitly or implicitly, in corporate policy.

French's argument regarding the intentionality of institutions in the original paper of 1979 rested on his adoption of the belief/desire model of intentionality. Subsequent to criticism of his use of that model, French abandoned it and adopted Michael

Bratman's planning theory of intentionality. On Bratman's account, intentions are elements of plans—that is, deliberations and reflections prior to action. On French's revised account, a CID structure synthesizes the actions, judgments, and attitudes of individuals into the intentions (plans) and actions of an institution while also providing a mechanism for self-reflection, which is essential to its responsive function and rational decision-making processes. Institutional plans might radically diverge from those that motivate the human persons who occupy institutional positions and whose bodily movements and judgments are necessary for the institution to act.

Underlying this position is the conception of moral personhood as an artifact of *redescription.* A CID structure licenses redescribing actions of humans as the devising and executing of institutional plans, thereby revealing the institutional moral person. Gunther Teubner, along the same lines, describes an institution as an autopoietic system of actions that reproduces itself. Carlos Gomez-Jara Diez maintains that (corporate-like) institutions are not made up of human beings or even human actions. They are composed of institutional decisions and actions that construct their own social realities, which may be quite different from the reality constructions of the humans working in them.

The Debate Over Affectivity

Some who favorably view the theory that institutions are capable of intentional actions qua institutions maintain that moral personhood essentially involves *affectivity,* whereas formal institutions lack that capacity qua institutions. Institutions cannot care about the moral quality of their actions or have reactive attitudes, and so they cannot be moral persons. Those who hold the view that institutions are moral persons might argue that there are different kinds of moral personhood and institutional moral personhood does not require affectivity. Alternatively, it might be maintained that the capacity for reactive attitudes is not a necessary condition for anything to be a moral person. According to Deborah Tollefsen, what is needed is an argument to the effect that institutions do not necessarily lack affectivity, though like some humans, they may not always show it. They certainly are objects of the reactive attitudes of humans, such as resentment and indignation; on this view human expressions of reactive attitudes toward institutions are read as a demonstration that institutions are morally addressable and assessable, and that, she maintains, entails that they are presumed to have the ability to consider criticism and respond in a morally appropriate fashion. Institutions also regularly express reactive attitudes and emotions in their communications with humans and each other. Tollefsen offers a vicarious emotion theory in which employees are "conduits" for institutional emotions to account for institutional affectivity. The idea is that an institutional employee in her role qua institutional employee may be the expresser of vicarious moral emotion for the institution in its dealings with those outside the institution. Tollefsen notes that humans can have vicarious reactive attitudes and moral emotions for others even if those others do not (cannot?) have the same attitudes about themselves. So on this account, though institutions cannot directly feel moral emotions, moral emotions can be institutionalized within them.

French had maintained that institutional intentional acts are typically human bodily movements under an institutional redescription, CID structures providing epistemically transparent bases for that descriptive transformation. This thesis suggests that a similar redescription account might be applied to expose institutional affectivity, rather than depending on a vicarious emotion theory. An institution's decision structure may contain rules for the conversion of descriptions of certain types of utterances by appropriate humans into descriptions of the expression of institutional reactive attitudes.

No one claims that institutions experience "pangs" of regret or remorse or sorrow as humans might when they express reactive attitudes with regard to the behavior of others or themselves, but the ability phenomenologically to feel emotions may not be a necessary element of moral personhood. Expressions of reactive attitudes generally are performative, ritualistic, and conventional. Perhaps the expression in accord with rules is all that is required to attribute affectivity. We might, of course, regard mere ritualistic expressions as insincere if they are not "backed" by a certain sort of feeling; however, even in human affairs, an apology is not void should the apologizer not feel sorrow, regret, or remorse. If the CEO of BP expresses the corporation's regret for the Deep Water Horizon oil disaster, it seems reasonable to take as prima facie true the sentence "BP

regrets the disaster," though we typically test the sincerity of such regret by monitoring subsequent institutional behavior. Something similar seems usually to occur in the case of human expressions of emotions. Where sincerity is the issue, subsequent behavior trumps appeals to feelings. If the expression of institutional reactive attitudes and other forms of affectivity can be functionally engineered by the inclusion of rules and policies in an institution's CID structure, so that when an occupant of a certain institutional role expresses regret, sorrow, or some other emotion, that just is the institution expressing the emotion, making the apology, or regretting what it has done, then, regardless of whether or not humans in the institution, individually, collectively, or vicariously, have the appropriate emotion, institutions would seem to meet the standard conditions of moral personhood and be normatively competent, their behavior being subject to moral assessment qua institutions.

Instrumentalism of Scientific Theories and Constructive Empiricism

Our scientific theories allow us to systematize and to predict observational experience; and in so doing, they frequently postulate the existence of various *unobservable entities* and processes that are supposedly responsible for, and thus help us to explain, such occurrences. For example, it is a commonplace that unsupported bodies drop; our scientific theories allow us to calculate how quickly they will fall and also tell us that this is because of the strength of the gravitational field.

An important question in the philosophy of science concerns the appropriate attitude that we should take toward this additional content. For the "scientific realist," the very fact that they allow us to successfully systematize and predict our observational experience gives us good reasons to believe that there really are microscopic organisms, gravitational fields, and atoms; and consequently, realists maintain that it is part of the scientific enterprise to investigate and to describe those parts of the external world that lie beyond our unaided senses. Ultimately, the scientific realist argues for a strong continuity between those claims of our scientific theories that concern our observational experiences and

those claims that concern the unobservable structure of the world.

By contrast, both "instrumentalists" and "constructive empiricists" have challenged this, arguing either that the unobservable content of our scientific theories does not fulfill the same semantic function as the observable content (instrumentalism) or that it does not serve the same cognitive role (constructive empiricism). Both positions are therefore committed to defending a principled distinction within our scientific theories—either logico-semantic or more broadly epistemological—and criticisms of them have largely targeted the feasibility of this project. Neither position has proved particularly popular; yet while instrumentalism has now been largely abandoned in the contemporary literature, constructive empiricism remains an ongoing research program and has evolved to include fundamental issues regarding the nature of empiricism and of the epistemology of science more generally.

Instrumentalism

According to the instrumentalist, the purpose of a scientific theory is simply to help *facilitate* the prediction of observable events. Instrumentalism is consequently committed to a sharp distinction within the language of our scientific theories, between the "observational vocabulary" that describes the observable events in which we are interested and the "theoretical vocabulary" that helps us systematize their prediction; and it maintains that the latter is to be understood as neither referring to additional unobservable events or processes nor providing any deeper level of explanation for the observable events it helps predict. On this account, a scientific theory is quite literally a *tool*—that is, an *instrument*; its theoretical vocabulary is not to be reduced or reinterpreted in terms of our observational vocabulary but shown to lack any assertoric content whatsoever.

Instrumentalism draws its inspiration from the work of the eminent German physicist Ernst Mach at the end of the 19th century, but it only achieved formal sophistication in the 1950s following the publication of various technical results by William Craig. According to Mach, science aims to provide us with an *economy of thought:* For instance, a scientific law to the effect that the acceleration due to gravity is equal to some constant does not describe the properties of some unobservable gravitational field, but it merely provides a neat summary of the results gained through observing the time taken for many individual unsupported bodies to drop to the floor. Central to Mach's position is the view that the putative content of our theoretical vocabulary is radically *dissimilar* from our observational experience—for instance, that the posited properties of atoms are clearly not mere extrapolations from the properties of the macroscopic objects that they are supposed to help explain—and thus that we do not have sufficient justification to treat our theoretical vocabulary on an ontological par with our observational vocabulary; Mach's instrumentalism is consequently a hostage to advances in our experimental technique and to the increasing justification that accrues to well-established theoretical postulates.

A more promising proposal is therefore to take the instrumentalist position as asserting a particular *logico-semantic* thesis: that, in contrast to Mach, it is not that our theoretical vocabulary is somehow too strange or insufficiently warranted but rather that it is entirely *dispensable* to the practice of science. If a scientific theory is merely a device for the systematization and prediction of observational experience, then the role of our theoretical vocabulary will be completely exhausted by the inferences it facilitates between one observable event and another. Consequently, it will in principle be possible to *eliminate* our theoretical vocabulary altogether in favor of a re-axiomatization that simply states the appropriate inferential rules entirely within the observational vocabulary of the theory. In 1953, William Craig published a result showing how this process can be made logically precise—that while the instrumentalist elimination of the theoretical vocabulary will inevitably prove to be considerably less elegant than the original scientific theory, the resulting reconstruction will be recursively enumerable and, by Craig's theorem, recursively axiomatizable.

Nevertheless, the instrumentalist re-axiomatization of a scientific theory will always consist of an infinite number of axioms, regardless of the complexity of the original theory; and, in addition, any such re-axiomatization will always be a post hoc affair, parasitic upon the existence of an already articulated scientific theory (presumably arrived at via some noninstrumentalist methodology). And while neither of these issues undermines the technical success of the instrumentalist re-axiomatization, they do indicate its epistemological undesirability.

Similarly, it is also objected that the purpose of a scientific theory is not merely to systematize and predict observable events—it is also to uncover the unobservable structure of the physical world and to explain the occurrence of observable events on their basis. These are all claims that the instrumentalist must simply deny.

More forceful objections concern the formal presuppositions of instrumentalist re-axiomatization: that it is committed to a syntactic account of scientific theories, whereby a theory is understood to consist of a set of sentences, propositions, or other linguistic devices, and that it is committed to the precise demarcation of a philosophically privileged observational vocabulary. Many contemporary philosophers of science maintain that an alternative, model-theoretic account of our scientific theories offers expressive resources consequently unavailable to the instrumentalist; and it is now widely acknowledged that the holistic nature of confirmation problematizes any attempt to cleanly differentiate between our "observational" and "theoretical" vocabularies.

Perhaps the most damaging objection to instrumentalism, however, concerns the role of probabilistic or statistical inference in the sciences. This was first formulated by Carl Hempel, who noted that instrumentalist re-axiomatization will only preserve the *deductive* inferential relations of the original scientific theory—it will therefore be completely unable to accommodate the wide range of *inductive* inferences frequently drawn in scientific practice, even those that only hold between observable events. Regardless of its philosophical merits, therefore, instrumentalism is often rejected as an inadequate account of contemporary scientific practice.

Constructive Empiricism

Constructive empiricism represents the most recent articulation of the underlying instrumentalist point of view; it has been developed—and almost exclusively defended—by Bas van Fraassen and received its first book-length presentation in 1980. Like the instrumentalist, the constructive empiricist also maintains that the aim of science is nothing more than *empirical adequacy,* that is, accuracy with respect to the observable phenomena. However, unlike the instrumentalist, the constructive empiricist does not therefore believe that our "theoretical vocabulary" can be dispensed with or indeed that the language of our scientific theories even admits of a principled distinction between its supposed subvocabularies. According to the constructive empiricist, the distinction between observable and unobservable phenomena is an *empirical* distinction, determined by the nature of the entities and processes in question rather than by the language we use to describe them; and the emphasis upon empirical adequacy is not due to a semantic inadequacy in the claims our theories make about unobservable phenomena or even due to skepticism regarding their relative justification—for the constructive empiricist, it is rather a *descriptive* claim about *scientific practice*—namely, that it just is not part of the aim of science to take us beyond observable phenomena. Consequently, while we will accept a scientific theory as a whole and continue to use its unobservable content in order to help us make predictions, construct research programs, and even offer explanations, we nevertheless *do not need to believe* what our theories say regarding atoms, fields, and other unobservable phenomena.

Constructive empiricism thus depends upon two crucial distinctions: (1) the distinction between observable and unobservable phenomena, which gives content to his notion of empirical adequacy, and (2) the distinction between *acceptance* and *belief,* which underlies how the constructive empiricist can use the unobservable content of his theories without thereby believing it.

Criticisms of the position have targeted both distinctions. With respect to the latter, it is often objected that the constructive empiricist's notion of "acceptance" is so rich that it is in fact indistinguishable from the allegedly contrasting one, "belief"—that in trying to satisfy the instrumentalist intuition that science is primarily concerned with our observational experience, yet without thereby diminishing the manifest utility of the extra-empirical content of our scientific theories, constructive empiricism simply collapses into a version of scientific realism.

Critics of the distinction between observable and unobservable phenomena have challenged both its cogency and its content. If the distinction rests upon empirical facts concerning the phenomena in question, then in order to determine its scope, we must rely upon our best scientific theories (in this case, regarding the behavior of light and the physiology of the human eye) to investigate the matter. Yet the distinction between observable and unobservable phenomena is

supposed to determine which parts of a scientific theory the constructive empiricist is to believe—including those theories that we must use in order to determine the content of the distinction. There is therefore a fundamental *circularity* in the constructive empiricist's distinction, which many take to be vicious.

Another complaint is that the constructive empiricist's distinction is *epistemologically dishonest*: that since a phenomenon counts as observable, provided there are *some* circumstances under which we would observe it (even if these circumstances could never actually be realized), there are no sound principles for privileging, say, our claims regarding the moons of a distant planet over those regarding the microscopic organisms in a petri dish. However, while this consideration may put some pressure on the constructive empiricist's contention that the aim of science is empirical adequacy, it must be remembered that the position itself does not depend upon an epistemological distinction between the claims of our scientific theories.

This last point has been made more explicit in van Fraassen's later work, where constructive empiricism is presented as part of a broader conception of empiricism and of the epistemology of the philosophy of science more generally. In van Fraassen's view, (scientific) rationality is to be thought of as a matter of *permission* rather than *obligation*—there are no universally applicable rules of inference, and an agent is justified in holding any set of beliefs provided they are not self-undermining. Specifically then, it cannot be a compelling objection to the constructive empiricist that our scientific claims regarding both observable and unobservable phenomena are on an epistemological par, since questions of justification are now inseparably bound up with questions of our epistemic *values*.

Consequently, constructive empiricism is no longer to be thought of as a rival to scientific realism but simply an alternative; and the challenge for the scientific realist, the constructive empiricist, and even the instrumentalist is merely to show that the position of each meets their own internal standards of philosophical adequacy.

INTELLIGENCE

Societies often differ as to which traits receive emphasis in defining intelligence: rote memory in preliterate societies, mapping among Australian Aboriginals, and so forth. On the other hand, disciplines such as philosophy or social science have also tried to pinpoint intelligence. This entry reviews various theoretical attempts at defining and measuring intelligence and raises some critical ethical points associated with such attempts.

Definitions and Theories

Different thinkers give different definitions of intelligence. Arthur Jensen thinks of it as *g* (the general intelligence factor derived from factor analysis of a variety of mental tests). This concept ranks mental skills in terms of their cognitive complexity: It places solving an arithmetic problem as more "intelligence loaded" than tasks of rote memory. Robert Sternberg believes that conventional IQ tests measure the analytic skills useful in schools and ignore creativity and practical intelligence (say, how to get people to cooperate). Howard Gardner is even more inclusive and applies the label "intelligence" to the cognitive operations of musicians and sports people.

David Wechsler, who designed the IQ tests most often used today, was more pragmatic. He used 10 subtests that collectively measure a variety of mental skills: mental acuity, or the ability to learn quickly and accurately and analyze novel situations;

information processing, or the ability to absorb information quickly about others and the world; memory and working memory, the latter referring to your ability to manipulate what is in your mind; mapping; the vocabulary we need to learn, analyze, and communicate; sufficient basic information; and learning to attack problems.

Many reject such definitions of intelligence as too imprecise. This may be a mistake, as signaled by the philosophy of science. Definitions of seminal concepts need to be general enough to accommodate a variety of proposals about *measurement*. No one would want a definition of "celestial influence" specific enough to dictate a choice between Ptolemy's sky geometry, Newton's concept of gravity, and Einstein's notion that mass affects the shape of space. No one would want a definition of the "origin of species" that dictates a choice between Darwin and creationism. Seminal concepts do not dictate which theories are viable; that is the role of theory building and evidence.

The philosophy of science does brand a certain tendency in psychology a mistake: A definition must not preempt the role of a measuring instrument. For example, Jensen once defined intelligence as what IQ tests measure. This allows no room for IQ tests to improve. No one would define heat as what the thermometers of any given time measured. It was a struggle to develop adequate thermometers, and even today, under extreme conditions, we have to develop new measuring devices.

Measurement

Given their dominance, it is worth describing the Wechsler subtests and the cognitive skills they measure: Block Design and Visual Puzzles (mental acuity); Coding and Symbol Search (information processing); Mental Arithmetic and Digit Span (working memory); Vocabulary (verbal communication); Similarities (classification); Arithmetic (numeracy); Information (acquaintance with the mechanics of the modern world); Comprehension (knowledge of everyday life).

It is often objected that such tests are biased because they measure mental traits valuable primarily in a modern industrial society. In response, it is claimed that that is what they are designed to do. However, three points are legitimate.

First, the fact that people who have not yet entered modernity and do badly on IQ tests should not be interpreted as meaning that they lack cognitive capacity. Wechsler does not assume that all societies would weigh mental skills the same. Rote memory would be more important in preliterate societies, mapping among Australian Aboriginals, and so forth. As shown by massive IQ gains over time, even our own (Western) ancestors in 1900 would have had very low IQs scored against current norms. That is because they placed less weight on analytic skills and more on the utilitarian skills they needed in everyday life. The people of developing nations are beginning to make huge IQ gains as they enter modernity.

Second, Jim Heckman and others have shown that noncognitive factors, such as motivation and self-discipline, are at least as important as IQ in predicting academic success. Third, the jury is still out on whether there are valid measures of creativity and practical intelligence or even whether or not the Wechsler tests miss these traits.

There is a debate among specialists as to the significance of massive IQ gains over time. That there have been such huge intelligence gains seems improbable. There is general agreement that human brains have no greater cognitive potential at conception than they did in 1900. There is general agreement that we are better at the analytic and classification skills that schools and professions value more today than in the past. Rather than saying our minds are more intelligent, it may make sense to say that they are more *modern*.

Ethics

Ethical problems in definitions and measurement of intelligence immediately surface: individual rights versus group membership (affirmative action policy to achieve ethnic balance), justice (as equal treatment) versus equity (equal treatment qualified by equal opportunity), utilitarian considerations (efficiency) versus individual self-esteem (employment for all), justice versus self-interest (renting your spare room to a Black male rather than waiting for, say, a Korean American female, as some do), and so on.

These problems are not solved by the slogan that we should treat everyone as an individual rather than as a member of a group. This stance can be used against affirmative action as well as against racism. Moreover, people tend to treat other people as members of a group when information about individuals is expensive. A landlord cannot afford private detectives and, therefore, uses race as a cheap information-bearing trait.

Ethical controversies in the area of intelligence and in particular over attempts to link genetics and IQ have been extremely acrimonious, as evidenced by the furor over Hans Eysenck's and others' views in the recent past. Controversies such as these often mingle philosophy and social science, blurring the distinction.

Ethical problems such as the foregoing are complicated by the question of whether ethnic differences are environmental or partly genetic. Affirmative action as a temporary expedient is different from affirmative action as a permanent option. Flynn has argued that IQ differences are primarily environmental, but other scholars who have looked at the same evidence differ. Another ethical problem is this: Should speaking the truth be qualified by its consequences? John Stuart Mill would have said that the truth cannot be racist and that the consequences of suppressing truth to spare feelings are counterproductive for everyone, including the group concerned.

Intention, Social Psychology of

In our everyday lives, we use the term *intention* in the sense that our intentions are not always realized by our actions. It is this problem of *weakness of the will* or the *intention–behavior gap* that the psychology of intentions has studied. Under this conception, intentions are virtually indistinguishable from goals.

To elucidate the characteristics of such intentions or goals, this entry first discusses the weakness of the will. Next, self-regulation strategies of intention formation (goal setting) and implementation (goal striving) are introduced. Finally, the role of context for goal pursuit is highlighted—in particular, the activation of nonconscious goals and the elicitation of the "feeling of doing" or of the experience of conscious will.

Weakness of the Will

Weakness of the will has been one of the first puzzles philosophy has tried to grapple with (since the time of Socrates and Plato), but it is also central to social sciences. Weakness of the will is exhibited when agents fail to successfully pursue their intentions. A primary challenge in goal pursuit is therefore setting (committing to) goals that are not only attractive but also feasible. One method for bolstering such wise goal setting is mental contrasting of future and reality. This self-regulatory strategy asks the agent to imagine achieving a desired future outcome (e.g., getting an A in an upcoming exam) and then to imagine the most critical obstacle of reality standing in the way of achieving this future (e.g., an invitation to a party). The juxtaposition of the desired future and its obstacle automatically highlights both the perceived valence and the perceived feasibility of goal attainment. Consequently, mental contrasting strengthens commitment to and striving for goals that are perceived as not only attractive but also feasible and helps people stay away from or disengage from (attractive) goals that cannot be reached.

Goal Setting

Goals may vary not only in commitment but also in content. For instance, goals may be promotion or prevention oriented (promote good grades vs. prevent bad ones), and these facilitate goal attainment depending on whether they match the individual's self-view (ideal vs. ought) and the chosen means (eagerness vs. vigilance). Goals may contain learning versus performance outcomes (e.g., learning to solve vs. showing that one can solve problems), whereby the former type of goal fosters goal attainment when people must cope with setbacks. Finally, goals with specified standards (e.g., study for 2 hours per day) promote success more effectively than goals that keep the desired outcomes vague (e.g., study hard).

Goal Striving

Once a person has committed to a goal, it is useful to furnish it with plans specifying the where, when, and how of goal striving (i.e., form additional intentions called *implementation intentions*). It is particularly effective to lay down these plans in the format of "If I encounter situation *x*, then I will perform goal-directed behavior *y*." For example, if a student has the goal to attain an A in the upcoming test, she might form the following implementation: "If my friend invites me to her party, then I will immediately say no!" These plans derive their self-regulatory strength from the principle of strategic automaticity. The if–then structure links the selected contextual cue to an instrumental, goal-directed response, leading to increased recognition of specified cues for goal striving and the automatic initiation of the respective goal-directed response. Mental contrasting and implementation intentions complement each other in their goal-setting and goal-striving function, leading to more effective goal attainment than either self-regulation strategy separately.

Context and Unconscious Pursuit

Implementation intentions are not the only way to facilitate automatic goal striving. Cues in the agent's environment can lead to the nonconscious activation of goals. Take for example a person at a party where she does not know anyone and will never see the people there again. Even if she will walk into the party with no explicit goal to affiliate, the situational cues at the party (music, fancy clothes, etc.) will trigger her latent affiliation goal *automatically* (i.e., outside of awareness). The partygoer will thus display goal-directed behaviors such as preferring to affiliate over other tasks, continuing to socialize when interrupted, and ceasing affiliation efforts once the goal is completed. While she will not be able to report on having had this affiliation goal, one can see from her behavior that she was striving for this goal.

Finally, goals also affect people's experiences of acting. For example, goals may serve as quasi-premonitions. Privately witnessing our intentions contributes to our sense of not only having privileged access to our actions but also that we are the cause of them. Cues from the environment such as foreknowledge of the immediate event and lack of an obvious explanation of the event can trigger us to attribute an action to ourselves, though we have not *caused* the action. This phenomenon, called "the illusion of conscious will," when taken together with automatic goal striving, highlights that while intentions may be the cause of our actions, they may also be unduly influencing our beliefs regarding which actions we have caused.

Conclusion

People do not always attain their intentions or goals—a problem referred to as weakness of the will or the intention–behavior gap. The self-regulation strategy of mental contrasting fosters goal attainment by causing people to set goals that are both desirable and feasible. Goal contents can be framed in different ways (promotion vs. prevention, learning vs. performance, specific vs. vague), and the type of framing will affect the likelihood that the goal will be achieved. Difficulties on the way to achieving goals can be overcome by forming implementation intentions or if–then plans, a self-regulation strategy that guarantees goal attainment, particularly when used in combination with mental contrasting. Finally, goals may be activated outside of awareness; at the same time, awareness of goals may give agents the feeling that they caused an action they did not, in fact, effect—something that philosophical theories of introspection have identified too.

INTENTIONALITY

Intentionality is the phenomenon of something's being *about* something or *of* something (in the sense of "of" in which a picture can be *of* something, e.g., a battle). Discussions of intentionality typically focus on *mental* intentionality—for example, thinking that the economy is in a slump, seeing the shed at the bottom of the garden, or desiring an oatmeal butterscotch cookie.

This entry focuses on contemporary philosophical accounts of intentionality and in particular on attempts to naturalize it, addresses three main obstacles such naturalizing has faced, and looks at recent approaches in this area related to cognitive phenomenology.

Naturalistic Approaches to Intentionality

Many theorists take intentionality to be an entirely natural, *physical* phenomenon, and a commitment to reductive naturalism has dominated discussion of mental intentionality in recent years. *Reductive naturalism* requires one to give an account of mental intentionality in entirely *nonmental* terms, and the consensus has been that the way to do this is to identify a natural relation that holds between states of the brain and states of the environment when and only when the former are about the latter. Philosophers give the example of tree rings "tracking" the age of trees (an entirely nonmental phenomenon) to ground the sense in which intentionality can be a natural relation. Internal states of the brain are held to track the presence of specific external conditions in a fundamentally similar way and to carry information about the environment in virtue of this tracking relation. Different theories expand on this basic idea, diverging in their more detailed expositions of the tracking relation. The dominant naturalistic theories have been causal or covariation theories and teleosemantic theories.

Problems With Naturalizing Intentionality

The "naturalization project" faces certain well-known difficulties: (1) it must account for the possibility of misrepresentation, (2) it must deal with problems of indeterminacy of content, and (3) it must respond to the worry that, once naturalized, intentionality will turn out to be ubiquitous.

1. The problem of misrepresentation is (roughly) that if it is necessary, for a mental state *S* to represent a state of affairs *X*, that *S* reliably indicate (or causally covary with) *X*, then *S* cannot occur unless *X* occurs. But this means that there is no room for misrepresentation or mistakes—that is, for a case in which *S* occurs when *X* is not the case. But clearly, a mental phenomenon can misrepresent: I can represent a dog as being black even if it is brown, or I can think that someone is Santa Claus even though Santa Claus doesn't exist.
2. Two difficulties concerning the indeterminacy of content are the "disjunction problem" (the disjunction problem may also be classified as a special case of misrepresentation) and the "stopping problem." The disjunction problem arises because a mental state *S* may systematically covary with distinct states of affairs. For example, if *S* systematically covaries with both sheep on dark nights (=*X*) and goats on dark nights (=*Y*), does *S* represent *X* or *Y*, or perhaps the disjunction [$X \vee Y$] (sheep or goats on dark nights)? The contents of our mental states do not seem indeterminate in this way.

To illustrate the "stopping problem," consider a subject, Lucy, who is perceiving or thinking about a moose called Mandy. Assuming that Lucy has the appropriate causal connections to Mandy, how does Lucy's experience or thought manage to be about Mandy rather than about the set of Mandy-caused photons impinging on her retinas, or certain other sets of causes on the causal chain leading to the thought? The antireductionist suggestion is that we need to appeal to the character of Lucy's conscious experience to explain how Lucy's experience can be said to be precisely about Mandy rather than about some other stage on the causal chain.

The disjunction problem and the stopping problem differ in that in the former the subject latches onto an object, although which one is indeterminate, whereas in the latter it is unclear how the subject latches onto an appropriate object at all.

3. If intentionality is explained in terms of "carrying information," there seems to be too much of it. The idea is that since every effect is

a reliable sign of its cause, every effect carries information about its cause, and so every effect can be said to be about or represent its cause. Fred Dretske attempts to mark off *mental* intentional states by appealing to the criterion of misrepresentation. This, however, takes us back to Problem 1.

Intentionality and Phenomenal Consciousness

In analytic philosophy of mind, the phenomenon of intentionality has shared the limelight with the phenomenon of *consciousness,* or *phenomenology.* Phenomenology can be characterized as there being *something that it is like,* experientially, to be in a mental state—as a state's having an experiential, *qualitative* character or a subjective, phenomenal character. One of the central assumptions embedded in the naturalization project has been that there is a sharp theoretical distinction between intentional properties and phenomenological properties.

It has been generally assumed that there are mental states that have intentional properties and no phenomenological properties—for example, beliefs—and mental states that have phenomenological properties and no intentional properties—for example, pain. Given the apparent independence of these two kinds of properties, it has also been assumed that if a mental state *S* has both intentional and phenomenological properties, they are logically independent of one another.

Some of these assumptions have now come under attack for both conscious perception and conscious thought. "Representationalists" or "intentionalists" have argued that the phenomenological properties of conscious perceptions supervene on or are identical to their intentional properties. More striking, though, have been some recent claims about the bearing that phenomenological properties have on the intentionality of conscious thought.

Intentionality and Cognitive Phenomenology

Until recently, it has been a standard assumption that sensory phenomenology (e.g., what it's like to see colors, taste apples, hear music) is the only kind of phenomenology there is. Now, however, there is a strong field of philosophers arguing for the existence of what is now called *cognitive phenomenology.* Cognitive phenomenology is a kind of phenomenology centrally associated with conscious thought—but also with perception and emotion—that is irreducible to any sensory phenomenology that may be associated with thought. On this view, there is something that it is like to think that 2 + 2 = 4 that is different from what it is like to think that temperance is a virtue, and this difference cannot be accounted for in terms of any sensory phenomenology (e.g., images, inner speech) that may be associated with these thoughts.

Many proponents of cognitive phenomenology hold that there is an intimate link between the cognitive-phenomenological character of thought and the intentional content of thought. There are stronger and weaker accounts of the nature of this link. According to a strong version, each thought content has a uniquely associated cognitive-phenomenological character. On this view, everyone who thinks that temperance is a virtue, for example, experiences the same cognitive-phenomenological character relative to that thought. According to a weak version, although each thought has a certain cognitive-phenomenological character, that character may vary between subjects and for a subject at different times. Many complications arise in the detailed spelling out of this view, one of which has to do with whether one thinks that the kind of content associated with thought is broad or narrow, or a combination of these.

Philosophers have appealed to cognitive phenomenology to solve all three of the main outstanding problems faced by the naturalization project (Points 1–3 above). Uriah Kriegel argues for a partial solution to the misrepresentation problem by claiming that thinking about nonexistent objects is a matter of instantiating the relevant phenomenal character. Terence Horgan and John Tienson suggest that the determinacy of thought is partly grounded in phenomenal character. Given that what it is like to think about sheep is distinct from what it is like to think about goats on dark nights, we can appeal to this difference in "what it's likeness" to explain why an intentional state has one content rather than another. Galen Strawson responds to the stopping problem by claiming that the intentionality of Lucy's thought can zero in on Mandy the moose rather than any other causes along the causal chain because Lucy's experience includes a cognitive-phenomenological element: her consciously taking her experience to be an experience of a physical object at a certain distance from

her (rather than, say, an experience of photons). (See Jerry Fodor's 2008 book for a nonphenomenological solution to the stopping problem.)

INTERDISCIPLINARITY

This entry presents central features as well as different meanings of interdisciplinarity and its importance for the social sciences.

In the modern era, concepts pass in and out of fashion quickly. But some new coinages stick: They fit new and enduring needs. *Interdisciplinarity* is a term that seems destined to stay, for the term defines a new era of knowledge, the chief characteristics of which are the need to address problems that resist parameterizing, an insistence on a tight link between knowledge production and its use, and the democratizing of knowledge production.

Disciplines, a Western invention, did not truly come into existence until the second half of the 19th century. Until that time, colleges and universities emphasized the perennial aspects of knowledge, and the importance of passing down received wisdom from generation to generation. Mid-19th-century urbanization and industrialization changed this: New demands were made on institutions of knowledge to tie their work to the growing capitalist economy. Majors were created and disciplines formed, and professors were now expected to produce new knowledge rather than simply pass down received wisdom. This led to the development of disciplinary expertise and the progressive disaggregation of knowledge.

Calls for "interdisciplinarity" were the expected result. The term first appeared in Social Science Research Council awards listings and reports beginning in 1930. Since the 1960s, the term has become a commonplace across the academy—ubiquitous in strategic plans, curricular innovations, and research projects. There is a tendency, however, for the term to be treated as a code word for "relevance" rather than as an operational term with distinct meanings.

Meanings of Interdisciplinarity

First and most simply, interdisciplinarity is one of a set of cognate terms that describe different ways to organize knowledge. A *discipline* is a body of knowledge thought to be more or less discrete from other regions of knowledge. A *multidisciplinary* approach to knowledge seeks to link or juxtapose disparate bodies of knowledge without essentially changing those bodies of knowledge. In contrast, an interdisciplinary approach to knowledge emphasizes not the simple juxtaposition but rather the blending or integration of different types of knowledge.

All of these terms, however, designate research that stays within the walls of the academy. The term *transdisciplinarity* has been used in a number of ways—for instance, it has been used to describe the goal of unifying all of knowledge under a master trope or concept such as systems theory. But its predominant meaning today refers to efforts to adapt academic knowledge production for problem solving out in the larger world. Note that work can be transdisciplinary without being interdisciplinary in nature: It is possible for the knowledge of a single discipline to be used in a transdisciplinary project. Nor should these different types of knowledge be treated as hierarchical. *Inter-* or *trans*disciplinary knowledge is not "better" or more highly developed than multidisciplinary knowledge, except in terms of a specific goal or end.

These definitions are well established today—although it is worth noting that *interdisciplinarity* is also used as a more general term, including the meaning of transdisciplinarity—especially in the United States. But there is significant scholarly disagreement today about the overall goals or purpose of studying interdisciplinarity.

For some, especially those focused on the undergraduate experience, concerns with methodology dominate. Some researchers seek to identify a set of interdisciplinary procedures for the efficient development of undergraduate programs in areas such as environmental studies and Chicano studies. More problematically, they also seek to identify principles and methodology for interdisciplinary research. Others take a more descriptive approach. Some interdisciplinarians engage in what is sometimes called the "science of team science." For instance, members of different disciplines who share a research project may come together in a workshop setting under the auspices of a researcher, where they take a survey that helps them become more self-aware of their distinctive methodological and philosophical assumptions.

One can also find various types and degrees of *antimethodologism* within the study of interdisciplinarity. Some argue that interdisciplinarity is more a matter of manner than of method. While granting that those experienced in interdisciplinary education and research can identify a set of rules of thumb, interdisciplinary work is seen as primarily involving the cultivation of a set of personal virtues such as open-mindedness, disciplinary modesty, and the ability to see things from different perspectives. For instance, Wolfgang Krohn highlights the importance of a case-based approach to understanding interdisciplinarity. He views interdisciplinary research as involving a distinctive relationship between individual cases and more general knowledge. Rather than seeking lawlike principles to form part of a method, interdisciplinary knowledge calls for a critical reassessment of our concept of scientific laws and general principles.

Third, interdisciplinarity is also taken as highlighting an ongoing shift in culture. In this interpretation, *interdisciplinarity* points up increased attention to understanding the relation between knowledge production and its use. In its classic 19th- and 20th-century form, disciplinary knowledge assumed that knowledge was both inherently relevant and fundamentally benign. No extra step was necessary to make knowledge relevant to society. And if something bad resulted from the use of knowledge, this was not considered the responsibility of the producer of that knowledge. Today, however, it is becoming increasingly evident that knowledge must be *coproduced*—a process where the users of knowledge are involved in the very design and production of that knowledge. One sign of this coproduction is the development of user-driven content on the Internet via Web 2.0.

Conclusion

In closing, it is worth noting that the study of interdisciplinarity has become more professional in recent years. One finds a significant scholarly literature, including compendia such as the *Oxford Handbook of Interdisciplinarity.* There has also been a notable degree of institutionalization of inter- and transdisciplinarity, via centers, institutes, meetings, and associations. In Europe, TDnet has been

running an annual conference since 2004, and in the United States, the Association for Integrative Studies has been holding an annual meeting since 1979. In 2008, the Center for the Study for Interdisciplinarity was created at the University of North Texas. In 2011, these three groups joined to create INIT, the International Network for Interdisciplinarity and Transdisciplinarity, in Utrecht, The Netherlands. Given the increasing societal demands for greater relevance to academic research, we can expect the focus on interdisciplinarity to increase in the future.

International Relations, Philosophical and Methodological Debates

International relations emerged as a self-conscious discipline only at the beginning of the 20th century and by its end was in danger of vanishing in an amorphous field called *global studies*. The question is whether a discipline premised on the independence of the territorial state can survive the decline of that independence. Another question is whether its subject matter—interstate relations—poses a unique challenge to inquiry or whether its main challenges are those it shares with other human sciences. These include the tension between scientific and nonscientific modes of understanding and between the methods of inquiry they imply.

The study of international relations has thus raised crucial methodological and ontological questions of interest to the philosophy of the social sciences (questions of explanation or regarding the status of collective entities such as the state, issues of agency, etc.). In addition, the field of international relations has raised a number of important moral questions (e.g., just-war theories). Therefore, philosophy has been intimately linked with this social science. This entry considers whether there is a distinct international relations discipline, surveys debates over whether the discipline is a "scientific" one, and examines the relationship between the knowledge it offers and the methods needed to generate that knowledge.

Disciplinary Identity

The state is an idea, not a thing. In Western thought, it began as a legal idea in arguments about the claims of rulers to authority within a realm against internal rivals and external claimants (e.g., the papacy and the Holy Roman Empire). A state came to be understood as a community of persons united under a common body of law emanating from an authority recognized to be *sovereign*—that is, superior within its boundaries to any other authority, internal or external.

This legal debate was paralleled by debates about the moral foundation of such authority and its effectiveness. Considering states in relation to one another generates distinct questions, which we recognize as questions of international law, international ethics, and foreign policy or diplomacy, understood as the acquisition, preservation, and use of state power. It also raises philosophical questions, such as whether states can be said to have motives or make decisions. Scholars have investigated all these questions, and the discipline of international relations has been thus identified at times as a branch of jurisprudence or political philosophy and at other

times as an autonomous discipline concerned with power politics.

Disciplinary autonomy premised on the study of power is precarious, however, because power is not a quality unique to states. What distinguishes international relations is not that states are powers (many are not) but that they are, by definition, legally independent territorial associations that have relations with one another. But other entities including individuals, companies, nongovernmental associations, and criminal gangs also engage in transactions across territorial boundaries. If we consider these transactions, limiting the discipline to relations between governments fetishizes the state as the "thing" that defines the field, making a claim that is best defended as a choice justified by its results. The question of whether the results are worth the cost is what divides political realists from those who think that studying other kinds of cross-national relations is also worthwhile.

If national boundaries are losing significance, cross-national relations will cease to be distinctive. For those who see this happening, international relations is morphing into global relations, as the phrases of the moment—global warming, global migration, global democracy, global justice—suggest. Although the adjective "international" adds meaning to words like *migration* or *justice,* "global" does not. There is no clear distinction between the idea of justice, unmodified, and global justice. The emerging discipline of global studies—now a popular major in many universities—will face an identity crisis worse than that experienced by the discipline of international relations. Perhaps a sensible conclusion would be one that recognized that international relations can be studied in different ways and that to study it does not require a distinct and autonomous academic discipline.

The Science Question

Since the middle of the 20th century, the study of international relations has been embroiled in a debate about the degree to which that study could be scientific. Initially, the model of science was physics, which (following philosophers in the tradition of the late-19th-century and early-20th-century positivism) was believed to consist of general statements of invariant regularity ("covering laws") that could be combined with factual data to explain and predict particular events. This view of scientific explanation was adopted by the movement known as *behaviorism* (in political science, *behavioralism*), with psychology as a more proximate model. In the last decades of the 20th century, economics became the field to imitate. At the same time, a series of counterpositions emerged, first *traditionalism* or the classical approach and then *postpositivism,* a blanket label covering a variety of approaches, some rejecting and others claiming the mantle of science.

Some perspective on these disagreements can be gained by considering the German origins of political science, which in turn influenced the study of international politics. In 19th-century German thought, history had as much prestige as science. With the models of physics and history in mind, scholars at the end of that century distinguished between the natural and the human sciences, the latter (*Geisteswissenschaften*) defined by their concern not only with particulars but with meaning and therefore with interpretation. "Science," in this context, denoted the kind of inquiry appropriate to understanding and explaining intelligent human conduct, in contrast to inquiry into not-intelligent (natural) processes. Science, in short, was nothing more than systematic research governed by the canons of objectivity and validation appropriate to what was being studied.

This history is often forgotten by those who argue that the study of international relations should be scientific in the same way as the natural sciences. One response to that claim is to use the definition of science as systematic research and to advocate for a pluralist science of international relations. Another is to view "science" as one among a number of alternative modes of understanding and inquiry. Science, here, is natural science—the study of not-intelligent processes. History and other humanistic inquiries, in contrast, are those that interpret and explain intelligent human conduct in terms of ideas and meaning. And both are distinct from activities involved in making moral, legal, or political decisions, which are practical rather than explanatory activities.

To privilege any one of these modes in making sense of international relations is to mistake a mode of knowledge, which is by definition limited and partial, for the whole of knowledge. Thus, scientism is the error of privileging the natural sciences as the model of all genuine knowledge. Historicism is the error of thinking that nothing can be understood

except in relation to time and place. And pragmatism, which includes many versions of Marxism and critical theory, is the error of confusing theoretical inquiry with practical action. If theory is always for someone and for some purpose, its objectivity is always suspect, and the claim itself is exposed as self-refuting.

The failure to distinguish distinct modes of understanding and inquiry pervades the study of international relations, as it does other social sciences. Discussions of causal explanation, for example, often assume—mistakenly—that the idea of cause in physics or biology is the same as in history or jurisprudence. We can generalize about the causes of war, but such generalizations may not tell us much about the causes of this or that war or about who should be held responsible for causing it. To explain a decision that involves thought and ideas, one must know the antecedents that make it intelligible. Also fatal to explanation is the error of combining distinct modes, as if arguments in one mode could support or deny arguments in another. This error is found in realist and Marxist efforts to extract policy advice from presumed necessities and constructivist efforts to combine interpretive and naturalistic considerations within a single theory.

Recognizing that making sense of international relations benefits from different kinds of inquiry implies a pluralist understanding of the field. Whether its practitioners embrace pluralism by adopting a broad definition of science as systematic scholarship or define science narrowly as one mode of scholarship among others, they move beyond the barbarism of insisting that their preferred mode dominate the others. The humility gained through this recognition of modal pluralism can be used to good effect in appreciating what can and cannot be explained within the limits of a given mode and weeding out theories that fail the test of modal coherence.

Modes and Methods

If there are different modes of understanding and inquiry, it follows that research will require methods appropriate to the kinds of understanding possible in each. Modal pluralism implies methodological pluralism. It is widely acknowledged that we should start with questions rather than with methods, but the practice of teaching research using teaching methods undercuts this precept. The problem is made worse when quantitative methods are privileged. Doing so reinforces the assumption that all research is empirical and that the so-called qualitative methods are merely an alternative way of generating and analyzing empirical data and making empirical generalizations and causal inferences. All research from this point of view is "scientific" research. Antiscientistic epistemologies challenge this assumption and invite different methods for generating knowledge.

The student of diplomacy, for example, might need the skills of an anthropologist to understand contemporary diplomatic practices and those of a historian to understand the practices of earlier periods. Depending on their research questions, students of diplomatic discourse might use the methods of quantitative content analysis or rhetorical classification. Scholars who think the ideas of the people they are studying are important in explaining the behavior of those people will want information that differs from data collected by scholars who dismiss such self-understandings, and they will use different methods to obtain and analyze that information. Someone with a practical interest in just-war thinking might use its conventional principles to make judgments about a particular war; in contrast, someone more philosophically inclined might abstract a self-consistent theory of just war from arguments about particular cases, generating principles that differ significantly from the conventional ones. One might accept the principle that in combat enemies can be killed without blame, while another might reject that principle and in doing so challenge the received distinction between war and murder.

Social scientists need to make assumptions to get on with their research, but they also need to question assumptions to do innovative research. Thinking carefully about one's assumptions is logical prior to designing one's research, and laying out the research design must come before the choice of methods. An intelligent approach to research must start by recognizing the plural character of knowledge and proceed from clarity about the kind of knowledge sought to choosing designs and methods appropriate to generating it.

What are commonly identified as theories of international relations—realism, liberalism, constructivism, critical theory, poststructuralism, the English school, and others—are neither distinct

modes of understanding nor alternative methods of inquiry. Each provides a vocabulary for debating philosophical and methodological questions. Unfortunately, those vocabularies often carry one effortlessly to conclusions that are already implicit in them. Theory is best seen as an activity—the activity of theorizing—not as a body of conclusions. One can theorize by working out the implications of a set of assumptions, but one can also theorize by questioning those assumptions and heading off in a new direction. In doing so, theorists must rely on their own experience and insight and not look to philosophy for guidance, as naive scholars do when they invoke "the philosophy of science" as authoritative for scholarship. In this respect, the study of international relations is no different from any other study.

INTERSUBJECTIVITY

Intersubjectivity is an interdisciplinary concept that refers to the field of interaction between the self and other. Intersubjectivity has its origins in the philosophical rejection of René Descartes's philosophy of consciousness (as a private datum) and his notion of the isolated mind. From an intersubjective perspective, human beings exist not in isolation but in a world with others. The concept of intersubjectivity is of primary interest to philosophers, social and political theorists, and psychoanalytic psychologists. This entry provides an account of this notion in these fields.

Philosophy

From a philosophical perspective, intersubjectivity is generally associated with the continental tradition rather than the analytic and postanalytic tradition. However, parallels can be found with Ludwig Wittgenstein's philosophy of language, according to which humans are inherently connected through their use of language. Intersubjectivity is one of the dominant themes in the tradition of existential phenomenology, though not all thinkers who write about intersubjectivity employ the term.

In Edmund Husserl's phenomenology, intersubjectivity refers to the process by which other human beings are experienced as subjects rather than as objects in a separate world. From the perspective of phenomenology, Husserl emphasized that the world we intend is not a private world but a world common to and accessible to all. The lingering monadism at work in Husserl's philosophy led his student Martin Heidegger to reject the term *intersubjectivity.* Instead, Heidegger coined the notions of *Dasein* and *being-in-the-world* to refer to the situated nature of the human being and its fundamental contextualism. For Heidegger, the human being cannot be separated from the social contexts in which

experience always and already unfolds. However, Heidegger's account of sociality remains peculiarly underdeveloped and has been criticized for its ethical and political shortcomings by the contemporary continental philosophers Emmanuel Levinas and Jürgen Habermas, respectively.

A different perspective on intersubjectivity was introduced by Martin Buber, who delineates two modes of social being: *I–It* and *I–Thou*. For Buber, the subject only exists insofar as it swings "between" these two types of relations. The French philosophers Maurice Merleau-Ponty and Jean-Paul Sartre (both inspired by phenomenology, the latter being one of the fathers of existentialism) moved beyond the perspectives of Husserl and Heidegger to examine the role of embodiment and recognition in the social sphere. For Merleau-Ponty, the perception of others and the world occurs through the body, thus illustrating the fundamental embodiment of all human experience. For Sartre, social interaction is delineated in the "dialectic of the look," according to which the other is an immediate and threatening presence that I must seek to subjugate in turn. Sartre's account of the struggle for recognition is similar to Alexander Kojève's influential reading of modes of social interaction in G. W. F. Hegel's philosophy.

Social Theory

For social theorists, intersubjectivity provides a means to overcome the impasses associated with the philosophy of consciousness and a subject-centered notion of reason. Habermas uses the concept of intersubjectivity to develop an emancipatory social philosophy. Drawing on George Herbert Mead's account of symbolic interaction, Habermas's communicative framework is based on a symbolically structured life-world, in which subjectivity is constituted through reflexive linguistic interaction. According to Habermas, the potential for communicative reason is embedded in language. Based on the assumption that recognition of truth can be attained through dialogue, Habermas postulates a counterfactual "ideal speech situation" in which genuine communication and mutual recognition can be achieved. Habermas thus takes linguistic intersubjectivity as his starting point and construes subjectivity in relation to it.

A different approach to the concept of intersubjectivity is proposed by Anthony Giddens. His theory of *structuration* suggests that the reflective capabilities of the subject are inherently linked to social experience. The concepts of subject and society are not simply interacting but fundamentally interdependent. Neither can be understood or conceptualized without the other, and neither can exist by virtue of a recursive process. Giddens refers to the coproduction of action and structure as the recursive nature of social life, in which the structured properties of social activity are constantly re-created out of the very resources that constitute them. Human agency, on this view, is neither a capacity of the individual nor a function of the social context. Because human beings act in and through structures and systems, we are not independent actors in the world, and our actions are never entirely of our own choosing. In contrast to Habermas, for whom the subject is linguistically constituted, Giddens underlines the reflexive capacity of the subject but avoids the strict association of the subject with rational reflection and language.

Psychology and Psychoanalysis

For psychologists and psychoanalysts, the concept of intersubjectivity is interwoven with emotion, imagination, and embodiment. Intersubjectivity has become an important theme used by Daniel Stern to describe a progression of developmental stages, by Jessica Benjamin to define a feminist developmental theory, and by Robert Stolorow, George Atwood, and Donna Orange to refer to a mode of psychoanalytic theory and practice. Intersubjectivity was introduced to psychoanalytic psychology by Ludwig Binswanger and Jacques Lacan, who attended to the intersubjective nature of human experience, as evidenced in the patient's interpersonal and linguistic contexts.

In contemporary psychoanalysis, intersubjectivity refers to the ongoing and reciprocal engagement of patient and therapist in a mutually transforming interaction. In contrast to the traditional Freudian emphasis on the intrapsychic experience of the patient and the neutrality of the therapist, the intersubjective perspective focuses on the interacting subjective worlds of patient and therapist. The therapeutic relationship is seen as the domain of analytic inquiry, and the goal of treatment is to reach an understanding of psychological phenomena as they emerge between the patient and the therapist.

The intersubjective therapeutic perspective has evolved into a broad-based philosophy of practice termed *contextualism*. A common critique of intersubjectivity is that it fails sufficiently to account for the broader contexts of experience and remains focused on the individual subjectivities of patient and therapist. In contrast to traditional philosophical accounts of intersubjectivity, contextualism seeks to account for the sociocultural constitution of all experience. On this view, the psychological processes are actually made up within, as opposed to merely facilitated by, culture and society.

Introspection (Philosophical Psychology)

Etymologically, introspection means "looking within." The term *introspection* is typically used as a placeholder for the distinctive way, whatever it is, in which we know our own minds. Yet it is contentious whether we know our own minds by inner perception. The task for a theory of introspection is to provide a more substantive account of the way in which we know our own minds.

This entry surveys various theories of introspection, including inner sense theories, inferential theories, causal theories, constitutivist theories, transparency theories, and acquaintance theories. The final section raises further questions about the scope of introspection, its reliability, and its theoretical implications for wider issues in philosophy and cognitive science.

Inner Sense Theories

A classical view associated with modern European philosophy, and in particular with René Descartes, John Locke, and David Hume, is that introspection is a form of inner sense—that is, inner perception of one's own mind. On this view, there is an asymmetry between first-person and third-person perspectives such that the way we know our own minds is both *different* from and *better* than the way we know the minds of others. It is different because we know our own minds directly on the basis of inner perception, whereas we know the minds of others indirectly on the basis of inference from external perception of physical behavior. And it is better because inner perception, unlike external perception, is claimed to be immune from ignorance and error.

The problem with this classical view is that the notion of inner sense remains obscure. Does inner sense involve a sensory organ, such as an inner eye? And if not, then what is the substance of the claim that introspection is a form of nonsensory perception?

Inferential Theories

The 20th-century English philosopher Gilbert Ryle famously derides "Descartes's myth" of inner sense as a hopelessly confused metaphor. Ryle claims instead that the way in which we know our own minds is by inference from observation of our own physical behavior. On Ryle's theory, the way we know our own minds is no different from the way we know the minds of others; moreover, it is no better except insofar as we have more observational data about our own behavior than about others. Hence, there is no relevant asymmetry between first-person and third-person perspectives.

The problem with Ryle's theory is that it cannot explain the introspective self-knowledge that we plausibly have. For instance, I know that I am currently thinking about tomatoes, but I cannot know this by inference from perception of my behavior, since my current thoughts about tomatoes exert no causal influence on my behavior.

Ryle's inferentialism is motivated by his *behaviorism*: If the metaphysics of mind consist of behavioral dispositions, then the epistemology of mind consists of knowledge of those dispositions. However, others have attempted

to divorce inferentialism from these behaviorist commitments. For instance, the psychologist Alison Gopnik argues on the basis of evidence from developmental psychology that knowledge of one's intentional states relies on unconscious inferences informed by the acquisition of a theory of mind. However, she claims that these inferences rely not only on premises about behavior but also on conscious experience—what she calls "the Cartesian buzz." Thus, her inferentialism is restricted to knowledge of intentionality rather than conscious experience. Similarly, the philosopher Peter Carruthers defends an inferentialist theory restricted to our knowledge of cognition rather than perception.

Causal Theories

Ryle's behaviorism is widely rejected in favor of *functionalism,* which defines mental states by their causal roles in the production of other mental states as well as physical behavior. The philosopher David Armstrong, an early pioneer of functionalism, provides a causal analysis of the metaphor of introspection as inner perception. Perception, according to Armstrong, is merely the acquisition of true or false beliefs about the world by means of an appropriate causal mechanism. Accordingly, introspection involves the operation of a "self-scanning mechanism" that yields true or false beliefs about one's own mental states. Armstrong argues against the Cartesian view that introspection is immune from ignorance and error, on the grounds that no causal mechanism is immune to malfunction. Moreover, he argues that the reliability of our introspective mechanisms is sufficient to explain the possibility of introspective knowledge.

The contemporary philosophical literature contains various analogs of Armstrong's self-scanning mechanism. For instance, Shaun Nichols and Stephen Stich posit a "monitoring mechanism" that takes a representation that *p* as input and yields a representation that I believe that *p* as output, together with a related cluster of perceptual monitoring mechanisms designed to explain our introspective knowledge of perceptual states. Similarly, Alvin Goldman proposes a causal theory on which introspective mechanisms are sensitive to the neural states that realize mental states.

Constitutivist Theories

The philosopher Sydney Shoemaker classifies causal theories as examples of a "broad perceptual model" of introspection, which he rejects in favor of a *constitutivist* theory of introspection. According to causal theories, our introspective beliefs are independent of and caused by the mental states they are about, whereas according to constitutive theories, our introspective beliefs are partially constituted by those mental states.

Shoemaker argues for constitutivism on the grounds that there is no genuine possibility of *self-blindness* in which one is rational and one has concepts of one's mental states but one has no introspective self-knowledge of one's mental states. According to Shoemaker, any rational and conceptually competent subject who is in a mental state of the relevant kind thereby believes that she is in that mental state. Thus, he argues, introspective beliefs are partially constituted by the mental states they are about together with certain background conditions such as rationality and conceptual competence. On this view, introspective beliefs are neither independent of nor caused by those mental states but are partially constituted by them.

Shoemaker's arguments against the possibility of self-blindness have received criticism, but many critics acknowledge a close relationship between rationality and introspective self-knowledge. Intuitively, rationality is consistent with massive ignorance and error about the external world but not one's own mental states. Therefore, the challenge for causal theories of introspection is either to explain the connection between rationality and self-knowledge or to explain it away.

Transparency Theories

Others argue against inner sense theories on the grounds that introspection is a matter of "looking outward" rather than "looking within." For instance, Gareth Evans observes that if I want to know whether I believe there will be a third world war, I can simply ask myself, "Will there be a third world war?" Evans claims that belief is *transparent* in the sense that I can answer the question whether I believe that *p* by answering the question whether *p*. Moreover, if I form the second-order belief that I believe that *p* on the basis of my first-order belief

that *p,* then my second-order belief is guaranteed to be true, which promises to vindicate the Cartesian commitment to the infallibility of introspection.

It is an open question whether transparency extends from belief to other mental states. Evans argues that perceptual experience is transparent in the sense that I can answer the question whether it perceptually seems to me that *p* by answering the question whether *p* on the basis of the way things perceptually seem, while excluding any extraneous information. However, this threatens the vindication of Cartesian infallibility, since mistaken perceptual beliefs about the world can lead to mistaken introspective beliefs about how things seem perceptually. Recent work by Alex Byrne explores analogs of transparency for other mental states, including desire, intention, and thought.

The phenomenon of transparency gives rise to a puzzle. What justifies me in treating evidence about the world as evidence of my own mental states? Richard Moran argues that the transparency phenomenon reflects a fact about rationality—namely, that I am rationally entitled to take my beliefs to reflect my evidence about the world. Here again, the connection between rationality and self-knowledge is a crucial theme.

Acquaintance Theories

Proponents of acquaintance theories, including David Chalmers, argue that introspective knowledge of conscious experience is made possible by *acquaintance*—that is, a relation to conscious experience that explains one's ability to acquire introspective knowledge of conscious experience. Chalmers defines acquaintance by its epistemic role, but this raises the question "What is the nature of the acquaintance relation that plays this epistemic role?"

One answer is suggested by Terry Horgan and Uriah Kriegel's claim that conscious experience is *self-representing* in the sense that conscious experience represents itself. Moreover, Horgan and Kriegel argue that the self-representation built into conscious experience constitutes a form of acquaintance with conscious experience and thereby explains the possibility of introspective knowledge. However, it is debatable whether we need the claim that conscious experience is self-representing in order to explain our introspective knowledge of conscious experience.

Further Questions

It seems obvious that each of us has a capacity for introspective knowledge of our own minds, which is not available to anyone else. However, it is much less obvious how a theory of introspection should explain this capacity for introspective knowledge. Moreover, in addition to questions about the nature of introspection, further questions arise concerning its scope, reliability, and theoretical significance:

On the scope of introspection: Which mental states can we know by introspection? On a classical Cartesian conception of mind, we know all our mental states by introspection. However, the Freudian and Chomskian revolutions have shown that there are unconscious mental states that cannot be known by introspection. Therefore, some restrict the scope of introspection to one's current stream of conscious experience, while others claim that one's introspective knowledge extends to one's standing beliefs and desires.

On the reliability of introspection: Is there any sense in which introspection is more reliable than other ways of knowing about the world? On the classical Cartesian conception, introspection is immune from ignorance and error. However, there is psychological evidence that we are often mistaken about our mental states and processes—including the classic experiments by Richard Nisbett and Timothy Wilson in which subjects confabulate the reasons for action, such as choosing a pair of socks. One response is to argue that introspection is immune from ignorance and error when it concerns one's current stream of conscious experience. However, Eric Schwitzgebel has recently argued that introspection of conscious experience is even less reliable than sensory perception.

On the theoretical significance of introspection: What are the implications of these questions about introspection for wider issues in philosophy and cognitive science? First, there are important questions in epistemology about whether introspective knowledge is immune from skeptical doubt, whether it serves as a foundation of empirical knowledge, and whether it provides us with reflective access to our reasons for belief and action. Second, there are important questions in philosophy of mind and cognitive science about whether introspection is sufficiently reliable to

provide a source of evidence about conscious experience and its neural correlates. Therefore, questions about the nature, scope, and reliability of introspection have important consequences for central issues in philosophy and cognitive science.

Invisible Hand Explanations

Originally used in the 18th century by Adam Smith in both *An Inquiry Into the Nature and Causes of the Wealth of Nations* (1776) and *The Theory of Moral Sentiments* (1759), the phrase *invisible hand* posits a metaphor that communicates the idea that a beneficial outcome may arise without anyone's intention or design. In this original understanding, to say that some outcome, pattern, or end was brought about by an invisible hand is to say that the result in question carries some benefit (and for that reason appears to have been brought about by design), yet the outcome is not something that the agents intended to bring about. Since the invisible hand refers to the process by which an outcome is generated, it should be possible to set forth *explanations* of such processes: Such "invisible hand explanations" are of particular interest to social science because much of the social realm would seem to be the outcome of unintended action. In the 20th century, Karl Popper, in his attack on all forms of social engineering and historicism, has championed the notion of unintended consequences as a phenomenon considered by him as central to social reality.

Uses

Adam Smith was the first to use the phrase, but he employed it only three times in all of his works. In the *Theory of Moral Sentiments,* Smith suggests that wealthy individuals who seek their own interests will through the employment of labor effectively distribute the same amount of wealth to working individuals as if the land had been equally distributed all along. In the *Wealth of Nations,* Smith contests the practice of restricting imports and contends that in fact individuals prefer domestic over foreign goods, so that the domestic benefit will accrue without the need of restrictions on imports. In these and in other instances, such as the emergence in society of a pattern of specialization (the division of labor), Smith contends that

processes are at work that generate beneficial outcomes without any design, intention, or agreement.

Smith was not the first, or the last, to appeal to such processes. Bernard Mandeville had argued (in *The Fable of the Bees: Or, Private Vices, Public Benefits,* 1714) that prosperity could be achieved by setting in place a rule of law and allowing self-interested individuals to produce, create, and buy and sell. In the 19th century, the Austrian economist Carl Menger explained the genesis of money by invoking an account of how individuals endeavor to trade without the encumbrances of bartering good for good.

In the 20th century, F. A. Hayek (in *The Constitution of Liberty; Law, Legislation, and Liberty*) reiterated the theme of unintended processes, contending that most of the institutions and rules on which a complex civilization depends could only arise via some sort of invisible hand evolution. In political philosophy, Robert Nozick used the idea of the invisible hand to show (in *Anarchy, State, and Utopia*) how a governing state might arise even though no one intended it to emerge. Others have suggested that the emergence of everyday conventions, even those of language (David Lewis, in *Convention*), arise via an unintended or invisible hand process. Another recent use of the notion of an invisible hand guiding a process can be found in theories modeling the advancement of science on economics: for example, Michael Polanyi, explicitly invoking Adam Smith's phrase, suggested, in his article "The Republic of Science: Its Political and Economic Theory" in 1962, that scientific progress can be seen as a spontaneous order resulting from the independent initiatives of scientists.

Explanations

An invisible hand explanation may be called for in any instance in which some relatively complex state of affairs—a rule, pattern, or institution—could have arisen without design or agreement. Although Adam Smith used the original metaphor to suggest that the resultant pattern was beneficial, this is not a necessary part of the explanation. In this sense, an invisible hand explanation is value free: It can be invoked for any complex outcome, regardless of its benefit or harm. The primary kind of invisible hand explanation begins from the description of initial conditions. These would include a description of the circumstances or constraints on action, as well as an account of the agents, their motives and beliefs, as well as their capacity to reason. Given this starting point, the explanation must posit some kind of law or at least a lawlike tendency that would explain why the agents act in the way they do. Finally, the explanation must set forth a narrative in which it is made plain that the outcome was not a part of any agent's intention. The outcome would be shown to emerge via the accumulation or aggregation of individual actions and results. The narrative may reveal that the process occurred over a long period of time or over a narrow slice of time. Many of those who posit such processes suggest that there are evolutionary accounts in which the final outcome occurs over years. One problem with such accounts is that it is crucial to show how the acting agents generated the result in question. Over a long-enough period any outcome could be shown to be an unintended result of human action! Therefore, it is essential to show the causal links between individual actions and the overall outcome.

Joint Attention and Social Cognition

This entry explains what the capacity for joint attention involves and reviews the main theories about its role in social cognition, as well as theories about its development and mechanism, showing its psychological and philosophical underpinnings.

Joint attention is the capacity enjoyed by humans and, on some accounts, nonhuman primates to attend to objects in their environment together with others. For this to be possible, at least two conditions have to be met: First, the involved creatures have to be attending to the same thing and, second, they have to be aware that they are attending to the same thing. The capacity for joint attention is initially displayed by human infants at the age of around 9 months, when they begin to expand upon earlier face-to-face interactions with their caregivers, through the acts of pointing and diversion of gaze, so as to attract the caregiver's attention to a third object, or through reaction to caregivers' similar acts. It is widely agreed that the display of joint attention marks a key step in infants' cognitive development: It attests to the infant's ability to grasp, and operate within, a triadic epistemic constellation that involves the infant, the caregiver, and the object of attention.

Over the last two decades or so, it has increasingly been recognized that the ability to participate in such constellations is of key relevance for concept acquisition, the ability to distinguish between self and other, the capacity to grasp aspects of another's state of mind, and the ability to share feelings and emotions. It thus occupies a central role in research concerned with social cognition, in a variety of disciplines that include psychology, philosophy of mind, and social neuroscience. The cognitive importance of the phenomenon is highlighted further by the fact that the capacity to jointly attend to objects with others is impaired in persons with autism, which has given rise to medical interest in the topic.

To organize the increasingly rich and varied literature on joint attention, this entry will distinguish between two main issues. The first one is the hotly debated question of just what role joint attention plays in social cognition and how it is acquired. The second question is concerned with the psychological and philosophical frameworks that are meant to explain how joint attention is possible. The entry will address each in turn, and it will conclude with some remarks about the relevance of joint attention for the philosophy of social science.

The Development and Function of Joint Attention

There are two fundamentally distinct views on the place of joint attention in humans' cognitive development. Michael Tomasello has suggested that the capacity for joint attention can be obtained only when the involved persons have acquired the ability to understand each other as intentional agents and to be committed to the joint pursuit of shared goals. This is, on the present view, a uniquely human capacity that gives rise, at around 12 months of

age, to triadic interactions in which the infant plays the leading role. Without the capacity for this kind of commitment, the joint pursuit of goals that are shared between the involved agents is not possible and the knowledge that others choose what to attend to within their visual fields remains unavailable. One immediate consequence of this approach is that only humans can, in principle, be capable of joint attention, since no other creature is thought to possess the range of concepts necessary for meeting the second condition.

The other position, which is held, for instance, by Colwyn Trevarthen, Peter Hobson, Vasu Reddy, and others, holds that meeting the second condition does not depend upon the display of an array of sophisticated concepts. On this view, joint attention plays an important role with regard to the acquisition of a range of social and otherwise cognitive capacities. Thus, one may think that joint attention is necessary (though, according to Ingar Brinck and Peter Gärdenfors, not sufficient) for creatures to engage in collective acts; or it may be supposed that joint attention plays a crucial role in the understanding of spatial perspectives; or one may argue, as Jose Bermudez does, that joint attention gives rise to an understanding of self that plays out in a contrast space with a corresponding understanding of the other creature.

Explanatory Frameworks

The debate about the developmental role of joint attention is closely integrated with, though not identical to, the discussion of which conceptual framework is best suited to explain the phenomenon. What one's views are on the above range of questions will have an impact on which framework one thinks is appropriate in this context, and vice versa. The main contenders here can be grouped into three categories, two of which share a commitment to a representational theory of mind that adherents to the third group reject.

One theory that has been invoked in order to explain joint attention, particularly in connection with issues pertaining to autism research, is the so-called theory theory of mindreading. Simon Baron-Cohen is, as far as joint attention is concerned, perhaps the most prominent defender of this account. He suggests that the capacity for joint attention relies on a set of mental modules that process information in isolation from their environments in a swift and nonconscious way. The capacity to focus on what another creature is focusing on is facilitated by an "eye direction detector" that builds dyadic representations of eye behavior. In humans, this module is coupled with a "shared attention mechanism" that constructs triadic representations, which include an embedded element specifying that other and self are both attending to the same thing. These modules facilitate the development of a theory of mind that allows you to ascribe mental states to yourself and to others.

The second conceptual framework, and probably the most popular one to be invoked in the explanation of joint attention, is Simulation Theory. In the very broadest terms, it explains how persons can come to attend jointly to objects with others in terms of a process of perspective taking. You understand what the other person focuses on by stepping into her shoes, by simulating her point of view. Originally marshalled as a less conceptually demanding alternative to the Theory Theory, the simulationist account has been developed in a variety of ways and with considerable sophistication. Some versions, such as that of Tomasello and his colleagues, are committed to the view that an explicit grasp of the other as intentional agent has to be in place for joint attention to be possible, while other accounts deny that this is necessary. Alvin Goldman distinguishes between "high-level" and "low-level" mindreading; the latter relies on unconscious and conceptually undemanding mental processes. One prominent account is Vittorio Gallese's, who thinks of simulation as an embodied modeling process concerned with the expected motor consequences of an action, which can be mapped onto either the agent or her co-attender. This move is designed to avoid the often raised criticism by defenders of the third conceptual framework that Simulation Theory relies on a conception of self and other that 9-month-old infants, or arguably nonhuman primates, are unlikely to possess.

The third framework really is a collection of views that can be seen as alternatives to both Theory Theory and Simulation Theory and that are united in their rejection of a representational theory of mind. The views contained within this group differ quite significantly in their commitments, however. Shaun Gallagher defends an enactivist view of joint attention, which argues that the meaning of actions that occur in a joint activity is directly present to the

other creature, without reliance on simulative processes of any kind. John Campbell defends a relational view of joint attention, according to which the three-place epistemic relation that obtains between attender, co-attender, and object of attention is to be thought of as primitive. In a joint constellation, the other person (rather than a representation of her) features directly in your experience.

One final approach that could be grouped under the third category but that has been so influential in the debate about joint attention that it may also be seen as an independent set of views comes from developmental psychology and was pioneered, in the 1970s and 1980s, by Colwyn Trevarthen; its most important defenders today are Peter Hobson and Vasu Reddy. The key notion this approach builds on is *intersubjectivity,* the capacity of human infants to attune their states of mind, in social interactions with their caregivers, to others. This sharing of feelings is first evident in what Trevarthen calls "primary intersubjectivity," the face-to-face interactions that develop into episodes of joint attention. Hobson and Reddy both argue, in different ways, that these early encounters amount to a sharing of feelings that carries over into and explains the capacity for joint attention. Joint attention, in this approach, ought to be seen as a fundamentally second-person phenomenon. This line of thought is at odds with both of the two other frameworks outlined previously.

Joint Attention and the Philosophy of Social Science

Joint attention has not so far been recognized as being of key importance for the philosophy of social science. It is quite obviously a cornerstone of human interaction and thus needs to be taken seriously by anyone interested in the psychological foundations of the social domain. However, the social sciences are primarily concerned with the behavior of complex collectives, and phenomena as elusive as joint attention in humans less than one year of age are not governed by the kinds of robust laws that you may expect the social sciences, or at least those that are concerned with the scientific explanation of social phenomena rather than their empathic understanding, to be dealing with. On the other hand, the rapidly increasing amount of work on the foundations of social cognition, in which joint attention plays a crucial role, is now an established research program within which a vigorous conceptual and methodological debate is taking place. The future relevance of joint attention for the philosophy of social science will thus depend, first, on the degree to which the social sciences recognize the importance of social cognition for a comprehensive understanding of the social domain; second, it will also depend on the degree to which they are open to research methodologies that can accommodate insights that aren't always most helpfully expressed in lawlike statements.

Judgment Aggregation and the Discursive Dilemma

This entry explains the important phenomenon of discursive dilemma, which can arise in certain cases of collective judgments in various social institution settings; outlines the main approaches to it; and shows how an interdisciplinary body of research involving philosophy as well as several social sciences has developed around it.

Judgment aggregation theory investigates which procedures a group could or should use to form collective judgments ("yes" or "no") on a given set of propositions or issues, based on the judgments of the group members. How, for instance, should the citizens of a state reach collective judgments on the three propositions—that multiculturalism is desirable, that immigration should be promoted, and that the former implies the latter? And how should a jury in court form collective judgments on the propositions that the defendant has broken the contract, that this contract was legally valid, and that the defendant is liable to pay damages?

The Discursive Dilemma and Political Philosophy

Such collective decision problems are vulnerable to the *discursive dilemma*, a phenomenon generalizing the doctrinal paradox in jurisprudence. The source of the dilemma is that the propositions under consideration are logically interconnected. In our first example, the third proposition is a conditional involving the first two propositions; and in our second example, the third proposition is equivalent to the conjunction of the first two propositions (according to the generally acknowledged legal doctrine that breach of a valid contract is necessary and sufficient for liability).

The problem is that the initially most natural and democratically appealing procedure—proposition-wise majority voting—may generate inconsistent collective judgments. In the case of our first example, Table 1 illustrates a situation in which the population is split into three camps such that, overall, a majority believes that multiculturalism is desirable (proposition *P*), another majority believes that *if* multiculturalism is desirable *then* immigration should be promoted (proposition *if-P-then-Q*), and yet another majority believes that immigration should *not* be promoted (*not-Q*).

Thus, this phenomenon of majoritarian inconsistencies poses a serious challenge to the very meaning and possibility of democracy, since it seems that collective judgments cannot be both consistent and democratically responsive to people's judgments.

To restore collective rationality, two routes are often contrasted. Under the *premise-based* route, the collective adopts the majority-supported judgments *P* and *if-P-then-Q* (interpreted as two *premises*), from

Table 1 Inconsistent Majority Judgments

	P	*If-P-then-Q*	*Q*
1/3 of the population	Yes	Yes	Yes
1/3 of the population	Yes	No	No
1/3 of the population	No	Yes	No
The majority	Yes	Yes	No

Source: Author.

which it derives the judgment *Q* (interpreted as a *conclusion*). Under the *conclusion-based* route, the collective instead adopts the majority-supported judgment *not-Q,* and it either forms no judgments at all on the premise propositions or forms some judgments on them that are logically consistent with *not-Q,* such as the judgments *not-P* and *if-P-then-Q*. In short, the premise-based approach respects majorities on premises while overruling majorities on conclusions, while the conclusion-based approach does the converse.

In response to the discursive dilemma, a highly interdisciplinary body of research has developed, conducted mainly by economists, philosophers, political scientists, and computer scientists. The less formal branch of research has its home in political philosophy. It focuses on the nature and role of the collective agent and the extent to which such an agent should provide reasons (premises) for its policies (conclusions). As is sometimes argued from the perspective of republican democratic theory, the state must act upon and publicly provide reasons for its actions to be contestable. Contestability of state actions is in turn important for preventing arbitrary state interference in citizens' lives, that is, to render citizens free in the republican sense. The need for reason-based state actions or policies is often taken to imply the superiority of premise-based over conclusion-based aggregation.

The Formal Theory of Judgment Aggregation

The more formal area of research stands in the tradition of Arrovian Social Choice Theory. The judgment aggregation problem is formulated in full abstract generality. Two central ingredients of the theory are, first, the group's *agenda,* that is, the set of propositions on which judgments are formed, and second, the notion of an *aggregation rule* or *procedure,* that is, a function that takes each person's set of judgments as input and returns a collective set of judgments. Simple examples of aggregation rules are proposition-wise majority rule, proposition-wise quota rules (with acceptance thresholds that may differ from the majority threshold and may vary across propositions), premise-based voting, conclusion-based voting, and the "expert rule," which universally adopts the judgments of a fixed individual (the "expert" or "dictator"). The generality of the framework stems from the fact that virtually any kind of decision can be construed as the formation of judgments on particular propositions. Notably, the classical preference aggregation problem in Social Choice Theory emerges as a special case, because a preference relation can be construed as a set of judgments on propositions of the form "*x* is better than *y,*" where *x* and *y* denote choice alternatives.

The Axiomatic Approach

Within judgment aggregation theory, one may broadly distinguish between an *axiomatic* and a *constructive* approach, the two of which go hand in hand. The axiomatic approach starts by formulating general requirements ("axioms") on aggregation rules that capture normative principles or intuitions. An example of an axiom of procedural fairness is *anonymity,* which forbids differential treatment of voters—in other words requires that the collective judgment set only depends on the number of individuals holding each given judgment set, regardless of their identity. This axiom, for instance, excludes the aforementioned expert rule. The axiom of consistency of collective judgment sets excludes proposition-wise majority rule, as the discursive dilemma shows. Once a set of axioms is specified, one proceeds by determining all the judgment aggregation rules satisfying the axioms, a more or less difficult mathematical exercise. Ideally, there is a single such rule, but often there are *many* rules (leaving a choice to be made) or *no* rules (forcing one to abandon an axiom). Indeed, in a series of *impossibility theorems,* it has been established that various combinations of axioms are not satisfied by any aggregation rule if the agenda of propositions is sufficiently complex. Many of these theorems are in a similar spirit to Kenneth Arrow's famous impossibility theorem in preference aggregation theory. Indeed, one of them stands out as being an exact generalization of Arrow's theorem from preference aggregation problems to arbitrary-judgment aggregation problems.

A quite different impossibility theorem generalizes Amartya Sen's influential "Impossibility of a Paretian Liberal"; it brings to light a conflict between respecting unanimous judgments and respecting the right of individuals or minorities to alone determine the collective judgment on propositions within the private sphere or the area of special competence.

The Constructive Approach

This approach tries directly to devise concrete aggregation rules for reaching consistent and democratically responsive collective judgments, without a preceding axiomatic derivation. The following salient proposals or paradigms can be contrasted: (a) *premise-* or *conclusion-based* aggregation rules; (b) *quota rules* with well-calibrated acceptance thresholds; (c) *sequential* rules, where the propositions in the agenda are voted upon one by one in an order of priority and where the vote on any proposition is suspended if the previous voting outcomes on propositions of higher priority already imply a judgment ("yes" or "no") on the current propositions; (d) *distance-based* rules, where the collective adopts a consistent set of judgments whose sum-total distance to people's sets of judgments is as small as possible, with respect to some distance measure between judgment sets; and (e) *scoring* rules, where the collective adopts a consistent set of judgments that receives maximal sum-total score from the individuals, with respect to some definition of "scores."

Localistic Versus Holistic Aggregation

Under a *localistic* (or *proposition-wise*) understanding of democratic responsiveness, the collective judgment on any given proposition should be formed solely on the basis of people's judgments on this proposition, independently of their judgments on other propositions. By contrast, under a *holistic* conception of democratic responsiveness, the collective judgment on, say, whether immigration should be promoted may be influenced by people's judgments on other propositions, such as "premises" or even unrelated propositions about taxation. Here, even an overwhelming majority judgment on whether immigration should be promoted may be overruled in the name of people's judgments elsewhere.

Localism is the content of the (controversial) *independence* axiom, the counterpart in judgment aggregation theory of the (equally controversial) axiom of "independence of irrelevant alternatives" in preference aggregation theory. A virtue of independence is that it is necessary for preventing the manipulation of outcomes through certain types of strategic voting or strategic agenda setting, as was proved. However, independence features as the central axiom in most impossibility theorems. Hence, the goal of aggregating localistically is unachievable (for agendas subject to the impossibility result)—whether or not localism is normatively desirable.

The Procedural Versus the Epistemic Approach

Two contrasting approaches or aims may be pursued when designing the aggregation rule. The *procedural* approach aims for a "procedurally fair" rule; for instance, anonymity is usually a central procedural virtue. The *epistemic* approach aims for a rule that generates "correct" or "true" collective judgments by an external, procedure-independent standard of correctness or truth; here, anonymity may be violated in the name of differences in information or competence. While most of the literature has a proceduralist flavor, some work takes the epistemic perspective and stands in the tradition of Condorcet's jury theorem.

Kinds: Natural Kinds Versus Human Kinds

Both the natural and the social sciences posit taxonomies or classification schemes that divide their objects of study into various categories. Many philosophers hold that what makes some taxonomic schemes more legitimate than others is that they correspond to actually existing divisions in nature, which they label "natural kinds." In other words, some classification schemes "carve nature at the joints" (to use a phrase inspired by Plato), while others are merely arbitrary or gerrymandered. In the natural world, examples of natural kinds would be *insect* and *metal,* but not *bug* and *rock,* or *insects-born-on-Monday* and *metals-whose-names-start-with-"s,"* which are nonnatural or "artificial" kinds.

When it comes to the social sciences, the question is "Do some categories correspond to social kinds or human kinds (the two terms are often used interchangeably), just as some categories in the natural sciences correspond to natural kinds?" Social scientists posit kinds of human being (e.g., *consumer, psychopath*), kinds of social institution (e.g., *political party, economic market*), kinds of social process (e.g., *ritual, immigration*), and so on. But is it enough for a social scientist simply to invoke a human or social category to conclude that such a kind really exists and that it ought to be admitted into our ontology?

This entry begins by examining purported differences between natural kinds and human or social kinds. Then, whether or not human kinds are fundamentally different from natural kinds, it will ask how we can distinguish genuine human kinds from spurious ones. Finally, the issue of natural kinds and human kinds will be related to the common claim that certain categories in both the natural and the social sciences are "social constructs."

Differences Between Natural Kinds and Human Kinds

Recent philosophical work has tended to favor an essentialist understanding of what it is for a category to correspond to a natural kind. Although essentialists are not united on the precise features that characterize natural kinds, they tend to posit that each natural kind is characterized by all or some of the following: (a) properties that are necessary and sufficient for membership in the kind, (b) microstructural properties, (c) intrinsic properties, (d) modally necessary properties, and (e) properties that are discoverable by science. If one understands natural kinds in this essentialist fashion, then it is fairly clear that most if not all social categories will fail to qualify as natural kinds. Without going into these features in detail, it would appear that many social categories are not definable in terms of necessary and sufficient properties, are not characterized by an underlying microstructure, are not wholly determined by their intrinsic properties, and do not have their properties as a matter of metaphysical necessity. Moreover, if they are discoverable by science, it will be a social rather than a natural science. Hence, this essentialist account of natural kinds would seem to be a nonstarter for the social domain.

But the essentialist account of natural kinds, though currently popular among some philosophers, is not universally held. Without taking the social sciences into account, the essentialist consensus is showing signs of unraveling under the pressure of categories in biology and many of the other "special sciences" (e.g., geology, biochemistry, etc.). Still, even if one does not endorse an essentialist understanding of natural kinds, there may be fundamental differences between natural kinds and human or social kinds.

The first obstacle to assimilating human kinds to natural kinds lies in the fact that real entities are often distinguished from artificial ones on the grounds that the latter are mind dependent or the result of human artifice. But if we adopt that criterion, then we would be led to judge all human or social kinds to be nonreal. Even though they may not be intentionally and consciously produced by human beings, all human or social kinds are influenced in some way by human action and social forces and cannot be regarded as independent of human beings and their minds. This seems to be one obvious way in which human kinds are different from natural kinds.

A second difference between human and natural kinds has been elaborated by Ian Hacking, who argues that human kinds are "interactive" or subject to the "looping effect." Hacking has illustrated this claim with various categories, such as *child abuse, multiple-personality disorder, fugue* ("mad traveler" syndrome), and others. Consider the category of *child abuse*. Once this practice is identified and labeled, those who engage in it may alter their behavior either by refraining from the practice altogether or by engaging in it more covertly or in some other way. In these cases, the phenomenon may be altered as a result of human intervention, for instance, by becoming less visible. Since the very nature of the phenomenon has changed, it then "loops back" to influence our beliefs about it, which may in turn have further effects on this practice, and so on. Though looping effects undoubtedly influence the nature of social phenomena, it is not clear that such effects are confined to the social realm. For instance, some have suggested that biological species that are a product of artificial selection can be subject to looping effects too, such as the domestic dog (*Canis familiaris*), whose phenotypical traits have been shaped by the beliefs and actions of human beings.

A third difference between natural kinds and human or social kinds has been emphasized by John Searle, who says that what it is for some social kind *x* to be *x* is simply to be regarded as *x*. For example, what it is for something to be money is for it to be regarded as money, to be used as money, and to be believed to be money. Hence, social kinds are ontologically subjective, being dependent for their very existence on human attitudes toward them, which distinguishes them from natural kinds. But critics have observed that Searle's account seems to apply only to the most conventional of social kinds, such as *money* or *government,* which depend for their very existence on human attitudes concerning those very categories. Other social kinds, such as *racism* or *economic recession,* do not seem to depend on our having attitudes toward them at all. They are therefore arguably not ontologically subjective, at least not in the same sense as kinds such as *money.*

Finally, perhaps the most widely cited difference between natural kinds and human kinds pertains to their purported value-ladenness or their alleged normative dimension. Some social scientists and philosophers regard many social categories to be evaluative and consider that their range of application and the properties associated with them are not determined solely by the nature of the social phenomena themselves but at least partly by our moral and ideological attitudes toward those social phenomena. If categories like *race, gender,* and *child abuse* are shaped by our value judgments or ideological stances, then that may set them apart from categories denoting natural kinds. But even those social theorists who insist that the very aims of social science ought to be normative (e.g., aiming at human empowerment or emancipation) seem to distinguish between the descriptive and normative dimensions of social theorizing. If so, this leaves room for the possibility that at least some of our social categories can serve a more purely descriptive and explanatory purpose.

Genuine and Spurious Human Kinds

Whether or not there are fundamental differences between natural kinds and human or social kinds, it is possible to maintain that at least some social categories correspond to social or human kinds. The next challenge consists in saying just which categories delineate genuine as opposed to spurious human

kinds, or how to distinguish between real and nonreal kinds in the social domain.

One promising route might be to return to one of the original sources of the notion of a natural kind (or "real kind") in the work of the 19th-century English philosopher John Stuart Mill. Mill was skeptical as to whether races constituted real kinds of humans that would constitute species or subspecies of human beings. His reasoning depended on the idea that a real or natural kind, whether in the natural or social sciences, ought to be characterized by a multitude of properties that are not simply deducible from one another. These properties ought to be scientifically important in the sense of being explanatory and playing a role in inductive inference. Moreover, he accorded the primary responsibility for determining whether this was the case to the investigators in each branch of knowledge, also accepting that there may be different classification schemes deployed by theorists in different scientific disciplines or subdisciplines. If we follow Mill broadly in this approach, we may consider human kinds to correspond to those categories identified by social scientists and investigators studying the properties of human beings and human society. The categories that they arrive at as a result of their investigations, provided they are genuinely explanatory and feature in inductive inference, would be the ones that correspond to real human kinds, while those that are not can be safely dismissed. Also following Mill, there need be no unique classification of human beings, their institutions, processes, and so on, into a hierarchy of categories. Rather, we may end up classifying humans into many crosscutting systems of kinds (e.g., in terms of both *class* and *ethnicity*) without undermining the reality of those kinds.

Social Kinds and Social Construction

What should we make of ubiquitous claims that at least some social kinds are "social constructions"? There is a sense in which any such claim about a social kind is vacuous, since social processes, institutions, and attitudes are all in some way constructed by human society. But is there a more interesting sense in which such claims are warranted? There would seem to be at least two possibilities. The first is that a socially constructed kind is one that is more deliberately a result of human artifice than might appear at first. (This may occur along the lines of Hacking's looping effect or in the manner of Searle's conventional social kinds.) In connection with this, social constructionists may provide informative accounts of the way in which the process of construction took place, tracing it back to particular historical eras or identifying it with certain social movements with specific ideologies or interests. A second possibility is that saying that a kind is a social construct is opposed to regarding it as biological or physiological in nature. Such claims are often made with regard to kinds that are commonly thought to be in the domain of the natural sciences but should rather be regarded as pertaining to the social sciences, such as *race* and *gender*. In such cases, to claim that a kind is a social construct is to say that the basis of the kind is not biological but can be found in social processes and relations instead.

Conclusion

Categories in the social sciences may be more mind dependent, interactive, conventional, and normative than those in the natural sciences, but that may not prevent them from corresponding to genuine human or social kinds. Moreover, genuine human kinds may be distinguished from spurious kinds on the basis of features such as their role in inductive inference and their explanatory value. This may enable us to better address some questions regarding categories that arise in the practice of social science, such as the reality of the category of *race* or how many *gender* categories there are in the human species.

Knowing-How Versus Knowing-That

This entry introduces the epistemic distinction between *knowing-how* and *knowing-that* and its philosophical provenance and goes on to present the various positions and nuances regarding that distinction in recent analytical philosophy.

The British philosopher Gilbert Ryle famously highlighted the distinction between knowing that something is the case (e.g., knowing *that* Antarctica is a continent) and knowing how to do things (e.g., knowing *how* to traverse Antarctica). This distinction is sometimes said to be related to others, for example, *epistêmê* and *technê,* reflection and habit/practice/craft, explicit knowledge and tacit/implicit knowledge, and declarative knowledge and procedural knowledge. However, the precise relations between these distinctions is contentious and a matter of substantive debate.

There are at least two ways in which knowing-that and knowing-how might be considered distinct. First, they might be said to be *inequivalent* (perhaps because not all instances of knowing-that are instances of knowing-how). Second, and more strongly, they might be said to be *exclusive* or *strongly contrastable.* The second is stronger in that it entails, but is not entailed by, the first.

The stronger claim was the centerpiece in Ryle's attack on "intellectualism," a position that views internal, nonovert intellectual states (e.g., belief, opinion, knowledge-that, and other propositional or factual attitudes) and intellectual operations (e.g., reasoning) as the key to intelligence and intelligent action, understood to include skill and expertise. Ryle contended that intellectualism entails a "vicious regress," which he proposed to avoid by maintaining that knowing-how, unlike knowing-that, is a type of power to act (e.g., an ability or disposition to behavior), hence his anti-intellectualism, which views such a power to act—rather than propositional attitudes or reasoning—as the key to intelligence and intelligent action.

It is, however, important to keep separate the following four Rylean theses (the first two we have already distinguished):

1. Knowing-how and knowing-that are not equivalent.
2. Knowing-how and knowing-that are strongly contrastable.
3. Knowing-how is a power to act.
4. Knowing-how is the key to intelligence and intelligent action.

In Ryle's view, (4) is a neglected but important truth, to be explained in terms of (3); the latter can be seen as a further specification of (2), which as noted above entails (1). But these four theses can come apart. For example, one might reduce all knowing-that to (a type of) knowing-how and all knowing-how to (a type of) ability: One version of such a position would accept (3) and (4) while rejecting (1) and (2).

Intellectualism, by contrast, rejects both (2) and (3). In defense of (2), it is argued that knowing-how lacks the "standard marks" of knowing-that, such as expressibility, explicitness, justification, and nonaccidental truth. In defense of (3), it is argued that intellectualist alternatives "overintellectualize" everyday knowing-how, skill, and expertise, as well as the mental lives of infants and nonhuman animals. And there is also Ryle's regress argument, mentioned above.

Yet while (2) and (3) were long regarded as orthodoxy, it is fair to say that at the time of writing, the increasingly dominant (though by no means consensus) view among epistemologists working on knowing-how is that these theses cannot be sustained.

Several reasons have been offered for this intellectualist conclusion. First, Paul Snowdon argues that many instances of knowledge-how involve

substantive knowledge-that; for example, knowing *how* to get from London to Swansea before midday depends on knowing *that* one first catches the 7.30 a.m. train to Reading from Paddington, then one . . . , etc." Second, a standard approach to the syntax and semantics of embedded questions within contemporary linguistics treats ascriptions of knowing-how as equivalent to ascriptions of knowing-that: Thus, in an influential paper published in 2001, Jason Stanley and Timothy Williamson argue that "S knows how to A" is true if and only if, for some W such that W is a way of A-ing, S knows *that* W is a way to A. Third, several counterexamples have been offered against (3). To illustrate, King describes a ski instructor who knows how to perform ski stunts, which he teaches his students, even though he is not able to do them himself, and Katherine Hawley describes a hiker who does not know how to escape avalanches although, given her "accidental success" when an avalanche occurs, she is nevertheless able to do so.

Other considerations motivating rejection of (2) and (3) include the causal-explanatory significance of rules and symbolic representations in cognitive science (see Fodor, 1968), the differences between practical knowledge and mere "knacks," and the role of know-how in (performing, learning, practicing) intentional action and our knowledge thereof.

Such intellectualist challenges are compatible with (1). How do they cohere with the datum, which seems to underlie (4), that knowing-how is intimately tied to action? It is open to intellectualists to treat some instances of knowing-that—and intellectual states or operations more generally—as likewise intimately tied to action. From this perspective, (2) and (3) fail not because knowing-how is "theoretical," or action-neutral, but rather because intellectual states such as knowing-that are sometimes "practical," or action oriented.

But we must keep separate the position that (2) and (3) are false from the following, further thesis:

5. Knowing-how is (a type of) knowing-that.

It is often assumed that there are only two options: Knowledge-how is a power to act (3), or it is knowledge-that (5). However, there may be other possibilities, for example, knowing-how might be *familiarity with a practical universal* or a kind of *nonpropositional understanding*. Such views reject (2) and (3) while also denying (5).

Debate over knowing-how and knowing-that has influenced philosophical discussion of, for example, linguistic, logical, moral, and experiential knowledge and has the potential to inform research in psychology and cognitive science (e.g., skills learning, artificial intelligence), linguistics, and theory of education, among other areas.

Knowledge Society

This entry introduces the emergence of novel forms of postindustrial society, known as *knowledge society,* explains the new place of knowledge in social life as well as the rise of knowledge economies and reviews several repercussions for social and political conduct in such new forms of societies.

Background

The foundations for the transformation of modern societies into "knowledge societies" continues to be based, as was the case for *industrial society,* on changes in the structure of the economies of advanced societies. Economic capital—or, more precisely, the source of economic growth and value-adding activities—increasingly relies on *knowledge.* The transformation of the structures of the modern economy by knowledge as a productive force constitutes the "material" basis and justification for designating advanced modern society as a *knowledge society.*

The significance of knowledge grows in all spheres of life and in all social institutions of modern society. The historical emergence of knowledge societies represents not a revolutionary development but rather a gradual process during which the defining characteristics of society change and new traits emerge. Until recently, modern society was conceived primarily in terms of property and labor. While the traditional attributes of labor and property certainly have not disappeared entirely, a *new* principle, *knowledge,* has been added, which, to an extent, challenges as well as transforms property and labor as the constitutive mechanisms of society.

Knowledge About Knowledge

Knowledge may be defined as a *capacity for action.* The definition of knowledge as capacity for action indicates that implementation of knowledge is open and is dependent on or embedded within the context of specific social, economic, and intellectual conditions.

Knowledge is a peculiar entity with properties unlike those of commodities or of secrets, for example. Knowledge exists in *objectified* and *embodied* forms. If sold, it enters other domains—and yet it remains within the domain of its producer. Unlike money, property rights, and symbolic attributes such as titles, knowledge cannot be transmitted instantaneously. Its acquisition takes time and often is based on intermediary cognitive capacities and skills. Despite its reputation, knowledge is virtually never uncontested. *Scientific* and *technical* knowledge is uniquely important in modern social systems because it produces *incremental* capacities for social and economic action that may be "privately appropriated," at least temporarily. Knowledge has, of course, always had a major function in social life. Social groups, social situations, social interaction, and social roles all depend on, and are mediated by, knowledge. *Power* too has frequently been based on knowledge advantages, not merely on physical strength.

The Knowledge-Based Economy

The emergence of knowledge societies signals, first and foremost, a radical transformation in the *structure of the economy.* What changes are the dynamics of the supply and demand for primary products or raw materials, the dependence of employment on production, the importance of the manufacturing sector that processes primary products, the role of manual labor and the social organization of work, the role of international trade in manufactured

goods and services, the function of time and place in production, and the nature of the limits to economic growth. The common denominator of the changing economic structure is a shift away from an economy driven and governed by *material* inputs into the productive process and its organization toward an economy in which the transformations of productive and distributive processes are increasingly determined by symbolic or knowledge-based inputs.

Social and Political Conduct in Knowledge Societies

The transformation of modern societies into knowledge societies has profound consequences apart from those of its economic system. One of the more remarkable consequences is the extent to which modern societies become *fragile* societies. The fragility of modern societies is a unique condition. Modern societies tend to be fragile from the viewpoint of those large and once-dominant social institutions (e.g., the state, the economy, science) that find it increasingly difficult to impose their will on all of society. Societies are fragile because individuals and small groups are capable, within certain established rules, of asserting their own interests by opposing or resisting the—not too long ago—almost unassailable monopoly of truth by major societal institutions. That is to say, legitimate cultural practices based on the enlargement and diffusion of knowledge enable a much larger segment of society to effectively oppose power configurations that turned out or are apprehended to be tenuous and brittle.

Knowledge societies are (to adopt a phrase from Adam Ferguson) the result of human action, but often not of deliberate human design. Knowledge societies emerge as adaptations to persistent but evolving needs and the changing circumstances of human conduct.

Modern societies are also increasingly *vulnerable* entities. More specifically, the economy as well as the communication or traffic systems are vulnerable to malfunctions of self-imposed practices typically designed to avoid breakdowns. Modern infrastructures and technological regimes are subject to accidents, including large-scale disasters, as the result of fortuitous, unanticipated human action; to nonmarginal or extreme natural events that may dramatically undermine the taken-for-granted routines of everyday life in modern societies; or to deliberate sabotage.

Present-day social systems may be seen to be fragile and vulnerable entities in yet another sense. Such fragility results from conduct as well as the deployment of artifacts designed to stabilize, routinize, and delimit social action. An example is the so-called computer trap or, more generally, the unintended outcomes of intentional social action. In the process of even more deeply embedding computers into the social fabric of society, that is, redesigning and reengineering large-scale social and socio-technical systems in order to manage the complexities of modern society, novel risks and vulnerabilities are created.

Among the major but widely invisible social innovations in modern society is the immense growth of the "civil society" sector. This sector provides an organized basis through which citizens can exercise individual initiative in the private pursuit of public purposes. One is therefore able to interpret the considerable enlargement of the informal economy and also corruption and the growth of wealth in modern society, as well as the increasing but often unsuccessful efforts to police these spheres, as evidence of the diverse as well as expanded capacity of individuals, households, and small groups to take advantage of and benefit from contexts in which the degree of social control exercised by larger (legitimate) social institutions has diminished considerably.

The future of modern society no longer mimics the past to the extent to which this has been the case. History will increasingly be full of unanticipated incertitudes, peculiar reversals, and proliferating surprises, and we will have to cope with the ever greater speed of significantly compressed events. The changing agendas of social, political, and economic life as the result of our growing capacity to make history will also place inordinate demands on our mental capacities and social resources.

Kuhn and Social Science

This entry presents the influences the social sciences had on Thomas Kuhn's theorizing about science, Kuhn's view on the relationship between the natural and social sciences, his influence on the social sciences generally, and, finally, his influence on the sociology of science.

How the Social Sciences Influenced Kuhn

In *The Structure of Scientific Revolutions,* Thomas Kuhn develops a general theory of scientific change. According to Kuhn, scientists working in a field can only make significant progress after they settle on a *paradigm,* a concrete scientific achievement that provides a template for future research in the field. Johannes Kepler's mathematical model for the orbit of Mars is a typical paradigm. It solved an outstanding research problem, providing a model for determining the location of Mars. Furthermore, Kepler's solution provided a general schema for modeling related phenomena, including the orbits of other planets and the orbit of the moon. As far as Kuhn is concerned, a scientific field only becomes mature when a paradigm becomes widely accepted. Only then can the field make the sort of progress we associate with the growth of science.

Kuhn made this insight about the role of paradigms in science while he was working at the Center for Advanced Studies in the Behavioral Sciences. Interacting with social scientists, he discovered the important role paradigms play in research in the natural sciences. Paradigms, Kuhn claimed, are largely absent in the social sciences. Kuhn thus believes that the social and natural sciences are fundamentally different.

Kuhn's Philosophy of the Social Sciences

Though Kuhn never claimed to have any special expertise on the social sciences, he reflected on the relationship between the social and natural sciences later in his career. He believed that the traditional view, a view associated with the sociologist Max Weber, was mistaken. According to this view, the key difference between the natural sciences and the social sciences is that the latter are interpretative whereas the former are not. The former "explain" observable natural facts, while the latter "understand/interpret" meaningful human action. As a result, the objects studied by the social sciences are subject to change as we theorize about them. The objects studied by natural scientists, like cells and atoms, are indifferent to our theorizing.

Kuhn believed that this alleged difference between the natural and social sciences had been exaggerated. The objects studied by natural scientists are not as ready-made as this popular view implies. The natural world is not merely awaiting our discovery. Rather, Kuhn believed that the objects studied by natural scientists are partly constituted by their theorizing. Different theories lead us to understand objects in the natural world differently. Observation is thus theory-laden. Different theories of the atom, for example, will lead us to "see" the world in different ways and to work in different worlds. Kuhn is not claiming there are no significant differences between the natural and social sciences. Rather, his point is that Weber's approach, and that of the British philosopher Peter Winch, to understanding rule-following behavior as fundamentally opposite to natural-scientific inquiry have misidentified what the key difference is.

Kuhn's Influence on the Social Sciences

Kuhn's account of scientific change, outlined above, was greeted with mixed reactions. Many philosophers of science, concerned only with the natural sciences, regarded Kuhn's theory of scientific change as a threat to the rationality of science. Kuhn seemed to suggest that the change from one paradigm to another in a field cannot be made in a rational manner for there are no paradigm-transcending standards by which to evaluate competing paradigms. This was widely regarded as a serious threat to the epistemic integrity of science.

Social scientists responded quite differently to Kuhn's theory of scientific change. Many thought that Kuhn was suggesting that no field was fully scientific unless it had a paradigm. This led many reflective social scientists to search for the paradigms in their fields. This search created some disappointments as social scientists in a number of fields discovered that they did not in fact have a paradigm. Some believed that this offered insight into why

the social sciences do not progress like the natural sciences. Others took it as an indication that their fields were in a preparadigm stage, still awaiting the creation of their first paradigms. In time, as Kuhn's general account of scientific change was challenged, concern about the scientific status of the social sciences passed.

Kuhn and the Sociology of Science

The social-scientific field most profoundly influenced by Kuhn is the sociology of science. Kuhn's *Structure* led to the development of the Strong Program in the Sociology of Scientific Knowledge, with Barry Barnes and David Bloor as its protagonists. The strong program was built on a particular reading of Kuhn's theory of concept application, a view they called "finitism." According to the strong program, every act of classifying an object is underdetermined by evidence and logic. This makes room for the influence of social factors on science. The strong program had a profound influence on developments in the sociology of science, leading to important investigations into how various social factors influence the content of science.

Kuhn was quite uncomfortable with the way sociologists of science interpreted his theory. He distinguished his own view from finitism, insisting that nature plays a far greater role in science than the Strong Program suggests. And, like many philosophers of science, Kuhn rejected the relativism of the strong program.

Kuhn's influence in the social sciences persists, as a number of the concepts he made popular—*paradigm, incommensurability, theory-ladenness*—continue to be employed by social scientists.

Kuhn on Scientific Revolutions and Incommensurability

It is not simple to give a concise definition of Thomas S. Kuhn's concepts of *scientific revolution* and *incommensurability* because in these somehow interwoven conceptions, all the essential elements of his philosophical position are present in a highly concentrated form. For a start, it is sufficient to characterize scientific revolutions as deep ruptures within the development of science, which separate modes of research in a particular way. The term *incommensurable* means "no common measure" and is meant to specify the relation of the succeeding traditions. The term has its origins in Ancient Greek mathematics (and particularly in Plato), where it meant no common measure between magnitudes. Since Kuhn's main work *The Structure of Scientific Revolutions* (*SSR;* 1962/1970), the metaphorical application of this mathematical notion to the relation between successive scientific theories has been a widely discussed idea. The concept of incommensurability as well as Kuhn's theory of scientific revolutions have had a great impact on the social sciences, although their applicability within this framework remains highly controversial. Nevertheless, it can be stated that Kuhn's ideas have resulted in increasing interrelations between philosophy and the social sciences.

This entry (a) gives a brief outline of Kuhn's philosophy of science, (b) explains his concepts of scientific revolution and incommensurability in detail, and (c) describes the impact of Kuhn's ideas as well as major misunderstandings of his theory.

Kuhn's Philosophy of Science

In order to attain a deeper understanding of Kuhn's concepts of scientific revolutions and incommensurability, it is necessary to sketch briefly his theory of scientific development.

Kuhn's main subject in philosophy of science is a developmental scheme, or a schematic description of scientific development, which primarily concerns the basic natural sciences, in particular physics and chemistry. The intended description is schematic in the sense that it presents scientific development as a succession of different phases whose main features are independent of the specific subject matter of the respective science. For each one of these phases a specific mode of scientific practice is characteristic. The developmental scheme that Kuhn suggests should hold true for all basic scientific disciplines, with only minor variations. It consists of the following: Before reaching maturity, nascent scientific fields are typically characterized by controversies between competing schools. There is no consensus among the practitioners of the emerging field. Each one of these schools has a particular view of the respective research domain, and typically these views are derived from extrascientific sources. Kuhn has called this phase of scientific development *preparadigmatic*. The competition among the schools may eventually come to an end when one group produces an exemplary solution to a preeminent research problem with the following two characteristics: It is sufficiently unprecedented to attract the members of the other schools, and it is sufficiently open-ended to leave enough interesting problems for further scientific work. These model solutions are called *paradigms*. They serve to implicitly guide research in the succeeding period called *normal science*. Normal science is characterized by a broad consensus by the practitioners in the field on fundamental questions, and, consequently, on a particular mode of research based on the particular paradigm.

Normal science is always confronted with *anomalies,* that is, with recalcitrant phenomena or problems that behave contrary to the expectations supplied by the paradigm. Anomalies do not usually call the validity of the guiding regulations of normal research into question. However, under special circumstances, they may, and then they are called *significant anomalies*. In such cases, the practice of science changes from normal science to *extraordinary science* or *science in crisis*. This aims to amend or even overthrow the still-binding regulations. Its research focuses on the significant anomalies and their context.

Extraordinary science resembles prenormal science in that it has a tendency to develop competing schools. However, it is more focused than prenormal science as all the various different schools must deal with the same set of significant anomalies while retaining as much as possible from the earlier period of normal science. If this research leads to a new theory that is accepted by the scientific community because it can lead to a new phase of normal science, a "scientific revolution" has occurred.

Scientific revolutions in Kuhn's *SSR* (1962/1970) are thus "the tradition-shattering complements to the tradition-bound activity of normal science" (p. 6). The rejection of the older theory is accompanied by a change in the problem field, including its related standards of solution, and by a corresponding change in basic scientific concepts. Some old concepts are discarded, some new ones are introduced, while some other concepts change meaning, sometimes in a subtle way. Kuhn even describes revolutions as *transformations of the world* in which scientific work is done, although it is not easy to make explicit and plausible what exactly is meant by this locution (something that has become a bone of contention among scholars debating the Kuhnian approach to scientific change—we shall encounter this again below). Kuhn compresses these features of revolutions into the concept of *incommensurability:* a relationship between successive traditions of normal science.

According to Kuhn, logical reasoning and empirical data play an important role in a scientific revolution, but they do not *determine* its outcome—that is, the decision for or against a new paradigm. It is rather epistemic values, for instance, the scope, simplicity, or accuracy of a theory that guide—but do not determine—theory choice during scientific revolutions. It is important to note that in this view science is basically a *social* enterprise. Scientific communities are the social enterprises that share

epistemic values and are the ultimate evaluators of knowledge claims. These communities ultimately decide between competing theories and their associated modes of research, and it is such communities that are seen by themselves and by others as responsible for some domain of scientific knowledge. Kuhn's position, therefore, has a sociological basis.

Scientific Revolutions and the Concept of Incommensurability

The most far-reaching and controversial core of Kuhn's philosophy is his thesis of the occurrence of incommensurable scientific theories as a consequence of a scientific revolution. Now, what does Kuhn mean by this notion? Let us start by considering the concept of incommensurability as it is developed in *SSR*. Incommensurability is a relational concept: It holds (or does not hold) between an A and a B. In *SSR,* A and B mainly are consecutive traditions of normal science. Think of the Ptolemaic geocentric system of the planets and the Copernican heliocentric system. In both conceptions, there was a relatively unanimous research tradition mainly dealing with the prediction of planetary positions. In such traditions that are separated by a scientific revolution, incommensurability prevails, according to Kuhn. This kind of incommensurability has three different aspects.

First, through a scientific revolution, a change in the field of scientific problems that must be addressed by any theory of that domain occurs, as well as a change in the field of problems that are legitimately addressed. Problems whose solutions are vitally important to the older tradition may disappear as obsolete or even unscientific; problems that did not exist, or whose solution was considered trivial, may gain extraordinary significance for the new tradition. Along with the problems, quite often the standards imposed upon scientifically admissible solutions change. Think of the requirement of classical mechanics—that explanations must be deterministic—which vanishes with the advent of the quantum-mechanical revolution.

A second aspect of Kuhn's (1962/1970) incommensurability theory concerns scientific methods and concepts. After a revolution, many of the older concepts and methods are still used, but in modified ways. The change of concepts discussed in *SSR* is of prime importance. It has an extensional and an intensional aspect. Extension has to do with the reference of a term (the objects it denotes or refers to), while intension has to do with the meaning of a term. The extensional aspect of a change of concepts consists of the movement of objects belonging to the extension of one concept into the extension of another concept, the two concepts being mutually exclusive. The striking example that Kuhn uses in *SSR* is the change of the concept of "planet" in the Copernican revolution. After the revolution, the earth, for instance, is a planet, whereas the sun and the moon are not planets anymore. The intentional aspect of the change of concepts consists of a change of meaning of the respective concepts. This is the case since the properties of the objects that are subsumed under these concepts change.

As the third and most fundamental aspect of incommensurability, Kuhn claims in *SSR* that, as we saw above, scientists belonging to different paradigms conduct their research in *different worlds*. But what does it mean to say that the world changes with a revolution? This question is not answered in *SSR,* although Kuhn has clearly seen its urgency there.

To understand this aspect of Kuhn's theory, it is important to distinguish between two meanings of the term *world* in Kuhn's philosophy, namely, the phenomenal world and the world in itself. It is the phenomenological world to which we actually have access in everyday life or in science. We can perceive and describe such a world, and in such a world there are octopuses, lecture halls, and electrons, for example. Such a world has a certain conceptual structure, for instance, the categories just mentioned. At this point, Kuhn holds that these concepts are of human origin; that is, we impose a structure on the world by means of these concepts, and we do not read off these concepts from the world itself, as a more familiar (realist) story would have us believe. Although it is not possible to impose any and every structure on the world, clearly more than just one is possible, which implies *a certain degree* of historical contingency of these structures. This is illustrated by the historical change of these conceptual structures (paradigms). As a consequence, paradigms are constitutive of a perceptually and conceptually subdivided world. In other words, the subjects of knowledge contribute to the constitution of the objects of knowledge (by means of paradigms) insofar as they structure the world of these objects.

The second sense of the term *world* in *SSR* is obtained by asking what is left if one subtracts all these human (subject-sided) contributions—that is, when we subtract all this perceptual and conceptual structuring from the world taken in the first sense. Then one is left with a world that is completely independent of our perceptions and conceptions, a world—as one might say—that is purely object-sided. But we have, according to Kuhn, no access whatsoever to this purely object-sided world. According to Kuhn, what we, or a particular scientific community, describe as reality is *a*—but not the only possible—phenomenal world. Due to the historical change of these worlds, Kuhn's theory has sometimes been described as "Kant on wheels."

Furthermore, because of such incommensurability, we must, according to Kuhn, rethink the concept of *scientific progress* in the natural sciences. First, scientific progress is not cumulative, due to conceptual changes during revolutions. Cumulativity implies that something that is a part of science at some point in time will, neglecting small corrections, remain a part of science forever. However, the conceptual changes that occur during revolutions are much more than small corrections of the existing body of knowledge. They amount to a thorough conceptual reorganization, and typically to a changed ontological perspective. Furthermore, Kuhn denies that scientific progress is an approach to truth. Instead of conceiving scientific progress as a goal-directed process, we should think of scientific progress in an analogous way as Darwinian evolutionary theory conceives of evolution. Darwinian evolutionary theory states that there is no goal toward which evolution is directed. In a similar way, in scientific development, there is no "set goal," which would be a "permanent fixed scientific truth," that science approaches.

In *SSR,* the concept of incommensurability is not entirely clear. Thus, it has been the subject of much criticism as well as misunderstanding. Most of Kuhn's later work has further developed and refined the conception of incommensurability in order to answer critical questions regarding his ideas of "world change" and "semantic incommensurability." For instance, is it really appropriate to speak of the Kuhnian cases as examples of meaning change? Is it not that the respective concepts themselves remain constant and are only used differently? And would it even speak against "approaching the truth" if the concepts actually did change in meaning, as long as they still refer to the same entities as before, but in a more precise way (as a scientific realist might ask)? It is mainly these questions and problems that Kuhn worked on from the late 1960s on. However, his answers to these questions remain controversial.

The Impact of Kuhn's Ideas and Major Misunderstandings

Kuhn's theory brought forth a significant change within the philosophy of science of the 20th century as it stressed the need to include sociological thinking and in particular detailed knowledge of the actual history of science in order to arrive at a reasonable philosophy of science. This post-positivist turn was antithetical to the "standard conception" of science as advocated by logical positivists as well as Karl Popper and led to the emergence of various new subdisciplines in philosophy and the social sciences (and between them), such as studies in history and philosophy of science, science and technology studies, and the developing field of social epistemology. Furthermore, Kuhn's ideas were widely adopted by the social sciences. The predominant use of Kuhn's work in the social sciences concerns the current status of a particular discipline or its history. Is the discipline still in its preparadigmatic state, or does it already have a paradigm? Are the changes that the discipline experienced in the past veritable Kuhnian revolutions? Could competing theories, say in sociology, be described as incommensurable? These questions received the most diverse answers from different authors. Elements from Kuhn's theory were used by some to defend mainstream social science and by others to develop a critical attitude toward it or to defend or attack alternatives. Some authors attempted to show that on Kuhnian terms, a given social science is very similar to natural science, whereas others tried to demonstrate the opposite, and so on. No consensus has been reached in any of the social sciences about these and related questions. Kuhn himself said very little about the social sciences, basically only that they are typically in the preparadigmatic state. This, however, did not prevent many social scientists from uncritically applying parts of Kuhn's theory to different aspects of their disciplines, without further arguments or corroborating case studies. On top of that, Kuhn's ideas have been (mis)used for the most diverse purposes. On the basis of his—indeed sometimes ambiguous—texts, even outright contradictory assertions have been

made by some social scientists, often to promote their own agenda. Take, for example, the sociology of science following Kuhn: With the advent of *SSR,* the production of scientific knowledge seemed not at all determined by time-independent, universal methodological rules anymore. Instead of binding rules, research and theory choice in times of extraordinary science is guided by values that only influence but do not determine scientific behavior. Such values are influenced by group-specific and even idiosyncratic factors. In other words, scientific knowledge now indeed seemed socially contingent, which licenses and even appears to demand sociological analysis. Typically, the content of science was now seen as the result of negotiations among scientists in which human interests of a personal or political nature, or power relations, played an important and sometimes even decisive role. Science, therefore, was assumed to be a completely contingent enterprise without any rational aspects. It should be noted, however, that Kuhn himself remained extremely skeptical toward those claims. In his view, the *epistemological* dimension of scientific knowledge—the possibility of its normative evaluation from within science—must be an essential part of an integrated image of science, but it had been entirely dismissed by many social scientists.

Next to this point, Kuhn's concept of incommensurability has often been understood as the "absolute incomparableness" of scientific theories with respect to their scientific merits, implying that it is impossible to rationally compare and evaluate successive scientific theories. At first glance, this seems to be a compelling consequence of incommensurability. Since incommensurable theories deal with "different worlds," they seem to stand in the same relationship as theories about the unconscious stand to theories about the stability of galaxies: These theories clearly describe different domains with mutually untranslatable vocabularies. Because there cannot be any empirical friction between such theories, there cannot be any real competition between them, and consequently, the question of a rational choice between them cannot arise either. The same seems to hold true for incommensurable theories.

However, that is not Kuhn's point at all. Instead, he asserts that it is impossible to compare two theories point by point; that is, he denies the possibility that each (general) statement of one theory (e.g., Newtonian mechanics) can be confronted with the corresponding statement of the other theory (e.g., Einstein's theory of relativity). This holds since, with the new conceptual vocabulary, statements can be formulated that are incapable of articulation by the old vocabulary. Additionally, even corresponding empirical statements may carry different weights among the two theories, so that the merits of one theory may be depreciated from the viewpoint of the other. Yet the two theories can be compared globally, with respect to their simplicity, accuracy, fruitfulness, predictive power, and so on. Nevertheless, two scientists in agreement on the list of such epistemic values may still disagree on which theory should be preferred, for example, due to different weights of the shared values. This is indeed the case during the phase of extraordinary science. Therefore, theory comparison and theory choice do not resemble an algorithmic procedure in which all applicants of the algorithm must get the same since they have to follow fixed rules mechanically. Yet this form of theory comparison is far from being irrational, at least if one supposes that the sort of epistemic values mentioned form a reasonable ground for theory choice within scientific communities.

Lakatos, Methodology of Scientific Research Programs

Imre Lakatos (1922–1974) was an émigré who left his native Hungary for Britain during the 1956 uprising. He had already completed a doctorate from the University of Debrecen, having submitted a dissertation titled *On the Sociology of Concept Formation in the Sciences*. A further doctorate was completed at the University of Cambridge, with the thesis *Essays in the Logic of Mathematical Discovery*. In 1960, he became a member of the Department of Philosophy, Logic, and Scientific Method at the London School of Economics, eventually becoming a professor in 1969. He died suddenly at the age of 52. The three major influences on Lakatos were Karl Popper, the mathematician George Pólya (with his heuristic approach to mathematics), and in a strange way the Marxist György Lukács (since Lakatos's approach to matters can be broadly called "dialectical").

As the titles of his two doctorates indicate, his overall main interest was in the *dynamical growth* of theories, both within mathematics and the empirical sciences, and in the rationality that such growth exhibits. The emphasis on growth put him at odds with more formal and axiomatic approaches in science and mathematics, and this took him in the direction of the history of the development of ideas in these fields. However, Lakatos did not regard himself strictly as a historian, since he provided what he called *rational reconstructions* of developments in mathematics and the sciences, which may well be at odds with the fine details of the actual course of the development of the sciences. Lakatos's approach gives us deep insights into the complexities of the historical growth in all sciences, from mathematics to the social sciences (including economics), and the ways in which the growth can be deemed to be rationally based.

The Growth of Science I: Proofs and Refutations (Deductive Science: Mathematics)

Lakatos's first major publication, a sequence of four articles in the *British Journal for the Philosophy of Science* 1963–1964, was drawn from his Cambridge thesis and titled *Proofs and Refutations* (it is dedicated to Pólya and Popper). At the time of his death, revisions were not complete; but essentially, the original papers along with other writings were published in the 1976 collection brought out by Cambridge University Press, with other papers on philosophy of mathematics appearing in the 1978 publication *Mathematics, Science and Epistemology* (Philosophical Papers, Volume 2). It is cast in the form of a dialogue between a teacher and pupils and investigates the conjecture that for all polyhedra the number of *V*ertices minus the number of *E*dges plus the number of *F*aces is equal to 2, namely, $V - E + F = 2$ (a result originally proposed by Leonhard Euler). In the dialogue, a "proof" of this is offered; it is not a formal proof in the sense of mathematical philosophers like Gottlob Frege, Bertrand Russell, or David Hilbert but rather an informal proof that depends on a number of "thought experiments" that are embedded in other subconjectures or lemmas, such

as whether solids can be "projected" into deformable rubber sheets.

As the dialogue amply shows, the proof is open to "counterexamples" or *refutations*. What should one do in the face of alleged counterexamples? Either one could accept them, in which case Lakatos elaborates a "method of surrender," or one could reject them, in which case Lakatos elaborates a "method of monster barring." The latter approach may be such that if the Euler theorem does not hold of a figure then it can be denied that the figure is really a polyhedron. This in turn leads to the strategy of *concept contraction* or concept stretching. In a brief outline, this is Lakatos's more dialectical approach involving a "method of proof and refutations," which, he insists, really underlies the way in which axioms and proofs in mathematics are discovered and then critically evaluated, something obscured by more formal approaches.

Later in the dialogue, Lakatos proposes four heuristic rules of procedure. But these are not fully developed, nor do they provide a recipe for generating proof or refutations. Rather, they are guidelines that govern the way in which hypotheses within a theory evolve as a sequence of proofs and refutations. Just how closely does such a procedure capture the actual history of what has historically gone on in mathematical thought in this area? Lakatos (1976) says that it "should reflect the dialectic of the story; it is meant to contain a sort of *rationally constructed or 'distilled' history. The real history will chime in the footnotes . . . as an organic part of the essay*" (p. 5). Lakatos's approach generated a lot of interest at the time in the philosophy of mathematics, but few followed him fully in rejecting what he dubbed the "formalist" metamathematical approach to mathematics, which in his view "disconnects the history of mathematics from the philosophy of mathematics" (p. 1).

The Growth of Science II: Scientific Research Programs (Inductive Reasoning: The Empirical Sciences)

In 1965, Lakatos organized at the London School of Economics an international colloquium in the philosophy of science, which attracted leading philosophers of science from around the world. The proceedings were published in four volumes, with Lakatos himself contributing some important papers, two of which will be mentioned. The first of these is a long paper analyzing the approach of Popper and Carnap to the problem of evidence in science, titled "Changes in the Problem of Inductive Logic" (reprinted in Lakatos, 1978b, chap. 8). Lakatos had picked up on a phrase previously used by Popper—"research program." Lakatos developed this as a framework within which problems can be posed and solved and that may be characterized as "progressive" or "degenerating." Framing matters this way, Lakatos was able to present an important part of the history of the development of inductive reasoning in a manner akin to the way he had done for proofs and conjectures within mathematics.

Even more important is Lakatos's "Falsification and the Methodology of Scientific Research Programmes" (SRPs), in which he turns to the application of his general approach to the empirical sciences. This originally appeared in Lakatos and Musgrave (1970) (reprinted in Lakatos, 1978a, chap. 1). The conception of science and scientific method that Lakatos proposed has had wide application not only in the physical sciences but also in the social sciences, particularly economics.

As in his work on mathematics, Lakatos's framework focuses on two aspects of science: (1) the dynamical growth of theories and (2) the rationality that this growth exhibits. In respect of (1), Lakatos's position resembles that of Kuhn's paradigms, but the emphasis on (2) gives a much more prominent role to the rationality of science. Also, his framework takes him away from the common axiomatic approach to the structure of scientific theories (something that is also characteristic of his approach to mathematics, as shown above). Since few theories are presented in an axiomatized form and even fewer are given a more rigorous formal presentation, Lakatos's theory of SRPs, with its more historically presented dynamical structure of theories, was welcomed.

Lakatos proposed that SRPs be understood as a historically generated (finite) sequence of theories (T_1, T_2, T_3, . . .) each of which is a conjunction of a "hard core" (HC) and a "protective belt" of auxiliary hypotheses A_i (i.e., T_i = (HC) & A_i). The HC is a set of hypotheses that remains the same for the life of the program. It need not be true, but it is treated as if it were true by those working on the program. The auxiliaries are the variants, which can change from theory to theory within the program. These may be simply additional hypotheses, or they could

be descriptions of models to which the hypotheses of HC are to apply. Lakatos illustrates his approach in the case of Newton's theory. In the Newtonian SRP, the HC is Newton's three laws of motion and the law of universal gravitation. The auxiliaries are the various models of, say, the solar system, which is initially understood as a single-point particle orbiting a central-point particle; this is then developed to remove simplifications so that the two particles become massive bodies; they are then (in the model) made to rotate on their axes; they are then embedded in an even more realistic model of the solar system in which a number of planets orbit a central body each of which perturbs the other, and so on.

A second important feature of an SRP is the heuristic associated with it. The *negative heuristic* bids that when any of the sequence of theories is in trouble, the HC is not to be altered, but the auxiliaries are to be changed. The *positive heuristic* specifies guidelines to which alterations to the auxiliaries are to conform; but they do not provide an "algorithm" that tells us *how* to alter the auxiliaries. So in the Newtonian SRP, the negative heuristic does not permit us to change Newton's fundamental laws, while the positive heuristic tells us to treat all systems as mutually gravitationally attracting bodies. The heuristic may be sufficiently powerful for the program to develop under its own steam and uncover many novel facts without necessarily focusing on the anomalies that it might face. As Lakatos says, a program can develop in an "ocean of anomalies."

Rationality in Scientific Growth

The *rationality* of a program can be determined by investigating its sequences of theories. A pair of theories may have the following characteristics. The second is *theoretically progressive* if it has consequences (e.g., predictions) that the first does not. And it will be *empirically progressive* if some of those consequences turn out to be true—that is, a new fact is predicted (if none are true, then it is *empirically degenerating,* i.e., Lakatos says it is *ad hoc*$_2$). A pair will be *theoretically degenerating* if the second makes no predictive advance over the first; and it will be *theoretically stagnating* if it makes even fewer predictions (i.e., it is *ad hoc*$_1$). Finally, if the SRP runs out of heuristic steam, it might well accommodate facts relevant to it but uncovered in a rival program by simply altering the auxiliaries in any fashion (perhaps breaking the positive heuristic); it is then said to be *heuristically degenerate* (i.e., *ad hoc*$_3$). This leads to a *criterion for demarcating science from pseudoscience:* An SRP must have at least one phase that is empirically progressive.

Assessing Rival Scientific Methodologies

When Lakatos developed his methodology of SRP (MSRP), it led to a number of comparative studies about how various methodologies, such as inductivism, probabilism, Popperian falsificationism, and conventionalism, can deal with some of the central episodes in science; and it also invited comparison with methodologies that tended to be nonrational from Thomas Kuhn's theory of paradigm shifts (though the later Kuhn made more explicit his methodology of weighted values), Polanyi's account of tacit knowledge, and Paul Feyerabend's antimethodology stance.

Lakatos proposed a metacriterion for judging rival methodologies: We are to adopt that methodology that maximizes rational explanations of moves in the game of science and minimizes other moves, which are then relegated to leftovers for sociologists of science to explain. Lakatos and his supporters argued that MSRP gave maximally the best explanations. This led to a wide-ranging critical discussion of the value of various theories of method and complaints from historians of science that MSRP was a distorting lens through which to view the complexities of actual science. But as in the case of his approach to the history of mathematics, Lakatos took his application of MSRP to the sciences to give a *rational reconstruction* of that history and not one that gets lost in the complex details of actual history. For Lakatos, methodology without history of science is empty, but history of science without a rationalizing methodology is blind.

Language, Philosophy of

The philosophy of language has played an extremely important role in 20th-century and early-21st-century philosophical thought, but it is no newcomer to the scene. Plato's dialogue *Cratylus* is a sustained look at the nature of word meanings that contrasts conventionalism about meaning with naturalism. Aristotle developed a logic of quantification and of modality and showed that we can study both natural language and logic using a formal language. The Stoics, too, made contributions to linguistic analysis, provided a division of the parts of language into five categories, and offered an analysis of these parts based on syntactic and semantic functions. They also contributed to the notion of complete and incomplete meanings, thus contributing to the theory of propositions and the semantics of predicates. Work on vagueness, ambiguity, and logic continued through the medieval and modern periods. However, the modern watershed achievement is the invention of modern logic by the great mathematician, logician, and philosopher Gottlob Frege and his subsequent work in both logic and metalogic. Frege's generalization of the mathematical notions of function and argument and his logic's ability to handle the interaction of multiple quantifiers provided the impetus for the "linguistic turn" that has characterized much of 20th-century analytic philosophy. This turn has resulted in the vigorous study of various logics (modal, temporal, erotetic, deontic, etc.). It provides analytic philosophy with its focus on logic and language and reveals how the exploration of these informs philosophical questions in general.

A few of the puzzles considered within the bailiwick of philosophy of language are as follows:

- What is meaning, and how do words, phrases, and sentences acquire it?
- What logic (if any) governs natural language?
- Does the language you acquire affect your cognitive and conceptualizing abilities?
- What are the different actions (especially speech acts) we can undertake using language?
- What norms govern language use?
- Are all philosophical puzzles really linguistic puzzles?

These questions are obviously related. Generally, the philosophical study of language has been divided into three parts: (1) syntax, (2) semantics, and (3) pragmatics. *Syntax* is the study of the rules and principles that generate the sentences and phrases in a language out of its basic parts. *Semantics* is the study of (linguistic) meaning. *Pragmatics* is the study of language use. Many linguistic phenomena are difficult to classify as belonging properly to any one area, and the borders of semantics and pragmatics are often highly controversial.

Syntax

One very popular approach to syntax was initiated by Noam Chomsky, leading to a conception of grammar as (a) universal, (b) known innately by humans, (c) generative, and (d) the study of an individual's linguistic competence—her I-language (or internal language), as opposed to E-language (or external language, e.g., French or English). The features of grammar (a) to (d) are interrelated: Universality is the result of generative rules that humans know as part of their linguistic competence.

The focus of these sorts of theories has raised very interesting questions in epistemology. In particular, there is controversy over the nature of the epistemic relation humans have to the rules of generative grammar that characterize their linguistic competence. Chomskians argue that it is simply propositional knowledge of various parameters that constrain possible grammars (albeit knowledge that the users find extremely difficult to articulate), but

others have found this sort of tacit knowledge to be extremely puzzling. The innateness of the knowledge is controversial as well. It is often justified by an argument from the *poverty of the stimulus:* Children aren't exposed to enough evidence, namely, external stimuli, in order to explain the rapidity and ease with which they master a language.

Philosophers often proceed on the assumption that syntactic representations are the inputs for semantic interpretation. This requires reification of the objects of syntactic theory as things to be interpreted. This reification, in many syntactic theories, requires positing a great deal of "unvoiced structure"—parts of the representation that receive no actual phonological execution at all. For example, it is often argued that "to leave" in (1) contains an unvoiced subject as represented by (2):

1. John wants to leave.
2. $John_1$ wants [PRO_1 to leave]

"PRO"[1] is co-indexed with "John," and semantically, it is interpreted as coreferring with John (if "John" refers at all). This is a surprising result but not one without justification. If PRO is represented in (1)'s LF,[2] it is fair game for semantic interpretation. The extent to which a sentence's syntactic structure constrains its meaning in a context is a hotly debated issue.

Semantics

Two constraints that seem to apply to any theory of linguistic meaning are as follows:

1. *Compositionality (C):* The meaning(s) of complex linguistic units are determined by the meanings of their parts and how the parts are syntactically structured.
2. *Publicity (P):* Linguistic meaning must be public.

(C) is not obviously true of all meaningful units: The idiomatic meaning of "kick the bucket" doesn't seem to be a function of the meanings of the words *kick, the,* and *bucket.* However, linguistic meaning is generally argued to be compositional since we can understand novel sentences. Consider the following:

(NS): A gentleman from Nova Scotia who travels with a fish was accosted by a troop of extremist ballerina protestors.

(NS) has a clear meaning despite its novelty. This is difficult to explain on any theory that doesn't explain the structure of complex units via the meanings of their parts and how they are structured. (P) is plausible because we can communicate using language, which would be inexplicable if meaning was private. On this basis, Frege argues that communicable meanings can't be subjective ideas. Some philosophers (cf. Wittgenstein) argue that private meaning is impossible (and not merely incommunicable). Like most bold claims in the philosophy of language, the extent to which privacy is compatible with meaning has proven highly controversial.

If (communicable) meaning has to be both compositional and public, it is natural to think of meaning as involving something that linguistic users can all converge on. Several options have been advanced as possibilities that can be grouped together. In general, philosophers of language have taken indicative sentences as a starting point. This isn't surprising given the assumption that language is a device of communication and information exchange. This leaves imperatives, interrogatives, performatives, and the like on the side, since "Finish your spinach" isn't truth evaluable. Philosophers of language have generally hoped that an account of the meaning-indicative sentences will provide the basis for a theory of the other parts of speech. "Finish your spinach," for example, may have satisfaction conditions involving states of affairs in which "You finished your spinach" is true.

Meaning and Reference

If meaning is compositional, the atomic parts of sentences must have meanings. It has proven useful to posit a relation—*reference*—that holds between atomic units of meaning and the world. While it is fairly easy to make sense of names referring, the thesis that predicates, quantifiers, aspect, and tense morphemes refer is much more controversial.

If we posit reference for predicates and names, we can offer a toy theory of the meaning for the following:

(A) Agamemnon fathered Orestes.

(A)'s meaning (ignoring tense) can be given as a composition of the referents of *Agamemnon, Orestes,* and *fathered.* We can then deal with the tense marker by treating it either as an operator on the sentence, which effectively means "in the past of the time of the context of utterance of (A)," or as

referring to a time in the past. The meaning of (A) is thus compositionally determined by the referents of the parts of the sentence and how it is structured.

The theory faces two well-known problems. First is the problem of empty names. Neither "Zeus" nor "Pegasus" refer, but they seem to contribute different meanings to sentences. Second is the problem of informative identities. While

(SS) Spiderman is Spiderman is trivially true,

(SP) Spiderman is Peter Parker

is true but highly informative. Mary Jane can believe (SS) without believing (SP). However, given that Spiderman and Peter Parker corefer, compositionality requires that (SS) and (SP) mean the same thing.

A solution, according to Frege, divides meaning into two dimensions: (1) sense and (2) reference. The role of sense is to determine reference, and senses can bear a many-to-one relation to the referent they determine. Thus, while Peter Parker and Spiderman corefer, the sense of "Peter Parker" is different from the sense of "Spiderman." (SS) and (SP) express different compositionally determined semantic objects at the level of sense, but they determine the same reference. We can explain both why (SP) is informative and why one can believe (SP) but not (SS). However, positing senses for names is the target of many powerful arguments that have led philosophers to rethink the relationship between informativeness and meaning. It is generally an open question as to how the cognitive aspects of reference are to be integrated into a theory of meaning.

Another interesting set of questions regarding reference involves context-sensitive expressions. Indexicals (*I, here, now*) and demonstratives (*this, that*) have stable meanings but refer to different objects on different occasions of use. Providing a semantics for indexical expressions led to a view that sentence truth is doubly indexed—to both a context of use and the circumstances relative to which you evaluate the sentence. This approach opens new venues for the study of context and meaning. For example, a popular view in epistemology takes "know" to operate in a manner similar to "now": It has different referents in different contexts of utterance.

Sentence Meaning

Some sentences in different languages are synonymous, leading to the question of whether or not to reify sentence meaning. Those who are happy to do so think of meanings as propositions, though there is little consensus on what propositions are. On one view, the meaning of a sentence is the set of possible worlds at which it is true: Propositions are neither true nor false, but they are true or false at worlds. This view of propositions is beset with a challenge: Surely, "2 + 2 = 4" and "3 + 3 = 6" don't mean the same thing even though they are true at all the same worlds (i.e., all of them). A more fine-grained view of propositions takes propositions to be set theoretic structures containing either objects, properties, and relations as members, or senses. Both views face the problem of the unity of the proposition: What unifies these structures in the right sort of way to constitute something thinkable, judgeable, and truth evaluable?

Philosophers eschew reification of sentence meaning and insist that meaning is to be identified with truth conditions, in a theory that specifies "T sentences" such as

S is true iff p.

S ranges over (structural descriptions of) sentences of the language we are giving the theory for (the "object language"); the rest of the sentence is in the language we are using to give the theory (the "metalanguage"). If English is used as a metalanguage for French, we get

(F) "La neige est blanche" is true iff snow is white.

(F) is informative and displays what the object-level sentence means. One prominent worry for this sort of theory is that the "iff" is an extensional connective: It's true only in cases where the two sentences it conjoins have the same truth-value. Consider (G):

(G) "La neige est blanche" is true iff snow is cold.

(G) is true but not a suitable candidate for specifying the meaning of "La neige est blanche." Truth-conditional theorists try to solve this by invoking *radical interpretation* and *charity:* You take your subjects and interpret their language by trying to make most of what they say (and believe) come true and be reasonable. While the success of this gambit is much disputed, the idea that some principle of charity constrains interpretation has been very powerful in the philosophy of language.

Other theories tie meaning to epistemic abilities. Logical positivists tried to explain sentence meaning in terms of verification (or falsification) conditions, while ordinary language philosophers took sentence

meaning to be the set of sanctioned moves in a language-game that the community both played and policed. Both views had far-reaching implications for philosophy, seeing most traditional philosophical problems as simply the result of a subtle misunderstanding of meaning.

Externalism and Internalism

The philosophy of mind and the philosophy of language share an interesting question: Is the content of a thought or sentence determined by the psychological properties of the thinker/speaker or by external features (as well)? Powerful arguments have been marshaled to show that the environment plays a role in determining content. Often these arguments take the following form: Imagine a perfect duplicate of yours who uses the word *w* in the same way you do but for whom the apparent referent of *w* is different in microstructure from the actual referent of *w*. Intuition has been taken to favor the view that *w* is distinct in referent and the speakers distinct in their thoughts as regards *w*.

Externalism is implicated in another set of arguments concerning meaning and underdetermination. Take any set of facts that can plausibly serve the role of determining meaning. Any number of rules regarding the use of these terms can be "fitted" to these facts. In fact, results in metalogic show that we can take any theory we like and interpret it using only the natural numbers and retain all the same theorems. This means that unless the world provides better or worse referents for our terms it is very hard to see what could possibly ensure that words refer to the referents we take and expect them to refer to. Some have taken this result to be a clear victory for anti-realism and pragmatism. Others have taken this result to show that the world really does come with better and worse referents for our terms—some properties (or classes) are simply more natural than others, and naturalness makes for more eligible candidates for reference.

Pragmatics

Pragmatics is broadly divided into two parts. First, there is *speech act theory*. We use language in all sorts of interesting ways: We assert, we question, we command, we flirt, we apologize. Often the same sentence can be used to perform different speech acts: "The police are coming" could be an assertion or a warning. While the study of assertion has dominated much of the literature, there is lively study of the other types of speech acts we perform and how they interact with the meaning of the sentences we use to perform them. The study of speech acts connects closely with the study of mind: Many of the felicity conditions governing speech acts depend on the speaker being in correlated mental states. Assertion is arguably felicitous only if the speaker believes the content of the assertion. Promises aren't felicitous without the correlative intention to make the content of the promise true.

Second, we often use sentences in order to convey more information than they literally mean. Responding, "I am free tonight" to a request to go out for drinks *implies* that you will accompany your interlocutor without *saying* so. This relation is not accidental, and philosophers of language have appealed to the rational, cooperative character of conversation to explain these implications, which are known as "implicatures." A complicated issue arises over the scope of these sorts of explanations. If Joe claims that "it is raining" when in Paris, we can work out that he means that it is raining in Paris, not merely that it is raining. If Joe claims that "Tipper didn't quit smoking," we can work out that Tipper used to smoke even though Joe didn't assert that she did. Accounting for these cases under the same rubric as implicature has been and continues to be a matter of much controversy.

Language and Thought

There are a great deal of interesting questions about the interaction of language and thought. One extreme claim is that an individual's language has very strong effects on her cognitive and conceptual abilities, though it isn't clear how to make this sort of claim more precise and testable. There are powerful philosophical arguments to the effect that linguistic relativity of any strong sort is literally a priori incoherent. The universality of various domains of thought remains an interesting and controversial issue.

A related, bold claim is that thought itself is done using a language of thought (LOT). LOT theorists claim that a naturalistic, computational theory of mind presupposes a LOT given certain apparent facts about the compositionality of thought. The thesis is controversial as it requires that we have a language that we don't learn but simply possess and whose linguistic parts are, at least in part, not learned but simply had.

Finally, there is broad agreement that what a speaker means by uttering a sentence has a lot to do with the speaker's intentions in uttering it. An ambitious project has involved trying to give as large a role as possible to a speaker's intentions in determining meaning in general in order to ground meaning in the operations of mind. This approach usually involves a speaker's intentions in both exchanging information by her utterance and having her interlocutor bare complex relationships to the information in recognition of the speaker's intention. The success of this project, however, is a difficult and controversial issue.

Notes

1. PRO is, roughly speaking a pronoun in generative grammar that provides a subject to clauses such as "to stay."
2. LF is a level of syntactic representation that is often taken to be the structure that is interpreted semantically. It plays the role of providing the sentence's logical and semantic structure.

Language and Society

Society consists entirely of interactions between people, to the extent that people discuss them. Put differently, society is the ensemble of social structures to which meaning is assigned. Society can be viewed as the verbalized conventions about how to interact with each other, including ways to distinguish between "us" and "them," all the stories told, all the "facts," and all the ideas, including all the controversies talked about, everything said about the visible and the invisible worlds, and the entirety of arguments exchanged by its members.

In order to discuss the relationship obtaining between discourse and society, we therefore have to look at the role of discourse in the construction of reality, social reality in particular. What distinguishes (human) society from a horde of chimpanzees is that one part of the social structure, namely, all that is symbolic, is discursively negotiated between its members. There are no doubt behavioral universals embedded in our genes, and also there is much interpersonal behavior acquired by observing and imitating other members of the group. While the acceptance of hierarchy may be programmed by our genome, the ways we express submission may to some extent be learned. But without engaging in discourse, we cannot assign meaning to the behavior we encounter or form any ideas, for instance, the idea of hierarchy and, its inverse, the idea of equality.

Society and its foundation—that is, linguistic discourse—are therefore what distinguish groups of humans involved with each other from chimpanzees. Chimpanzees also live together in social structures. They interact with each other in ways we often find similar to our own ways. Mothers tend to their offspring, the young ones learn lots of things by imitating grown-ups, and grooming maintains interpersonal relationships. They share food, they cooperate when attacked, and they seem to organize

themselves in a hierarchy. Yet these social structures are defined by nature, not by culture. There is no "signifying system"—no signs standing for something else—that would enable them to communicate symbolic content. They have no control over their social structures. Groups of humans, on the other hand, are defined both by nature and by culture. Often it is not easy or even possible to clearly draw a line between the two. Language, however, is one such line. Language is symbolic, nature is not.

Human society organizes itself along the ideas exchanged between and shared by people. Chimpanzees do not talk about their social structures. Like humans, they distinguish between "us" and "them," but they are not known to enter an argument on who is friend and who is foe. Humans do. They keep discussing, for instance, whether group membership is based on territory, bloodline, race, or class. Concepts such as *race* or *bloodline* are discourse constructs, and they mean what people contributing to the discourse say they mean. They refer to nothing in particular in the world outside. Such concepts have their place only in the discourse, not in a discourse-external reality. Thus, language replaces instinctive behavior by a behavior based on shared ideas, a behavior based on culture, whether individually accepted or not. Chimpanzees do not discuss their mates' behavior, while humans continually talk about it, assigning meaning to it. Chimpanzees behave without being aware of their behavior; they do not carry out acts, and they are not known to talk about their intentions. Humans, on the other hand, have learned to explain why they do what they do. To have ideas means also to be aware of them. This happens when people tell us about them. Once we have become accustomed to living in a world of ideas, we replace the world out there, the world that has no meaning, by a world to which meaning has been assigned through language. To a large extent, we have substituted culture for nature.

Language, as understood here, is not a fixed system, a kind of innate language organ humans are endowed with; it is what people say (or sign or write) and what they recognize as being said. Language is communication by signs. Language thus is social, and this aspect of language is what is here called *discourse:* It is the entirety of utterances that have been and are being communicated between people ever since they began talking to each other. Discourse comes with its rules and conventions. They, too, are not inherent in a language system; they are worked out by speakers. As long as people keep talking, discourse will grow, and while it grows, it will undergo gradual change. While all human society shares the capability for language, each group, separated from other groups by the specifics of their discourse, develops its own culture. Culture is about sharing ideas and thus presupposes discourse. Culture is about negotiating distinctions. Therefore, we should talk about different discourse communities rather than about different societies.

There are as many discourses as there are discourse communities. Whenever they feel like it, people can form new discourse communities. What defines a discourse community is how it distinguishes itself from other communities. Though every individual owes her or his symbolic world to discourse, each has her or his own world, different from anyone else's, due to the interactions in which she or he took part, due to the discourses she or he took part in, and of course also due to the ways in which she or he has processed the content of these interactions, forgetting much, remembering a lot wrongly, and recalling very little correctly. It makes sense to look at a discourse as the collective mind of the apposite discourse community. But being part of a collective mind does not imply sameness of the individual minds of which it is made up.

Discourse and the Construction of Reality

Discourses, and discourse communities, are cultural constructs. They are not "real"-world entities.

Whenever humans are introduced to a new thing, they are taught a new sign. They point to it, and they tell us we should know about it. That is more than knowing how it looks. The things out there have become cues, making us aware of the meaning of signs. This means that the reality of humans who have grown up in society is not "the real world out there" as it is perceived through our senses but a reality as it has been constructed by people talking about it. Some philosophers, such as John Searle, prefer to distinguish between a social reality they accept as discursively constructed, and thus as the result of what Searle calls *collaborative speech acts of declaration* (e.g., more or less abstract institutions such as marriage, citizenship, or education), and the natural world, namely, the world to which the natural sciences are said to give us direct access. Social reality consists of facts created, constituted, and maintained through discourse. But the reality

of nature is for Searle not a social construct. He is adamant that things such as hydrogen atoms, tectonic plates, viruses, trees, and galaxies exist independently of people talking about them. This is also the stance of the framework of the sociology of knowledge. In the tradition of Karl Mannheim, the cofounder of this movement, it is claimed that talking about culture, about social institutions, is different from talking about nature. Beliefs and attitudes, law, custom, art, and so on are ideas the members of a social group, a community, have collaborated to construct. They are neither true nor false, and in their place, there could be other ideas. What is more, these concepts tend to change over time. Everything we find in social groups that is not universal (and thus brought about by our genetic heritage) is contingent. However, the sociology of knowledge, and John Searle, claim that what is said about a natural phenomenon is either true or not true.

Other paradigms, for instance, social constructionism, whether in its British variation (e.g., Jonathan Potter) or in its U.S. version (e.g., Kenneth Gergen) deny that dealing with the natural world is systematically different from dealing with the social world. The natural sciences today may employ a methodology that is more elaborate than the classification of so-called primitive societies. But all taxonomies have to be negotiated. They are contingent. We can classify deviant moods in the tradition of Hippocrates as the disturbed homoeostasis of bodily humors or, in today's notions, as the result of hormonal imbalances. The taxonomies we use are outgrowths of discursively negotiated arrangements, not a mirror image of the "real" world. The poststructuralist philosopher Jacques Derrida points out that however far back we go, a language sign, a symbol, never refers to a thing of a discourse-external natural reality but only ever to former discourse events in which this sign has been used. We cannot hope to find out the truth about reality; we can only try to make sense of what has been said.

Discourse and Society From a Constructionist Perspective

So far, we have defined society as people symbolically interacting with each other, and a specific society, or discourse community, as a subset of people who are observed (by themselves or others) to distinguish themselves from other subsets in ways expressed in their specific discourse. But this is only one way to look at society. We can also define it as the entirety of symbolic interactions happening between people, thus excluding individuals from it. For Niklas Luhmann, discourse, or as he calls it "communication," which is, for him, coextensive with society, is a system that is not directly linked to the intentionality of the people contributing to it. We can view society as a system that manifests itself in discourse, a system that in principle does not require to be populated by individuals and their intentionalities. Society in this sense can be compared with a computational system, such as a distributed network of computers doing things together that no single computer could do. All computers together are involved in a process that delivers results according to a program that controls the subprocesses carried out by each computer and coordinates the exchange of data between them. What each individual computer contributes becomes relevant only within the process as a whole. In a similar way, we can define discourse as an emerging system consisting of distributed parts that turn out text after text. It is autopoietic in the sense that that there is no programmer endowed with intentionality who has generated it and assigned meaning to it. The individuals themselves with their intentionalities have no part in this system; they are outside it.

From a radically constructionist perspective, discourses are processes, like apples growing on a tree or computer programs generating haiku after haiku. If computers can do poems, then people and their intentionalities do not have to be part of the system. We can view discourses as running without anyone's agency or intentionality. We can look at a discourse as a random process churning out texts, while at the same time gradually modifying their own rules for what can be said and what cannot. From this perspective, the individuals, the people populating discourse, including the "I" and the "you," are themselves just objects, and all we can know about them (including ourselves) is what is said about them in discourse by the others and by ourselves. While each of us is absolutely certain of our individual unique selfhood (unless we believe ourselves to be schizophrenic), this self-awareness as such cannot be communicated. Of course, people talk about themselves, their feelings, their attitudes, and their opinions. But from the outside, we can never be sure if it is a person endowed with intentionality or a robot imitating such a person. All that is available to us is what we find in discourse, in what this avatar of a speaker says in reaction to what has been said before.

While we normally do not doubt our individual selfhood, everyone else's selfhood is closed to us and inaccessible to us. All we can ever know about the "speaker" is what we are told by him or by others.

Discourse does not necessarily presuppose human intentionalities; it goes on, whether people say they are making sense of it or not. When we are asked by someone how we feel, we normally respond by saying something that has been said before. What for us appears to be the result of our deliberation is, for the hearer, indistinguishable from an arbitrary, random choice from a rather limited list. What is said within the evolving rules constraining what can be said is, from the outside, indistinguishable from randomness. We may well believe that what we say is the result of serious deliberation, but there is no way to verify this claim.

In the perspective of a radical constructionism, intentional agents are not needed for discourse to thrive. The same is the case for society. The framework of philosophical eliminativism, too, assumes that intentionality is a contingent, supervenient feature in the evolution of the mind, indistinguishable from an illusion. As eliminativists see it, society would function just as well without intentionality. Society is a discourse construct, and discourse is an autopoietic system sui generis, a system generating utterance after utterance whether or not there are people consciously deciding to make their contributions. Society is creating sense, in Luhmann's sense, without being in need of someone making sense of it. Society is, for him, what happens between people, and it is only loosely coupled with the people between whom discourse is happening. Perhaps, though, people are not entirely expendable. The innovation on which a healthy discourse thrives can well be seen as brought about by what is the natural (and not the cultural) side of a person. Without the everlasting tensions between nature and culture, discourse might actually come to a halt.

Reconciling Perspectives: Randomness and Intentionality

All contributions to discourse, whether generated by intentional minds or by randomly operating computers, can be analyzed for their meaning. This is called "making sense" of them, or "interpreting" them. People believe that interpretation is something requiring the intentionality of a human mind, actually the intentionalities of all those who take part in the collaborative act of interpretation. For we do not interpret the world of discourse for ourselves; we offer our interpretations normally to the other members of an interpretive community. Making sense is something discourse communities engage in. The outcome of such a collaborative endeavor, however, is unpredictable. Board members, for instance, do not know in advance where the interactions taking place at their meeting will take them. They come equipped with intentions. But soon the "collective mind" of their little community takes over, having them make contributions they had not planned when preparing for the meeting. The meeting will often take a course no one had foreseen. It is as if a sense-making collectivity emerges with its own intentionality.

Making sense of what has been said—of ourselves, others, and the world around us—is not something happening on a higher level of discourse; it is not looking at discourse from the outside. Every contribution to any discourse involves commenting on previous contributions, evaluating them, and viewing them from a slightly different perspective. Indeed, we can look at the diachronic dimension of discourse as adding layer upon layer of interpretation on what was never anything but interpretation in the first place. We take these previous utterances as they are, keen to find out what they mean, ascribing to ourselves, but not to these texts, intentionality, a capability for reasoning, for making decisions based on justifiable intuitions. For their meaning, it is irrelevant if these utterances have been produced by computers or humans. Intentionality is something we only ascribe to ourselves, as members of the interpretive community.

In the same way that we make sense of the diachronic dimension of discourse, we also make sense of social history, indeed of all human history. We can never be sure why an individual or a group of individuals engaged in this or that behavior. We have no way to distinguish what these people did from random acts. But in our endeavor to make sense of them, we apply our intentionality—an intentionality, it has to be repeated, we were not born with but that is the outcome of having been engaged in symbolic interaction. We cannot pretend otherwise. Once we have acquired it, we forego the possibility of viewing what we do as random. Both perspectives, the intentional and the random, are complementary. But they are compatible as well. They view discourse and society not as the necessary results of the workings of inalterable laws. Such laws are our focus when we

attempt to make sense of what happens, for instance, in an ant colony, in a group of chimpanzees, or in the fission of an atom. There we search for common denominators for what we see happening. For discourse and society, our focus is different. What interests us is not what the texts have in common but how they differ. Our focus is the contingencies we observe in each discourse and in each discourse community, regardless of whether these contingencies are due to intentionality or randomness.

Language-Games and Forms of Life

This entry introduces the later Wittgenstein's core ideas about language-games and forms of life and reviews in some detail their various aspects. These two notions, along with the related one of rule following (see separate entry on this topic), have been particularly important during the earlier phases of the philosophy of the social sciences in the English-speaking world. This has been especially so following Peter Winch's appropriation of such key notions from the philosophy of Wittgenstein and his use of them in underlining the essential difference between understanding social action and explaining natural phenomena.

Introduction

Ludwig Wittgenstein (1889–1951), among the foremost philosophers of the 20th century, introduced the notion of a language-game. There are three important philosophical uses of the language-game. First, it is a methodological tool in the critical examination of theories of language and mind. Second, it plays a pedagogical role in teaching the child or an initiate learner language and mathematics. Third, it is a descriptive/explanatory device for illuminating the structure of language, in particular the way in which words are bound up with actions.

Language-games are so called because they are analogous to games people play: board games, ball games, gambling games, and so on. Language does not have a single uniform structure, identified by its syntax (grammatical rules for combining words into meaningful whole sentences) and semantics (theory of meaning for words). It is rather a motley of language-games, which overlap, crisscross, and interpenetrate in various ways. Chess and checkers are very similar, but they are quite distant from basketball or hockey. Language is used in lots of different ways, to do different things for different purposes; accordingly, there can be no single theory for language. Like ordinary games, language-games have rules or norms for how one is to play the game; and also like most games, language-games use markers or signs in playing the game.

As a game of chess uses pawns, knights, bishops, and other pieces and as basketball uses a basketball, speakers use words and sentences to make moves within a language-game, to do various things. We use language to get married, describe an itch, recite a poem, or follow instructions. A language-game can be as simple as the child's game of ring-a-ring-a-roses or as complex as algebra or physics. But most interesting are the ordinary language-games through which we live our lives. Games like going to the

grocery store, expressing pain verbally, or expecting someone for coffee. These language-games require, as the necessary background to their being played, our human form of life.

Methodological Role of Language-Games

Language-games are tools for the critical and diagnostic inquiry into traditional philosophical theories of language and mind. There are four primary foci of this scrutiny: (1) names (the way words label objects), (2) rules and rule following, (3) self-knowledge, and (4) consciousness. In each case, Wittgenstein constructs a simple language-game, complete in itself, as a diagnostic tool for identifying the mistakes and incoherence of the philosophical theory under examination. Indeed, he opens his examination of the way in which words relate to objects by introducing his first methodological language-game: the Builders. The Builders is a very primitive form of language-game. Two builders, A and B, use a limited vocabulary (terms for four types of building blocks) to coordinate their behavior. A calls out one of the four terms, and B brings to A the building block corresponding to that term. It is only natural to hold that the four terms mean the four kinds of building stones. This simple language-game is the cornerstone of Wittgenstein's critique of so-called referential theories of meaning.

The methodological role of the Builders (or any other language-game so used) is subject to two important constraints: First, it is an artificially constructed language-game that is designed to fit the requirements of the philosophical theory in question. The Builders game consists of four signs, each of which corresponds to a type of building stone. In short, each word labels a type of building stone. This is one prominent theory of how words relate to the world, but one that is undermined by the use of language-games. The static relation between label and object is belied by the dynamic character of the language-game. The second constraint is that the language-game, selected for methodological use, cannot use proprietary notions in describing the game. If the only way in which a language-game could be described requires technical or proprietary notions, then that language-game simply begs the question in favor of the theory under scrutiny. The language-game provides a simple world in which the explanatory elements of the targeted philosophical theory become transparent to the theorist or critic.

There is a striking similarity between simple language-games and those of the young child just learning language or the pupil just learning mathematics. As the simple language-games are spare and cognitively primitive, so the learning games of the young child or pupil are very simple. The initiate's learning situation—that is, one that involves a learner who is just beginning—is one that helps reveal how rules or norms are acquired and subsequently shape the child's life. Acquiring mastery of language is realized through learning techniques and skills in the *use* of words. This very basic way of learning is closer to a causal process, but it is a causal process that is formed by the child's relation to the adult, one who knows how the skill or technique is to be exercised. Language-games, as techniques for using language, must be learned in such a way that the causal susceptibilities of the child are exploited by the adult in teaching the child rules. The child is trained in the use of words. The learning situation thus bridges the methodological use of language-games and the descriptive/explanatory use. It elucidates the word–object relation within a simple language; and it displays the complex normative and causal interaction that is definitive of language mastery.

Descriptive/Explanatory Use of Language-Games

The third use of language-games is to provide a way of describing our linguistic practices that highlights the ways in which words are integrated into, and so are essential to, our actions. The first thing to note in shifting from the methodological use of language-games to the descriptive/explanatory use is that the notion of a language-game is freed from the conditions of its methodological use. This opens up space to recognize the enormous flexibility of the concept "language-game." It is applicable to an indefinitely large number of cases, which vary in the complexity and kind of action that are involved. The use of this term is not restricted to the simple primitive language-games used in constructing objections to philosophical theories of language.

The second point of contrast with the methodological use of language-games is that it constitutes an alternative picture of language—an alternative, that is, to the standard conception. According to the standard conception, language consists, at base, of a set of formal syntactic and logical rules and a

vocabulary list. Though the specific set of grammatical rules and vocabulary words may differ from one natural language to another, all languages share the logical structure of rules applicable to words in a determinate way. The consequences of imposing this rigid structure on language is that the logical space for all that is sayable is fixed once and for all. On this standard conception of language, differences among the uses of language concern superficial variations, while at a deep level, every legitimate or meaningful use of language is already fixed by the structure of language. By contrast, language as an array of language-games does not have this feature. It is indeterminate as to what will count as a meaningful use of language.

There are a number of ways in which the language-game conception differs from the standard conception. The number of different kinds of language-game is countless. The space for possible new games is open-ended. There is no principled way to draw a boundary around the range or kind of meaningful language-games. Though playing language-games is a normative undertaking—that is, it is rule governed—there is no set of universal rules that governs all uses of language. In emphasizing the multiplicity of games, that speaking a language is part of an activity is highlighted. Language-games, like ordinary games, require the participants to act in certain ways. Once again, we can find an analogy with the child learning simple language-games. The point, in teaching, is not to engage the child intellectually but to get the child to respond in the right ways to certain objects or expressions with his or her own words. Language-games are normatively structured activities, multifarious, showing a *family resemblance* among each other and an *open texture*. The situation of initiate learning is entry into language-games. And entry into a language-game is ipso facto expressive of a form of life, the human form of life.

Form of Life

Though there is no set of rules of language applicable to all language-games, and because the rules of a language-game cannot be fully extracted from the context in which the rules have life, there is no way that rules per se—that is, as abstracted from the activities of the participants—can explain our orientation to the world and to others. Such rules, whether explicitly obeyed or only implicitly followed, exist against the background of our human form of life. This is a much more nebulous notion than that of language-game. It is the idea that there is something like human nature, which is universal to all human beings and indeed to any being who acts and reacts in the ways that we find natural. The human form of life is the locus for what we find similar at the bedrock of each language-game, whether this is the recognition of colors or knowing how to continue the natural number sequence or what behavior to expect from chairs. Our human form of life is the universal context within which we live and agree (or disagree). It is what we share as human beings. It is what is necessary if the novice is to acquire mastery of language. Our shared reactions as to what is similar, our orientation toward our fellow human beings, are exploited in the successful navigation of our various language-games. Our norms, rules, and rule following are embedded in our language-games, in a bedrock of shared judgments of similarity and communal agreement. The human form of life, as the context within which rules can be followed, cannot be successfully abstracted from its active role within language-games.

This foundational role of form of life for language-games reveals the ways in which *trust* and *certainty* are essential to our linguistic practices. In playing chess, we are certain of the board's boundaries remaining fixed. In seeing that another is in pain, we trust that she is not deceiving us. These sound like the banalities that they are. But their implicit role in our linguistic lives, which is to say within our lives, is of fundamental importance. It is not just that language-games are composed of norms and linguistic signs. Playing the games must presuppose certainty with respect to many matters and trust with respect to our social partners. Lose either of these foundational features, and the language-game dissolves. It is this background, the way we human beings are situated in the world, that enables us to become participants in normative practices. When a person sits down in a chair, he expects it to remain solid. When one moves a rook in the context of a game of chess, one is certain that the targeted queen will not fly away. When the student learns history, it remains constant for her that Napoleon was exiled to Elba. Our language-games are anchored in the tacit, and often never articulated, background of certainties that make the moves in the game possible and that reflect the character of our human way of believing.

In sum, the notion of a language-game, especially as enriched by certainty and trust, has an essential connection to our form of life. Our shared form of life requires both a human nature as well as natural facts of the sort that support the language-games within which we live our lives. The certainty expressed in our language-games is not one that has been justified. On the contrary, the certainties of our form of life are like something animal. That is what it is to *be* as of a form of life. The peculiarity of our form of life, as opposed to that of other animals, is that we must live our lives in normatively informed and self-conscious language-games.

Law, Social Phenomenon of

Reflection on the fundamental characteristics of law, and law's relation to morality and to religious edicts, is probably as old as law itself and has been central to Western thought since its earliest recorded history. This entry focuses only on its more recent incarnations. The growth and greater distinctness of legal phenomena, on the one hand, and the rise of scientific anthropology and analytic philosophy, on the other, have given these questions particular urgency in recent times.

The Anthropological Perspective: What Are the Characteristics of a Community Governed by Law?

Probably the first to show interest in identifying the unique features of law were sociologists and anthropologists. Roughly speaking, one can speak of two schools of thought: According to one view, more often voiced by scholars interested in modern societies (e.g., Max Weber), the legal domain is to be identified with formally promulgated rules backed by formal mechanisms of coercion. The other view, typically held by those studying indigenous societies (e.g., the social anthropologist Bronisław Malinowsky), identified law with a set of widely shared norms and explicitly declined to associate law with central authority. When law is understood in this way, it is hard to imagine—indeed, it may be conceptually impossible to conceive of—a social community without law, as arguably what makes a group of people a community is the existence of shared norms. By contrast, understood in the other way, law is a feature of larger and more complex communities but is not necessarily found in every society.

Proponents of the first approach have argued that the latter approach cannot distinguish between law and a host of other norms that govern people's lives; in response, defenders of the latter approach have argued that the focus on formal institutions biases the account in favor of the particular form law has taken in modern states and fails to account for the functionally similar phenomena found in other societies.

In subsequent writings, the divergence in views has roughly followed academic divisions. Among legal sociologists and anthropologists, growing skepticism over "essentialism" and doubts about the point of such inquiries have led to a decline in interest in identifying the distinctive features of law. In its stead has emerged a view that dominates much of social-scientific work—called "legal pluralism." According to a well-known characterization of legal pluralism,

"people experience justice (and injustice) not only (or usually) in forums sponsored by the state but at the primary institutional locations of their activity—home, neighborhood, workplace, business deal and so on" (Galanter, 1981, p. 17). Legal pluralists thus extend the second of the two approaches outlined above to large, modern societies, arguing that even in such societies the normative domain is filled with a multiplicity of overlapping normative structures that are impossible to distinguish; moreover, because of their constant interaction and mutual influence, attempts to isolate one part of that picture will in all likelihood be misleading.

The Analytic Perspective: What Is Law?

In contrast to this inclusive attitude of sociologists, legal philosophers have largely adopted the opposite approach, which identifies law with institutionalized normative structures of formal law. This has been the starting point, more often assumed than explicitly defended, of most of the literature on the "analytic" or "conceptual" question "What is law?"—the question that quickly became the fundamental question of general jurisprudence in modern times. The academic divide has naturally led to a change in the way the question was understood and the methodology adopted for answering it. Instead of examining indigenous societies or attempting to identify historical trends, the favored approach has been philosophical reflection and conceptual analysis.

In the English-speaking world, by far the most influential book in this field remains H. L. A. Hart's *The Concept of Law,* which revived (with significant modifications) the analytical jurisprudence of John Austin. Hart famously offered a quasi-historical account of the emergence of law, according to which the move from prelegal to legal society takes place when society adds to its list of prohibitions and prescriptions (which he called "primary rules") a set of "rules about rules" ("secondary rules") concerned with identifying, changing, and adjudicating disputes about primary rules.

Hart's narrative was not meant to describe historical reality; it is better understood as a thought experiment that ties the existence of law to the existence of certain institutions and formalized characteristics: Law becomes a reality when one finds certain institutions that turn an amalgamation of norms (a "set" of rules in Hart's language) into a "system."

Despite being a paradigmatic study of the approach that sought to distinguish law from other normative structures, Hart's account could be embraced by some legal sociologists who favored the alternative view. Because his account focused on *rules* rather than *institutions,* such thinkers could adopt Hart's view by arguing that there were societies governed exclusively by primary rules. Even in societies that lack clearly defined formal legal institutions (legislature, judiciary, etc.), one could identify rules dealing with change, dispute resolution, and so on.

This convergence in view and cross-disciplinary attention is perhaps not surprising. In Hart's work, one finds fleeting reference to the sociological work, and when he was writing, the disciplinary boundaries were less clearly defined than they are today. In subsequent philosophical work, the divide between the sociological and philosophical work has become more pronounced. The boundaries manifested themselves not just in a growing methodological divide but also in a subtle shift in the question asked: The sociological concern with describing the distinct features of a *society* ruled by law (as opposed to one without law) has become the more distinctly philosophical interest in identifying the distinct features of *law itself*. Even though this underlying question has sometimes become obscured in some highly technical and abstruse debates, arguably this is what has been at the heart of the debates on questions such as the relationship between law and morality, the place of coercion and sanctions in law, and the difference between a legal regime and that of a crime syndicate, all issues that preoccupied legal philosophers since the publication of Hart's book.

It is in this context that the search for the "nature of law" as the search for the existence conditions of law was born, in particular the debate that has been at the heart of philosophical thinking about law in the past 50 years: the debate between legal positivism (LP) and antipositivism. (LP is often contrasted with natural law, but this contrast is historically inaccurate and in the present context somewhat underinclusive if it is to include some of the most prominent antipositivists.) In Hart's work and in that of many others, LP was meant as a rather general rejection of a necessary connection between law and morality, but in the context of the question "What is law?" it would be useful to distinguish between four different senses, in which one could reject a necessary

connection between law and morality. The first two are methodological: One is the view that legal philosophy is distinct from political and moral philosophy, as it is concerned with providing a "description" of the nature of law. More precisely, it is sometimes stated that one need not rely on any other evaluative considerations (moral or otherwise) when providing a theory of law. In the second methodological thesis, LP is used with a meaning close to the way "positivism" is used by sociologists following Auguste Comte—that is, as the thesis that the methods of the natural sciences should be extended to the social sciences. Hart and many of his followers adopted the first methodological thesis but rejected the second. In this, incidentally, they stand in sharp contrast to Thomas Hobbes and Jeremy Bentham, sometimes considered the founders of LP, who rejected the first and adopted the second, and to most contemporary antipositivists, who rejected both methodological theses (Brian Leiter may be an example of someone who accepted both).

In addition to these methodological theses, we can identify at least two additional substantive LP theses. One is that the existence conditions of legal norms, the terms of legal validity, do not necessarily contain moral conditions (with other proponents of "hard" or "exclusive" LP taking the stronger stance that the terms of legal validity necessarily do not contain moral conditions). The second substantive LP thesis in Hart's work is that law's normative force, the sense in which it creates obligations, does not depend on moral premises. Again, one finds different views among legal philosophers, with some (e.g., Hart) adopting both, some (e.g., Joseph Raz) adopting only the first, and antipositivists like Ronald Dworkin rejecting both.

While these questions preoccupied the literature for the first few decades after the publication of Hart's main work, more recently, and especially after the publication of the second edition of the book, there has been growing interest in the methodological LP theses. Here, the lines are drawn somewhat differently, but generally speaking, there are important links between certain methodological and substantive positions. Thus, the alternative, antipositivist perspective is best understood not simply as a rejection of certain substantive views about what law is but more fundamentally as an alternative view about how one should go about answering this question. On this view, one cannot explain the nature of law outside a certain moral or political context. What makes something into law does not depend on a certain institutional framework but must be explained as part of an account of what makes for a legitimate political order. Some have sought to show that law must be understood as part of a substantive theory of the good (e.g., the Oxford legal philosopher John Finnis) or a legitimate political order (e.g., Dworkin), while others have laid more emphasis on the procedural aspects of law (as Lon Fuller does, and Tom Tyler, from a sociological perspective). These thinkers all reject the view that legal philosophy can be descriptive.

These differences notwithstanding, the prevailing view among legal philosophers on both sides of the positivist/antipositivist divide sees legal philosophy as concerned with fundamentally different questions from those of social scientists. This attitude has led to a neglect of potential connections, more explicitly pursued in the past, between legal philosophy and social-scientific study of law.

The Institutional Perspective: The Limits of What the Law Can Do

Alongside these conceptual inquiries on the boundaries of law, there emerged a more practical concern with the limits of legal action. (This question is distinct from, although possibly connected to, the *moral* question of the limits of law, namely, whether there are certain things law should not be used for, even if it can be used effectively against them.) This question presupposes the multiplicity of norms governing society, as emphasized by legal pluralists, but contrary to them, it assumes the possibility of distinguishing, however imprecisely, between legal and nonlegal norms. Given the fact of normative plurality, the question such scholars ask is the extent to which law can be used together with, or in opposition to, nonlegal norms.

As a positive matter, various scholars (e.g., Robert Ellickson and Stewart Macaulay) have criticized what they perceive as lawyers' excessive focus on law and the distorted image they paint of its impact. Such works point out that in many contexts legal norms are often ignored in favor of nonlegal norms with a different content. From a more critical perspective, work on the interaction of social norms and the law has often cast doubt on the ability of legal norms to bring about significant changes to

prevailing social norms (as Gerald Rosenberg has explored). Law, it is argued, is quite often a follower of nonlegal norms rather than their generator, and when its edicts differ markedly from existing social norms, they are likely to be ignored. These controversial claims are difficult to assess in general, and it is possible that the seemingly more "technical" legal rules that often receive less attention (e.g., tax or welfare provisions) have greater power to change social norms in less direct ways.

Be that as it may, such claims may seem quite distinct from the questions philosophers are interested in, but there are important connections between them. At one level, such claims may vindicate some forms of LP, for example, the claim that it is possible to identify the "limits" of law (as Raz has argued). In a different sense, however, such claims may support more antipositivist views of law as they show that law cannot depart significantly from social norms and that the content of legal norms is not fixed by legal materials alone. This in turn suggests a stronger link than LP assumes exists between what counts as law and the content of legal norms, between the content of legal norms and social acceptability, and between the latter and questions of legitimacy.

Conclusion

Perhaps all this suggests that in identifying and understanding law we must acknowledge the truth of seemingly conflicting perspectives. Positivists argue that what distinguishes law from nonlaw are certain structural features; this leads them to a perception of law as a morally neutral social phenomenon and correspondingly conceives of legal philosophy as broadly separate from moral and political philosophy. By contrast, on antipositivist views, what distinguishes law from nonlaw is the fact that legal edicts, unlike nonlegal ones, are potentially legitimate. Unsurprisingly, this approach blurs the dividing line between legal, moral, and political philosophy. Within the confines of philosophical inquiry, these two perspectives seem to be self-validating, hence the mutual incomprehension between the positivist and antipositivist camps in jurisprudence. The key to breaking this impasse may be in recognizing that law is both the product of an autonomous domain, with its set of technical rules that allow lawyers from different jurisdictions to converse more easily with one another than with nonlawyers within their community, and a product of a particular culture bearing the distinct marks of the community from which it emerged. Likewise, it has both institutional, structural features that may be relatively universal andnormative, justificatory ones that are likely to be more local. Greater recognition of the complexity of legal phenomena and openness to the links between philosophical and social-scientific work on law could prove helpful in addressing these questions.

Laws of Nature

After centuries of neglect, an intense interest in scientific laws was generated in the mid 20th century, principally by the seminal work on scientific explanation by the philosopher of science Carl Hempel. It became evident that the concept of law had an important role not only in the philosophy of science but more generally for the philosophy of mind, psychology, and the social sciences.

The entry gives an overview of two ways of explicating what a "law of nature" is and draws connections with the social sciences.

Definitional Approaches

The now numerous accounts of scientific law fall into two distinct types. One type we might call *definitional* because it involves a familiar way of clarifying a concept—by giving a definition. That involves filling in the blank in the expression

"A is a law of nature if and only if . . . ,"

so that the resulting sentence is one that must be true. There are at least four known proposals of this definitional type:

1. A is a law if and only if it is a general empirical conditional.

A conditional is an "if . . . then" set of sentences. A is a law (say "All metals expand upon heating" or "If a metal is heated, then it expands") for which there is evidence of a strong kind. This is usually called the *Humean account of laws,* after the 18th-century Scottish philosopher David Hume. It has been rejected on the grounds that a law not only expresses what happens to be the case, but it also expresses what must be the case, where this "must" is a special requirement of physical necessity.

2. A is a law if and only if A is a general empirical conditional and it is physically necessary.

There have been many different philosophical accounts of physical necessity. Sometimes those accounts begin with the intuitive idea that if it is a law that all metals expand when heated, then not only is it false that there are metals that do not as a matter of fact expand upon heating, it is also not physically possible that there are such cases. Sometimes this concept is explained by requiring that something is physically possible, if it is not ruled out by laws. But this explanation relies on the concept of law and cannot be used to define the notion of scientific law, on pain of circularity. Consequently, defining the modal notion of physical possibility in contrast to metaphysical and logical possibility is an open and important problem even today.

There is a view of laws that marks a radical contrast with the preceding accounts. This is the Armstrong–Dretske–Tooley view, according to which (with slight differences between the three accounts), laws are not conditionals. That is,

3. A is a law if and only if it is a special kind of "necessitation" relation between universals.

There are several versions of this account. On one version, we are told that one special kind of property (a universal) generates or brings about another, but there is no hint of what is meant by "generation." On another, the relation is supposed to be one of causation that holds between two states of affairs. It is difficult to see how any of the standard laws fit this pattern. In fact, on the first version, the universals or properties that enter into laws are required to be true of things that exist. The result is that Newton's Law of Inertia ("If there are no forces acting on a body, then that body will not accelerate") fails to be a law. It is serious when the grandfather of all laws doesn't satisfy the condition for being a law.

The next account ("the best-systems account") is probably the most widely accepted account at present. It originated with the 19th-century English philosopher John Stuart Mill and, with subsequent refinements, is now known as the Mill–Ramsey–Lewis account. Consider any collection of true sentences. There will be many such collections. Some

will be simpler than others, and some will contain more information than others. Choose the one that is the best combination of simplicity and information. The best-systems account then defines the concept of a law in the following way:

4. If A is any empirical generalization, then A is a law if and only if it is a member of the best collection of true sentences.

If there are several collections that are the best combination of simplicity and informativeness, then this account is modified so that "A is a law if and only if it belongs to all of them."

There are several problems. There is the issue of how to understand the required notions of simplicity and informativeness that are not specified. If different people specify what is meant, then the concept of law will vary with those differences. That seems to speak against the objectivity of the best-systems account. Another difficulty is that we do not know at any given time whether a particular empirical generalization is a law. To determine that, one has to know whether that generalization belongs to the best system of truths, and at any given time, we do not know what that system is. We may have a hunch, we may guess, but we do not know.

A further problem with this account motivates a fifth account. There is the possibility that various different sciences may have laws of their own, but the requirements for being a law of physics, psychology, biology, or economics may be different. The best-systems account does not allow for the possibility that the concept of scientific law may be different for different sciences. This possibility may be important for those scholars who work in any of the social sciences for whom the standard for being a law of physics, for example, may not be appropriate for social sciences such as sociology, social psychology, anthropology, political science, and economics. Thus, there is another definitional type of account:

5. If A is any empirical generalization and T is any theory, then A is a law of the theory T if and only if A plays a distinctive special role in that theory.

There are several ways in which the "distinctive role" has been understood. There is the early attempt by Richard Braithwaite, in which the special role is a deductive one within a deductive system that includes the theory. A more recent variation of this theme is that of John Roberts, who explains the special theoretical role of laws as follows: Associated with any theory there are certain physical quantities, and a general empirical statement is a law of a theory if an only if it is a logical consequence of certain reliability conditions of measurement.

Conceptual Approaches

We turn now from the definitional approach but consider instead those attempts to clarify the concept of law by relating it to other concepts and uniting the whole into a general framework—a minitheory of sorts. The result is not meant to be a definition. We shall call this approach *conceptual*. To illustrate what is meant, we shall list several conditions that, taken together, state how the concept of law is related to those other seminal concepts. It is not precluded that still other ways could be added to the theory to make it less "mini."

1. Laws are true general statements that are empirical.

This requirement is widely adopted, and for those laws that occur in explanations, truth is a consequence of the requirement that anything occurring in an explanation has to be true.

2. If A is a law, then its corresponding counterfactual must be true.

This too is also widely regarded as a hallmark of laws. It holds for laws that are conditional in form, such as the example we saw above: If anything is a metal, then it expands when heated. A counterfactual is an assertion contrary to actual fact—that is, to what actually is the case. So the corresponding counterfactual in this case is the conditional: If anything were a metal, then it would expand upon heating. This condition reflects the view that the first conditional seems to be about those things that in fact are metals, while the counterfactual expands that claim to the wider case, where not only all things that are in fact metals but also anything that could possibly be a metal would expand upon heating. It has to be said that some might not find this motivation convincing but would endorse the condition anyway.

3. If A is a law, then it is not an accidental generalization.

This condition is also regarded as a hallmark of laws (i.e., that unlike an accidental generalization, a law supports a counterfactual conditional), though it has to be added that, to date, no one has given an adequate account of the concept of an accidental generalization. Nevertheless, the usual support for this requirement relies heavily on intuitive examples. Thus, it is sometimes argued that the statement "All the people in a particular room are intelligent," even if true, is not a law because it is clearly a case of an accidental generalization. Well, maybe so. It may seem obvious that it is. Nevertheless, there is still the question as to what considerations show that it is accidental.

The next condition will be familiar from our discussion of it under the definitional approach. Nevertheless, it ought to be listed under the conceptual approach as a consideration of the connection between being a law and being a necessary generalization. That is,

4. If A is a law, then it is also necessary.

Last, we come to a condition that relates the concept of *explanation* with that of laws. It is a somewhat controversial matter whether all explanations involve laws. This may be a problem for some of the social sciences. If it was true that some social sciences have no laws to speak of, then it would follow that those sciences have no explanations to speak of. And that would be a serious matter. We do not wish to decide that matter here. However, there is a condition that, if endorsed, would indicate one very important use of explanations. The condition is this:

5. If A is an empirical generalization and there is some explanation of A, then A is also a law.

In short, even if explanations may not always use laws, they would always yield laws whenever they explain empirical generalizations.

This condition may have important consequence for the social sciences. If it is endorsed, and if it is assumed that although the social sciences have empirical generalizations, none of them are laws, then it follows that the social sciences do not have any explanations. That contentious conclusion seems to be unwarranted. A fuller discussion is beyond the scope of the present entry, but it is worth noting that although philosophers such as Sir Isaiah Berlin have argued that the social sciences do not have any laws, other philosophers, such as Sidney Morgenbesser, have argued forcefully that there are what he called "causal schemata" in the social sciences as well as in the physical sciences, which are very intimately connected with laws. Although they are not themselves laws, they are close cousins. Moreover, Morgenbesser has argued that some social sciences have ideal-type explanations, and in his account of them, he has also argued that they sometimes appeal to general ideal-type laws about human behavior.

Laws Versus Teleology

The word *teleology* derives from the Greek *telos* (τέλος) meaning "end" (goal, aim, completion, fulfillment, or perfection). *Telos* includes the best

condition, activity, or operation of a natural or human agent, such as a prize-winning animal or an excellent (virtuoso) performance by a performing artist. The telos of a process is that for the sake of which each stage occurs. It is the final and most authoritative cause. Most generally, teleology is the account (*logos*) of the ends at which human beings, nature, history, and God aim.

This entry is restricted to two of these: (1) teleology in human action and (2) teleology in nonhuman nature. Its telos is to explain the modern (post–17th-century) rejection of teleology in favor of nonteleological laws—both natural (laws of physics) and human (legislative acts). Even so, this is a large terrain, and the constraints of an entry require considerable truncation of the subject matter. However, an important core theme in the philosophy of social science has been the issue of part–whole relations (as, e.g., in the form of holism versus individualism), and this is an issue that is also central to teleology. Similarly, the idea of mechanical causation or causal mechanisms in general plays an important role in social-scientific explanation. Therefore, the discussion of the contrast between mechanical laws and teleology, though it may be misleadingly thought to be of importance only to the emergence of modern science, is also illuminating in the philosophy of social sciences, where part–whole relations as well as social mechanisms and causation are central. The discussion can also shed light on the issue of whether social institutions, groups, or organizations can be properly said to exhibit virtuous behavior.

Background: Natural Form and Human Virtue

The rejection of teleology in modern philosophy and science can best be understood against the background of the premodern, teleological understanding of nature and human law. Emblematic of the teleological understanding of nature is the notorious Aristotelian term *form*. The form of a natural substance, for example, of a cat, "is [its] nature more than the matter"; form (cat-form) is the "end (telos) and that-for-the-sake-of-which" in the generation of the cat (Aristotle, 1995, 193b7; 1999, 1015a12). Emblematic of the teleological understanding of human law is the term *virtue* (Greek *arête:* αρετή, hence "virtuoso"), for "virtue [e.g., moderation] must be a care for every city" (Aristotle, 1984, 1280b7); indeed, "the proper effect of law is to lead its subjects to their proper virtue" (Aquinas, 1948, I-II, q. 92, a. 1, resp.). We must make an attempt, however brief, to understand these obsolete doctrines.

Natural Form

Form and matter are the constitutive principles of natural substances, which are noteworthy because, unlike artifacts, natural substances "all appear to have *within themselves* [italics added] a principle of motion and rest. . . . So nature is a cause and principle of motion and rest *in* [italics added] that to which it belongs, primarily and essentially and not accidentally" (Aristotle, 1995, 192b14–15, 192b21–23). The complicated adverbial phrase "primarily and essentially and not accidentally" means (among other things) that natural form is internal to the moved thing in a way that cannot be fully derived from, or completely reduced to, its material parts: "[Natural] things will be neither without matter nor determined by their matter"(Aristotle, 1995, 194a14–15). Form is thus a holistic principle. A watch, in contrast, lacks the substantial unity of a cat; it can be taken apart, its parts can be analyzed in isolation from each other, and then both the parts and our knowledge of the parts can be re-aggregated in the whole or even rearranged in a new and different whole. The clock is thus a paradigm for the reductionist or mechanical and anti-Aristotelian conception of the whole–part relation.

The Aristotelian conception of the whole–part relation in natural compounds implies limits to the alteration, manipulation, and transformation of bodies by separation and recombination of their parts. Within this understanding, form is not only a source but also a limit of our knowledge and control of nature (Aristotle, 1999, 1022a5–10)—something that will get rejected by modern scientific thought, as we shall see below, toward the end of the entry, with repercussions for human form and its possible (nonlimited) manipulation (as a river flowing) too.

Form specifies a visible natural kind, or *species,* especially a living species, in which case form is also called *soul*. Form is understood to be the source of the behavior that is most distinctive and characteristic of the species—for example, the distinctive, feline way of moving and meowing specific to cats. Consider the specific difference that is perhaps of greatest importance—the use of words by us human animals and the immense impact of their meanings on the

way we behave; in this, we are unlike any other species. The salient feature determined by the form of a species is also the good—in its exercise of the telos—of that species: "For what is proper to each kind of thing is best and most pleasant for it" (Aristotle, 2002, 1178a5). So it is good and pleasant for the cat to act in that feline (not canine) way, and it is best (and most pleasant) for us humans to use words well for the sake of truth in thought and action. Form is thus a principle that is *species specific,* a term that will acquire a sharper sense when contrasted, below, with the *species-neutral* laws of physics. In any case, form can be at work only in appropriate matter; "for a different form, a different matter, [and so] for each motion it is the subject capable of that motion which has that motion" (Aristotle, 1995, 194b9, 251a14). Now, of all the natural motions visible to us human beings, it is the ones in the heavens, the celestial motions, that are the most distinct, for they are orderly and (as far as we can see) never cease, unlike all earthly changes. But eternal motion can take place only in appropriate—and thus eternal—matter, the indestructible matter of the crystalline spheres in which the visible lights in the heavens must be embedded. Thus, the Aristotelian and Scholastic doctrine of natural form—suited well enough to the heterogeneity of biological phenomena—also concludes to the heterogeneity of terrestrial and celestial matter. And so we can foresee a major reason for the rejection of the teleological account of nonhuman nature: The modern Scientific Revolution, starting in the 17th century, specifically the success of Isaac Newton's theory of universal gravitation, entails the essential homogeneity of celestial and terrestrial matter. Let us sum up the key result on the meaning of natural form in premodern philosophy.

Things that move, change, and behave in essentially different ways as manifested to our senses possess correspondingly different materials and sources of motion. They have different natures. This means that what the different natural kinds have in common, such as mass, is not as fundamental as what differentiates and specifies them. The opposite notion—that what the *apparently* different kinds (e.g., celestial and terrestrial, human and nonhuman) have in common *is* more important than what differentiates and specifies them—is a defining characteristic of *modern* natural science.

Against the premodern background, the significance of Darwinism stands out in stark relief: The successes of evolutionary biology show that the forms (species) are not causes and principles but effects and products (of variation and selection) and, in the current interpretation of the theory, that they are so not according to any purposive (teleological) intention of nature or God but merely by accident.

Human Form and Human Law

It remains to discuss the premodern, teleological understanding of human law: What can it mean to claim that "the proper effect of law is to lead its subjects to their proper virtue"? After all, we just said that the form of any species determines its characteristic behavior (e.g., from cat-soul flows feline behavior, from dog-soul, canine behavior). Therefore—by this analogy to other animal species—human-soul should be the sufficient source of our behavior. But the analogy to other animal species fails; we humans do not operate simply from natural instinct. Rather, the human form is open to a great variety of behaviors according to our very different *dispositions* or character types. Aristotle makes this clear in *Nicomachean Ethics* (2002, 1176a8–12).

In this premodern, Aristotelian account, a person's disposition or character has four sources: (1) individual traits from birth, (2) childhood training, (3) the laws and customs of the community, and (4) one's own past choices. Of these, the third source gives rise to the teleological understanding of human law—that is, law as *formative* of character, of the stable capacity for making good or virtuous choices and avoiding bad or vicious ones.

Character refers to the way we come over time to have our emotions and appetites, thus the way we come to be *disposed* toward and act in the face of the pleasures and pains to which we are subject as animate, rational (possessing speech) individuals in a political community. Our dispositions in turn give rise to our characteristic patterns of choices. Disposition is thus both effect and cause of choice. We make choices for the attainment of ends or goods whose appearance to us is a function of our disposition. (Alcoholism and the alcoholic disposition illustrate the sense of the preceding sentences.) To choose well, therefore, we must be rightly disposed toward pleasures and pains in order to be free of extremes of passion that distort perception and judgment. We must be disposed to the *virtuous mean* between excess and deficiency of passion such that action is

correspondingly appropriate to the particular situation. For example, how do people come, over the course of their lives from childhood to adulthood, to experience fear in facing danger? If slight dangers cause great fear and result in flight, one has acquired a cowardly disposition. If great dangers and risk cause little or no fear, leading to foolhardy actions, one has acquired a rash disposition. The disposition lying in the mean between cowardice and rashness is the virtue of courage. To the defective extremes correspond the distorted perceptions: "The courageous person appears rash to the coward, and cowardly to the rash" (Aristotle, 2002, 1108b20). The courageous person feels, perceives, and acts in the mean "for the sake of the noble, for this is the end (telos) of virtue" (Aristotle, 2002, 1115b12–13). Laws mandating and directing military training lead soldiers to their proper virtue, namely, courage and combat effectiveness. For the problem of the noble, see below.

It is important to emphasize that not only individuals but also groups have dispositions; thus, we speak of the *culture* or *mentality* of a corporation or a country. A person's or group's character is the set of dispositions (e.g., toward dangers, bodily pleasures, work, leisure, money, power, honor, perceived slights, one's own worth, the fortunes of others, humor) that they have acquired over their individual or collective history.

As we depart from this ancient teaching on law, consider whether there is not significant truth to it. But—as Aristotle (2002) himself makes clear—there is also a serious problem: "The courageous person acts for the sake of the noble" (1115b12–13), yet "the noble and the just, about which politics investigates, involve great disagreement and irregularity" (1094b14–16). We can thus easily imagine courageous men getting themselves and others killed over clashing conceptions of the noble, the just, and, let us add, the holy—as happened in the religious wars of the 16th and 17th centuries and as happens again today. The transition from the understanding of law as formative to the nonteleological (and secular) doctrine of law as *limitative*—that is, that law should merely limit the actions of others against my life, liberty, and property—has much to do with this unfortunate history of violent conflict. Concurrent with the religious wars, however, is another salient historical development, the Scientific Revolution, which promised vastly enhanced human power over nature. Essential to the new science is a new type of intelligible principle: the mathematical and experimental law of nature. The modern rejection of teleology in favor of nonteleological natural and human laws may thus be seen to derive in significant part from the desires for civil peace and for technological power.

Laws of Nature Versus Natural Forms

Isaac Newton's law of gravitational force (Newton, 1969, Book 3, Proposition 7 and Corollary 2) is written today as $F = -GMm/R^2$, where M and m are the masses of any two bodies, R is the distance between them, G is the universal gravitational constant, and the minus sign indicates that the force, F, is attractive. It is a paradigm for the laws of classical physics and is remarkable for the new type of universality that it exhibits. Normally, the way two bodies interact depends on what kind or species each is. A dog and a cat, for example, interact in a certain way, a cat and a mouse in another. In fundamental contrast, the law of gravity expresses a principle of motion in nature that is independent of the kind, size, shape, internal structure, and function—in other words, the nature—of the two interacting bodies. For *all* bodies—celestial and terrestrial, natural and artificial, living and nonliving, human and nonhuman—possess mass and relative position, and also velocity, momentum, acceleration, kinetic energy, and so on. These measurable and mathematically representable terms of classical physics are common to all bodies and their parts, unlike Aristotelian forms. As such, they are form or species neutral. Principles of motion that can be expressed in such terms—the mathematical laws of physics expressed in equations—are thus species neutral. The modern philosopher Baruch Spinoza (1985) provides a most succinct formulation of species neutrality in its opposition to natural form:

> That which is common to all . . . and which is equally in a part and in the whole [e.g., mass] does not constitute the essence [i.e., the species in Aristotle's teleological terminology] of any particular thing. . . . Those things which are common to all . . . cannot be conceived except adequately. (II.37–38)

In contrast, forms cannot be conceived except confusedly, due to Aristotle's overreliance on unassisted

sense perception. Thus, to the modern mind, an Aristotelian form must be rejected.

Although it is not expressed in terms of mathematical laws, Darwinian biology is species neutral in the above sense—that is, what is common to all living bodies are the principles of random variation and natural selection. The specific (i.e., in the sense of *species*) behaviors and interactions of the cat, dog, and mouse are thus understood to be ultimately reducible to the universal drive for reproductive success. Similarly so for human behavior as conceived by evolutionary psychology. It is because of classical (atomic-mechanical) natural science, such as particle physics, and Darwinian (gene) biology that species neutrality is a defining characteristic of modern natural science. This means that no account of the human on its own species-specific terms, for example, in terms of speech about the noble, the just, and the holy, can count as scientific today.

A second remarkable feature of Newton's law of gravity is that it (together with his second law, $F = ma$, (where m is mass, a is acceleration, and F is force) enables us to calculate, and thus predict, the trajectory of a body moved under gravitational force if we know or deliberately produce the body's position and velocity at the initiation of motion—for example, rockets. Humanly controlled space flight—impossible according to ancient and medieval astronomy—becomes a reality through mathematical laws of physics. Here, we see the relation between a law of nature and mastery of nature, a major theme in the works of one of the principal fathers of modern science, Francis Bacon, especially in his *The New Organon* (1620/1960). There we find a severe critique of the premodern understanding of nature:

> When man contemplates nature working freely, he meets with different species of things, of animals, of plants, of minerals; whence he readily passes into the opinion that there are in nature certain primary forms which nature endeavors to educe. . . . [But in] nature nothing really exists besides individual bodies [true particles], performing pure individual acts according to law. (I.66, II.2, II.8)

Baconian laws go hand in hand with material reductionism, the idea that sensible wholes are no more than collections of subsensible particles that interact according to the laws. This directly rejects Aristotle's holism of natural form, described above. Indeed,

> forms are figments of the human mind, unless you call those laws of action forms. . . . [Now] whosoever is acquainted with forms [i.e., laws] embraces the unity of nature in materials the most unlike, and is able therefore to detect and bring to light things never yet done, and such as neither the vicissitudes of nature, nor industry in experimenting, nor accident itself, would ever have brought into act. (Bacon, 1620/1960, I.51, II.3)

Bacon's audacious reasoning is that if the true intelligible principles are species neutral, then the apparent heterogeneity of species (evident to our senses) is not rooted in the essential nature of things and, furthermore, might not be a barrier to our operation. For the founders of modern science, the point is not to comprehend the world but to transform it, "whence there cannot but follow an improvement in man's estate" (1620/1960, II.51).

A major anti-Aristotelian, antiteleological premodern voice had been medieval nominalism, which emphasized the radical contingency of all things before the immense power of the biblical creator God and, thereby, undermined the Aristotelian notion of natural form as a stable, intelligible principle. But it was still a long way from the contingency of nature in relation to God's power to the malleability of nature in the face of human power.

Human Law as Limitative Not Formative

The core of the rejection of the teleological account of human law is that it is based on a false understanding of human behavior: If we are honest with ourselves, we will see that our motives are powerfully and irreducibly self-centered. It is unrealistic—and will be ineffective or counterproductive—to think that weak reason can control or moderate the selfish passions. The most fundamental human passion is the compulsory drive for self-preservation, after which come the desires for comforts (convenience), the pleasures, and wealth. These drives cannot be gainsaid; they will move human beings necessarily like the physical forces that move a river, whose flow is involuntary (as Nicoló Machiavelli describes it in *The Prince*, 1985, chap. 25). But human behavior, like the flow of the river, can be directed through

the clever imposition of channels that bring beneficial effects (like cultivation) and avoid harmful ones (like flooding) (compare the contrasting case above in the first section). In the case of human behavior, the channels are well-enforced laws that aim not at "proper virtue," such as courage and moderation, as in the old Aristotelian account, but at channeling the selfish drives of individuals to good public effect (peace and prosperity). Thus, for example, "private vice is public virtue," through legally protected enterprise accompanied by tax laws with teeth in them—that is, in a quasi-mechanical way. As John Locke (1952) puts it memorably, "That prince who shall be so wise and godlike as by established laws of liberty to secure the honest industry of mankind, against the oppression of power and narrowness of party, will quickly be too hard for his neighbors" (sec. 42).

Most generally, individuals are to be guaranteed a protected space in which to pursue happiness as each understands it, consistent with an equal right of others to do the same. Law becomes like a fence around my property, limiting the action of others against me and of me against others without our mutual consent. In this contractual understanding, law "is the direction of a free and intelligent agent to his proper interest" (Locke, 1952, secs. 17 and 57). There is no concern here with disposition or character, for the necessary (involuntary) forces of human self-interest are virtue neutral, somewhat like the forces of nature that are species neutral: Different visible patterns of both natural and human behavior arise not from different internal causes (celestial and terrestrial natures, courageous and cowardly dispositions) but from one and the same forces (gravitation, self-preservation), specified only by differing external conditions. Necessitarianism is thus common to both nonteleological accounts: the natural scientific and the human.

Despite its success in the protection of individual liberty and the production of wealth, the bleak realism of the nonteleological doctrine of human behavior (we are moved exclusively by involuntary and self-centered drives) provoked a reaction in German Idealism. According to Immanuel Kant (1976, sec. 1), free will is restored, and with that a sense of virtue, as the resolve to do one's duty according to the moral law (the categorical imperative). Humanity can thus progress over time toward greater rationality; history becomes the domain of a new moral teleology in which individuals are respected as ends, not used as means. Nonhuman nature, however, remains "material to work on" (Locke, 1952, sec. 35).

Legal Epistemology

Legal epistemology studies the relations between law and truth. To date, the bulk of work in legal epistemology has occurred in two areas. The first examines the ways in which Western criminal law systems, through their rules of evidence and procedure, standards and burdens of proof, and adversarial or inquisitorial forms of litigation, either facilitate or compromise truth finding in investigations of criminal wrongdoing. The second area covers debates over the truth status of propositions of law.

Law and Truth in Fact

All law addresses social situations that law purports to describe accurately as a first step toward regulating those social situations. For example, in deciding whether a plaintiff has had her interests damaged by a defendant in a way prohibited by law, courts must form a view regarding what is to count as the facts underlying the dispute. In deciding for either party, courts must rely on this picture of the facts when applying certain standards of proof to determine the likelihood or probability of a causal link between the defendant's action or inaction and the damage done to the plaintiff's person or property. In serving justice, courts must inevitably rely on a conception of truth, or at least a conception of what constitutes a reliable demonstration that a claim of fact ought to be treated as true.

Yet while all areas of law are committed in some fashion to truth, the most prominent work in legal epistemology is found in criminal law theory. Several features of criminal law attract analysis from legal epistemologists, precisely because they might either assist courts and juries in finding the truth about criminal wrongdoing or increase the chances of error. Exclusionary rules of evidence—for example, rules that prohibit the presentation of relevant and accurate evidence if the presentation of such evidence is likely to mislead juries, because juries are likely to overestimate its weight—are particularly interesting. Such rules might compromise truth finding by excluding relevant evidence or might, instead, indirectly better assist courts and juries in reaching true or warranted verdicts. Legal epistemologists also examine the level of a standard of proof for a finding of guilt and especially how such a standard of proof is explained in judicial instructions to juries. Still other aspects of criminal law of epistemological interest include the evaluation of expert testimony, the admissibility of confessions, the right of defendants and witnesses to remain silent, and the prevalence of adversarial forms of litigation. To settle many of the questions surrounding the success or failure of these features of criminal law, legal epistemologists are increasingly turning to complementary studies in the social sciences, especially those that investigate the social psychology and behavior of judges and juries.

Propositions of Law and Truth

Legal epistemology also refers to work on a central problem in the philosophy of law: What makes a proposition of law true? There are several, often competing answers that are typically associated with particular philosophical theories of knowledge.

According to legal *positivist* views, a proposition of law is true if it can be traced back to the foundational sources of law of a particular legal system. While positivists diverge in their characterizations of the foundational sources of law, nearly all agree that the foundational sources are rooted in observable social facts. For this reason, legal positivist views rely on empiricist types of epistemology, in which knowledge of law is grounded primarily in observation and experience. *Natural law* theories, by contrast, maintain that the truth of propositions of law is determined by objective moral standards. Such theories

therefore rely on teleological and objectivist moral epistemology, in which knowledge of law is acquired through moral reasoning about life's basic and ultimate goods. *Constructivist* theories occupy something of a middle ground between positivist theories and natural law theories. They posit an essential connection between the truth of propositions of law and moral principles but insist that the relevant moral principles are not to be found in some objective world of basic goods that exists outside and independently of the legal system. Instead, the relevant moral principles are to be found in the underlying purposes, aims, and rationales of existing judicial decisions, statutes, and constitutions. On constructivist views, a proposition of law is true if it forms part of the best holistic moral account of positive law.

Not all theories of law suppose, however, that the truth of propositions of law depends upon a correct view of rules, standards, or principles, whether legal or moral. Critical theories such as *legal realism* insist that the truth of propositions of law depends upon the dispositions, inclinations, and backgrounds of judges and courts. On this social-scientific view, law is inescapably shaped by historical, political, psychological, and economic factors, and so to understand law properly requires engaging in these and other social-scientific investigations. Later critical theories, such as feminist, critical race, and postmodern theories, have gone further and deny that propositions of law can be true at all; instead, propositions of law simply track the interests of the dominant class of society. Postmodern theories, for example, deny that there is truth in criminal judgments because these are merely expressions of state oppression.

Legal epistemology is by all accounts still in its infancy, and much work remains to be done in exploring how new work in epistemology might shed light on problems in legal theory beyond those surrounding criminal law and what makes a proposition of law true. These are exemplary areas of work but by no means exhaustive.

Libertarianism, Metaphysical

Metaphysical libertarianism is a thesis about *free will.* It holds that free will is incompatible with determinism, and we have free will. This entry explains what is distinctive about this view of free will and describes several kinds of libertarian views.

Free will may be understood simply as what it takes to act freely—the requisite powers of recognizing reasons, deliberating, choosing, and executing one's intentions. When you act freely, you exercise free will; you perform a free action.

Philosophers employ different conceptions of free action. According to one of these, your action on some occasion was free, just in case you were able to do what you did and were able to do some other thing instead, and it was up to you which of these things you did. According to another conception, your action was free in case it can ground your moral responsibility for what you did on that occasion. While some philosophers think that these two conceptions of free action apply to exactly the same things, others think that an action can be free in the second respect without being free in the first respect.

Determinism is the thesis that the laws of nature are such that how the world is at any given point in time completely determines how it is at any subsequent time. If determinism is true, then a complete statement of the laws, together with a complete description of how the world is at any time, entails all the truths about how the world is at any later time. For example, if our world is deterministic, then given its laws, how the world was shortly after the big bang completely determines the fact that you

are reading this entry right now (see Pierre Simon Laplace's famous "demon" or, more accurately, "intelligence" so vast and powerful that by knowing the state of the whole universe at a certain moment can predict any of its future ones: "We may regard the present state of the universe as the effect of its past and the cause of its future").

To say that free will is incompatible with determinism is to say that if determinism is true, then free will cannot exist. In other words, if we have free will, it must be the case that determinism is false, that our world is indeterministic. The laws of nature must be such that there are some occurrences that are not completely determined by what happens prior to them. Libertarians typically think that free actions themselves—and particularly free choices—must be among these undetermined occurrences. Libertarians, then, deny *compatibilism,* which holds that we can have free will even if our world is deterministic (i.e., free will and causal determination are compatible).

What must a free choice be like according to libertarianism? For example, suppose that you deliberate about whether to tell the truth or to lie about some important matter, and you choose to tell the truth. What must your choosing be like for it to be the case that you freely choose to tell the truth?

Some libertarians hold that a free choice must be entirely uncaused, and it need not have any internal causal structure—it need not consist of one thing causing another. Two difficulties for this view concern how one can have any control at all over whether such an uncaused event occurs and how a choice can be made for reasons if one's deliberations do not cause that choice (these critical puzzles are even more evident when one tries to build social-scientific explanations of human actions in terms of a dichotomy between a world of freely acting human beings who control their social activities on the basis of deliberation and a natural world of causally determined physical events).

A second libertarian view holds that a free choice must be caused but not determined by prior events, including things such as the agent's appreciating various reasons for doing this or that. It is widely accepted that causal relations need not be deterministic. They can, for example, instantiate probabilistic laws. There could be a law that certain prior events will, with a probability of .6, cause an outcome of type E_1 or will, instead, with a probability of .4, cause an outcome of type E_2. When an agent's choice is caused but not determined, the laws of nature might allow that even with all prior events as they were the agent might have chosen otherwise. Still, a difficulty for this kind of view concerns whether it can really be up to the agent that she makes one choice rather than another.

A third kind of libertarian view invokes a special kind of causation—"agent causation"—that is said to be causation by the agent and not by any states of the agent (cognitive or motivational) or events involving the agent (her coming to have certain thoughts or motives). According to this kind of view, when an agent deliberates about what to do and freely chooses to do so, no states or events prior to the choice determine that choice, but the agent herself causes her coming to have some particular intention and thereby determines which choice she makes. Difficulties for this view include the task of explaining what this special kind of causation is supposed to be as well as providing reasons for thinking that it exists.

All these libertarian views face a challenge from science, for they all require that the laws of nature not be deterministic, that is, that our world be indeterministic. Some philosophers think that the well-confirmed status of quantum mechanics constitutes good evidence for indeterminism; but there are interpretations of quantum mechanics that are consistent with determinism, and the question remains open. Furthermore, libertarian views require that certain events, such as the making of choices, be undetermined by what precedes them. It is often thought that what is then required is that there be some undetermined neural events in our brains. Scientists have conducted some interesting experiments to find out whether this is so. As of yet, the verdict is uncertain.

Libertarianism, Political

Libertarianism is a theory of justice that holds that agents initially fully own themselves and have moral powers to acquire private property rights in external things. It judges nonconsensual force against a person to be just only when it is necessary to prevent that person from infringing someone's rights or to impose rectification for such infringement (e.g., compensation or punishment). These limits on the use of force radically limit the just powers of government.

Libertarianism is often thought of as "right-wing" doctrine. This, however, is mistaken for at least two reasons. First, on social—rather than economic—issues, libertarianism tends to be "left wing." It opposes laws that restrict consensual and private sexual relationships between adults, laws that restrict drug use, laws that impose religious views or practices on individuals, and compulsory military service. Second, in addition to the better-known version of libertarianism—*right libertarianism*—there is also a version known as *left libertarianism* (described below), which holds that unappropriated natural resources belong to everyone in some egalitarian manner.

Libertarianism can be understood as a basic principle or as a derivative one. Here, it will be understood as a basic moral/principle (i.e., based on natural rights). It is possible, however, to defend libertarianism as a derivative principle. Rule utilitarianism could lead to libertarian principles, as could rule contractarianism.

Libertarianism is normally advocated as a theory of justice in one of two senses. In one sense, justice is concerned with the *moral duties that we owe others*. It does not address *impersonal* duties (duties owed to no one) or *duties owed to self*. In a second sense, justice is concerned with the morally *enforceable* duties that we have. It does not address duties for which it is impermissible to use force to ensure compliance or to rectify noncompliance (e.g., a duty to see your mother on her birthday).

Libertarianism holds that agents are, at least initially, *full self-owners*. This means that they own themselves in just the same way that they can fully own inanimate objects. This full private ownership of a person or thing includes (a) *full control rights* over its *use,* (b) a *full power to transfer* these rights to others (by sale, rental, gift, or loan), (c) a *full right to compensation* if someone infringes these rights, (d) *full enforcement rights* to prevent infringement of these rights, and (e) *full immunity from the nonconsensual loss* of any of the rights of ownership, as long as one does not infringe the rights of others. The property rights in question are *moral* rights and may not be legally recognized.

Something like self-ownership is arguably needed to recognize the fact that there are some things (e.g., various forms of physical contact) that may not be done to a person without her consent but that may be done with that consent. One might, however, endorse full-*control* self-ownership without endorsing the other rights of full self-ownership.

Three main objections to full self-ownership are the following: (1) Because it holds that agents have not only the right to control the use of their person but also the right to *transfer* that right (e.g., by sale or gift) to others, voluntary enslavement is permitted; (2) full self-ownership entails that individuals have no duty of justice, except by voluntary agreement, to perform actions that help the needy; and (3) full self-ownership entails that forced service (e.g., draft into the military) is unjust, even when such service is needed to provide public goods. Libertarians typically defend voluntary slavery on the ground (roughly) that the right to *exercise* one's autonomy is more fundamental than the *protection or promotion* of one's autonomy. Libertarians typically defend the lack of a duty of justice to help the needy or to provide public goods on the ground that such duties involve a kind of partial involuntary slavery.

So far, we have considered agent self-ownership. There is an important distinction between *right libertarianism* and *left libertarianism,* depending on the stance taken on how natural resources can be owned.

Right libertarianism—the traditional form of libertarianism—holds that natural resources are initially nonowned and, typically, may be appropriated without the consent of or significant payment to others. It holds, for example, that whoever first discovers, first mixes her labor with, or first claims a natural resource owns that resource, provided, perhaps, that certain minimal conditions are satisfied. *Radical-right libertarians* hold that that there are no constraining conditions. Natural resources are

simply up for grabs. *Lockean right libertarians,* on the other hand, hold that appropriation is morally valid only if "enough and as good" is left for others (this is known as the Lockean proviso and is John Locke's position).

Left libertarianism, by contrast, holds that natural resources are owned by the members of society in some egalitarian sense, so that appropriation is legitimate only with their consent or with a significant payment to them. According to one version of left libertarianism, natural resources are *jointly owned* in the sense that authorization to use or to appropriate is given through some specified collective decision-making process (e.g., by majority or unanimous decision). The most well-developed and best-known form of left libertarianism is *Georgist left libertarianism* (as developed, e.g., by Henry George). It holds that agents may appropriate unappropriated natural resources as long as they pay for the competitive value (based on supply and demand) of the rights they claim. Equal-share versions divide up the rent pool equally among all, whereas "equal opportunity for well-being" versions divide up the rent pool unequally so as to equalize the opportunity for well-being.

Life-World

The *life-world* is the world of immediate experience, existing prior to any organized or systematic form of objectification. When we think, feel, or perceive something or when we act, the life-world is presupposed as a horizon of certainties that are always already there, pregiven to us, and existing independently of active verification. Consisting of all the things we take for granted, it is the "ground" on which we stand as human beings. While structures of the life-world can be explored and revealed to us, it is impossible to grasp it as a totality or as some kind of complex object.

The concept of the life-world has played an important role both in philosophy and in the social sciences, as this entry will show.

The Concept of the Life-World in Philosophy

The concept of the life-world (*Lebenswelt*) has its origin in the works of Wilhelm Dilthey, who argued that knowledge is always situated in contexts of dynamic structures of meaning and perception. Prior to scientific activity, there is "life" (*Leben*)—hence the so-called Lebensphilosophie, which was highly influential in the latter half of the 19th century.

In the late works of Edmund Husserl, in particular *The Crisis of European Sciences and Transcendental Phenomenology,* the notion of the life-world attains crucial importance not only for understanding the formation of human knowledge but also for thinking about subjectivity, consciousness, experience, and meaning. Husserl makes various claims about the life-world. It is, first, the world as naively and immediately encountered, prior to any theorizing. In that sense, the life-world is the world of immediately encountered objects. However, it is also the world of such objects considered as use-objects or objects that may have some particular significance for us. Second, even when we do not think about them, the various features of the life-world are taken for granted. We unreflectively trust the life-world and do not expect any surprises. The life-world is essentially familiar to us. Third, although parts of it may be made explicit to us, we usually do not think much about the life-world. Fourth, Husserl compares the life-world to a horizon of certainties, suggesting that the horizon

must be there as a background for any individual objects, events, or tasks to emerge as meaningful. For example, the driving of a car makes sense to us because we presuppose all sorts of facts about the car and its physical environment, as well as about the traffic regulations and the possible actions of other drivers, which we rarely make explicit. Among other things, we presuppose that there is an engine in it, but we usually do not think about the engine unless it breaks down, needs service, and so on. Fifth, in Husserl's view, while the life-world exists independently of scientific idealization, science is grounded in the immediate experience of the life-world.

According to Husserl, the objectivating and idealizing physical sciences have tended to forget or refuse to acknowledge their dependence on the life-world. A crucial task of phenomenology is to recover these unacknowledged meaning-structures and make them relevant when thinking about subjectivity and man's place in the world.

Martin Heidegger, Maurice Merleau-Ponty, and other thinkers in the phenomenological tradition have used Husserl's account of the life-world as a foil for developing ontological theories of the human subject and its existence in the world. In part, through the body and its responses, the subject is viewed as profoundly situated in its environment—it has "being-in-the-world" as its most fundamental determination. The Cartesian notion that the subject and its mental states can be analyzed independently of the subject's dynamic relation to its surroundings is in this tradition rejected.

The Concept of the Life-World in the Social Sciences

The concept of the life-world has also been of great significance to the social sciences. In the work of Alfred Schütz and Thomas Luckmann, for example, the life-world is viewed as a repertoire of tacit knowledge not only of the physical surroundings but also of the social meanings available to the agent. Thus, an office space, a family home, or a factory is structured on the basis of numerous social codes and expectations the mastery of which is required for successful social coordination to be possible. Most of these codes are rarely made explicit to the relevant agents. They can be studied by the social scientist, yet ordinarily, they function as resources that the individual agent draws on in making sense of the situations at hand.

Jürgen Habermas has proposed that the concept of the life-world should be viewed as complementary to the concept of communicative action. According to Habermas, the life-world consists of a cultural, a social, and a personal component. Through communicative action—the making of speech acts—the life-world is both presupposed and reproduced. Habermas also claims that the life-world, especially in modernity, stands in danger of being "colonized" by processes originating in the economic and administrative systems. Thus, universities, for example, can be considered in terms of the notion of the life-world. Among other things, people in these institutions study, debate, and transmit cultural meaning. However, universities are also institutions that will have to respond to economic and administrative imperatives. In such cases, the life-world may be both supported and threatened by "the system."

According to some theorists, the life-world should not be theorized independently of social power and ideology. Thus, Pierre Bourdieu uses the term *habitus* to refer to the ways in which society at large, including its systems of power and ideology, is present in the individual and in the formation of individual identity.

The concept of the life-world has mainly been of importance to interpretive forms of social research. It tends to play a limited role in more formal approaches such as structuralism or system functionalism.

Logical Positivism/Logical Empiricism

This entry gives an overview of the once influential philosophical movement of the Logical Positivists or Logical Empiricists, among the main contributors who shaped 20th-century analytic philosophy and philosophy of science in particular. The history of the philosophy of the social sciences has been particularly entangled with the fortunes of the logical-positivist views of science. The entry situates the movement within classical positivism, presents its main doctrines, and recounts its rise and fall as well as its current echoes, among which one may still discern a philosophical predilection in favor of science.

Background

The terms *logical positivism* and *logical empiricism* refer to the movement of scientific philosophy that originated in the late 1920s with the Vienna Circle and the Berlin Circle, had a major impact on philosophy in America and elsewhere, and was widely abandoned in the 1960s. The two labels are often used synonymously (as in this entry). Some authors employ the former to refer to the Vienna Circle and the latter to the Berlin Circle, while others apply them, respectively, to the early phase and the later phase of the movement, after its migration, mainly to the United States, during the Nazi era.

Following the assassination of the philosopher Moritz Schlick in 1936, the mathematical logician Rudolf Carnap and the social scientist Otto Neurath became the leaders of the Vienna Circle, while the physicist-philosopher Hans Reichenbach headed the Berlin group. Recent scholarship has disclosed the logical empiricist movement to be far more diverse and interesting than previously portrayed. The founders had advanced scientific training, but their interests differed. A full account of the various streams of the movement is beyond the scope of a brief encyclopedia entry. The movement's overall aim, which invited accusations of scientism, was to continue the project of the scientific Enlightenment by bringing all aspects of culture—from politics to art and architecture—in line with modern science as the most reliable and progressive human endeavor.

Logical Empiricism in the Positivist Tradition

Positivism is a family of strongly empiricist philosophies that anchor inquiry in facts established by observation as the basic units of scientific achievement. Theoretical claims are suspect insofar as they cannot be appropriately anchored in the facts. Positivists have always regarded human culture, not only including political and religious debate but also science, as being needlessly burdened by turgid metaphysical language that obfuscates and hence promotes ignorance. Accordingly, the most general aims of positivist movements have been to purify culture, to make human communication and decision making transparent across all social levels and thereby more rational, and to satisfy the human need to know by replacing outdated religious and other metaphysical ideas by modern science as providing our best account of our place in the universe.

The logical positivists/logical empiricists formulated a positivism that combines an empiricist epistemology with the resources of the new symbolic logic of Bertrand Russell and Alfred North Whitehead, given the latter's remarkably increased richness of precise symbolic expression and deductive power. For them, science is best characterized by its method, and in Carnap's influential view, method is to be understood as the logic of science. Nineteenth-century methodologists had used similar language, but now "logic" meant the new formal logic, not the sometimes woolly, idealist disquisitions from the past. Meanwhile, Neurath dreamed of a new *Encyclopedia of Unified Science* as the primary

cultural expression of the movement, just as the 18th-century French *Encyclopédie* had epitomized the original scientific Enlightenment. Relatively few installments were published, the last of which, Thomas Kuhn's *Structure of Scientific Revolutions,* in 1962, was widely perceived as marking the end of the movement. Later scholarship, however, has revealed a surprising degree of continuity, especially in Kuhn's treatment of scientific language and in his quasi-Kantian, two-tier conception of science, in which a stable layer or framework of constitutive rules or understandings makes possible the normal, esoteric work of everyday research. Reichenbach and Carnap held somewhat similar views prior to Kuhn, although Kuhn emphasized that even mature sciences will, of necessity, undergo revolutionary transformations from time to time. This residue of Kantianism distinguishes the Germanic empiricism of leading logical empiricists from that of the English empiricist tradition from John Locke to Bertrand Russell and A. J. Ayer.

Characteristic Doctrines

Attributing a collection of theses to the logical empiricists runs the risk of underplaying the internal diversity of the movement, but it is safe to say that the following themes were central to their scientific world picture:

a. *The unity of science, with physics as the model science:* All sciences can be reconstructed as employing the method of physics and as based on the same pure observation language, a "physical thing language" based on easily detectable properties and relations of physical objects. Thus, according to Carl Hempel and contrary to the *Verstehen* or historical understanding tradition, historical explanations are good only insofar as they can be regarded as sketches of deductions from law statements, like those found in physics.

b. *Physicalism, reducibility to physics:* All scientific claims can be given a physical meaning, and at least some theories or sciences are reducible to physics as the basic science—perhaps the entire hierarchy, from the social sciences through psychology, biology, and chemistry.

c. *An empiricist theory of meaning:* Theoretical statements are admissible if and only if they are empirically verifiable or at least rigorously testable against experience, since they derive their meaning from connections to the observation language.

d. *Rejection of metaphysics:* Any claim that pretends to assert something about the world but fails the above criterion is meaningless nonsense.

e. *A sharp fact/value distinction:* Value claims such as those of ethics and aesthetics are emotional expressions, not factual claims.

f. *Descriptionism or instrumentalism versus theoretical realism:* Since theoretical language is inherently problematic, science should bridge the traditional gap between appearance and reality by regarding theories as descriptive reorganizations of bodies of experimental facts rather than as representing a reality behind the appearances; in other words, theories should be seen merely as instruments for calculating predictions.

g. *Reconstructive purity:* Whatever is worth saving in theoretical science can be reconstructed transparently in terms of formal logical structures satisfying the above empiricist criterion of meaning, hence the goal of providing a general, structural account of theories, confirmation, probabilistic inference, prediction, explanation, theory reduction, and so on.

h. *The distinction between context of discovery and context of justification:* There exists a logic of confirmation but no logic of discovery. Thus, the process of research, and the history of science more generally, can be ignored. Only the logical structure of the finished product is relevant to epistemology.

i. *The normative/descriptive distinction:* Philosophy (including philosophy of science) is a normative discipline, not merely descriptive.

j. *The context freedom and hence objectivity of scientific claims:* The logic of science and the empirical facts together provide a strong directive to research, one that is immune to the disputes over interpretation and the biases and

contextual relativity that characterize the humanities and political and religious discourse.

k. *Value freedom:* Science itself is value-free. While crucially important to an enlightened society, it provides no particular political agenda.

l. *Science and scientific philosophy are construed as cooperative, incremental, cumulative, and progressive enterprises:* The linguistic and methodological unity of science enables the sciences, unlike other human endeavors, to make steady progress, adding to the storehouse of scientific knowledge, always within the same, gradually expanding conceptual framework. Technical philosophy can emulate this model.

The sometimes crazy politics and social movements of the Weimar period motivated the logical empiricists' language reform program. A related, democratic motivation was to make scientific language so transparent as to be intelligible even to the working class. They struggled to solve the problem that logic, mathematics, and hence philosophy were not, in their view, empirically testable yet were indispensable. Clues from Russell and Ludwig Wittgenstein inspired their solution to the problem: These statements do not need to satisfy the criterion because they make no claims about the world. They are empty of empirical content but in a good way. Their function is to provide inferential structure only. Writ large, this implied that philosophy, as the logical analysis of the language of science, can be scientific without itself being an empirical science.

When logical empiricism came to America, it fairly quickly achieved a degree of hegemony, displacing the then reigning pragmatism of William James and, especially, John Dewey. Pragmatism was fairly congenial to positivism but seemed imprecise and out of date by comparison, and the central logical empiricist theses did hang together well. Of course, highly integrated approaches are robust in some respects but vulnerable in others in that serious trouble anywhere can propagate quickly through the entire system. That is ultimately what happened to logical empiricism.

The Fall of Logical Empiricism

The logical empiricists were their own worst critics. Already by 1950, Hempel could argue that attempts to formulate a logical criterion of cognitive significance were doomed. He added that concept formation cannot be done in isolation as the operationists insisted, that it is intimately coupled with active theorizing. About the same time, the American logician and philosopher Willard Van Orman Quine parted intellectually from Carnap by rejecting the so-called analytic/synthetic distinction, thereby denying that logic and mathematics have a special, nonempirical status, forever immune to revision. Soon, others began to challenge the observational/theoretical distinction and the idea that human learning starts from bare experience and proceeds only gradually up the empiricist ladder of increasing grades of theoreticity. Moreover, it was becoming apparent that theory and experimental observation are often tightly coupled and that many observations are scientifically significant only in light of some theory. The discovery/justification distinction also came under attack; for the new history of science suggested that the research process (i.e., discovery) could be studied in epistemologically interesting ways and that focusing solely on the logical structure of finished products (i.e., on justification of existing theories), as orthodox logical positivism demanded, produced only formalizations of textbook science and failed to capture real science as practiced. To analysts such as Stephen Toulmin, Kuhn, Paul Feyerabend, Imre Lakatos, and Larry Laudan, science does not escape from history but is itself subject to dynamic changes that cannot be captured by static, "time-slice" logical structures. The disparity between the positivist model of science (including the somewhat similar views of Karl Popper) and what historians were disclosing was so great that it was not enough for logical empiricists to fall back on the defense that philosophy of science is normative rather than descriptive (i.e., it dictates what correct scientific reasoning and justification should be rather than describes actual scientific practice). Kuhn and Feyerabend especially attacked the view that science is cumulative over historical time, always within the same, albeit expanding, conceptual framework. On the contrary, Kuhn said, even the most mature sciences will occasionally and unpredictably undergo transformative revolutions that change the rules of the game. Logic and facts do not suffice to determine major scientific decisions. Alternative interpretations and rhetorical persuasion are possible at every stage but are normally suppressed. Revolutions do

not result from large inputs of new facts but from wholesale conceptual reinterpretations of established results already in hand. As the 1960s and 1970s wore on, it became clear to most parties that logical empiricism lacked the resources to respond adequately to these criticisms. That the movement was judged to be wrong about science itself did not bode well for its original program to reshape modern culture, which, anyway, the logical empiricists abandoned in the conservative American political context.

Nonetheless, the logical empiricists left a legacy of high standards of clarity and rigor that have been fundamental to analytic philosophy. They also shaped the discipline of philosophy of science in a manner recognizable today. Although most philosophers now reject the logical empiricist positions, they often engage the same problematic. Thus, the unity of science remains a central issue, although many writers now reject unity in favor of diversity. Scientific realism remains a central topic, and some philosophers persist in the attempt to develop general theories of confirmation, explanation, and so on. Philosophers of science still tend to have a pro-attitude toward the sciences and to be more normative than other science studies experts, who strive to achieve a stance of descriptive neutrality.

Love, in Social Theory

This entry presents the changing conceptual and social frameworks within which relations of love must now be conceptualized in conditions of cosmopolitanism and globalization. It also explains the emergence of the novel social phenomena of "long-distance love" and "world family" and sets the tasks of social sciences vis-à-vis these novel social relations of intimacy.

Introduction

We are living in an era of migration and globalization. Yet until now, research on love and the family has paid scant attention to this. Instead, it continues to focus mostly on the forms of personal life and the relationships characteristic of the majority society. Thus, it remains prisoner to the unholy trinity of territory, state, and nation. In other words, it remains trapped in "methodological nationalism"—that is, in a frame of reference that equates society as such with nationally organized societies. Yet today, this frame of reference is rapidly becoming anachronistic. It cannot deal with the emergence of ever more forms of personal life and relationships that extend across (national) borders.

Changing Frameworks

The longer family research clings to the "container model" of the nation-state, the less it will be able to understand and explain the situation of long-distance love and families in today's cosmopolitanized world. What is needed is a *cosmopolitan turn* in research on love and families. But what does cosmopolitanism mean?

Cosmopolitanism is a very old and highly contested set of ethical and political ideas, dating back to Hellenistic (Stoic) and Roman antiquity, combining—as the word *cosmo-polis* says—two worlds: Every human being is, first, a member of the *cosmos* (the unity of nature and humanity) and, second, at the same time, a member of the *polis*—that is, different states, ethnicities, and religions.

This idea was revived by the philosophies of the European enlightenment, most notably by Immanuel Kant, who foretold a future era of polite civilization, commerce, and global peace. By the 20th century, however, cosmopolitanism had virtually disappeared as a serious intellectual, let alone political, position.

"Great powers"–based realism instead dominated the mood of politics and the mode of analysis in an era defined by raging nationalisms, the trauma of world wars, and a Cold War in which competing superpower "internationalisms" vied for global dominance.

With the emergence of *globalization* as a master concept in the social sciences, cosmopolitanism regained currency within the academy. But in the process, cosmopolitanism also refashioned itself, moving beyond political theory, its conventional home, and ranging widely across anthropology, cultural studies, literary criticism, legal studies, and social history. New, more or less reflexive cosmopolitanisms have since proliferated, preoccupied, first, with squaring the circle of abstract universalism by emphasizing respect for the particularity of human diversity and, second, with expanding the boundaries of the circle to include (if not to favor) those for whom cosmopolitanism is not a lifestyle choice but the tragic involuntary condition of the refugee or the otherwise dispossessed.

Changes in Conceptualizing "Love"

What changes are love and family undergoing in the "global age"? The belief in the either/or, which was once taken to be a "natural" self-evident fact—either we or they, either here or there—seems to be on the wane or has actually disappeared from the horizon of love. Nothing now seems to separate human beings any longer in any absolute way, not skin color, not national hostility, not religious differences, not the distance between continents, and so forth. On the contrary, people are susceptible to the attractions, even the lure, of the unlimited possibilities represented by the global other—by those who are far away: *long-distance love*. This marks the disappearance of unbridgeable chasms; for since they now appear bridgeable, they are already in the process of being bridged.

To begin with, we have to distinguish between the social model of *national* families and love and the social model of *world* families and *long-distance* love. The vantage point that enables us to gauge the dimensions of the new landscapes opening up for love, family, and the household in the global age is as follows: The national or territorial face-to-face model of the "family"—defined by the unholy trinity of territory, passport, and skin color—is now breaking down.

The "world families" and "long-distance love" model, by contrast, includes a variety of forms in which the members/partners coexist across national, geographical, and religious boundaries—at the one extreme, different native cultures coexist in a single place; at the other extreme, a single native culture is scattered across the world (and between these extremes there are many transitional and hybrid forms). Including these different forms of the global other in one's own life calls for active trust from all sides across institutionalized boundaries. Only thus can the world's antagonisms be contained under the roof of the family or be rendered useful for familial purposes. The territorial or national family and love model is founded on the fact that the modern dualisms—national and international, global and local, we and the others—are accepted as "natural"; by contrast, the world families and the long-distance love model rests on exactly the opposite fact, namely, that these dualisms are placed in question in the practice of coexistence beyond boundaries.

Long-distance love and world families, including binational couples, marriage migrants, fertility tourists, foreign domestic workers and transnational households, "global care chains," and so on, are no longer marginal phenomena; they have long since taken root at the heart of the "majority society." "The global 'other' lives in our midst" acquires here a literal, intimate, and familial connotation. One's brother-in-law now has a wife from Thailand. A woman from Poland has been hired to look after grandpa. One's godchild has recently started living with a theologian from Togo. Where is Togo, actually? How come he is here? Is he here for the sake of a residence permit or out of "true" love?

World families integrate a "global other"—who as a result is no longer a global other. To bridge the institutionalized national and religious stereotypes and enemy images of the globe in everyday family life requires *active trust* from both sides in order to open up a passage for hope, by acknowledging being equal and different at the same time.

This vision might then become a source of disappointment and failure. But it is necessary because world families embody the contradictions of the world, and these contradictions are worked out in them. Not all families embody all contradictions, but some families embody some of them. For example, there are marriages, parents, and couples with dual nationality, and they may embody the tensions between two countries or between the majority and

minority communities within those countries, while immigrant families may incorporate the tensions between the center and the periphery or between legal and illegal members.

World families and long-distance relationships mirror a state of ignorance that has been nationally programmed and embodied in law. It follows that love and the family become the setting in which the "cultural wounds"—the rage and the anger that global inequalities and their imperial history continue to inspire in the souls of the living to this day—are endured and fought out.

World families, therefore, are not families with global *power* or families with global *horizons;* nor are they *one*-world families or families of world *citizens*. We might instead call them families embodying *world conflicts,* families ripe for *world adventures,* or even families *seeking their fortunes* in the world—families attempting to turn poverty and conflict into "gold." But what they demonstrate is that the universal image of the "good family," which has always been taken for granted, is now fundamentally in flux—a development that bears some responsibility for fundamentalist reactions and countermovements.

Social Science's Task

In order to study global intimacy, long distance love, and world families—that is, to bring the social sciences in—there is an urgent need to clearly distinguish *cosmopolitanism* in the normative sense of philosophy and political theory from *cosmopolitization* as a social-scientific concept and a program for empirical research. Cosmopolitanism is about *norms,* cosmopolitization is about *facts*. The argument is that the interrelatedness of people and of populations around the globe can only be understood from a cosmopolitan standpoint. Building this cosmopolitan approach implies the erosion of distinct boundaries dividing markets, states, civilizations, cultures, and, not the least, all life-worlds of different peoples. This is true not only for the study of love and family relations but also for the study of work conditions, religions, classes, nation-states, climate change, and so on.

Cosmopolitization does *not* mean that individuals living in "world families" are becoming cosmopolitan. We have to make a clear distinction between the perspective of the actor and the perspective of the social-scientific observer. The word *cosmopolitan* becomes indispensable for describing a situation in which—not only in world families but also in relation to world religions or global risks—*humanity* and *world* are not merely thinkable but unavoidable categories for describing the realities we live in—a "cosmopolitan situation," resulting in a growing *consciousness* of both the world as a single place and humanity as a unity of (often contradictory) differences. Culturally speaking, then, cosmopolitization has gained significance in a set of collective existential dilemmas at the start of the third millennium. Thus, with the empirical phenomena of "long-distance love" and "world families," we are witnessing the opening of a new chapter full of strife and controversy over the very meaning of "romantic love," "good family," or, more generally, the "good world"—and, significantly, who gets to define it.

Love, Philosophy of

Love has attracted philosophical interest from antiquity to the present. Analytically speaking, love has been divided into many types: romantic love, parental love, and sexual love; love for friends, religion, country, food; and so on. This entry focuses on *romantic love,* which appears to be one of the most complex of emotions. It gives an overview of various philosophical analyses of its features and presents points of dispute about its nature.

The experience of romantic love involves two basic evaluative patterns, referring to (1) attractiveness, an attraction to external appearance, and (2) praiseworthiness, positively appraising personal characteristics. Falling and staying in love requires the presence of both patterns. These patterns are not independent: A positive appraisal of your partner's characteristics is greatly influenced by his or her attractiveness. A common phenomenon in romantic relationships is the "attractiveness halo," in which attractiveness positively influences ratings of intelligence, sociality, and morality.

In contrast to romantic love, where both evaluative patterns are essential, in sexual desire attraction is far more dominant. Sexual desire is a simpler attitude, based largely on spontaneous evaluations, whereas romantic love often requires both spontaneous and deliberative evaluations. In friendship, which is a kind of companionate love, praiseworthiness is by far more dominant than attractiveness.

Change is of greater weight in generating sexual desire; conversely, friendship depends more on familiarity and shared history. Since romantic love consists of both patterns, it is often difficult to maintain romantic relationships over the course of many years. In some cases, romantic love can remain intense for many years; in others, it becomes companionate love, in which the passionate aspect is reduced; and in yet other cases, the relationship does not survive in the long term. This raises doubts concerning whether, as in the popular song of the mid 20th century, "love and marriage go together like a horse and carriage."

A few classical disputes concerning the nature of romantic love are on (a) love at first sight, (b) whether love is blind, (c) the importance of similarities and differences in generating love, and (d) the exclusiveness of love.

a. Despite its glamorous place in our culture, love at first sight is not easy to explain. How can we explain that after one quick glance we can fall profoundly in love? Although people often confuse love at first sight with sexual desire at first sight, there are nevertheless genuine cases of love at first sight. The fundamental mistake in denying the existence of such love is the assumption that we cannot attribute to a person characteristics that are not present at the moment. Praiseworthiness can be evaluated spontaneously, much like attractiveness. This is done in many types of stereotypic evaluations, and it is also present in the aforementioned "attractiveness halo," in which what is beautiful is also evaluated as good. Accordingly, attractive people are more likely to be the object of love at first sight.

   There is, however, no need to adopt Shakespeare's assumption that "whoever loves, loves at first sight." Love can develop over time. We may discover characteristics that we adore but that were not evident at first sight, and we may evaluate differently those characteristics that at the beginning were evident or were not positive enough to make us fall in love. Hence, we can fall in love with people once we get to know them better. Sometimes, "to love him is to know him."

b. Lovers in general, but particularly lovers at first sight, are often blind to the beloved's negative traits. We frequently love the idealized person rather than the real one. Idealization of the beloved may also be considered as a kind of a defense mechanism, enabling us to justify our relatively arbitrary choice. The lover's blindness is not necessarily due to misperception of the beloved's traits; it may also be a matter of emphasis (or overemphasis), namely, focusing upon positive qualities only.

   To persist, an idealized loving relationship requires a moderate but constantly distorted perception of reality; its moderate nature enables lovers to believe in it despite its known inaccuracies. Stable and satisfying relationships

reflect the intimate partners' ability to see their imperfect partner in an idealized light. Love is thus not blind, but its sight is often blurred.

c. Concerning the classical dispute of whether "birds of a feather flock together" or "opposites attract," there is consistent evidence for similarity. Romantic partners show (i) strong similarity in age and in political and religious attitudes; (ii) moderate similarity in education, general intelligence, and values; and (iii) little or no similarity in personality characteristics. We tend to fall in love and stay with people who share with us profound similarities; the presence of such essential similarities need not preclude—and may even encourage—differences related to surface manifestations within the basic similarity. Differences attract, but only within a shared general framework that leaves ample space for complementary differences.

d. Romantic love requires components of both exclusiveness and uniqueness. Exclusiveness is characterized in negative terms, such as "not permitting" and "restricting," that establish rigid boundaries, like not being intimate with other people. Uniqueness is characterized in positive terms that celebrate an ideal and establish distinctiveness: "being made for each other." While romantic love involves both components, uniqueness is of greater significance for a profound, long-term romantic relationship.

Romantic love is frequently characterized in ideal terms, such as being comprehensive (there are no boundaries to this love), uncompromising (nothing can dilute or impede such a love), and unconditional (reality is almost irrelevant to love and has scant impact on it). Ideal love is perceived as an overwhelming force that can cope with all obstacles, not merely in the sense that it can solve all difficulties but also in the more profound sense that such difficulties, even if they continue to exist, become less important. The assumption that love can conquer all gives no weight to changing personal and contextual features and can be a source of disappointment and distress, as people might blame themselves or their beloved for having a relationship that is short of perfect.

Like other types of relationships, romantic love involves various compromises, such as (a) compromising on the overall value of the person, (b) compromising on the value of the person as a partner, and (c) compromising on the nonromantic activities within the given framework of their togetherness. In cases of profound, long-term romantic love, the feeling of compromising scarcely exists.

Our current era can be considered as the best and worst of times for lovers. This is indeed both a happy and a difficult time for relationships—happy in that available and willing potential lovers are all around but difficult in that maintaining a loving and committed relationship is harder than before since alternative romantic options have become easier to explore and to realize. The need to make romantic compromises is therefore greater, but making them is more difficult.

Luhmann's Social Theory

The work of Niklas Luhmann occupied a central, albeit paradoxical, position in debates in the later 20th century regarding the position of philosophy vis-à-vis the social sciences. This entry presents an overview of Luhmann's social theory, his views on the relation between philosophy and social science,

and the importance of his theory for social-scientific epistemological issues.

In many respects, Luhmann's theory was conceived as a frontal assault on philosophy. In his inaugural lecture of 1967, titled "Sociological Enlightenment," he dismissed the residues of post-Enlightenment subjectivism and philosophical ontology in the social sciences. Indeed, he declared a programmatic intention to develop his sociology—or his *theory of society*—as a line of inquiry defined by a rejection of philosophical epistemologies and committed to strategies of positivistic/functionalist social analysis without reliance on implicitly metaphysical concepts of rationality, reflexive norm production, or cognitive monadicism.

In this respect, Luhmann positioned his thought around a sharp dichotomy between sociology and philosophy. He defined philosophy as the study of the human mind, and he construed sociology, strictly, as the study of society. In making this distinction, Luhmann proposed an *apersonal and anti-anthropological* conception of society, which defined society as a densely contingent repository of *social communications*. The communications forming society, for Luhmann, are not in any determinate way *human* communications. They are in fact *functional* or *systemic* communications: That is, they are communications within the various function systems that society comprises. The primary *function systems* in society are economy, art, science, law, politics, medicine, media, religion, and education. For Luhmann, each system possesses a distinct functional rationality, and through this rationality, it constructs a realm of differentiated functional meaning, which is in itself entirely self-referential, self-reproductive, or *autopoietic*. For example, those exchanges in society that are communicated as law (prosecutions, hearings, jury appointments, draft statutes, white papers, etc.) are communicated in categories that are exclusively internal to the functions of the legal system. Such exchanges are articulated for society around the code lawful/nonlawful. Similarly, those exchanges in society that are communicated as economics (e.g., transactions, loans, investments, warranties, taxation, etc.) are communicated in categories that have meaning solely for the functions of the economic system. Such exchanges are expressed for society around the code payment/nonpayment. As social meaning is communicated in differentiated systems, there is no overarching human rationality that encompasses all communications in society or reaches across systemically differentiated communications. There are in fact *multiple rationalities* in society, each inhering in a given social system, and each of these rationalities constructs inner-systemic meanings in indifference to any originally human rational substrate.

This systemic-communicative account of society underpinned Luhmann's attitude to philosophy. Like Émile Durkheim, he concluded that to approach societal objects from the presumption that they are interpretable by a unifying human rationality is to ignore the radical fact of functional and communicative differentiation, which is foundational for modern society. On this basis, furthermore, he concluded that the methodological preconditions of philosophy are inherently false and that in positing generalized principles of rationality, philosophy obstructs understanding of phenomena as specifically societal constructs. It is specific to sociology, however, that, *contra* philosophy, it can accept high levels of differentiated contingency, multirationality, communicative self-reference, and systemic internality as preconditions for the emergence of societal phenomena. Sociology, in other words, has the methodological distinction of being capable of interpreting objects *postontologically*—as phenomena arising as articulations of highly differentiated, and fundamentally abstracted, communicative contingency.

As an extension of this radical-functionalist approach, Luhmann concluded that the most basic assumption of philosophy—namely, that there exists a perennially constructed human intelligence capable of expressing itself as *theory*—is misguided. Against the classical idea of *theory,* he asserted a concept of *semantics*. The concept of semantics implies that each social system has an internal theoretical structure, and it consolidates its internal rationality by generating distinct theoretical concepts (semantics) to secure and temporally to stabilize the meanings specific to it. In consequence, the theoretical models emerging in different realms of social practice need to be examined, not—philosophically—as autonomous expressions of intelligence but rather—sociologically—as objectivized *self-descriptions* of particular social systems. Against the entire tradition of post-Platonist philosophical reflection, therefore, Luhmann concluded that the ideal structure of reason and the material structure of society need to be viewed as in essence *communicatively identical.*

Luhmann's ultracontingent conceptions of theory and rationality brought him into repeated conflict with intellectuals in the philosophical mainstream. For example, these constructions formed the basis of high-profile controversies between Luhmann and Jürgen Habermas, which punctuated West German intellectual life in the 1970s and 1980s. In these exchanges, Luhmann argued for a concept of theoretical communication as absolutely contingent meaning. Habermas rebutted this from a remotely post-Kantian perspective, defining theoretical communication as a bearer of anthropologically constitutive rational norms. Central to this dispute was the fact that Luhmann dismissed Habermas's normative sociology as a belated example of archaic metaphysical-ontological thinking, which was incapable of true sociological comprehension.

Although he positioned his theory of society as a denunciation of the ontological residues of philosophy, Luhmann's work was formed through interaction, albeit dialectical, with the philosophical canon. His account of sociology as variable interpretation has a certain proximity to the historicist-hermeneutical tradition. Most strikingly, however, Luhmann's view of society reposes on a philosophical construction of *difference,* in contrast to identity, as the basic substructure for social meaning. That is, Luhmann argued that meaning is generated in (or *as*) society through the endless differentiation of one social system from its environment (other systems) and that each act of systemic self-differentiation constitutes meaning as a contingent negation of other meanings (meaning constructed through the rationality of other systems). In this regard, Luhmann's thought discloses a distant affinity to Hegelian phenomenology.

More palpably, however, his theory of society was organized as a sociological reconstruction of Martin Heidegger's critique of post-Cartesian ontology, and it transposed the *Sein/Dasein-Differenz* in Heidegger's work into a sociological theory of systemic differentiation and contingent social meaning. For Luhmann, as for Heidegger, intelligible meaning is the result of societal communications defining themselves, contingently, in incessant and *ex-static* inner-societal difference from all other meanings and from all perennial or universally founded intelligence. Like Heidegger, Luhmann saw his own work as containing a method for capturing such meanings. To this extent, Luhmann appears to have viewed his theory of society as the culminating position in the radically temporalizing and radically pluralistic critique of formal ontology first promoted by Heidegger.

LYING

To a very great extent, social relations and institutions presuppose honest communication. However, communication is not always honest: Individuals and groups deliberately misrepresent reality to others, in the service of personal, political, or ideological ends. In short, people lie. Lying is found at all levels of social intercourse, and its study is therefore of relevance to the entire spectrum of the social sciences. This entry summarizes philosophical conceptions of lying.

At the most general level, we can say that lying is communicative behavior that is undertaken for the purpose of misleading others. Most philosophers accept this characterization, or something very near to it, but they disagree on how it should

be understood. Generally speaking, there are two camps: (1) fine-grained or "narrow" approaches and (2) more coarse-grained or "broad" approaches. Although highly schematic, and therefore inevitably oversimplified, this taxonomy gives a panoramic view of the relevant conceptual landscape.

The dichotomy between the narrow and broad conceptions turns on a difference of opinion about what sorts of behaviors should count as lying. Narrowly conceived, lies are misleading *statements*. A person lies if and only if he or she makes an assertion for the purpose of misleading someone by causing them to embrace a false belief. Although this definition covers a great deal of what we ordinarily mean by the word *lying,* there are some clear counterexamples to it. Consider a boy who cries "Wolf!" with the intention of causing his neighbors to falsely believe that there is a wolf in the vicinity. Even though "Wolf!" is not a statement, we are inclined to think of the boy's behavior as an example of lying. Proponents of the narrow view of lying can respond to this objection by insisting that "Wolf!" is actually a statement in disguise and that in crying "Wolf!" the boy is asserting something like "There is a wolf nearby!" However, there are other cases that are less easily disposed of. Consider groans of pleasure. Groans of pleasure are not statements: They *express* feelings of pleasure without *asserting* them. Now, suppose that a person groans to give a false impression of experiencing pleasure. If the misleading groan is a lie, then the narrow view of lying must give way to a broader one.

According to the broad conception, there are many forms of behavior—both verbal and nonverbal—that are properly included under the umbrella of lying. Removing one's wedding ring to give a false impression of one's marital status, presenting a forged passport to an immigration officer, coloring one's hair to conceal telltale signs of age, and remaining silent in order to hide the truth are just a few examples. Advocates of the broad conception deny that there is no *essential* difference between verbal and nonverbal deception that would justify restricting the term *lying* to the former.

Proponents of both the narrow and the broad approach typically hold that a communicative act is a lie only if it is motivated by an *intention* to deceive. Whether or not the act succeeds is immaterial to its status as a lie. On these accounts, then, there is no such thing as an unintentional lie. Suppose that you are driving along an unfamiliar road and stop to ask for directions to the nearest filling station. Your interlocutor tells you where to go, but unbeknownst to him, the filling station was recently torn down. He misled you, but he did not lie to you, because he misled you inadvertently. Now, contrast the foregoing scenario with one in which your interlocutor deliberately gives you what he believes to be erroneous directions with the intention of leading you astray; however, unbeknownst to him, a filling station had recently been built at the precise location to which he directed you. In this case, the man lied to you about the location of the filling station, even though he did not mislead you. These considerations suggest that it is the *intentions* of the agent, rather than the truth or falsity of his or her assertions, that determine whether or not any given communication is a lie.

There is a third approach to lying—call it the *very broad conception*—which rejects the claim that deceptive intentions are an essential feature of lying. Advocates of this view accept that lying must be purposive, and also accept that intentional behavior is purposive, but they deny that all purposive phenomena are intentional. Biological organs are purposive in function but have nonintentional purposes. For instance, hearts have the purpose of pumping blood around the body, but hearts do not have this purpose by dint of someone's intending it. We can say that biological organs like hearts have *biological purposes* rather than intentional ones.

Nonhuman organisms, even quite simple ones, often mislead one another. For example, the mirror orchid (*Orphys speculum*) produces flowers that mimic the form and scent of female scolid wasps. As a result, male wasps mistake the flowers for females of their own species and attempt to mate with them. In doing this, pollen adheres to their bodies, which they then transport to other flowers. The form and chemical composition of the orchid blossoms have the biological purpose of misleading scolid wasps. That they have this purpose is explained by facts about their evolution. On a very broad conception of lying, then, we can say that mirror orchids lie to the wasps that pollinate them.

The dispute about competing conceptions of lying may appear to be merely semantic. However,

this appearance is misleading, because each conceptual option has ramifications for a variety of fundamental philosophical issues, including the nature of language, testimony, the theory of action, moral psychology, and the relevance of evolutionary biology for explanations in the social sciences.

Machiavelli's Art of Politics

Niccolò Machiavelli (1469–1527) is without comparison the most accomplished and influential political thinker and social theorist of the Italian Renaissance. Over the centuries, the Florentine's work has given rise to numerous conflicting interpretations and continues to this day to spark debate and controversy. His political writings, state papers, private correspondence, comedies, and poems attract the interest of historians, political theorists, literary scholars, and students of classical republicanism alike. Outside academia, politicians, political commentators, and public figures continue to draw on his work as a manual for political success and a source of worldly wisdom. The strategic aspects of his writings and his penetrating analysis of human motivations and power relations have, in a burgeoning literature on leadership and management, come to be applied to the world of corporate business and enterprise. Machiavelli's status as a major classical thinker cannot be denied.

Machiavelli's originality as a political thinker and as a social theorist is intimately linked to his method. As the opening statements in three of his main works, *The Prince* (1513), the *Discourses on Livy* (ca. 1514–1518), and *The Art of War* (1520), make clear, his approach to politics is based on a dual optics. On the one hand, he shares the Renaissance humanist's penchant for ancient history and literature, contending that human nature and the basic conditions of political and social life have not undergone any major changes since antiquity. Consequently, lessons from ancient history, if interpreted correctly, can be applied to modern conditions, offering principles, maxims, and general rules of conduct upon which a well-balanced and vigorous republic can be erected. On the other hand, Machiavelli inaugurates a new type of political theorizing based on first-hand observations of the political affairs of the day. Here, his personal experiences as a diplomatic envoy and as a military observer come to inform a general outlook that places great emphasis on the exigencies of the political here-and-now. In Machiavelli's work, these two perspectives superimpose and blend into a new type of pragmatic and classically inspired political discourse.

Machiavelli's art of politics is centered on his innovative notion of virtue. While traditional Aristotelian ethics had defined virtue as a mean between two extremes, Machiavellian virtue, in contrast, involves a capacity to employ the extremes according to the circumstances. The Machiavellian prince or statesman should thus abide by the law and conventional morality when he serves his or his republic's interest, but he must be prepared to use deception and force, metaphorically described as the fox and the lion, when so required.

The underlying logic of Machiavelli's notion of virtue is illustrated by his semiconceptual notion "cruelties well used" (*crudeltà bene usate*). The violent methods employed by the ruthless Cesare Borgia qualify as "well used," since they enabled the ruler to lay a strong foundation for his power, which later allowed him to adopt a more civil and peaceful form of rule. As the example of Cesare Borgia teaches, the means employed are retroactively justified by the political outcome. By arguing that cruelty

(and other traditional vices) can be a political, and perhaps even a moral, good, Machiavelli dislodges the very notions of good and evil from their theological underpinnings. In Machiavelli's art of politics, cruelty and, consequently, the other traditional vices are no longer regarded as an absolute evil but are conceived of as instruments of rule that can be used well or badly according to the circumstances and the designated ends.

One of Machiavelli's main contributions to social theory consists in his conception of social conflict and partisan strife as fundamental facts that legislators and rulers need to acknowledge, contain, and channel. In keeping with the main tendency of Florentine republicanism, Machiavelli argues that a republic has a dual aim: one internal, associated with the classical concept of liberty, and the other external, aspiring to acquisition of dominion (*imperium*), material goods, greatness, and glory. In the republicanism of the *Discourse*, an intimate link exists between this dual pursuit of liberty and empire, on the one hand, and the republic's mixed constitution and internal ordering, on the other. According to Machiavelli, there are, broadly speaking, two categories of men: (1) those who desire not to be oppressed but to live as free individuals and (2) those who want to command and dominate others. The former group Machiavelli calls the people (*popolo*) and the latter the great (*grandi*). From the viewpoint of classical constitutionalism, the two categories correspond to the many and the few, respectively. One of the chief concerns of the Machiavellian statesman is to find artful ways of satisfying, or accommodating, each of these contrasting desires, or appetites, without suppressing the demands of the other, conflicting humor, or category, and without endangering the republic as a whole.

As a true partisan of the mixed regime, Machiavelli refuses to side with either of the two categories, and therefore, his republicanism cannot easily be characterized as either popular or elitist. At the same time as he praises the ancient Roman elite's manipulation of the populace's religious beliefs for political ends, and exhorts his contemporaries to revive it, as he puts it, by reinterpreting Christianity "according to virtue," he endorses an aggressive and ferocious form of popular republicanism in which the general populace, acting as "the guardians of liberty," controls the elites by often harsh and brutal methods.

By taking human beings as they are, with all their imperfections, partialities, and vices, as his starting point, rather than humankind as it ought to be, Machiavelli occupies a central position in the prudential and realist tradition in Western political philosophy. For him, as for thinkers like Thucydides, Aristotle, Montesquieu, Madison, Burke, and Tocqueville, politics is not a means for implementing a philosophical ideal but an inherently messy business, full of contradictions and conflicts. In its Machiavellian variety, this pragmatic approach involves developing a double viewpoint that comprises the irreconcilable demands of liberty and empire. Consequently, the Machiavellian art of politics consists of balancing the interests of the modest and peace-loving citizen and the exceptional individual's quest for greatness, conquest, and glory. Insofar, it can be argued, it addresses basic aspects of the human condition and comes to acquire a timeless quality.

Machine Consciousness and Autonomous Agents

Machine consciousness (MC) concerns the development of computer models of human mental features that are closely associated with consciousness

in humans and other biological creatures. How far can consciousness be modeled or replicated in an inorganic machine? The study of MC is closely associated with the larger and more established field of artificial (or machine) intelligence (AI). MC is sometimes referred to as "artificial consciousness," but the latter is arguably wider in scope. For instance, one could imagine creating complete conscious biological beings by building and growing tissues in a lab using possible future biosynthesis techniques; they would perhaps count as being artificially conscious but not as MCs. The specific challenge of MC is to see how far developments using the well-understood computer-based technologies available today can shed light on consciousness.

MC and Artificial Intelligence

Clearly, there is a close association between AI and MC and, indeed, between cognition and consciousness. Humans and many animals need to be consciously aware to exercise various kinds of intelligence or cognition. Tasks such as checking for predators or dangers or concluding a chess endgame are usually best performed in a condition of concentrated alertness. However, other kinds of cognition—visual processing, for example—seem to occur, to a substantial degree, below the threshold of consciousness. There is much debate over what kinds of cognition are integral to consciousness: Many argue that the "raw feels" of sentience, which are possibly present even in species with relatively primitive nervous systems, are quite distinct from cognitive processing. Nevertheless, "higher" forms of consciousness, such as self-awareness or self-monitoring, are probably integrally linked with cognitive processing. Ironically, but perhaps not too surprisingly, MC researchers seem to have more success in modeling more sophisticated kinds of consciousness than the more primitive types; this encourages sceptics about MC to say that such models are really providing insight only into the cognitive *accompaniments* to consciousness, rather than into states of consciousness in themselves.

"Strong" and "Weak'" MC

It has been customary for decades to distinguish between "weak" and "strong" AI. Supporters of strong AI believe that computers will one day literally have mental states (and perhaps, they already do). Supporters of weak AI do not accept this but still maintain that computer models can give important insights into the nature of intelligence and mind. A similar distinction can be made between weak and strong MC. (It is probably best to talk about a weak–strong spectrum in each case.) For weak MC, computational or robotic techniques provide useful models of consciousness but not real consciousness in machines, whereas strong MC suggests that such machines are possible and may even be imminent. Strong MC shares with strong AI an acceptance of the philosophical functionalist view, which asserts that the mind is best explained in terms of abstract computational operations of the brain, or of functionally equivalent hardware, and which emphasizes in particular that consciousness can be explained without residue in cognitive/computational terms. Weak MC dissents from such strong claims about the theoretical relation between mind and computational processes.

Current work on MC follows a number of hypotheses about cognitive processes that may be necessary or sufficient for a system to be conscious. Several researchers work on developing computational or robotic systems that implement existing theoretical frameworks, such as Global Workspace theory, or self-modeling approaches to consciousness. Other approaches seek to build artifacts that instantiate specific cognitive faculties, such as imagination, that may be sufficient for consciousness, or a broad set of cognitive functions that may be jointly sufficient. Some others set out to challenge common understandings of consciousness—for example, by building models that depart from the idea of a singular "stream of consciousness." Most current work does not explicitly attempt the (strong MC) target of building actual conscious machines but rather holds to the (weak MC) idea that building models of various processes underlying consciousness will produce new insights about consciousness as such. However, successful work of the latter kind may well reinforce confidence in future work directed at the strong-MC target.

Ethical Aspects of MC

Weak MC raises many interesting technical issues, but strong MC (like its AI counterpart) raises some important challenges concerning how far computers and robots can possess a mental life. The quest to create computer-based consciousness arguably introduces a strong ethical element into the debate. Mainstream AI and robotics raise ethical issues to

do with the responsibilities of those who design and deploy such cognitive agents. Computer-based agents that were conscious would also raise questions to do with our responsibilities toward such agents themselves. In the late 18th century, the English philosopher and advocate of social reforms Jeremy Bentham (the father of utilitarianism) argued that nonhuman animals deserve our moral consideration, not because they reason but because they *suffer*, that is, have sentient awareness of harm done to them. One supposes that Bentham would have wished to extend his ethical concern to potential artificial agents if they, too, had conscious awareness of their states.

The link between conscious awareness and moral concern seems to be difficult to deny. So if some machines were admitted to be genuinely conscious, in the sense of being capable of suffering, feeling pain or fear, and so on, then arguably they should be deemed to have genuine moral interests. As with animals, their inclusion in our moral constituency would be amplified if they had higher, more cognitively scaffolded forms of consciousness. If such MCs were to proliferate, this would surely create some deep social conundrums for future generations, particularly if the conscious mental life of such beings were to be enhanced by levels of intelligence far greater than those of humans, as seems highly possible given the current levels of attainment in some branches of AI.

Strong MC is perhaps ethically or socially significant for another kind of reason. Artificial systems that incorporated higher, more self-reflective, forms of consciousness could possibly be considered as moral or social subjects, not just in the "receptive" sense just mentioned but also in the sense of being *autonomous agents* that could deliberate over and be given moral credit or blame for their actions and choices. Being a morally responsible agent, arguably, requires being capable of understanding what it is like to experience the positive or negative effects of different courses of action on the course of experience of the people affected. Such an understanding may in turn require being capable of having such experiences oneself, at least in principle.

Some researchers in the field of machine ethics are developing ethical deliberation systems that arguably have some key features of conscious agents. For example, they claim, such systems may be considered morally autonomous agents to the extent to which their mental organization involves a kind of global integration that many people believe to be crucial to self-awareness or consciousness. So the enterprise of modeling of consciousness and of modeling ethical thinking may be closely associated.

Scientific Versus Engineering Motives for MC

Why do work in MC? One can distinguish between scientific and engineering—or theoretical and practical—motives for doing research in MC. (Again, a similar distinction can be made within AI research.) Someone pursuing scientific MC would be primarily motivated by the wish to understand the nature of consciousness and to explain it in scientific, or maybe philosophical, terms. Someone pursuing engineering MC would be rather motivated by the idea that if we can replicate or simulate consciousness in artificial systems, they are likely to work better for us. As mentioned above, we generally do things better when we consciously attend to them: Our consciousness allows us to be more sensitive or responsive to our environment, and so on.

Of course, a given research program may be fueled by both motives, but they may pull in different ways. It would be disingenuous to criticize an engineering design project that seeks to incorporate characteristics of self-awareness into a plant control or aircraft navigation system simply on the grounds that it gives little insight into the nature of consciousness per se.

MC, Attached and Unattached

A further distinction worth drawing is between attached and unattached MC. *Attached* (or "prosthetic") MC concerns the development of devices that may provide an already conscious individual with enhanced or additional kinds of consciousness. *Unattached* (or "autonomous") MC is targeted at developing self-standing systems that have consciousness in their own right. Seemingly, the latter provides a deeper challenge, since the former seems to "piggyback" on an existing consciousness. It is relatively easy (while still deeply challenging, of course) to integrate devices that modify an already existing conscious creature, as compared with progressing from sophisticated but phenomenally null computational systems to computational agents that have their own independent experiential awareness.

There have already been a number of breakthroughs in neural implant or perceptual supplementation technologies that count as forms of attached or prosthetic MC. An example is the tactile–visual

sensory systems developed by Bach-y-Rita and others, where blind subjects are equipped with arrays of tactile stimulus points on the back or tongue, creating patterns of two-dimensional stimulation corresponding to input from a camera attached to the head. Fluent users of such devices report experiences that are vision-like (e.g., including depth perception) but not truly visual, while not tactile either. Such devices are important in expanding our conception of what might be involved in consciousness and therefore provide useful support for the idea that computer-powered agents may have forms of experience or phenomenology that are quite different from human phenomenology but that still deserve to be called consciousness.

Human MC Versus General MC

Human consciousness is what we know best. Some would define consciousness in such a way that only humans, or beings very much like them, are conscious: for example, by requiring of conscious creatures that they be capable of certain forms of higher-order thoughts or perceptions or be otherwise self-reflective in ways that require a sophisticated cognitive apparatus involving, in the natural world, human or primate levels of intelligence. Such conceptions of consciousness, of course, lend themselves to various kinds of AI or robotic developments that mimic rich human cognitive and bodily capabilities. However, one approach to MC research seeks to replicate the consciousness of more primitive creatures—for example, concentrating on fairly simple embodied or "enactive" aspects. Other avenues of MC research deliberately avoid slavishly copying the biological realm at all, targeting only the most abstract features of existing conscious organisms in order to stretch the envelope of possibilities for what it is to be a conscious agent or system.

Super-Consciousness in Super-Intelligent Machines?

Another way in which one can extend the possibilities for MC—at least speculatively, if not currently, in terms of working systems—is by seeing human-level forms of consciousness and intelligence as a baseline from which one may go up as well as down. Thus, some researchers inspired by transhumanism, for example, may favor the view that as systems develop progressively more complex and expanded kinds of cognitive attainment, rich forms of consciousness—perhaps "superconsciousness"?—will be present in those systems, with enhanced kinds of experiences that are in some sense deeper or "higher" than those available to human subjectivity. Some are even envisaging a situation where the informational contents of individual human brains may be uploaded onto a silicon base, allowing one a form of personal, experiential survival—including a subjective sense of psychological continuity with one's former self—after the decay of one's original body. Talk of such possibilities raises deep issues concerning the philosophy of personal identity, as well as further profound questions concerning the way technologies may shape our sense of what it is to be a social being and to be conscious.

MC and Autonomy

There are many other kinds of human-like properties, besides consciousness and intelligence, that are often discussed in relation to machines. In particular, people often talk of machine "autonomy"—for example, agents that can think, plan, act, and so on, "for themselves" rather than only under direction. There are a number of ways in which the term *autonomy* can be taken, which are relevant to investigations in MC.

In its most basic sense, an *autonomous agent* is one that can choose, plan, and act "for itself" rather than merely act under external control or guidance. An airborne attack drone could be autonomous in this sense (most are remotely controlled by humans at present, but this could change). One might call this *operational* autonomy. An agent that is operationally autonomous in this minimal way does not seem to be a candidate for being considered conscious or self-aware in any deep sense.

Operational autonomy can be distinguished from *normative* autonomy. The latter might apply to a robot that is considered to be independently responsible or accountable for its decisions and actions. It is not clear what might be necessary for autonomy in this latter, stronger, sense. Arguably, some kind of conscious awareness might be a prerequisite, but this could be challenged.

A third, but related, kind of autonomy would be *social* autonomy: An agent might be considered to be a member of society in the sense of having particular kinds of social or legal rights and/or obligations. For example, social autonomy might entail rights and duties that go with the ownership of property or

wealth or with having other kinds of social status. Some kind of conscious awareness may be thought to be necessary for autonomy of this latter kind, but again, this can be disputed. In many jurisdictions, commercial corporations are considered as legally autonomous "persons," which can own property, and so on, without their being deemed to have any independent consciousness (over and above the humans who co-own or operate them). So it is a moot point if attributing social autonomy to an artificial agent implies the attribution of consciousness.

A final kind of autonomy worth mentioning is *biological* autonomy. It is often claimed that any self-standing biological organism possesses a kind of autonomy (sometimes referred to as *autopoiesis*) that enables that organism to differentiate itself from its surroundings and to maintain itself, via a set of chemical and metabolic processes, as a continuing living system. It has often been asserted that no human-engineered machine—at least if built using existing technologies—could be autonomous or autopoietic in this deep sense and, further, that it is just this lack of biological autonomy that makes the development of a genuine MC impossible or even paradoxical.

This is also a contested claim; but if it were true, then MC would be a far more limited field than many of its enthusiasts would accept. However, perhaps some form of artificial autopoiesis could be developed using computer-modeling techniques. If so, perhaps a machine that had something akin to a biological autonomy, but without itself being a biological system, could be perfected. It is far from clear what would be involved in such a possibility, but investigating it both theoretically and experimentally might be an important future development path for the field of MC, as well as for the understanding of consciousness in its natural, biological forms.

Markets and Economic Theory

This entry introduces the basic aspects of the institution of the market, describing its normative significance and basic functions. It then proceeds to examine the controversial relationship of markets to the distribution and consumption of public goods and concludes by raising some critical points.

Foundational Aspects

Economists see markets as the primary institutional site for bilateral exchange. Market exchange is *normatively* significant because the parties to the exchange are both made better off in expected terms and because exchange permits the separation of production and consumption activities, which facilitates specialization and the division of labor. The first aspect allows individuals to benefit from natural differences in tastes and talents and (in the case of international trade) differences in climate and

institutional arrangements. The second aspect allows individuals to take advantage of the productivity increases that specialization creates—increases that, according to Adam Smith, are the primary source of human progress. In this sense, markets are first and foremost an institutional device for mobilizing the benefits of human cooperation. Cooperation rather than competition is the central feature of the market order.

Basic Functions of Markets

Because market exchange is essentially *voluntary*, within the bounds set by an initial assignment of the rights and rules of contract (e.g., rules against fraud), markets are also seen by some philosophers as instantiations of *free* interactions—though most economists value "liberty," so understood for its consequences for material well-being rather than intrinsically.

A well-functioning free market performs *three functions*: (1) it allocates the available supply of goods among individual demanders according to the intensity of their effective demands (their willingness to pay), (2) it ensures that aggregate supply is distributed among suppliers so that demanders are supplied at minimal cost, and (3) it connects demand to supply by providing both the information and the incentive that suppliers require in order to meet the prevailing demand.

Nonmarket mechanisms for the allocation of goods (such as queuing or rationing) will routinely fail in one or other of the three aforementioned functions. Queuing, for example, may allow demanders to express their demand (by waiting in line) and allow suppliers to assess demand (by examining the length of the queue). But in nonmarket institutions, the waiting time given up by queuers does not translate into any benefit to suppliers, so suppliers have no incentive to adjust supply in light of the demand conditions: The critical link between demand and supply that a market would provide is thus severed.

The informational and incentive features of markets are worth special (and separate) emphasis. Within the free market system, prices constitute signals as to the value that others place on alternative activities that potential suppliers might engage in. Prices operate as a kind of gauge for measuring the effect that my choices have on the well-being of others (as they themselves assess it). In the absence of market prices, such information would be unavailable (a point mobilized against those who might look to socialist planning to simulate the beneficial effects of markets). Furthermore, in the market system, each player has an incentive to act in the way others "most prefer": The beneficial effects of markets emerge "invisibly"—that is, without those beneficial effects being the central intention of any of the participants. Put another way, the benefits of human cooperation are reaped with only a minimal claim on the players' dispositions to act "cooperatively." Achieving the beneficial effects of markets does require that participants refrain from fraud and deception—but, to some extent, markets themselves provide rewards for individuals who so refrain. A reputation for reliably good service is an asset in market transactions, especially for products whose quality is not easy to assess on inspection.

Markets and Public Goods

Although markets work broadly in the public interest for ordinary "private" goods, like apples and houses, they often fail to work well in the case of so-called public goods. Public goods are goods that all members of a relevant community consume in common, in such a way that none can be excluded from the benefits. More specifically, public goods have two properties: (1) they are *non-rival*, in the sense that each consumer enjoys full use of the good without diminishing the amount available for the other users (as in the case of a concert performance, where an "encore" for one consumer means an encore for all the others), and (2) they are *non-excludable*, in the sense that individuals who do not pay cannot be prevented from consuming what is available. Both non-rivalry and non-excludability can come in degrees, and either can be present without the other. Economists often associate public goods with "market failure," since rational actors in a market will fail to produce goods for which there is potential demand when they lack the ability to charge consumers.

Market failure is typically identified as providing scope for government intervention in markets. To be sure, many of the standard activities of governments—the provision of a legal system, with enforcement of rights; provision of national defense; and certain kinds of public health provision (including pollution control and vaccination programs)—fit the public goods categorization. But many others (such as private health provision and public housing subsidies) appear to exemplify the public goods category much less well. In these latter cases, the

standard results about market success and market failure do not support government intervention.

But nor do those results in themselves argue *against* government intervention. Any case for or against such intervention (in relation to public or private goods) requires a corresponding examination of the normative properties of the relevant institutional alternative. Such "examination" involves a specification of the incentives of agents operating in democratic political settings and an investigation of the ways in which "public supply" can be expected to respond to "citizen demand." Undertaking this exercise has been the motivation for the development of "rational actor political theory" (or "public choice theory").

Critical Issues

The general point here is that no discussion of the normative properties of any institutional arrangement—including markets—can be undertaken without an answer to the "compared with what?" question. Claims about market success and market failure only have normative bite when the analogous analysis of alternatives (primarily government action) has been completed.

Markets are often criticized—even by those who accept their many advantages—on the grounds that they give rise to distributions of income that are "unjust" or, more modestly, "could be made more equal." We do not here explore this line of criticism. We note, however, that even here the normative exercise is ultimately a comparative one: If the market fails to provide a distribution of income that meets all normative standards, it remains to be shown that the distributional modifications that emerge under alternative political institutions will predictably improve things.

Marxism and Social/Historical Explanation

This entry reviews Marx's theory of social and historical explanation and his own methodological stance vis-à-vis what counts as "science," explains what is distinctive about it, shows the way the theory was subsequently developed or altered, and ends by introducing one of the most formidable critiques and an equally powerful defense of it in the 20th century.

Introduction

Explanation as a distinctive methodological concept and problem was posed during the development of the social sciences in the later 19th and early 20th centuries. It, thus, postdates the original practices of history writing by more than 2,000 years, though various historians, beginning with Thucydides in ancient Greece, have commented on good and bad ways of being a historian. On the other hand, social science, including social theory, is a modern intellectual and academic set of disciplines, which has self-consciously generated and absorbed various methods and formalized methodologies, in particular those derived from or projected onto the physical sciences.

The methodological problems inherent in social/historical explanation thus largely postdate the major works of Karl Marx (1818–1883), though not the development of the various Marxisms through which his thought was later interpreted. Within those Marxisms, there have been notable claims and consequent debates through which the current methodological pluralisms of the social sciences and

historiography have developed. The most famous of these controversies was in the later 20th century and concerned the concept of explanation in relation to "the materialist conception of history."

Marx and "Science"

Marx considered his own work to be *wissenschaftlich*, usually translated as "scientific" but better understood as "systematic" and "rigorous." As construed by preceding German philosophers, this outlook did not pose a dichotomy between philosophy and other humanistic studies, on the one hand, and the physical sciences, on the other. Rather, it was presumed that all studies were amenable to *wissenschaftlich* treatment and methods of inquiry. This reflects the Aristotelian and Thomistic ambitions and concepts of "school philosophy" and also profoundly rejects early-modern Anglophone empiricisms that privileged a materialism of sensory experience. Thus, it is *a mistake to project a dichotomy between the natural or physical sciences and the social or human sciences onto Marx's own theorizations of history and society*. Similarly, it is also a mistake to presume that he accepted a hierarchy of methods in which the physical sciences ranked more highly than historical or other humanistic forms of knowledge production.

Marx's most original work in social theory is his claim that *historical progress (or otherwise) is marked by changes in economic practices and structures*, in particular changing technologies of production and varying systems of property and other legal relations. He occasionally identified his studies as "empirical" and his presuppositions as "material," but his works have been commonly misconstrued as endorsing various philosophical materialisms, often said to be coincident with those of the physical sciences. In his writings, Marx conceptualized human social systems *historically*, arguing that productive activities were necessarily pursued there, but always within constitutive conceptual frameworks that have distinctive histories and logical structures. Common to these historical formations were relations of domination and oppression, which he termed *class struggle*.

Marx was critical of synchronic and individualistic social theory, charging famous political economists of preceding generations with ignoring history and effectively promoting the interests of property owners, whether in land, trade, or manufacture. He also criticized conventional materialisms, even when construed as coincident with the physical sciences, and rejected the presumptions of the political economists and, by extension, of modern economists in the marginalist, mathematical tradition.

Marx was thus not particularly concerned to formulate protocols of "explanation" or to adhere closely to any particular vocabulary that would make his writings "scientific." His self-conscious comments on his work and methods were not extensive, and his now most famous effort, the Preface to *A Contribution to the Critique of Political Economy*, published in 1859 (but not widely circulated until 1897), employs a bewildering array of important concepts in relations of ambiguous synonymy. It uses the verb "explain" (*erklären*) but once and then in an apposition with the verb "judge" (*beurteilen*).

Engels and the "Materialist Dialectic"

This was not the case with Marx's close friend, political associate, and occasional coauthor Friedrich Engels (1820–1895). In 1859, he began to popularize Marx's first published version of his lifetime project, namely, a critique of political economy. Engels broached the issue of method, attributing a unique set to Marx. He parsed Marx's methodology into logical and historical divisions but failed to sustain these distinctions. However, returning to the task of conveying Marx's thought in summary form in the later 1870s, Engels published *Herr Eugen Dühring's Revolution in Science* (commonly known as *Anti-Dühring*). This was ironically titled with reference to revolution but not to science. In the intervening years, Engels had adopted an outlook that privileged the physical sciences in terms of a matter-in-motion materialism. But he also claimed to recoup what he took to be the Hegelian dialectic of progress through conceptual contradiction and developmental resolution.

Asserting that the two sides of this dichotomy were in fact coincident, Engels argued that this was the foundation of Marx's work and the guarantor of its truth in relation to both historical explanation and political prediction. In this narrative, he mirrored the intellectual currents later generalized as positivist or empirical philosophies of scientific explanation. This was a view that all sciences establish facts through specific methodologies determined by logic and nature. Explanation occurs when facts that demonstrate regularities are assembled under

laws that possess predictive power. By publishing a formidable set of new prefaces and introductions to new editions of Marx's works between 1883 and 1895, Engels effectively inserted Marx into the frameworks through which "explanation" was arising as a problem in social science. He also outlined a solution to which many Marxists adhered but against which not a few rebelled.

Historical and Dialectical Materialisms

At the close of the 19th century and during the first decade of the 20th, G. V. Plekhanov (1857–1918) and Karl Kautsky (1854–1938) circulated influential works on what Engels had formulated in 1859 as the materialist conception of history. These reproduced Engels's later methodological claims of the 1870s that Marxism comprises a universal science based on laws—common to nature, history, and thought—that would be explanatory and therefore predictive. The predominant assumption in this orthodoxy was that causal and predictive determinism—modeled on the supposed certainties of the physical sciences—would give Marxists a real advantage over their other socialist rivals.

However, both thinkers, and those in their respective Marxist communities in Russia and Germany, also grappled with the specifics of explaining particular historical and contemporary social formations. In political terms, they also addressed the apparently intractable problem of individual agency, given that "history" and "thought" were conceptualized as effects of processes that were more fundamental, more regular, more effectual, and more predictable than the apparent "voluntarism" of human decision making. Both thinkers therefore confronted contrary views as to how correct and efficacious explanations for social phenomena should be constructed; Plekhanov attempted to integrate a view of individual action into the explanatory architecture of historical materialism without contradiction, and Kautsky defended a deterministic view against the apparent contradiction generated by introducing an ethical element into Marxism.

Max Weber's (1864–1920) early-20th-century essays on "The Protestant Ethic and the Spirit of Capitalism" represented a challenge both to Marx's emphasis on the development (or otherwise) of productive activities as crucially important in historical change and in structuring social life and to Marxist claims that lawlike regularities—understood as ultimately determining for human development—were the most valid explanatory model for understanding society and politics. The distinction Weber invoked between *erklären* (clarification with objectivity) and *verstehen* (understanding with subjectivity) effectively set up the problem of explanation for the social sciences during the rest of the 20th century.

Acton's Attack and Cohen's Defence

In 1955, the British philosopher H. B. Acton (1908–1974) published a full-length polemical attack on Marxism, which he took to be a worldview based on dialectical and historical materialism. He argued that Marxism was incoherent because it attempted to combine positivism—by accepting modern science and its methods—with metaphysics—in particular Hegelian or "speculative" notions of development through contradiction. Marxists were thus projecting contradictions (which could not be empirically observed) into material phenomena (which could), so Marxism was consequently a farrago of idealism and materialism.

In his longest chapter, Acton argued that the materialist interpretation of history was either anodyne (economic factors are always of some interest and influence in historical explanations) or formulated in terms of untenable or incoherent distinctions (e.g., "basis/superstructure" or "productive forces" vs. "productive relationships"). He concluded that the Marxist version of technological determinism could not possibly be true, because it was untestable against facts and was therefore, in his view, unscientific. It was "the illusion of the epoch."

In the later 1960s, the Canadian philosopher G. A. Cohen (1941–2009) began work in the United Kingdom on a refutation of Acton's critique, though in philosophical terms quite similar to Acton's and in terms of Acton's own formulation of the issues. Eventually published in 1978, *Karl Marx's Theory of History: A Defence* caused a considerable stir in Anglophone philosophical and social science circles by claiming that if clearly and parsimoniously reformulated and if rigorously tested against historical evidence, the materialist interpretation of history as espoused by Marxists could be salvaged and successfully defended.

Following Acton, Cohen understood historical materialism as a theory of explanation applicable

to social structures and sociopolitical change. He argued that the level of development of productive forces or technologies had explanatory primacy in human history because humans were somewhat rational, possessed intelligence, and faced scarce material resources. However, Marxists had construed their explanatory claims as scientific in form and resting on fact, whereas Cohen contrarily construed these claims—reformulated by him in propositional statements—as "functional" explanations, of which Marxists and many others had always been suspicious.

In Cohen's account, functional explanations demonstrate that the character of a thing to be explained is determined by its effect on the thing that explains it. For example, production relations have a profound effect on productive forces, yet the character of productive relations is explained by the level of development of the productive forces themselves. The chain of causation thus runs opposite to the directionality of the explanation; that is, x has an effect on y, yet the character of x is explained by its functional (rather than causal) relationship with y.

Merely identifying various existent or possible functionalities did not in itself generate explanations. Cohen argued that further empirical elaborations were necessary and that, when rigorously formulated and satisfactorily evidenced, such functional explanations could be true. In Cohen's view, Darwin's theory of the origin of species by natural selection, when convincingly elaborated in specific cases, shows in what manner the useful equipment possessed by plants and animals accounts for the existence of these observable features and utilities in plants and animals themselves.

Cohen's chapter on functional explanation in the social sciences attracted even more interest than his defence of historical materialism, not the least because it addressed the social sciences and philosophies of science more generally. After more than a decade of debate, however, he withdrew his defense of functional explanation and also his defense of the materialist interpretation of history, saying that even in his own rigorous reformulation it was unfortunately false.

Displacement of the Problem

The terms of the problem of explanation were set by presumptions that the physical sciences represent a methodological ideal for the social sciences. Thomas Kuhn's (1922–1996) *The Structure of Scientific Revolutions* (1962) undermined this idealization of science and its supposed methodological unities, though Cohen chose not to engage with this challenging work. The development of poststructuralism, and in particular the "linguistic turn" in discourse analysis, together with the influence of Foucauldian archaeologies and genealogies, has for many historians and social scientists displaced methodological issues having to do with explanation and science. Marx's general ideas survive, loosely construed, in the construction of social and historical explanations, but the impetus to update Marxism as a specifically scientific and/or explanatory theory has passed.

Marxist Economics

Neither Karl Marx nor Friedrich Engels left a detailed explanation of the philosophical underpinnings of Marxist economics. Therefore, Marxist economists and other scholars of Marx's critique of political economy have had to interpret the philosophy at work in Marx's actual texts on economics, especially *Capital*, in order to understand and further develop Marxist economics. This entry includes an introduction to Marx's main texts on his philosophical approach to economics as well as an explanation of the three major interpretations of that philosophy: modernism, postmodernism, and critique.

Marx

The key source of Marxist economics is Marx's *Capital*, in three volumes. In that text, Marx develops his "critique of political economy" (the subtitle of *Capital*), in two senses: (1) a critique of capitalism and (2) a critique of the mainstream economic theory of his day that celebrated capitalism. Marx criticized capitalism because it is based on the exploitation of workers by capitalists and because it leads to recurring economic crises, and he criticized the classical political economists (e.g., Adam Smith, David Ricardo, and others) because they ignored exploitation and failed to see that capitalism's own dynamic creates periodic crises.

Marx (and, after he died, Engels) offers a few words of explanation of the philosophy guiding his writings on economics in the various prefaces and postfaces to *Capital*. But scholars tend to look to other writings, especially the Preface to *A Contribution to the Critique of Political Economy* and the Introduction to the *Grundrisse* (the notebooks Marx wrote in preparation for writing *Capital*), for the introduction of key concepts and more general statements of that philosophy. In those texts, Marx emphasizes his commitment to materialism (as opposed to idealism), the role of contradiction and historical change (in the sense that capitalism and capitalist forms of thought are neither universal nor transhistorical), and the dialectical movement from the abstract to the concrete (as a way of producing a different, many-sided knowledge of the economic and social world). Scholars have discussed and debated the philosophy of Marxist economics, based on those texts and *Capital* itself, ever since.

Modernism

Traditional interpretations of Marxist economics are based on a modernist philosophy. As David F. Ruccio and Jack Amariglio discuss in some detail, modernist Marxist economists tend to invoke a "mirror of nature" epistemology and a deterministic notion of causality. For them, *Capital* presents a science of capitalism based on an objective labor theory of value (as against, e.g., the preference-based subjective theory of value of neoclassical economics). The problem of Marxist economics, on this interpretation, is to identify the order underlying the apparent disorder of capitalism and to point in the direction of a transition from capitalist disorder to the planned order of socialism.

Exchange: Prices/Profits
↑
Production: Value/Surplus value.

One illustrative example concerns the relationship between production and exchange. According to the modernist reading, the value and surplus value (the extra value created by laborers and appropriated by capitalists) created in the orderly process of capitalist production determine, and thus explain, the prices and profits that obtain in the chaotic and uncertain realm of capitalist exchange. Since the anarchy of a capitalist economy leads to crises, modernist Marxists argue that the disorder and irrationality of private property and markets can and should be replaced by the order and rationality of state property and planning within socialism.

Postmodernism

The postmodern interpretation is quite different. The theory of knowledge is relativist (Marx's approach, like all economic theories, is distinguished by a particular entry point, logic, and set of social consequences), and causality is nondeterministic (in the sense that everything is conceived to be both cause and effect, or "overdetermined"). The aim of Marxist economics, according to this philosophy, is to produce a particular class-analytical story about capitalism and to establish a nonexploitative

or communal way of organizing the economy and social life.

Production: Value/Surplus value → Exchange: Prices/Profits.

Again, the relationship between production and exchange can be used to illustrate the approach. On the postmodern interpretation, they exist on the same level. Thus, for example, capitalists need to purchase commodity inputs at their exchange value, which are then used to produce new commodities, which in turn need to be sold to realize the embodied value and surplus value. So each commodity has two numbers attached to it—production value and exchange value—each of which determines the other. Capitalism faces problems, related to class exploitation, that occur in both production and exchange (and the interaction between them). For postmodern Marxian economists, socialism is a way of eliminating capitalist exploitation (and its consequences) and creating a situation in which workers appropriate and distribute the surplus they create.

Critique

A third interpretation is best categorized as a *non-philosophy*. The idea is that *Capital* and other economic texts by Marx are distinguished less by a fully worked-out philosophy than by an approach emphasizing the critique of existing concepts and theories. Therefore, what is of interest today is the way Marx critically engaged dominant economic ideas. Since most of the categories that appear in Marx's economic writings (including the labor theory of value) are taken over from classical political economy, what is specifically Marxian (Marx's own) is the critique of the way the classical economists conceptualized those categories. Marx deconstructed the accepted understanding of those categories, taking what was natural or given by classical economics and denaturalizing them and making them social and historical. On this reading, *Capital* is not a Marxian theory of capitalism but a Marxian critique of mainstream economists' conception and celebration of capitalism—and thus a critique of capitalism itself.

This non-philosophy can also be illustrated in terms of the relationship between production and exchange. Marx began with the strongest assumptions of classical political economy—such as the ideas of fairness and equality—in order to show that the equality of production and exchange cannot but be accompanied by a fundamental unfairness: the extraction of labor from labor power. Laborers, under capitalism, get less in the form of wages than the value they create in production. Thus, Marx's idea of exploitation is both defined by and demonstrates the impossibility of capitalist conceptions of justice. Socialism, on this interpretation, represents a refusal of capitalist economic ideas—of production, exchange, justice, and so on—and a way of imagining and creating alternative (including collective or communal) forms of economy.

Marxist Ethics

For more than a century, it has been well documented that Marx's relationship with the canonical philosophical terms of ethical inquiry is a troubled one. On one level of analysis, the troubled relationship runs parallel to the relationship between Marxism and philosophy, more generally. On another level, Marx and many Marxist thinkers have simply been skeptical of the role that ethical language plays in understanding and changing society.

This entry reviews the ambivalent nature of Marx's own pronouncement on ethics and of Marxist ethics as it developed, presents the main issues and

alternative interpretations, and raises a number of critical points.

Ambivalence

On the theoretical plane, the predominant line of Marxist thought has been to empty out philosophy into political economy. It is significant that Marx and much of Marxism followed the positivist paradigm in this. On the plane of practical struggle, Marx continually reminds us that "being determines consciousness," not the other way around; the lesson seems to be that people seek to change systems not first of all as a response to injustice but rather because they cannot live within the existing social parameters any longer. Under this paradigm, all struggle is reactive—and so ethical (and even political) concepts are epiphenomenal and insubstantial. Sometimes these concepts are even distinctly unhelpful, or they foster illusions; in Marx, there does not seem to be a difference between the ethical critique and "bourgeois moralizing," and all ethical language for Marx also carries with it theological overtones.

At the same time, Marx's writings are filled with ethical language; there are moments when he writes in the tonalities of an Old Testament prophet. However, this "ethical track" detected in Marx is clearly subordinate, and a great deal of Marxism since Marx has wrestled with the question of what to do with this subordinate track: Does one (1) excise it altogether, (2) recognize it but keep it in a subordinate position, (3) integrate it more fully with Marx's "scientific socialism," or (4) even raise it to a predominant position? Of Marxist thinkers since the time of Marx, a map of sorts can be made using these four possibilities. However, even understanding the nature of the "it" (the "ethical track," Marx's employment at times of ethical terms or terms with an ethical resonance, as, e.g., in his undisputed masterpiece, *Capital*, where Marx calls capitalists "vampires") is difficult.

Issues

One fruitful line of inquiry is to ask the following questions: Assuming that Marx does at times employ ethical language in a substantial and not merely ephiphenomenal or purely rhetorical way, is there a connection that can and should be made with thinking on ethics in the philosophical canon? Is it possible and fruitful to argue, for instance, that, insomuch as Marx's arguments have to do with ethics, this ethics most resembles the ethical theorizing of a particular figure or system?

Speaking very broadly, there are many things in Marx that find precedence in Judaism and Christianity. These systems of thought and forms of life, in turn, have been interpreted through the philosophies of Plato and Aristotle. Marx accepts the distinction in Plato between appearance and reality, though in terms of a materialist dialectic that has no need of a realm of forms. It could be argued that Marx accepts Aristotle's distinction, in the *Politics*, between caring for a household and the "mere getting of money." However, in Plato's and Aristotle's thinking, there is a central place for "the good" or "justice" as an "independent variable" as it were; such "metaphysical" and even "theological" tendencies are what Marx hopes to banish with a theory that is purely descriptive and not at all normative.

So, again, Marx's theory of labor, property, and wealth creation seems to have precedents in Thomas Aquinas and John Locke. However, there is a normative dimension in their shared sense of what is "proper" to a person—this has to do with making some part of the earth proper to oneself by mixing one's labor with the earth. In Aquinas, this notion again goes back to Aristotle, and it is the basis for the legitimate appropriation of that which, in nature, is the common inheritance of either all (even all creatures, not only humans) or, perhaps, none. In Locke, the further step is taken toward self-ownership (and the ownership of one's own body); a larger discussion of these issues would entail examining the shifts in culture and thought that allowed such a notion to gain traction. In Marx's early work, before *The German Ideology* (considered the first work of "scientific Marxism," written around 1845 but not published until 1932), Marx at least coexisted with (but sometimes actively embraced) the resonances of his work with strictly ethical terminology.

In his early work, injustice is manifest in alienation. While in his early work alienation is understood in a materialist framework, as the illegitimate expropriation of the fruits of an individual's labor (and, with the development of capitalism, the predominance of the strange "need for money," already an indication in Aristotle, Aquinas, and the Renaissance tradition of civic republicanism, of which Thomas Jefferson was one important inheritor, that something in society is increasingly out of

kilter), in the later work the notion of alienation is replaced by that of exploitation (specifically, exploitation of the ability to work, or "labor-power," as Marx called it), and this is given a purely mechanistic definition. Exploitation is a mechanism that, as it unfolds in the midst of other mechanisms (technical change, the tendency of the rate of profit to fall, the rising organic composition of capital, the increasing preponderance of "dead labor" over "living labor," the increasing impoverishment of the proletariat—but this last is not a category of ethical judgment), leads to crises of capital, and first of all a crisis of overproduction. None of this in Marx's view requires ethical categories—or, again, perhaps not even philosophical categories more generally, except perhaps for some concept of dialectics.

That exploitation—and the articulation of a society based on exploitation (of "labor-power")—is oppressive, that it requires political mechanisms that are those of domination, and that it requires ideological mechanisms that foster false consciousness (significantly, on the model of religion and with the help of "metaphysics") cannot be doubted, not even by Marx. Indeed, he opened up the examination of these mechanisms in a whole new way. But to discuss all of these things in ethical terms is beside the point. It is beside the point politically, economically, and socially, at best a distraction and mere sentimentality and at worst a fostering of dangerous illusions, another way of promoting *false consciousness*.

Coming at this from the other direction (which leads not to the breakdown of capitalism but rather to the formation of an alternative), the basis of working-class or proletarian solidarity *is not ethical*. This is a key point for Marx and for almost all that has called itself "Marxism": The basis of solidarity is not ethics but, rather, *interests*. As one might expect, granting a central place for the interests of the working class (which, of course, Marx does in a thoroughly systematic and rigorous way—these are not interests understood crudely or narrowly) brings Marx into proximity with utilitarianism.

Recent Alternative Interpretations

This line of analysis has led, in more recent years, to the interweaving of methodological individualism and rational choice theory with certain aspects of Marxism, as seen in the work of Jon Elster and others. This discussion was presaged in certain aspects by the debate in French Marxism in the 1960s on the question of humanism (Jean-Paul Sartre) and antihumanism (Luis Althusser). It is indicative to point out, in relation to our discussion of Marxist ethics, that Althusser and other structuralist Marxists advocated "theoretical antihumanism," an antiteleological, antihistoricist version of scientific Marxism, combined with "practical humanism." On the other hand, a different approach, the explicit articulation of Marxism as a form of utilitarianism, is found in the work of Steven Lukes and David Schweickart (the latter a leading proponent of market socialism).

There has been a great deal of discussion on the question of whether it is possible to get Kant and Marx on the same page, perhaps with the help of Aristotle. It is even conceivable to imagine anything recognizable of Marx or Marxism that is at the same time a form of moral realism or moral cognitivism in the broad sense of recognizing ethical questions as real and not simply epiphenomenal or merely ideological or rhetorical.

Contemporary Critical Challenges

The emergence, in the 20th century, of capitalism as an integrated, global system, one that takes up into itself the oppressive schemes of colonialism, patriarchy, racial hierarchy, and heteronormativity, makes these pressing questions. Two things seem clear by now. First, a calculus of interests alone will not close the gaps in such a way as to ground an effective and enduring solidarity. Second, for all that Marx was right to expose bourgeois moralizing (this is still an important aspect of ideology critique), even if there are moments when this exposure seems misdirected (as in the case of animal concerns, for example), it was wrong to go so far as to dismiss "the ethical" altogether.

One place to start with a correction of Marx on these points is a response to Hegel's dismissal of Kant's ethics as "empty formalism," a dismissal that Marx and Engels affirmed.

Finally, the term *Marxist ethics* also has another, somewhat different connotation: If one is a socialist, Marxist, or communist, what "ethics" should one have? Is there a "proletarian" ethics? Is there a sense in which ethics (and politics, for that matter) could be both "universal" and "partisan" at the same time? Marx urged that the proletariat must liberate itself and all humankind, too. Is there a way to contribute

to this emancipatory task that does not sacrifice ethics to "politics" or even to economics or revolutionary military tactics? Even though these questions have also been debated for more than a century, the challenge of the new century will almost certainly require new approaches. However, there remains much that deserves to be brought forward, even if recast in significant ways, in the tradition of ethical thought that Marx and Engels were too quick to leave behind.

Mathematical Models, Use in the Social Sciences

Mathematics, in general, is widely used in social science disciplines such as economics, sociology, and political science. Mathematical models, in particular, are used to study phenomena that are very different in nature, such as individual economic behavior, population growth, and aggregation in urban areas. The branches of mathematics used in these models are also very different: They span differential equations, matrix calculus, computational algorithms, probability, and statistics.

This entry focuses on the use of probability and statistics in "structural models." These are models used in quantitative (causal) analysis in, for example, econometrics or demography. One reason to focus on structural models is the vivid debate they generate, especially with respect to the notions of *causation*, *intervention*, and *mechanism*—notions central to the social sciences.

Probability theory and statistics offer tools to analyze random phenomena, such as coin tossing or waiting time in a queue, or more complex social phenomena, such as migration behavior or changes in mortality, morbidity, and fertility of populations. Probability and statistics are very useful in the analysis of data collected through censuses, surveys, or other types of methods. Data are observations about a number of different aspects of populations or individuals and are organized into *variables*. There are different types of variables that can be categorized according to the following criteria:

Genre and scale: continuous/discrete, quantitative/qualitative

Role: explanatory/response, observed/latent/instrumental/proxy

Level: individual/aggregate

Field: socioeconomic/demographic/biological/and so on

Quantitative analysis has a long tradition, starting with the pioneering and seminal works of the demographer and astronomer Adolphe Quetelet and the sociologist Émile Durkheim. Major improvements have been done by, to name a few, Sewall Wright and Otis Dudley Duncan, up to the most recent advancement by econometricians such as Jim Heckman or Kevin Hoover and computer scientists such as Judea Pearl or Peter Spirtes, Clark Glymour, and Richard Scheines. What is peculiar to this development is that while the early methodologists overtly and explicitly adopted a causalist perspective, the most recent generations have shown some skepticism as to whether we can infer causation from statistics.

The use of probability and statistics in the social sciences has consequences for the kind of explanation that the models offer. Statistical explanations

are partial and incomplete in the sense that no phenomenon will be "fully" explained. Any explanations will carry a certain amount of indeterminacy. However, this is not necessarily a statement about the social phenomena themselves but just about our *knowledge of them*.

Quantitative analysis can be used to provide a description of a social phenomenon (*associational models*) or to go beyond description and to find out its causes (*causal models*). More precisely, associational models study how one variable changes in response to changes in other variables. For instance, a number of studies in the 1960s revealed that in developing countries, variations in child survival rates were constantly associated to variations in levels of maternal education: Child survival was higher for higher levels of maternal education. Causal models try to go beyond associations by imposing further constraints that allow interpreting associations causally. For instance, to follow up on the same example, in the 1980s, a more structured model to explain the association between mother's education and child survival was proposed. This model introduced a structure of proximate biological factors (e.g., nutrient deficiency) and more remote social factors (access to infrastructures) that explained the intermediate steps between mother's education and child survival. In addition to adding "theoretical" support to the associations, causal models have a more sophisticated statistical apparatus.

Both associational and causal models share a minimum set of "technical features." Notably, both kinds of model make assumptions about some characteristics of the variables (typically, normality, linearity, nonmeasurement error, and noncorrelation of error terms.). The apparatus of causal models is, however, richer, and this is what allows us to interpret models causally. In particular, causal models (ought to) (a) make background knowledge explicit, (b) specify the conceptual hypothesis to put forward for empirical testing, and (c) make a number of assumptions that go beyond statistics, for instance, about causal ordering of the variables or the underlying mechanism, about the structure of the causal relation, or about sufficiency (viz., that all and only the relevant factors have been included in the model).

Another important difference between associational and causal models lies in the tests they perform on the joint variations between variables of interest. Associational models are mainly concerned with ensuring that co-variation is not spurious. Causal models go much further, instead, and perform a number of additional tests. Tests for invariance, for instance, are meant to ensure that the (putative) causal relation is sufficiently stable across different partitions of the data set or under suitable interventions. Tests for exogeneity are instead meant to ensure that causes and effects are correctly "separated" and therefore the causal structure is correct. This last test is performed against the "recursive decomposition," which breaks down an initial joint probability distribution into "smaller" pieces.

Two issues are worth emphasizing. First, according to some interpretations of causal models, the recursive decomposition may be viewed as representing a mechanism underlying the data (also called *data-generating process*). Thus, the recursive decomposition carries explanatory power insofar as it gives the "functioning" of the underlying mechanism. Second, the condition of invariance is a matter of controversy. According to one school of thought, invariance has to be tested against manipulations (whether actual or ideal) of the putative cause. But according to another view, invariance doesn't need to be tested against manipulations. It is often the case in the social sciences that manipulations are unfeasible or meaningless. In such cases, invariance is simply tested across chosen partitions of the population.

There is an important caveat. The mathematization of social research certainly is a positive step forward. Mathematization allows great precision in analysis, and it allows comparisons between different studies. However, it is questionable whether this mathematization, *alone*, solves all the problems related to causal inference, explanation, or prediction. Making background knowledge explicit looms large in making social studies as objective as possible. This also means having an overarching view of modeling, where statistical testing is but one part.

Mechanism and Mechanismic Explanation

This entry introduces the notion of mechanism in relation to that of system and shows the relevance of mechanism to explanation in both the natural and the social sciences.

Most things in nature and in society are composite: Only the elementary particles in empty space are simple, and even so just for a while. There are two kinds of composite things: agglomerates, such as sand dunes and spontaneous crowds, and systems, such as molecules and families. Unlike agglomerates, systems are structured.

System and Mechanism

A *system* can be identified by its composition or set of parts, structure (or set of relations among its parts), and environment or context. This description suffices for systems of symbols or of concepts, such as sonnets or proofs, but not for concrete systems, such as crystals or governments.

If concrete, a system has also one or more mechanisms, or characteristic processes. For example, metabolism and cell division are mechanisms of most living cells, and trade and competition are market mechanisms. In sum, a concrete system can be modeled by the ordered quadruple *composition–environment–structure–mechanism*.

The first two components of this quadruple suffice to characterize an agglomerate and the first three, a symbolic system. The five concepts in question should enjoy pride of place in any metaphysics, but they don't, because most metaphysicians care more for possible worlds than for the real world. In fact, the term *mechanism* has been practically absent from philosophy.

True, mechanisms have made a sort of cameo appearance in the recent philosophy of science literature, but in a loose way and, in particular, detached from system and, thus, remote from the usage of "mechanism" in science and technology. In these fields, it has been ubiquitous since the Scientific Revolution. Let us look at a few examples.

The concepts of system and mechanism are likely to have been used tacitly by craftsmen and engineers since remote antiquity. But they emerged explicitly only around 1600 in both astronomy and physiology: Recall the expressions "planetary system" and "cardiovascular system." Before that time, the Sun and its planets had been treated in isolation from one another, and only Newton provided the cement—gravity—that held those bodies together into a system. Likewise, before William Harvey, the organs of the human body were viewed separately from one another, and nobody knew that the heart's contractions and swellings kept the blood circulating.

Note that neither gravity nor the heart's systoles and diastoles are mechanical mechanisms. In fact, throughout modernity, the original concept of a mechanism as a mechanical contraption was silently broadened to all the fields of knowledge—unbeknown to most philosophers.

Here are a few examples of nonmechanical mechanisms. (a) The impressed electric field (voltage) moves the electric charges around a circuit, which in turn generate a magnetic field that opposes the current (self-induction). (b) Two of the more prevalent mechanisms that explain chemical reactions are electron transfer (electrovalent bond) and electron sharing (covalent bond). (c) Darwin explained evolution by two main processes: inheritance with modification and natural selection—both of which proceed from birth. (d) Aversive memories are extinguished not by the superego but by the cannabinoids secreted by our own bodies: These molecules wreck the neuronal process in the organ that stores such memories—the amygdala. (e) The central banks implement metamechanisms, such as currency control, to control the trade mechanisms. (f) Dogmatic education, bribing, censorship, and repression are mechanisms for checking the invention of ideas and practices feared to destabilize the mechanisms designed to prop up the powers that be.

Because a number of mechanisms may operate in parallel in one and the same system and because some of them may interfere with one another, it is convenient to distinguish essential from nonessential mechanisms. The former are those peculiar to systems of a certain kind, whereas the latter may also occur in systems of different kinds. For example,

contraction is essential to a muscle but inessential to a cell, and loaning money is essential to a bank but optional for a manufacturer.

We are now ready to propose and refine this definition: An *essential mechanism* of a system is its peculiar functioning or activity. In other words, an essential mechanism is the specific function of a system—that is, the process that only it and its kind can undergo. So much for mechanisms; let us now explore their role in explanation.

Explanation and Mechanism

The disclosure of mechanism is central to explanation. In fact, this is what counts as explanation in the sciences and technologies: to find out how things work and what their mechanisms or modi operandi are. In contrast, the pseudoscientists do not look for mechanisms. For example, parapsychologists do not explain how psychokinesis (moving things by sheer mental power) works, and believers in homeopathy do not exhibit the mechanism whereby a highly diluted solution, such as one with a single molecule of the "active principle" per galaxy, could cause or inhibit a biological process.

A similar reasoning is used to evaluate inventions: No patent is ever granted unless the inventor succeeds in explaining how the novel device works. This is why the most effective way for a patent office to deny a patent on an allegedly revolutionary design is to point out that the proposed mechanism is incompatible with well-known laws, such as the law of conservation of energy. No law, no possible mechanism; and no mechanism, no explanation. No wonder then that the hallmark of modern science is the search for the mechanisms behind facts, rather than the mindless search for data and the statistical correlations among them.

The standard conception of explanation in terms of law(s) and circumstance may be called *subsumptive*, as it subsumes the particular under the general. A *mechanismic* explanation, by contrast, resorts to law statements referring to mechanisms.

Here is an example from sociology and management science: "The inertia [resistance to change] of a social system is proportional to its size." This explains why even friendly takeovers, which require quick adaptations, are hazardous to corporations. In turn, the relevance of size to inertia is explained by the need for face-to-face (or at least screen-to-screen) contacts to maintain the cohesion of the system and, thus, ensure its behaving as a unit.

To put it schematically, we have split the initial statement "↑Bulkiness ⇒ ↑Inertia" into "↑Bulkiness ⇒ ↓Contacts" and "↓Contacts ⇒ ↑Inertia."

This argument is clarified when expressed with the help of the standard symbolism of elementary logic. We started with a law statement of the form "$\forall x(Ax \Rightarrow Bx)$" and analyzed it as the conjunction of hypotheses of the forms "$\forall x(Ax \Rightarrow Mx)$" and "$\forall x(Mx \Rightarrow Bx)$," where M refers to a key feature of some mechanism. When handling a particular fact, such as the failure of a megacorporation that resulted from the merger of two successful businesses, we must conjoin the former premises with information about the increase in size.

To summarize, look for system and explain by reference to mechanism.

Mereology: Parts and Wholes

The relationship of part to whole is familiar and universal. Like the relationship between a house and its front door, an elephant and its trunk, and Beethoven's *Eroica* and its first chord, we find part–whole relations all around and grasp the notion intuitively from infancy. Despite the ubiquitous applicability of the concept of part, and its not infrequent intrusion into philosophical discussion, it was not until the 20th century that philosophers and logicians progressed from an intuitive understanding to the first formal

axiomatic theories of part and whole. The general idea was envisaged but not executed by Edmund Husserl in 1901; it was then executed sketchily by Alfred North Whitehead and precisely by Stanisław Lesniewski in 1915. The axiomatic theory of part and whole became generally known to the English-speaking logico-philosophical world in 1940 under the title "calculus of individuals," after a paper of that name by Henry S. Leonard and Nelson Goodman. From the 1980s onward, it entered the toolkit of postpositivist ontology and is now an indispensable component of modern analytic metaphysics and its applications. The theory of part and whole is generally known by the name *mereology*, given to it in the 1920s by Lesniewski, from the Greek *meros*, "part."

This entry elucidates the core formal characteristics of the part relation, indicates what formal properties have been ascribed to it beyond this core and why, and considers what variations and extensions have been proposed concerning the part relation. We will look at several philosophical controversies that revolve around part–whole relations, before considering crucial applications of mereology outside philosophy. Mereological themes can be found in many different philosophical subfields, but the philosophical foundation of part–whole relations is of particular importance to the philosophy of the social sciences in view of the holism/individualism debate.

Core Formal Properties

The basic notion of one thing being a part of another is so familiar that it hardly needs introduction. But on reflection, we find that for a relation to be a part relation, it has to fulfill a small number of formal (logical) requirements. These may be set out as follows:

Existence: Nothing can be a part of another thing unless both things exist.

Irreflexivity: If one thing is a part of another, they cannot be the same thing.

Transitivity: If one thing is a part of another and the second thing is a part of a third, then the first is also a part of the third.

Supplementation: If one thing is a part of another, then the larger thing must have an additional part that is not shared with the smaller.

These requirements may be set out with a modicum more formality using variables and logical notions as follows, where the modal component of the above vernacular statements is transferred to the status of the principles as statements.

Existence: For all a and b, if a is a part of b, then a exists and b exists.

Irreflexivity: For all a and b, if a is part of b, then b is not identical with a.

Transitivity: For all a, b, and c, if a is a part of b and b is a part of c, then a is a part of c.

To prepare for the next requirement of supplementation, we define a couple of auxiliary notions:

Ingredient: a is an ingredient of b iff (definition) a is a part of b or a is identical with b.

Overlap: a overlaps b iff (definition) for some x, x is an ingredient of both a and b.

Supplementation: For all a and b, if a is a part of b, then for some x, x is a part of b and x does not overlap a.

The formal principles can be, and usually are, clothed in symbols, but they make no difference to the meaning intended.

Any relation that purports to be a part relation has to satisfy these principles, which can be taken to be analytic of the part relation. Other relations may by chance fulfill the principles, but only a relation that satisfies them by necessity is a part relation. Other than elucidating these formal properties and giving examples, the notion of part cannot be further explicated. While the notion of part is ontological rather than logical, it comes as close to being logical as an ontological relation can be. It is explicated by its formal properties. It is thus one of the principal notions of formal ontology.

Beyond the Core

So far we have expounded only the formal core of the part relation. But in many or most formal treatments, additional properties are ascribed to it. The two most important and frequently invoked properties are as follows:

Extensionality: Any things having parts and having the same parts are identical. For all a and b, if a and b both have parts and every part of a is a part of b and vice versa, then a is identical with b.

Summation: For any collection of (existing) objects *A*, there exists an object consisting of the objects in *A* and nothing else. For all *A*, if all of *A* exist, then there exists an object *s* such that every one of *A* is a part of *s* and every part of *s* overlaps one of *A*.

Of these, the former, the principle of (mereological) extensionality, is by a wide margin the less controversial. Most formal theories of part and whole assume it. In many contexts, it is self-evidently correct, so that finding potential counterexamples is not easy. The most likely counterexamples concern cases involving a material object and the matter of which it is made. For example, a clay statue and the lump of clay of which it is made seem to have the same parts, yet they may not be the same thing, because the clay may survive distortion and separation but the statue may not. However, there are theories that proclaim the clay and the statue to be identical and other theories that proclaim them to be different but not having the same parts. For example, if the clay predates the statue, then it is said that it has temporal parts that the statue lacks. Both of these strategies enable the Principle of Mereological Extensionality to be preserved: Both are metaphysically controversial. This offers an initial indication that mereological theory may go to the heart of metaphysics.

The Summation Principle is relatively much more controversial. It states that any existing objects whatever compose an individual, and for this reason, it is sometimes called the Principle of Universal Composition. Where objects are widely separated in space and time and/or come from diverse ontological categories, it is relatively less plausible than when objects form a relatively homogeneous category, as, for example, under forms of materialistic nominalism. We shall return to consider Summation below.

The motivation for the additional principles of Extensionality and Summation derives from the context in which modern formal mereology was born. In Leśniewski, mereology served as a nominalistic ersatz for set theory, and for this reason, it was expedient that its principles be as strong as possible, in fact amounting to those of an extended Boolean algebra minus the null element. In the case of Whitehead, mereology was formulated to serve as an acceptable ontological basis for physical geometry. In its first embodiment, Whitehead's mereology applied to a domain of four-dimensional events, and in its second, it applied to the spatiotemporal regions occupied by events. Whitehead did not accept the Summation Principle, since one of its consequences is that there is a unique maximal individual, the sum of everything, whereas he considered that everything both is and has a part (for the opposite view of *mereological nihilism,* see the entry on Nihilism). Nevertheless, the homogeneity of his domains means that Extensionality is unproblematic for him, as for Leśniewski. Away from such mathematical motivations, and in particular in application to everyday objects, the noncore principles lose a good deal of their plausibility. Nevertheless, there have been many metaphysicians who accept the strongest theory, that of Leśniewski, which is usually known as Classical Extensional Mereology. Much ingenuity has gone into the investigation of different primitives and axiom systems, all resulting in what is from a metaphysical point of view the same theory.

A further consequence of Whitehead's principle that everything has a part is anti-atomism. A mereological atom is an object that has no parts. Therefore, Whitehead considers that there are no atoms. By contrast, atomism states that everything is completely composed of atoms. Leśniewski's mereology leaves the question of atomism open: It can be extended by atomistic, anti-atomism, or indeed a third hybrid position. Empirical considerations also seem incapable at present of resolving the question of whether the world is atomistic or not.

Metaphysical Controversies

Many metaphysical disputes have a mereological dimension. For example, there is the question of whether substances can have parts (Leibniz: No) or whether substances can have other substances as parts (Spinoza: No, because only the biggest whole is a substance; Aristotle: No, because the parts of substances are not substances; Descartes: strictly No, because God is the sole substance and has no parts, but nonstrictly Yes, because spatially extended bodies are substances and can have other such bodies as parts).

Some metaphysical controversies, however, turn directly on mereology, most especially the question as to when a collection of things mereologically compose another thing. This is known, following Van Inwagen, as the Special Composition Question. Here, several kinds of answer can be and have been given: Never, because all that exists are atoms and they never compose anything (mereological nihilism); Never, because there is only the whole and it has no parts (Parmenidean monism); Always

(mereological universalism); and, finally, Sometimes but not Always. The last kind of answer breaks down into types according to the condition under which smaller things compose larger things. Van Inwagen himself proposes a fairly extreme view, *organicism*, according to which, things only compose a larger thing when the smaller things are atoms and the larger thing is an organism. So table legs as parts of tables and hands as parts of humans are out, in the first case, because neither table legs nor tables exist, and, in the second, because hands do not exist though humans do. According to common sense, things sometimes, but not always, compose larger things, but common sense harbors no principles as to when or why.

One reason offered in support of universalism is that it allows a simple answer to the question as to the relation between a composite whole and the complete collection of its parts or, alternatively, of its atomic parts. The thesis of composition as identity says that the whole simply is identical to this collection: They are it, and it is them. The disadvantage of this position is that it makes one thing, the whole, identical to many things, the parts taken together, which some consider to violate the logic of number.

An older mereological controversy with roots in medieval discussion is whether an object has its parts essentially. An object *a* has a part *b* essentially if *a* could not exist and fail to have *b* as a part. The view that every object has all its parts essentially is known as mereological essentialism. The most prominent modern representative of this view is Roderick Chisholm. The view has to explain the common-sense observation that most physical objects, such as stars, organisms, and artifacts, may change their parts over time and might have had other parts than those they do have. The usual way around this for mereological essentialists is to claim that only metaphysically second-rate objects flout essentialism, while "genuine" objects satisfy it. Away from the controversy, it remains of interest whether any objects satisfy essentialism. Events and regions of space and time seem good candidates, while physical objects do not. For the latter, one may still enquire which if any of an object's parts are essential to it: So to an atom, its nucleons appear essential; to a man, his hair is inessential; while for cases like a human's brain, it is not clear. A virtue of essentialism is that it answers the truthmaker problem for true part–whole propositions, the question as to what object or objects simply by existing necessitate the truth of the proposition. In a case of essentialism, the simple answer is "the whole." For nonessentialist cases, another and as yet untried solution must be found.

Variants and Extensions

Mereology is typically pursued logically as a theory of one binary relation, part–whole, and its cognates. But in application, additional factors enter in, notably time. Where an object like a car undergoes repair involving the replacement of one part by another, the simple binary relation generally does not specify the additional factor, which concerns when certain objects are parts of others. A part may, for example, be transitory or temporary, or it may be permanent, part of its whole as long as the whole exists. It may be an initial part, a terminal part, or a part the whole has partway through its life. To formulate such propositions, one must either add tense to the mereological propositions or relativize the part–whole relation to time. By adding the temporal specification "at *t*" to each of the predicates of the Core Mereology, or also its extensions, one obtains mereology for a time, or Synchronic Mereology. For example, a piston cannot be a part of a car at a time unless both piston and car exist at that time. Similar is the case for the other principles. Considerations of time, however, tend to undermine compositional universalism. It stretches credulity to envisage a whole consisting solely of Napoleon's left foot and Bismarck's moustache, which ceases to exist at the death of Napoleon and comes back into existence with the first labial hirsute growth of the Iron Chancellor.

Synchronic Mereology offers no guidance on what to do about identity through time, such as whether a certain object is required to have certain others as permanent parts or how the gain and loss of parts might affect the existence and identity of wholes. One notorious metaphysical conundrum concerns the fabled *Ship of Theseus*, which over time had all its parts replaced, so that philosophers disputed whether after the change it was the same ship or not. Thomas Hobbes compounded the agony by supposing the original parts to be saved and then reassembled, giving rise to two competing candidates to be considered as Theseus's ship. Mereology is needed to formulate the problem, but it does not on its own provide a solution. For mereological

essentialists, for example, the ship ceases to exist the moment the smallest part is removed, but this answer is too remote from standard practice and language to command assent, except among certain metaphysical purists.

Mereological essentialism requires modal notions for its formulation, whether necessity and possibility applied to whole sentences or essentiality applied to predicates. However, beyond the formulation of concepts of essential and accidental parts and wholes and the discussion of the merits of mereological essentialism modal mereology has remained rather undeveloped.

Collection and Mass

Mereology standardly concerns itself with relations among individuals: the leaf and the tree, for example. But formally, exactly analogous constructions apply to collections consisting of more than one individual. The left-handed children in a school class form part of the class, and in many contexts, "part of" and "some of" are interchangeable. A single child is like a mereological atom: No part of it is one of the collection of children in the class. Questions of essential and accidental parts apply to collections in the same way as they do among individuals. This use of mereology is clearly of interest to sociobiology and social science, where groups of people or other animals are under consideration. Likewise, the ontology of part and whole applies to masses, in particular to masses of matter: The gin in a gimlet is part of the cocktail, though it is not an individual but a mass of stuff.

Mereological Vagueness

Mereology has traditionally been pursued in logic on the assumption that of any two objects *a* and *b*, *a* is either a part of *b* or not and there is no third case. But in real life, we often come across cases where it is unclear, for whatever reason, whether *a* is a part of *b* or not. This applies especially to changing things, such as organisms, stars, rivers, and social groupings. The thought that it may not be determinate what *a*'s parts are gives rise to the idea of ontic vagueness, vagueness of the identity of objects. The nature of vagueness is a disputed territory in philosophy, but whichever solutions are offered, they need to apply plausibly to purported cases of ontic vagueness.

Kinds of Part

When discussing ontological categories, such as processes and material objects, or collections and masses, it is fair to assume homogeneity of parts and wholes: Parts of material objects are material objects, parts of processes are processes, and so on. A second perspective is afforded bydiffering kinds of part. We have already encountered essential and accidental, temporary and permanent, atomic and composite, but most of the parts in which we take natural cognitive and scientific interest come in different kinds. This is particularly important in applications and will be discussed below. The fact that we take special interest in certain kinds of part, functional parts in organisms and artifacts, for instance, allows mereology to serve as a general ontological framework within which questions of the nature and working of composite items from many categories can be debated. These varieties of kinds of part can be traced without compromising the univocity of the part relation among individuals, and they afford some reason for compositional universalists to claim that while their arbitrary sums may not be interesting, they are at least consistent and harmless and offer an encompassing framework for all the kinds of part in which we are interested.

Applications

Its universality renders mereology supremely applicable, and it automatically enters into anatomy, physical geography, engineering, and social theory, to name just some obvious areas. In anatomy, the delineation and description of parts and their layout is what the science is about, while physical geography is the anatomy of geophysical parts as well as less clearly bulky features, such as valleys and cliff faces. In engineering, the whole point is to construct artifacts from parts that can be suitably manufactured and assembled and that when in situ and in action perform their intended function. And sociology is centrally concerned with different parts of society and smaller social groups, such as classes, age-groups, institutions, migrants, children, and so on. In all of these cases, mereology offers its neutral conceptual framework, and as the electronic acquisition, storage, and manipulation of increasingly complex data from such areas increase, the use and proper formulation of mereological concepts and principles in the relevant databases acquire increased

importance. In future, mereology will be of greater interest to practitioners than to logicians.

Metacognition and Agency

Metacognition of agency is defined as the person's knowledge of the extent to which the self is in control. The ability to know about one's own causal impact on the world and on other people and to make attributions of self-agency accurately is essential in many domains, including the attribution of credit and blame. As such, it has legal implications. The cognitive characteristic that most poignantly characterizes the insanity seen in schizophrenia is the individual's loss of this ability to know whether or not the self was the agent—whether he or she did something or whether it occurred as a result of an external agent or accidental force.

The ability to exercise control over one's actions—to both be an intentional agent and to know that one is—is at the heart of what is meant to be an autonomous, self-controlling human being. Metacognition of agency is related to people's perceptions of intentionally willing or planning an action and then causing that action to happen. As such, it is inevitably linked to questions of free will and intentionality. Some researchers have argued that because people can be radically wrong in their judgments of agency—believing that they have done things when they have not and have not done things when they have—the construct of free will is suspect. Despite the importance of agency, the ontological status of this philosophical and psychological construct is still open to debate. Most scientists agree that the intention, at least for purposes of scientific investigation, cannot be considered as something separate from the brain or as a nonphysical entity that, nevertheless, causes a physical brain/body reaction. The mind does not tell our brain to do something that is then actualized materially. But, at the same time, there is unequivocal support for the idea that brain-based top-down processing, whereby actions are instigated by and modulated in conjunction with plans and expectations, is a fact of human mental life.

Cognitive scientists sidestep the issue of whether, when apparent intention–action correspondences do occur, they do so because people have free will, and they instead focus on the factors that contribute to people's feelings of being in control. The uncontested conclusion that has emerged is that knowledge of one's own agency—rather than being direct knowledge that is inherently and infallibly available to the individual—depends instead on particular cues that people use to make their judgments. Some of these cues are inherently diagnostic, while some are not.

The most diagnostic, and extensively studied, of these cues is the potential discrepancy between the individual's plans and expectations, and the outcome. According to this scheme, when a person has a goal, it gives rise to an internal model of his or her intentions (called the inverse model) and expectations (called the forward model) about achieving the goal. This initiates a motor plan that provides the specifications about what needs to be done to achieve the

goal. The plan runs simultaneously with the person's motor actions. A comparator mechanism evaluates the correspondence of the actions and the plan. When the two streams match, the person is in control; when they mismatch, it is a usable cue that the person is not in control. A mismatch can also trigger a motor correction. This mismatch signal could be processed unconsciously. Indeed, some studies have provided evidence that it sometimes is unconscious insofar as appropriate motor adjustments are made without conscious awareness about the nature of the adjustment. In some circumstances, though, it can provide a diagnostic signal to a metacognitive monitor concerning whether or not the person was in control. Conditions, such as when external interference or turbulence is systematically manipulated to distort a movement, have been used to allow evaluation of the use of a discrepancy cue in the judgment process. When such a mismatch signal occurs, people reliably report that they feel out of control.

This diagnostic "mismatch" cue is not the only cue that contributes to people's judgments of agency, however. Judgments of agency are also affected by a delay in the effect of people's actions. Furthermore, nondiagnostic cues also contribute to these judgments. Judgments of agency are strongly influenced by people's perception of performance. When outcomes are good, people tend to say that they were in control; when outcomes are bad, they tend to say that they were not in control, regardless of the extent of their actual control. Patients with schizophrenia use this nondiagnostic cue in making agency judgments, to the exclusion of the diagnostic "mismatch" cue. The mirror neuron system, too, appears to contribute a spurious cue by providing internal evidence that other people's actions are one's own. The pervasively seen claim that individuals are disproportionately responsible for shared tasks suggests that people are inclined to take credit for other people's actions as well as their own. Finally, judgments of agency are influenced by feelings of reward. For example, Matthew Kirkpatrick and colleagues found that when methamphetamine users received the drug as compared with a placebo, their feelings of being in control were inflated, even though their performance was not. Young children also respond to artificially induced increases in performance as if they were increases in their own agency, whereas young and older adults are less likely to do so.

While these cues may contribute to people's judgments of agency, the self-referential judgment is itself distinct from the cues that provide its informational basis. The cues alone, as noted above, could exert control over behavior without participants becoming aware of them or their implications for the role of the self in action. Indeed, it is highly likely that nonhuman primates have in place many of the systems that provide the cues that people use to assess their own agency. They control their complex movements with remarkable grace, they respond to reward, they can evaluate performance, and they have a mirror neuron system. But while the underlying cues are almost certainly present, what is unknown is whether nonhuman primates also have a sense of self and the capability to relate these cues in a self-referential way to produce full-blown metacognition of agency. In humans, though, although their use can sometimes be faulty, these underlying cues are used to make self-referential judgments about the individual's own personal responsibility for causing an action.

Studies that have investigated human brain correlates of metacognition of agency underline the distinction between the ongoing cues to agency that occur while the individual is performing a task and the self referential judgment that occurs retrospectively. Many studies have shown the involvement of an area in the right parietal junction in particular, which is related to processing of a discrepancy introduced into a motor task. Studies have also shown evidence of caudate-reward system involvement when movements are running off smoothly according to plan and people are "in control." However, the activation during the judgment phase is in a different location from those seen during task performance—an area of the frontal cortex (BA10) that has been shown to be related both to metacognitive and to self-referential processing.

Metaphor

The cognitive linguistic view of metaphor has a large number of implications for the social sciences. This entry discusses five general issues related to metaphor that are important for all social sciences: (1) the issue of the relationship between concepts and metaphors; (2) the issue of the types of understanding we have of the social world; (3) the issue of which metaphors are universal and which ones are nonuniversal, and why; (4) the issue of the distribution of metaphor in social-cultural life; and (5) the issue of the function of metaphor in social science.

Conceptual Metaphor Theory

It is useful to think of metaphor very broadly as conceptualizing one domain of experience in terms of another. The domain of experience that is used to comprehend another domain is typically more physical, more directly experienced, and better known than the domain we wish to comprehend, which is typically more abstract, less directly experienced, and less known. In the cognitive linguistic view of metaphor, originated in George Lakoff and Mark Johnson's *Metaphors We Live By*, the more concrete domain is called the *source domain* and the more abstract one is called the *target domain*. Domains of experience are represented in the mind as *concepts* given as mental frames. Hence, we talk about *conceptual* metaphors.

Thus, on this view, metaphor is a set of correspondences, or mappings, between the elements of two mental frames. For example, a set of correspondences between a traveler and a person leading a life, the way the traveler is going and the manner in which the person lives, the destination the traveler

wants to reach and the life goals of the person, the physical obstacles along the way and the difficulties the person has in life, all constitute the set of mappings that make up the conceptual metaphor *life is a journey*. A conceptual metaphor typically has a number of linguistic manifestations (metaphorically used words and more complex expressions) to talk about the target domain. In the example, the sentences "I *hit a roadblock*," "She *wanders aimlessly* in life," "This is not the *right way* to live," and so on, make manifest, or simply express, correspondences between the elements of obstacle and difficulty, destination and purpose, and path and manner, respectively. Taken together, they indicate that the highly abstract concept of life is understood in terms of the more concrete concept of journey.

There are several ways in which metaphors can be classified. They can be grouped according to their cognitive function, nature, conventionality, generality, grounding, and others. As regards *cognitive function*, conceptual metaphors can be structural (e.g., life is a journey) or nonstructural (as when, e.g., we evaluate a concept by assigning a positive or negative value to it—good is up, bad is down). As regards their *nature*, conceptual metaphors can be based on our general knowledge in connection with an area of experience or on the images we have of various domains of the world (e.g., the mind is a computer vs. the mind is a container). As regards *conventionality*, conceptual metaphors can be conventional or unconventional/novel (e.g., life is a journey vs. life is a box of chocolates). As regards *generality*, conceptual metaphors can be generic or specific (e.g., emotions are forces vs. anger is a hot fluid in a container vs. the angry person is a kettle). As regards *grounding*, conceptual metaphors may be grounded in analogical relationships between two domains or in bodily correlations in experience between the domains (e.g., life is a theater play vs. anger is heat). The kinds of metaphors these distinctions yield may combine with each other in particular cases of conceptual metaphors, and the distinctions come in various degrees between the two extremes.

Concepts and Metaphors

The subject matter of the social sciences is constituted by a large number of abstract concepts, such as emotions, politics, religion, society, nation, class, knowledge, communication, time, and so on. In the typical cases, concepts in general are characterized by a number of aspects. For this reason, since metaphors focus on a small number of aspects of concepts, abstract concepts are typically comprehended through a variety of different conceptual metaphors. It is not uncommon, however, that one or some of the conceptual metaphors pertaining to an abstract concept are more dominant than the others. Conceptual dominance can be defined and measured in terms of the productivity of a conceptual metaphor and/or the number of aspects of a target domain that it defines (by mapping source structure on it). This way, particular conceptual metaphors can emerge as "master metaphors" for particular abstract concepts. For example, as Zoltán Kövecses argues, the master metaphor for emotions is that emotions are forces, where, at least prototypically, emotion is viewed as a strong force overcoming a nonemotional self.

Folk Concepts and Expert Concepts

The *emotions-are-forces* metaphor reflects a naive, lay, or folk, understanding of emotions in Western cultures. Such naive, or lay, understandings of abstract concepts defined by our everyday metaphors are called *folk theories* of particular domains of experience. Folk theories are contrasted with *expert theories*, that is, theories that experts in a field propose, using their scientifically accepted methodologies. What is the relationship between a folk theory and an expert theory for a particular domain of experience? Sometimes, experts make unconscious use of folk theories, and they think about a particular domain that is closely related to a folk theory. A case in point is Freud's famous hydraulic model of the emotions, which is a version of the folk theory based on the *emotions-are-forces* conceptual metaphor, as found in everyday language in many Western languages. In many other cases, however, experts make a conscious effort to reconceptualize a domain. For example, the domain of time is widely conceptualized as space, yielding the *time-is-space* conceptual metaphor, but experts, such as philosophers, commonly argue that it is mistakenly conceptualized as space. It is, of course, also possible that particular expert theories become (part of) our folk theories.

Universality and Variation in Metaphor

Conceptual metaphors can be (near-) universal or language/culture specific. We get universal metaphors

when the source and target domains are grounded in universal bodily experience. Thus, the angry person as a pressurized container is a near-universal metaphor. With globalization, however, analogy-based cultural metaphors, such as *the mind is a computer*, can also become widespread, if not universal. Variation in metaphor can occur both cross-culturally and within cultures, as well as through time, as Kövecses has shown. The main causes of metaphor variation include differences in the key explanatory concepts of cultures and subcultures; physical environment; differential social and personal history; differential concerns of societies, subcultures, and persons; as well as differential uses of otherwise universal cognitive processes (such as metaphor and metonymy) within and across cultures.

Multimodality

Research by Charles Forceville has shown that conceptual metaphors also become visually manifest in cultures. Since conceptual metaphors are by definition in the mind, they can be widely distributed in culture, in the form of pictures, films, cartoons, and even material objects. Furthermore, our conceptual metaphors often define the actions people or organizations take or could take in society. George Lakoff argues that the conception of a nation in terms of *the nation is a strict-father family* versus *the nation is a nurturant-parent family* has far-reaching implications for political ideas and actions in American society.

Functions of Metaphor in Social Science

Metaphors have important functions in the social sciences. In order to understand a large number of concepts and issues important in the social sciences, folk theories are investigated. As we have seen, these are routinely constituted by metaphors. Furthermore, through the application of a master metaphor, conceptual metaphors can actually constitute a particular expert theory. Metaphor can also present a new way of understanding what understanding of the world is all about. Jacques Derrida's idea that the world is nothing but a text with an infinite number of interpretations can be regarded as a conceptual metaphor: *the world is a text*. Conceptual metaphors are also used for social criticism, especially in postmodernist theory. An example of a metaphor performing such a function is Julia Kristeva's theory of abjectness. We can interpret this idea as another conceptual metaphor, namely, *social abjectness is physical abjectness* or *social marginality is bodily marginality* (body fluids).

Metaphysics and Science

Metaphysics in the sense of the treatise that is known as Aristotle's *Metaphysics* is not concerned with entities that are supposed to exist beyond the empirical world but with the fundamental traits of the empirical world itself, taking into account the scientific theories about the world. That is why this treatise was ranged behind (or after—*meta* in Greek) the treatise on *Physics* and was called *Metaphysics*. This Aristotelian sense is the one that is pertinent to today's metaphysics, in contrast to an enquiry into entities that are supposed to exist beyond the empirical world (what poeple usually call "supernatural").

This entry first distinguishes between two different methodologies in contemporary metaphysics, then considers the relationship between metaphysics and science as regards fundamental science,

and finally focuses on functionalism as the main paradigm in the philosophy of the special sciences, including the social sciences.

Two Different Methodologies

There are two different methodological approaches in contemporary metaphysics—one that is based on a priori reasoning in the form of conceptual analysis ("armchair metaphysics") and another that sets out to naturalize metaphysics by seeing metaphysics as being continuous with science.

However, the contrast between these two approaches is not as sharp as it might seem at first glance. A priori reasoning in the form of conceptual analysis also depends on science mainly for the following two reasons: (1) The meaning of the concepts analyzed is subject to change, that change being notably due to scientific discoveries; thus, for instance, the meanings of concepts such as "particle," "atom," "soul," "mind," or "consciousness" are in more or less constant change as a result of progress in science. (2) The claims about the world put forward by metaphysicians subscribing to the method of conceptual analysis are based on empirical knowledge derived from science. For instance, the vast majority of metaphysicians today, including those subscribing to the method of conceptual analysis, defend a thesis of global supervenience according to which, to put the idea in simple terms, everything there is in the world is fixed by what there is in the fundamental physical domain. Thus, an exact physical duplicate of the real world would also contain all the people and their social institutions and interactions that there are in the real world. But this is a contingent claim, being based on modern science. It is maintained only with respect to possible worlds that are physically identical with the real world, not with respect to all possible worlds. By contrast, if one takes mathematics to be the paradigm of a priori knowledge, then one usually considers mathematics as applying to all possible worlds.

As regards naturalized metaphysics, there is no question of metaphysics being simply determined by science. If science were able to speak for itself, there would be no need for metaphysics at all. Scientific theories need interpretation in the sense of an answer to the question of what the world is like, provided that the scientific theory in question is true (or approximately true) and its interpretation cannot be simply read off from a scientific theory or settled by experiments. It requires philosophical argument. In fact, the actual practice of metaphysics is situated somewhere between the two methodological extremes of conceptual analysis and naturalized metaphysics.

The interplay between these two methodologies—conceptual analysis and naturalism—is also evident in the influential contemporary current known as *metaphysics of science*: Central topics considered by this current include the metaphysics of properties and laws, both in the fundamental and in the special sciences. Developing an answer to questions such as whether properties are purely qualitative (categorical) or dispositional (i.e., include the power to produce certain effects) and whether laws are contingent regularities or have a modal nature (necessity) requires both conceptual analysis as well as the consideration of scientific theories and explanations.

Metaphysics and Science in Physics

The fact that scientific theories call for an interpretation that requires philosophical argument is best illustrated by considering the current fundamental physical theory about matter, namely, *quantum mechanics*. The very formulation of the physical theory of quantum mechanics poses a problem that is known as the measurement problem. The problem is that the core formalism of quantum theory does not include the means to describe classical physical properties, that is, properties that have a definite numerical value, such as, for instance, either "plus" or "minus," and that occur notably at a definite location in space and time. Measurement outcomes, including the outcomes of measurements of quantum systems, are a paradigmatic example of classical properties. There are several strategies available to solve this problem, each of which leads to a different formalism of quantum mechanics, without there being a prospect in view of deciding between these strategies on the basis of experiments. That is why any solution to the measurement problem—and thus the very formulation of quantum mechanics—requires philosophical argument.

As regards space and time, since the days of Newton and Leibniz there has been a famous debate about whether space and time exist on their own, independent of the matter that is located in them

(substantivalism) or whether space and time consist only in the spatiotemporal relations between material entities (relationalism). Einstein's theory of general relativity has changed the features of this debate, but the question of the status of space and time is still hotly debated in today's metaphysics, and any answer to this question requires both taking the physics into account and developing a metaphysical argument.

Functionalism

Physics is a universal science, applying to the universe as a whole. Biology, psychology, economics, the social sciences, and so on, in contrast, are special sciences, since they apply only to a particular domain each. Functionalism is considered to be the appropriate paradigm as regards these sciences. Functionalism can be characterized in terms of the following three steps, quoted from Michael Esfeld and Christian Sachse (2011):

> (1) *The properties that constitute the domain of the special sciences are functional properties*. These are causal properties: they consist in having certain specific effects, given normal conditions, and possibly also in having certain specific causes.
>
> (2) *The functional properties that constitute the domain of the special sciences are realized by physical properties*. There is in each case a configuration of physical objects whose physical relations among themselves are such that, given normal conditions, they bring about qua configuration those effects that characterize a functional property of the special sciences. That is why they realize the functional property in question.
>
> (3) *The functional properties that constitute the domain of the special sciences can be multiply realized by physical properties*. Configurations of physical objects that are composed in different manners and that therefore come under different physical types (classifications) can nevertheless all realize a functional property of the same type of a special science, since they all bring about the same salient effects qua configurations under normal conditions. (p. 13)

Thus, for instance, the property of being a certain gene is a functional property, consisting in bringing about certain phenotypic effects under normal conditions (1). Genes are realized by certain configurations of molecules, notably certain DNA sequences (2). Molecular configurations (DNA sequences) that are composed in different physical manners can all produce qua configurations under normal conditions, those phenotypic effects that characterize a gene of a certain type. Consequently, genes can be *multiply realized* by molecular configurations of different types (3).

Steps 2 and 3 are the matter of empirical science, concerning the discovery of the realizers of a given functional property. As regards Step 1, again the methodological contrast between conceptual analysis and naturalism shows up: According to analytical functionalism, the functional definition of the properties that constitute the domain of the special sciences is a matter of conceptual analysis; according to scientific functionalism, such definitions have to be taken up from the most advanced scientific theories of the domain in question and are subject to change following scientific progress.

Even if one adopts the methodology of naturalism, functionalism leaves a number of issues open that depend on the scientific theories in question but that can only be settled by invoking philosophical, metaphysical argument. The most important of these issues are the following three interrelated ones:

1. *The status of the properties of the special sciences:* According to the position known as *role functionalism*, the properties with which the special sciences deal are second-order properties; having functional role properties consists in having certain other, first-order properties that realize the role in question; and functional properties thus are distinct from physical properties. According to the position known as *realizer functionalism*, there are only the realizer properties, in the sense that the functional properties with which the special sciences deal are identical with the physical realizer properties.
2. *The question of the reducibility of the special sciences:* The multiple realizability of functional properties excludes that the concepts of the special sciences that seize these properties can have the same extension as the concepts figuring in physical theories. Nonetheless, if a physical configuration of a certain type realizes

a functional property of a certain type, one can give a reductive explanation of why a functional property of the type in question occurs under certain circumstances. It is in dispute whether on this basis it is, in principle, possible to reduce the theories of the special sciences to physical theories despite multiple realization.

3. *The question of the causal efficacy of the properties of the special sciences:* According to what is known as the *completeness of the physical domain*, there is for any change in physical properties a sufficient physical cause (insofar as there is a cause at all). If the properties with which the special sciences deal are realized by physical properties, then any change in the domain of the special sciences requires a physical change. The question, therefore, is how the functional properties of the special sciences can be causally efficacious given the completeness of the physical domain. In particular, as noted by Jaegwon Kim, it is in dispute whether vindicating the causal efficacy of the properties of the special sciences requires regarding them as being identical with the physical properties that realize them.

METHODENSTREIT

The *Methodenstreit* (dispute over methods) began in 1883 as an argument between the Austrian school economist Carl Menger of the University of Vienna and the German Historical school scholar Gustav von Schmoller of the University of Berlin. The dispute ostensibly concerned the appropriate research methodology for economics—methodology being a fundamental concern for any area of study. Unfortunately, neither disputant seemed aware that their respective methodological arguments sprang from different theories of knowledge (epistemologies). Consequently, their contrasting views on the theories of concepts and of causality were never debated. Instead, there was a rancorous and inconclusive exchange of arguments on subsidiary questions, creating a lasting enmity between the two schools.

This entry summarizes the debate, identifies the key epistemological differences between the two disputants, and suggests that conflicts over research methodology may stem from deeper and less easily resolvable conflicts.

The German Historical School

The German Historical school is conventionally divided into the Older Historical school, the main figures of which were Wilhelm Roscher, Karl Knies, and Bruno Hildebrand, and the Younger Historical school, of which Gustav von Schmoller was the leading figure. The school began in the early 19th century partly as a reaction against the British Classical school of economics, the main figures of which were Adam Smith, Thomas Robert Malthus, and David Ricardo.

German scholars argued that the abstract deductive reasoning used by Classical school economic theorists created a separation between theory and

empirical reality. In addition, the Classicals used the individual person as their unit of analysis, rather than treating a social community as being itself an organism. The result was what Germans regarded as a universalist "dogma" of qualified laissez faire, and one that consequently supported the individualistic political philosophy that is current in Great Britain. In contrast, German historians argued that theoretical statements could only be empirical generalizations taken from actual experience and the history of a social organism itself. German experience being necessarily different from British, German institutions and economic laws would differ from those applicable to a British context. They argued that the German context was one of institutions and laws supporting German nationalism and the role of the state as an active force for social reform in Germany.

While members of the Older Historical school studied the economic development of nations using empirical generalization—a "historical method"—they differed among themselves concerning the question of the strictness of any generalizations, uniformities, or "laws" that they might find. They were united in the belief that there was no universal theory applicable to all cultures and throughout history.

Carl Menger's Critique and the Debate

Carl Menger began his 1883 published critique of the Historical school by asserting that the progress of economic science in Germany was blocked by an erroneous methodology—namely, the historical method. As a discipline, Menger divided economics into the areas of economic history, economic theory, economic policy, and public finance. He argued that general knowledge is only possible using economic theory, and no historical method—as the Historicists conceived it—could generate the theoretical laws needed to understand economic history, formulate policy, or practice public finance.

In his discussion of the derivation of the most important economic laws, those he termed the "exact laws" of economic theory, Menger made epistemological statements similar to those of contemporary Aristotelian "moderate realists." He did this in presenting both his theory of basic economic concepts and his theory of economic causality. He argued that economic concepts are derived from the essences or "simplest elements" of everything real, especially those of human nature and everyday life experience. The "exact" economic laws of economic theory are the result of logical deduction from those economic concepts. Menger's approach thus made the basic concepts and most important theoretical laws of economics not only ahistorical but also universal and an exemplification of intrinsic necessity—the ontology of the real.

Menger dismissed the idea of a "social organism," in favor of the concept of social phenomena as the collective result of the efforts of individual thinking and choosing human beings. He also argued that economic research methods must differ according to the formal knowledge of each area of research and that no one method is applicable to all areas in either the social or the natural sciences.

Schmoller responded to Menger's book with an adverse review in his journal, the principal one of the Historical school. He argued that Menger's concepts and abstract theorems not only lack reality but were also parochial and that his "atomistic" approach would miss the essence of social life. In contrast, the descriptive work of history and statistics was the foundation for economic theory. The more complete the description of a thing, the clearer would be the understanding of it and its relations to other things. Furthermore, "our law of thinking" requires that observed sequential events be recognized as revealing a current causal necessity. More careful and complete observations reveal more causal complexity in the connections of things and the necessary relativity of economic laws, tied as they are to the context of observation. Especially, individuals in society must be considered in their relationships to the mass. Schmoller's notion of causality resembles that of David Hume's nominalism, while his theory of concepts, although empirical, lacks the arbitrariness of a consistent nominalism. Whether nominalist or not, the contrast with Menger's epistemological views on concepts and causality is obvious. Menger responded in an abusive polemic, to which Schmoller replied by printing an insulting letter in his journal.

The polemics and inconclusive nature of the debate have led to negative assessments by almost all historians of economic thought. Recognizing that conflicting methods may imply epistemological conflict provides a basis for a reassessment.

MICROFOUNDATIONALISM

This entry analyzes the conceptual features and the wide use of the important concept of microfoundation in social ontology and social explanation.

Conceptual Analysis of Microfoundations

The concept of *microfoundations* is an important component within contemporary philosophy of social science. A microfoundation for a given compositional social phenomenon is a specification of the ways properties, structural features, and causal powers of a social entity are produced and reproduced by the actions and dispositions of socially situated individuals.

This concept is relevant to social ontology in this way. Social entities are understood to be *compositional*; they are assemblages constituted and maintained by the mentality and actions of individuals. So providing an account of the microfoundations of a structure or causal connection is a specification of the composition of the social-level fact. It is a description of the *agent-level* relationships and patterns of behavior that cohere in such a way as to bring about the higher-level structure or causal relationship.

The methodological requirement of microfoundationalism is a requirement regarding the validity of social explanations based on these assumptions about social ontology. It can be formulated in these terms: *An explanation of a macro-social phenomenon must be accompanied by a sketch of plausible microfoundations for the causal linkages it postulates*. In other words, if we assert a causal or explanatory relation between one social entity or condition and another, we must be prepared to offer a credible sketch of the ways in which this influence is conveyed through the mentalities and actions of individuals.

Much depends, however, on what precisely we mean to require of a satisfactory explanation: a full specification of the microfoundations in every case or a sketch of the way a given social-level process might readily be embodied in individual-level activities. If we accept the second version, we are licensing a fair amount of autonomy for the social-level explanation; whereas if we endorse the first version, we are leaning toward a requirement of reductionism from higher to lower levels in every case. It is most reasonable to interpret the requirement in the second way; it does not seem necessary to disaggregate every claim such as "Organizational deficiencies at the Bhopal chemical plant caused the devastating chemical spill" onto specific individual-level activities. We understand pretty well, in a generic way, what the microfoundations of organizations are, and it isn't necessary to provide a detailed account in order to have a satisfactory explanation.

The theory of microfoundationalism is very consistent with the methodology of *social mechanisms* as a basis for social explanations. When we ask about the microfoundations of a social process, we are asking about the mechanisms that exist at a lower level that create and maintain the social process.

Microfoundationalism falls in the general area *of methodological individualism* and *reductionism*, in that it insists on the compositional nature of the social. However, there is a recursive aspect of the theory that distinguishes it from strict reductionism. The individuals to whom microfoundations are traced are not asocial; rather, their psychology, beliefs, and motives are constituted and shaped by the social forces they and others constitute. So the microfoundational account of the workings of a social organization may well refer to the locally embodied effects of that organization on the current psychology of the members of the organization; their behavior in turn reproduces the organization in the next iteration. This is why some philosophers of social science, for example, David Little, prefer the idea of methodological localism over that of methodological individualism, while others, such as Peter Hedström, have preferred the idea of *structural individualism*.

The theory of *supervenience* is often invoked to express the idea that social entities and properties are constituted by individuals. Jaegwon Kim is the primary creator of the theory of supervenience in the philosophy of mind. This basic notion is expressed as the idea that a higher-level structure depends for its properties on the properties of its lower-level constituents. The advantage of the theory of supervenience is that it provides a way of recognizing the compositional nature of higher-level entities without presupposing explanatory reductionism from one level to the lower level. It is thus possible to allow for a degree of "explanatory autonomy" among factors that supervene upon lower-level processes if we are confident about the availability of microfoundations linking the supervening and lower levels.

Uses of "Microfoundations"

The explicit idea of microfoundations was first developed in the domain of *microeconomics*. There it referred to the necessity of deriving macroeconomic phenomena from the premises of rational economic behavior. Maarten Jansen describes the theory of microfoundations within economics as the attempt to understand aggregate economic phenomena in terms of the behavior of individual economic actors and the interactions among them.

The idea of microfoundations is now important in many areas of the social sciences, including especially sociology and political science. Early advocates of the microfoundations principle included contributors to the theories of analytical Marxism in the 1980s. David Little (1994) summarized the analytical Marxism approach in these terms:

> Marxist thinkers have argued that macro-explanations stand in need of microfoundations: detailed accounts of the pathways by which macro-level social patterns come about. These theorists have held that it is necessary to provide an account of the circumstances of individual choice and action that give rise to aggregate patterns if macro-explanations are to be adequate. (p. 479)

Particularly important within recent sociology were the theories formulated by James Coleman. Coleman does not use the term *microfoundations* explicitly, but his analysis of the relationship between the macro and the micro implies the requirement of providing microfoundations as a condition for good explanations in the social sciences. The "Coleman boat" linking macro and micro levels of explanation is a graphical way of representing the microfoundations of a macro-level fact.

The idea of microfoundations is also a core constituent of the methodology of analytical sociology. Peter Hedström, the leading advocate of the approach, does not use the term explicitly in *Dissecting the Social*, but the concept pervades the volume and the approach. Analytical sociology is interested in explaining macro-level social phenomena on the basis of social mechanisms at the level of the purposive agents who constitute social groups and processes.

The theory of microfoundationalism is often associated with the use of rational choice theory as a basis for explaining social outcomes. This association is not a necessary one, however. It is possible to maintain that agents are motivated by considerations that fall outside traditional rational choice assumptions without surrendering the idea that macro-level outcomes depend on the actions and thoughts of the individuals who make them up.

Mill and the Moral Sciences

John Stuart Mill (1806–1873) wrote extensively on the philosophy of the moral sciences, and in many key respects, he remains one of the leading champions for positioning the moral sciences on an epistemic par with the natural sciences. Mill's *oeuvre* fills an entire library shelf, but he is mostly known for two short works, *On Liberty* (1859) and *Utilitarianism* (1861), both of which remain pillars of the philosophical canon, especially as far as moral and political philosophy is concerned. But his philosophical assessment of the moral sciences can best be found in his *System of Logic* (1843), *Principles of Political Economy* (1848), *Considerations on Representative Government* (1861), *Examination of Sir William Hamilton's Philosophy* (1872), and various essays, particularly "On the Definition of Political Economy and on the Method of Investigation Proper to It" (1836) and "On Comte and Positivism" (1865).

As an empiricist, Mill believed that there are only particulars in the world. Nevertheless, there are sufficient uniformities among groupings or types of particulars such that one can arrive at laws, synchronous or successive. Mill recognized that there were many types of laws, notably conservation laws, causal laws, universal laws, tendency laws, as well as laws about emergent properties, or chemical laws. He much appreciated the tendency toward the unification of laws, particularly Newton's synthesis of the known laws of mechanics and astronomy. More significantly, our belief in the overarching uniformity of nature is deepened over time as each newly discovered law adds inductive support.

Although Mill admired the work of August Comte, he did not adopt Comte's hierarchical and reductionist schema for the sciences. Mill believed that there were several distinct moral sciences and each one had its own salient phenomena and set of methods. Following a number of the Scottish Enlightenment philosophers, including his own father, Mill viewed the study of the mind as the most fundamental moral science. He endorsed the main psychological theory of his day, known as *associationism*. Our specific perceptions yield impressions which then form ideas; these ideas can be joined with other ideas in accordance with three laws of association: resemblance, contiguity, and causation. Hence, the mechanisms of the human mind by which ideas are processed are uniform, and hence, there are laws that govern the formation of beliefs and actions. For Mill, psychology was a strongly empirical science that sought correlations between physical states of the brain and the body with inner states of the mind. Introspection was a key asset in these investigations.

Of all the moral sciences, Mill left his mark on political economy. He first cut his teeth on the work of the classical political economist David Ricardo at the age of 13, and much later, he sought to reinstate the leading Ricardian tenets embedded in a broader social and political context. Political economy was defined as the science that sought the laws of the production and distribution of wealth. It used the same deductive method as physics. It commenced with inductive generalizations drawn both from psychology, for example, that all humans seek to obtain the greatest amount of wealth with the minimum amount of exertion, and from the physical sciences, for example, the chemical laws that govern fermentation. From this are derived the laws that govern the production and distribution of wealth, for example, the inverse relation between profits and wages, or the principle of comparative advantage.

From these laws are derived specific observations, which are then matched to the world for verification. Since the initial laws require abstractions and idealizations, Mill maintained that the third step of verification also involved the search for disturbing causes, which would in turn draw upon other psychological, historical, or cultural dispositions, that is, patterns from the other moral sciences.

Mill also believed that there was great potential for the sciences of sociology and political science. The former was distinctively historical in his view, and therefore the laws would be located in the succession of social states. The closing chapters of his text on political economy offer a sketch of his sociology. Political science, by contrast, was conceived of as a deductive science using methods similar to economics. Although Mill laid out his own distinct system of representative government, he failed to ascend to the theoretical level.

Mill also believed that human nature evolves over time and that many of the laws for the moral sciences will thus be historically contingent. To attend to cultural and physical circumstances, Mill proposed a new science that he called "ethology," the study of human character. Although it held a central position in his schema for the moral sciences, Mill never followed up on this proposal; nor did he find disciplines, and as a result, ethology was stillborn. Nevertheless, it served as a reminder that for Mill, human nature was not just a subject for scientific study but could be significantly improved by absorbing scientific discoveries.

Mind–Body Relation

After the transgression in the Garden of Eden, which sealed our fates, God told Adam, "Dust thou art, and unto dust thou shalt return" (Genesis 3:19). *Genesis* tells us that God fashioned Adam from the dust of the earth and Eve from Adam's rib. The Old Testament contains no hint that we might have an immaterial soul. Nor is there any clear evidence for the presence of that idea in the New Testament. Eternal life for us will come, the Bible tells us, through the resurrection of the body. Several 100 years after the writing of *Genesis*, and a few 100 years before the birth of Jesus, Socrates sat at peace in his jail cell, surrounded by his students, awaiting the hemlock he was ordered by the court to drink as punishment for corrupting the young of Athens (Plato, 1961, pp. 40–98). His students marveled at his calm and wondered why he didn't fear his impending death. The reason, it turns out, is that he didn't really think that he was going to die but only that his body was going to die. He maintained that he had a soul that was not made of material parts, and so could not come apart and thereby cease to exist. The idea that we have immaterial souls seems to have entered Christian theology through the work of Augustine of Hippo, an African philosopher who tried to integrate Platonic philosophy with the teachings of Christianity (Van Inwagen, 1975). As concerns the question how our immaterial souls are related to our material bodies, Augustine tells us, "The manner in which spirits are united to bodies is altogether wonderful and transcends the understanding of men" (cited in Haldane, 1994, p. 335).

Dualism

By the 17th century, it was well-known among the intellectual class that the soul or mind is related in some intimate way to the brain. (That was not known in antiquity. Aristotle had no idea that the

soul or mind is related to the brain.) Rene Descartes (Cottingham. Stootoff, & Murdoch, 1985) maintained that the relationship between the two is one of cause and effect and speculated that the immediate locus of causal interaction is in the pineal gland of the brain. States of and changes in the mind can directly cause, and can be directly caused by, states of and changes in the pineal gland. There is mental-to-physical causation when we perform actions. Our minds produce changes in the physical realm by producing changes in the pineal gland, changes that cause other brain events that lead to contractions of muscles and, thereby, to movements of or postures in our skeletons or vocal cords, which, in turn, issue in environmental effects. There is physical-to-mental causation when we engage in sense perception: when we see, hear, smell, taste, or feel something. For example, when we see, the scene before our eyes directs light to our eyes, which initiates a causal chain of events that ultimately results in our having a visual experience of the scene—that is, with the scene's looking some way to us. This doctrine of two-way causal interaction is called "Cartesian Interactionism." Descartes also held that although the mind is located in time, it is not located in space. Minds are nonspatial substances (whose essence is to think) and thus are distinct from any physical substance since all such substances are in space. This doctrine is called "Cartesian Substance Dualism."

Princess Elizabeth of Bohemia saw a tension between this substance dualism and causal interactionism, one that was especially acute since at the time of her correspondence with Descartes it was held that an object can directly causally influence the motion of another object only if the objects are in spatial contact. She wrote to Descartes asking

> how the mind of a human being can determine the bodily spirits in producing voluntary actions . . . For it appears that all determination of movement is produced by the pushing of the thing being moved, by the manner in which it is pushed by that which moves it, or else by the qualification and figure of the latter. Contact is required for the first two conditions, and extension [in space] for the third. [But] you entirely exclude the latter from the notion you have of the soul, and the former seems incompatible with an immaterial thing. (Cited in Garber, 2001, p. 172)

In response to this how-question, Descartes maintains that although contact is required for direct physical causation, the mind and body are united in such a way that contact is not required for them to directly causally interact. His notion of mind–body union, however, went unexplained, and Princess Elizabeth was unconvinced. She responded, "And I admit it would be easier for me to concede matter and extension to the mind than it would be for me to concede the capacity to move a body and be moved by a body to an immaterial thing" (cited in Garber, 2001, p. 134). Even without the assumption that direct causation requires spatial contact (an idea that Newton eschewed for gravitational influence), it is indeed deeply mysterious how states of and changes in something not located at all in space can cause or be caused by states of and changes in something in space. Such causal transactions would have to be brute facts, facts that admit of no explanation; for there cannot be a mechanism that explains how such transactions occur, and so there can be no answer to the how-causation. (For a discussion of further difficulties, see Kim, 2006, chap. 2.) Descartes himself recognized the mystery. He made a remark at one point that is reminiscent of Augustine's remark quoted above: "It does not seem to me that the human mind is capable of conceiving quite distinctly and at the same time both the distinction between mind and body and their union" (cited in Kenny, 1970, p. 142).

Early Reactions to Dualism

In response to Descartes, Thomas Hobbes denied substance dualism, insisting that the mind is the brain. Gottlieb Leibniz and Nichols Malebranche denied interactionism, and both held versions of parallelism. Leibniz espoused the parallelist doctrine of preestablished harmony: There is no causal interaction between the mental realm and the physical realm, but there are mental–physical correlations because, of the infinity of possible worlds, God made actual a possible world in which such correlations hold. Malebranche espoused the doctrine of occasionalism: God is the only causal agent; he creates the world anew at each instant of time, but in a way that ensures mental and physical correlations. Baruch Spinoza held that God is the only substance and that the mental and the physical are just distinct modes or attributes of that one substance. He combined a kind of pantheism with a "dual-aspect theory of the mental and physical," a theory according to which mental and physical attributes are distinct attributes that are possessed by the same substance. Bishop Berkeley and Georg Wilhelm

Friedrich Hegel, among many others, held versions of idealism: the doctrine that everything is mental. According to Berkeley, everything is mental because everything is an idea in the mind of God.

Modern Science

If contemporary science can be trusted, *Genesis* is correct: We are made of the dust of the Earth—kinds of dust that science tells us were formed inside stars. We are thus made up of star dust. But there is no mind dust. The dust from which we are composed can be found not only in things that lack minds but even in nonliving things, such as rocks and water. To be sure, we are made up of cells, which are organic matter. But cells are made up of molecules, which are made up of atoms, which are made up of electrons, protons, and (with the exception of the hydrogen atom) neutrons; and neutrons and protons are in turn made up of quarks. Perhaps at the bottom of this constitutional hierarchy are not physical particles but rather something physical that is not particle-like: strings of energy or m-branes. Or perhaps there is no bottom level. It could be that below every peel of the physical onion is another peel. But be that as it may, we are composed of electrons, neutrons, and protons, just as are rocks. What differences there are between rocks and human brains are due to differences in the number and complexity of organization of these constituents. Moreover, it seems that the fundamental forces at work in sustaining the organizations and producing changes in organization, no matter how complex the organization, are all forces that are exerted below the level of complexity of atoms. Mechanics, a branch of physics, aims to be a comprehensive theory of motion: to formulate the general laws that all motion obeys (in Newtonian mechanics, they are the three laws of motion; in nonrelativistic quantum mechanics, the law is Schrödinger's equation) and to describe the fundamental causes of motion (in Newtonian mechanics, the force laws; in quantum mechanics, the Hamiltonians for the Schrödinger's equation). Mechanics tells us that the fundamental forces, the ones that are the bases of all forces, are gravity, electromagnetic force, weak force, and strong force. These forces are all ones that are exerted below the level of complexity of atoms. Electromagnetic force and weak force may be one force, and physicists hope for further reduction in the number of fundamental forces. But the idea often espoused in the history of science that there are fundamental forces that exert their influence only when matter becomes configured in certain complex ways is not incoherent. Contemporary mechanics, however, thus far has no need of that hypothesis; and the current received view is that there are no such forces. Moreover, even if physics were to discover that there is such a fundamental emergent force, physics would take the force to be due to microstructural properties of the relevant complex configurations of matter, not to an immaterial object (McLaughlin, 1992).

It should be noted, however, that science itself does not tell us that we have no immaterial part. (According to general relativity theory, though, nothing can be in time without being in space, even if only at a point in space.) It is, rather, that science has no need of that hypothesis in its aim to provide a comprehensive theory of motion. Our bodies and its organs at least, including our brains, are complex physical objects wholly made up of atoms and more fundamental physical particles. Moreover, the movements of our bodies and of its parts are governed by the blind physical forces of nature. How can we be constituted by a complex physical object, the movements of which and the movements of the parts of which are governed by the blind physical forces of nature and yet have a mind?

It has been argued that a mind isn't a special sort of object, material or immaterial (Ryle, 1949). What it is to have a mind is just to have certain kinds of abilities and capacities (abilities to acquire abilities). These abilities include in our case the ability to think, to sense, and to feel. When our brains are functioning properly, they are the material basis of our mental abilities. But how could such abilities be exercised in the brain? The exercise of such abilities will involve mental states that participate in mental processes. How could there be such states and processes within a brain?

Epiphenomenalism

In the last third of the 19th century, but even prior to the discovery of neurons in 1890, some biologists realized that the search for gaps in neurophysiological processes in the brain that might be filled by mental states was futile. The absence of such gaps led Thomas Huxley (1874) to maintain that animals

are "conscious automata," by which he meant that they are physical machines that are also conscious but that conscious states are merely effects of the brain, never causes; they are causally inert. Using an old medical term for symptoms of diseases, William James (1890) claimed that this view treats mental phenomena as "epiphenomena." James Ward (1896) coined the term *epiphenomenalism* for this view. Epiphenomenalism is the view that mental states and events are caused by physical states and events but mental states and events never cause anything. On this view, feeling pain never causes one to wince or to withdraw one's limb or to cry out; indeed, feeling pain never causes one even to believe that one is in pain. Moreover, thinking is not a causal process in which one thought leads to another. There are no mental causal processes. If epiphenomenalism is true, we don't exercise mental abilities. There is only the appearance that we do, because we undergo certain types of temporally ordered patterns of mental states. Instances of types of mental states in such patterns do not causally interact; the appearance of causal interaction is due to the fact that pairs of mental states are dual effects of some common physical cause in the brain. Moreover, the experience of instances of such patterns does not cause us to believe that there are mental casual processes. Experiences have no causal effects. The conscious mind, an effect of the physical brain produced anew on each occasion of consciousness (think here of an analogy with occasionalism), is causally impotent, powerless to effect any change in the course of events but pathetically under the illusion that it can.

The "How-Question"

Suppose—as seems at the very least enormously plausible—that minds really can change the world through the exercise of a subject's mental abilities. When we exercise mental abilities, the mental states we are in participate in processes as causes. This takes us back, then, to the question of how a physical object, no matter how complex, could be in a mental state. We've raised a number of how-questions. But let's call this last one "the how-question."

One answer to the how-question is that mental abilities are just complex behavioral abilities and that mental states are just complex dispositions to behave. Such behavior includes verbal behavior, which is sufficiently complex in our case to set it apart from the kind of auditory signal systems used by other animals. Analytical behaviorists attempted to define mental terms (e.g., *believes*, *desires*, *intends*, *pain*, *itch*, etc.) in terms of dispositions to overt or peripheral behavior—behavior that involves the movement or posture of some part of the periphery of the body (Carnap, 1932/1933). But they failed to provide even a single example of such a definition that had any credibility. And it became clear why the attempts failed. What one is disposed to do doesn't depend only on a belief or a desire, and so on, but on a vast range of one's beliefs and desires, as well as one's intentions, hopes, wishes, fears, and other mental states. If asked whether one believes that it will rain tomorrow, whether one utters the sound /yes/ in response will depend on much more than whether one believes it will rain tomorrow; it will depend on whether one understands what is being asked, knows what the sound means, and thinks the asker will hear and on whether one wants to answer truthfully more that one wants other relevant things, a matter that will depend, in part, on other beliefs one has (Chisholm, 1957, chap. 2). It was also convincingly argued that even terms for bodily sensations, such as "pain," cannot be defined in terms of dispositions to behave (Putnam, 1968). It is now widely acknowledged that analytical behaviorism is mistaken, since such definitions are impossible.

There is, however, a progeny of analytical behaviorism that has adherents, namely Real-Patterns Intentional System Theory (Dennett, 1991, 1996). This view does not entail that mental terms can be (finitely) defined in terms of dispositions to peripheral behavior. Indeed, on this view, no mental term can be so defined. The holism of the mental is acknowledged. But it is claimed that it is nevertheless the case that when a mental term correctly applies to an individual, it does so by virtue of the individual's having an enormously complex global pattern of dispositions to peripheral behavior. On this view, there can be no difference between two individuals with respect to whether they have mental states without a difference in their global patterns of dispositions to peripheral behavior. A thesis of the form "There can be no A-difference without a B-difference" is called "a supervenience thesis," and if a thesis of this form is true, then A-respects are said to "supervene on" B-respects. According

to Real-Patterns Intentional System Theory, having mental states supervenes on global patterns of dispositions to peripheral behavior. The supervenience thesis is taken to be true because mental states *are* patterns of dispositions to peripheral behavior.

Functionalism

A different answer to the how-question is that to be in a mental state is just to be in a type of state that has a complex causal role, a role as cause and as effect, which includes causes and effects among certain internal states of the individual. This view is called "functionalism." It comes in a number of varieties. There are at least three important distinctions that cross-classify functionalist theories of mind.

The first distinction is between role functionalism and filler functionalism (which is sometimes called "realization functionalism"). According to role functionalism, a type of mental state is a second-order state, a state of being in some state of a certain sort, one with a certain kind of conditional causal role. On this view, a type of mental state is a state of being in some state type or other whose instances are caused in certain ways under certain conditions and whose instances have certain kinds of effects under certain conditions, where the causes and effects include environmental stimuli, behavior, and internal states (see, e.g., Loar, 1980). The first-order states that occupy the causal roles are said to "realize" the mental state; thus, realization is the relation of role occupancy; and it is possible for a type of mental state to be multiply realizable—that is, to be realizable by a variety of different kinds of first-order states. According to filler functionalism, a type of mental state is the state that has a certain causal role (as characterized above) or the state that has it in normal members of the species of animal in question (human or otherwise) or in beings with a certain kind of physical structure (Armstrong, 1968; Lewis, 1966; Smart, 1959). On the filler functionalist view, there is multiple realization only in the sense that the state that occupies the causal role in one kind of animal or structural being can be different from the state that occupies it in another.

The second distinction is between narrow role functionalism and wide role functionalism. A functionalism (role or filler) is narrow if the causal role includes not only proximal environmental causes but also distal ones. Wide role functionalism can be wide indeed. On some wide role-functionalist theories, evolutionary history is even included among the causes.

The third distinction is between analytical functionalism and scientific functionalism. According to analytical functionalism, the relevant causal roles are only those that common sense or "folk psychology" associates with the state type in question. According to scientific functionalism, which is often labeled "psycho-functionalism," the relevant causal roles are those that the correct scientific psychology will associate with types of mental states. This view is often associated with computational psychology, according to which the mind is a computer and states of mind are types of computational states of the computer (Fodor, 1975; Putnam, 1973; Turing, 1950).

All versions of functionalism are committed to the supervenience thesis that there is no mental difference between two individuals without a difference in the causal roles (wide or narrow) of the individual's internal states. The supervenience thesis is claimed to be true because a type of mental state is a type of state with a certain conditional causal role (filler functionalism) or is a state of being in some type of state or other with a certain kind of conditional causal role (role functionalism).

Anomalous Monism

Proponents of the doctrine of anomalous monism (Davidson, 1970) maintain that types of intentional mental states such as believing that p, desiring that p, intending that one A, hoping that p, fearing that p, and the like—so-called propositional attitudes—cannot be reduced to types of physical or functional states, because our propositional attitude concepts are governed by the normative ideal of rationality, while our physical and functional concepts are governed by very different constitutive principles. If anomalous monism is correct, then we can never get a satisfactory answer to the how-question. Nevertheless, anomalous monists maintain that every concrete occurrence of a propositional attitude or a change in one is identical with some physical state or event. They maintain that on the grounds that if events are causally related, then they fall under some strict law of nature and all such laws are physical laws.

Consciousness and Qualia

A number of contemporary philosophers who are materialists nevertheless maintain that types of states of consciousness cannot be reduced to

behavioral or functional states of any sort (Block, 1978; Searle, 1992). Even some philosophers who maintain that propositional attitudes are functional states of some sort deny that such reduction is possible for consciousness states (Block, 1978; Chalmers, 1996; Levine, 2003). These philosophers agree with Thomas Nagel's (1974) assessment: "Consciousness is what makes the mind-body problem really intractable." The term *consciousness* has a number of uses. But in the intended sense here, states of consciousness are states such that it is like something for the subject of the state to be in the state. Such states are called "states of phenomenal consciousness." They are experiences. It is, for instance, like something for a subject feeling pain to feel pain; and it is like something for the subject of a visual experience of red to visually experience redness. The what-it-is-like for a subject's aspect of a state of phenomenal consciousness is sometimes called its "phenomenal (or qualitative) character"; the term *qualia* is also often used for the what-it-is-like aspect. Let's use the term *qualia* (singular "quale"). These philosophers deny that qualia are patterns of dispositions to peripheral behavior or just a matter of causal-role properties of any sort.

In response, there have been rigorous, detailed attempts to show how qualia can be understood in wide-functional-role terms (see especially Dretske, 1995; Hill, 2009; Lycan, 1996; Tye, 2000). But there are at least six main, interestingly different views that both eschew any kind of behavioral or functionalist accounts of states of phenomenal consciousness and have defenders in the contemporary philosophical community. All the views have historical roots; some have roots tracing back to antiquity.

Emergent materialism (to use C. D. Broad's, 1925, apt name for the doctrine) is the view that qualia are fundamental, irreducible properties of certain physical states of the brain (neural states, say). The linkage between kinds of qualia and kinds of physical states of the brain is one of natural law: There are fundamental laws to the effect that if the brain is in a certain kind of physical state, then there is a quale of a certain kind. Emergent materialism is a property-dualist view that eschews substance dualism. It is a kind of dual-aspect view where the two aspects are aspects of the brain and are linked by fundamental laws of nature. Since the linkage is via fundamental laws of nature and since laws of nature are logically contingent, emergent materialists are committed to the logical possibility of what are nowadays called "zombies" (Chalmers, 1996), that is, beings that are exact physical duplicates of conscious beings but that are not themselves conscious. On a different version of emergentism, zombies are impossible in that they are not even coherently conceivable, but the specific characters of qualia are linked to patterns of physical states of the brain only by fundamental laws of nature (Kim, 2005). Both versions are thus committed to the view that there are fundamental laws of nature linking qualia with physical states. (Herbert Feigl, 1958, famously criticized this view, calling the laws in question "nomological danglers.")

Pansychism is the view that everything in space-time has qualia—literally everything, and so electrons, rocks, puddles of water, clouds, and galaxies (Drake, 1925; James, 1890; Rosenberg, 2005; Seager, 2009; Skrbina, 2005; Strawson, 1994, 2006, 2008). This is property dualism all the way up and all the way down the micro–macro scale and all the way up and all the way down the scale of levels of complexity of physical organization. (These are different scales. Brains are middle-sized objects, objects that are in the middle of the micro–macro scale. But they are the most complex objects known.)

What we may call "pan-protophyicism" is the view that qualia are reducible, but reducible to properties that we have not yet discovered and that are very different both from causal-role properties and from any properties that have been posited by physical science (Nagel, 1974, 1986, 1999). These unknown properties are labeled "proto-mental properties." The claim is thus that qualia reduce to proto-mental properties. A completed physics will need to invoke such proto-mental properties, but in doing so, it will not be a recognizable descendant of current physics. There is no telling now exactly how different it will be, but it could turn out to be as different from current physics as air–earth–fire–water chemistry is from current chemistry.

Mysterianism is the view that qualia are reductively explainable but that we human beings are cognitively closed to the properties that reductively explain them (McGinn, 1989). (Recall Augustine's claim and the quote from Descartes.) Just as a dog, for instance, can't understand the mathematical property of being a square root, we can't understand the properties that reductively explain qualia. Those properties run against the grain of our thought; we can't get concepts around them; they are beyond our comprehension. Mysterianism is compatible with pan-protophysicism, but the latter doesn't entail the

former. A pan-protophyscist typically maintains that human beings may someday (with work and luck) discover the proto-mental properties that reductively explain qualia.

So-called Russellian physicalism (because it was a view once held by Bertrand Russell, 1927) is the view that physical properties are dispositional properties that have intrinsic, qualitative, categorical bases, that the qualia we know by direct acquaintance are the intrinsic, qualitative, categorical bases of certain physical properties that are exemplified in our brains but that we cannot know the qualitative bases of other physical properties by direct acquaintance; indeed, we can know other physical properties only by theoretical description, and so these qualitative bases are inaccessible to us (see, e.g., Stubenberg, 1988).

Finally, type materialism for phenomenal consciousness is the view that qualia are identical with neurobiological properties of the brain, ones of a sort that could be posited by a recognizable descendant of current neurobiology (Hill, 1991; Hill & McLaughlin, 1999; Loar, 1997; McLaughlin, 2001, 2006, 2010, 2012; Papineau, 2002). Claims asserting such identities will be a posteriori, not a priori. The reason is that our concepts of qualia (e.g., the concept of the feeling of pain) are very different from neurobiological concepts, which are theoretical concepts; the concepts play very different roles in our cognitive economy. It will thus always be coherently conceivable that something could have a quale and not have neurobiological properties, and conversely for any neurobiological property. On this view, zombies are coherently conceivable; but it is maintained that they are nevertheless impossible. The properties to which our qualia concepts refer are neurobiological properties. We can determine the relevant identities only by empirically searching for the strict neurobiological correlates of qualia. The emergent materialist would claim that the correlations are fundamental laws of nature. The type materialist claims that, on the contrary, if we find such strict lawful correlations, then we could justify the claim that qualia are identical with their neurobiological correlates by inference to the best explanation of those correlations.

Each of the above positions faces a host of truly formidable difficulties, difficulties beyond the scope of this essay. Let it suffice to note that the place of phenomenal consciousness in nature remains a topic of intense interest and debate.

Mirror Neurons and Motor Cognition in Action Explanation

Mirror neurons are brain cells that seem to provide a functional matching between the motor properties of one's own actions and the sensory properties of the actions of other individuals. This entry presents the core neurological findings about *mirror neurons*, their distinctive properties, functioning, and varieties, and goes on to discuss various interpretations offered about the role of mirror neurons in motor cognition and action explanation.

Basic Findings

Basic findings about mirror neurons have been obtained during single-cell recordings. While there is a large imaging literature on mirror neurons in humans, this literature is inherently ambiguous because brain imaging measures vascular changes related to neural activity in a large number of neurons. In contrast, the evidence obtained with depth electrodes is quite compelling, and now such evidence is finally also available in humans.

Mirror neurons were originally discovered in an area of the monkey brain that controls hand and mouth movements. In this area (called F5 and located in the ventral premotor cortex), neurons fire when the monkey makes object-oriented actions, for instance, when it grasps, holds, and manipulates objects with the hand. Neurons in F5 also fire when the animal uses its mouth to bite food, to drink, or to make communicative facial expressions, such as lip smacking and when the monkey makes hand-to-mouth movements. Among the F5 motor neurons that fire when the monkey makes the actions just described, there are also some neurons that fire when the monkey is *not moving at all* but is *watching* another individual making the same or similar actions that achieve the same goal (e.g., grasping a piece of food with the hand or with the mouth). These neurons are called *mirror neurons* because it is as if the monkey is watching its own actions reflected by a mirror when watching another individual making actions.

Mirror neurons in area F5 are divided into two major classes: (1) *strictly congruent* mirror neurons (about one third of the recorded mirror neurons in F5), which fire for the same action, executed and observed, and (2) *broadly congruent* mirror neurons (about two thirds of the recorded mirror neurons in F5), which, on the other hand, fire for executed and observed actions that need not be identical but that achieve the same goal (e.g., grasping a peanut with the right hand or the left hand), or are somewhat "logically related," as, for instance, watching somebody placing food on the table and grasping the food. The fact that the majority of mirror neurons belong to the "broadly congruent" category suggests that—as a population—these cells can provide a flexible coding of the relationships between the actions of the self and the actions of others. So the mirror metaphor should not be taken too literally. These mirrors seem smart.

Mirror neurons in F5 have also the following properties: They do not fire at the sight of somebody else pantomiming an action; they fire, however, at the sound of an action (like breaking a peanut), even though the action is not seen at all; they also fire if the completion of the action cannot be seen (e.g., when a screen covers the completion of a grasping action; as long as the monkey knows that there is something to be grasped behind the screen, watching somebody reaching behind the screen will trigger the firing of the cell). Mirror neurons in F5 will also fire at the sight of somebody using a tool (e.g., pliers to grasp food), as long as the action has been repeatedly observed and it achieves a goal (like grasping food) that can be achieved with an action that the F5 neuron codes from a motor standpoint (like grasping).

Taken together, these properties suggest that what is mirrored by these cells is mostly the *goal* of the action. This is not surprising if one considers that even purely motor neurons in F5 seem to code mainly the goal of the action. Indeed, some purely motor neurons in F5 code for grasping an object with the left hand, the right hand, and even the mouth. Clearly, there are no commonalities between these three actions from the standpoint of body

part displacement or muscle contraction. However, all three actions share the same goal, grabbing the object. The most dramatic example supporting this concept comes from an experiment in which monkeys were trained to use pliers to grasp objects. Monkeys were trained to use normal pliers, which require closing the hand (i.e., flexing the fingers, as in a natural grasp) when grasping. Monkeys were also trained to use reverse pliers (which require the monkey to open the hand, by extending the fingers) to grasp objects. The same F5 cell would fire when the monkey used both normal and reverse pliers, even though the two actions required the contractions of completely opposite muscles of the hand, muscles that naturally operate in an agonist–antagonist fashion (when one contracts, the other relaxes, and vice versa).

Area F5 is anatomically connected with the anterior part of the inferior parietal lobule (called PF/PFG). Here, there are also neurons with properties virtually identical to F5 neurons, purely motor neurons and mirror neurons that mainly code for hand and mouth object-oriented actions. An experiment conducted in this brain area in monkeys demonstrated that the majority of neurons, both motor and mirror, that fire when the monkey grasps an object, code not for the grasping act per se but rather for the *intention* associated with the grasping action. Using simple contextual cues (the presence or absence of a container), the study tested two main intentions associated with the grasping action, *grasping to eat* and *grasping to place in a container*. The majority of the neurons recorded had differential discharges for the grasping action associated with the two different intentions, even though at the time of grasping the two intentions were obviously indistinguishable. This is evidence that a majority of these neurons code even *beyond the immediate goal* of the act (grasping that object). Perhaps the neuronal coding of these neurons should be conceived of as embedded in a chain of activation of different neurons that support the unfolding of coordinated actions that achieve specific intentions.

Recent studies have also shown that approximately 50% of mirror neurons will fire selectively depending on the proximity of the sector of space in which the observed action occurs. While phenomenologically we feel that the space surrounding us is "just one thing," the primate brain, including our own, contains at least two distinct maps of space. There is a map for peripersonal space, the space surrounding our own body, and a map for extrapersonal space, the space outside our reach. These space maps are "pragmatic maps" because they are dictated by the kind of actions that can be performed in the two different space sectors. Neurons supporting peripersonal space maps tend to code for reaching movements, for movements of the face and neck, and for coordinated actions defending the body. Neurons supporting extrapersonal space maps tend to code for eye movements. Some mirror neurons code for observed actions only when they occur in one of the two space sectors. Some mirror neurons code for observed actions happening in extrapersonal space and others for observed actions occurring in peripersonal space. This coding is also flexible and pragmatic. For instance, neurons coding for extrapersonal space maps do not fire for an action in peripersonal space. However, if a glass screen is interposed between the animal and the action occurring in peripersonal space, such that the animal can still see the action but cannot intervene on it, because of the glass screen (so that from a pragmatic standpoint it is as if the action occurs in extrapersonal space), then the neurons fire. This evidence clearly suggests that at least some of the coding that mirror neurons provide can be used for "online" social interactions.

Although for many years neurons with mirroring properties have been recorded only in the F5-PF/PFG network, recently a series of studies in monkeys and one case in humans have demonstrated mirroring responses in other cortical areas and for other types of movements. Three different labs have reported mirroring responses for reaching movements in the dorsal premotor and primary motor cortex. Furthermore, mirror neurons have been recorded in area LIP (lateral intraparietal cortex), an area that codes for the ocular movements that direct attention to novel objects in the environment. Mirroring in LIP may support joint attention, a fundamental building block in the development of social cognition.

Mirroring responses have also been observed in VIP (ventral intraparietal area), an area implementing peripersonal space maps and defensive body movements. VIP neurons respond to arm, face, and neck movements and tend to have bimodal receptive fields, responding to tactile stimulation and to the sight of three-dimensional (3-D) objects near the

body. The tactile and visual receptive fields are also spatially congruent. For instance, if a bimodal VIP neuron has a tactile receptive field on the forearm, it also responds to the sight of 3-D objects near the forearm, generally within the 20 to 30 centimeters of space surrounding the tactile receptive field. The strongest responses in these VIP neurons are elicited with objects moving toward the body, which suggests that VIP implements a map of the space surrounding the body that can be used to defend the body. Indeed, prolonged stimulations over cortical parietal sites around the intraparietal sulcus can elicit highly coordinated defensive movements. A recent study has demonstrated that some VIP neurons fire not only at the sight of a 3-D object near the tactile receptive field of the neuron, but also when the monkey observes a 3-D object nearing the corresponding body part (say the forearm) of another monkey. It is unclear whether the mirroring is here for the sensory event itself or for preparing a related defensive movement. The same neurons code both the sensory (sight, touch) and the motor (defensive action) event.

Auditory-vocal mirror neurons have been recorded in songbirds. These cells are active both when the songbird sings and when it is simply listening to the birdsong. They code specific sequences of the birdsong, and their activity is highly reproducible during singing and during listening. The motor aspect of these cells is demonstrated by the fact that their activity is unchanged while singing, even when the auditory feedback to the songbird is distorted. The existence of mirror neurons in songbirds demonstrates that neural mirroring is not a prerogative of primates and could be much more widespread in the animal kingdom than was initially thought.

Depth electrode recordings in presurgical patients have recently discovered mirror neurons in two human neural systems: the supplementary motor area (SMA) in the medial wall of the frontal lobe, and in two areas of the medial temporal lobe (MTL). To understand these findings, one must keep in mind that the placement of the electrodes in these studies is dictated only by clinical considerations, not research ones. Thus, recordings were obtained only from a small set of areas. None of these areas included human brain areas that are the homologs of the monkey brain areas in which mirror neurons were previously recorded. The SMA is a premotor region that is especially important for the selection and initiation of actions and for action sequences. However, the study that reported the human mirror neurons in SMA was not designed to investigate action sequences. Furthermore, the firing of the SMA mirror neurons coincided with the onset of the action, both when executed and when observed. Thus, it is reasonable to conclude that this population of mirror neurons enables mirroring for action onset.

The discovery of MTL mirror neurons in humans is surprising, because MTL is not a brain structure known for motor properties but rather for high-level visual properties and for memory properties. A potential interpretation of mirror neurons in MTL is that they mirror the *memory trace* of the observed action. That is, when I grasp a cup of coffee, my brain not only activates the motor plan for grasping the cup but also creates a memory of the grasping action. When I see somebody else grasping something, my brain not only reactivates the motor plans for grasping (using my premotor mirror neurons) but also reactivates the memory trace of my own grasping actions (using MTL mirror neurons).

Taken together, the data from single-cell recordings suggest a very rich mirroring of the actions of others. While the original findings pointed to mirroring mostly of the goals of grasping actions and some facial communicative gestures, the new data suggest that movement onset, the memory of the actions, reaching, defensive actions, and attentional eye movements, are also mirrored. These, obviously, are only those actions, or some of their specific aspects, that we know for sure are coded by neural mirroring. Given the variety of the empirical findings collected so far, it is not unlikely that all sorts of actions and their specific aspects are coded by mirror neurons.

Interpretation

While watching the actions of others, the observer activates—through mirror neurons—neural activity that is associated with her or his own actions. Thus, mirror neurons seem to enable an understanding "from within" of the actions of other people. Since actions are typically associated with intentions, feelings, and mental states, a corollary assumption of this interpretation is that mirror neurons make it possible to understand the mental states of others, thus enabling *empathy*.

This interpretation of mirror neuron activity maps well onto the assumptions of *motor cognition*, according to which cognitive processes are grounded

in our motor experience. Similarly, *embodied cognition* assumes that cognitive processes are grounded in our perceptual and motor experience. According to the ideomotor model of action, perception and action share common representational formats (mirror neurons are nice empirical evidence in its support). Thus, there are many similarities between the embodied and the motor cognition framework.

These theoretical frameworks challenge traditional models in classical cognitivism, according to which the operations of the mind are rule-based manipulations of symbols, largely detached from perceptual and motor experience. Inspired by these more traditional views of the mind, a series of objections have been raised against the "action understanding" hypothesis of mirror neurons. One objection is that people understand actions that they don't know how to perform. This objection, however, accepts a very limited notion of action understanding. Phenomenologically, motor experience enables a much richer understanding of perceived actions. As a tennis player, I am amazed at how little my family members understand of a tennis match we all watch in the living room. My richer understanding can't be enabled simply by more visual experience, since the visual experience on the court and in the living room are radically different. Mirror neurons would enable this deeper and richer form of action understanding.

Another objection is that the activation of mirror neurons during action observation is only epiphenomenal. There would be a higher-level understanding of observed actions that triggers—top down—a cascade of activations, including the activation of the motor plan to perform the observed action. This objection makes a specific prediction that is empirically testable: Visual activation should precede motor and mirror activation during action observation. Data in humans, however, have shown simultaneous co-activation of mirror and purely sensory neurons, rejecting this hypothesis.

More trivial objections are that neurological patients with motor deficits still understand the actions of others, that mirror neurons are simply "motor selection" neurons, and that they are blind to contextual cues that completely change the meaning of the observed action (consider Stevenson's fictional character Dr. Jekyll and his alter ego, the murderous Mr. Hyde, each intent on performing the same action with a scalpel on another person, but with completely different intentions).

The existence of some neurological patients with motor deficits who do understand actions is not problematic for the theory. Not all motor neurons are mirror neurons. However, the existence of some patients with motor deficits who also have action-understanding deficit is supportive of the action-understanding hypothesis of mirror neurons.

The hypothesis that mirror neurons are "motor selection" neurons is rejected by the fact that the majority of them (with the exclusion of the human SMA neurons described above) fire throughout the action, well after the action has been selected. The "blindness to contextual cues" hypothesis is rejected by the empirical study reported above on coding intentions using contextual cues.

A key theoretical issue that has been largely neglected until now is the role of control systems for mirroring in action understanding. Clearly, there are control systems for mirroring that prevent people from imitating whatever action they see. This is demonstrated by the imitative behavior of some neurological patients who after brain damage cannot help but imitate what other people do. It is unclear whether these control systems are general-purpose cognitive control mechanisms or control mechanisms dedicated to mirror neurons. Also unclear is the role of these control systems in action understanding. Perhaps they may be critical for the understanding of alternative actions, such as, for instance, fleeing when attacked.

Modal Logic and Intentional Agency

Actions such as raising one's arm, switching on a computer, or killing someone are investigated in several areas of philosophy, among others in the philosophy of action, the philosophy of mind, and the philosophy of law. Through the analogy between actions and software programs, the concept of agency is also relevant in computer science, in particular in artificial intelligence (AI), multi-agent systems, and theoretical computer science. In the second half of the 20th century, philosophers and logicians like G. H. von Wright and Stig Kanger started to use "modal logic" as a tool for modeling intentional action and related concepts such as *omission*, *ability*, and *opportunity*.

The Two Approaches

There are two general views of the logical form of action sentences: (1) the "action as result" view and (2) the "action as means + result" view. The entry reviews these two approaches and recent developments.

According to the "action as result" view, an action can be identified with a state of affairs that is brought about by an agent. In other words, the action of an agent can be identified with the result that the agent causes. Examples of states of affairs are that an arm is up, that a computer is turned on, that somebody is dead, and so on. So my action of switching on the computer is identified with my bringing about the state of affairs that the computer is started, and my action of killing someone is identified with my bringing about the state of affairs that someone is dead. Examples of modal logics of action taking this perspective are the Logic of Seeing-To-It That (STIT), proposed by Nuel Belnap, John Horty and colleagues, and the Logic of Bringing-It-About-That (BIAT), proposed by Kanger and recently elaborated by Dag Elgesem. For instance, STIT logic has modal operators [*i*: **stit**], where *i* is an agent name. The STIT formula [*i*: **stit**]*p* means that "the agent *i* sees to it that the proposition *p* is true."

The alternative view, "action as means + result," focuses on both the result and the means by which an action is performed. It is about sentences such as "I bring it about that the computer is on by toggling the switch" or "I bring it about that someone is dead by poisoning him." Examples of modal logics of action taking this perspective are variants of Propositional Dynamic Logic (PDL), where an agent argument is added to events (which were introduced in theoretical computer science), as well as Krister Segerberg's Logic of "Bringing-About-By-Doing." For example, there exist variants of PDL that have modal operators of the form [*i*: α], where *i* is an agent name and α is an action name. The formula [*i:* α]*p* means that "after the agent *i* performs the action α, it is the case that *p*."

Recent Developments

In the past two decades, there have been several proposals to extend the modal logic analysis of action sentences expressing intentional action in both the "action as result" tradition and the "action as means + result" tradition.

Logicians in the "action as result" tradition, such as Jan Broersen (a contributor to this encyclopedia), Caroline Semmling, and Heinrich Wansing, have proposed to distiguish the fact that an agent *accidentally* sees to it that a given state of affairs is true from the fact that an agent *intentionally* sees to it that a given state of affairs is true. A way to capture this distinction is by extending STIT logic with special operators for intentional action of the form [*i*: **istit**], where [*i:* **istit**]*p* means that "the agent *i* intentionally sees to it that the proposition *p* is true." A fundamental relationship between these operators and standard STIT operators is expressed by the following logical axiom:

$$[i\text{: }\mathbf{istit}]p \rightarrow [i\text{: }\mathbf{stit}]p,$$

which means that if an agent intentionally causes *p* to be true, then he causes *p*. One can easily distinguish intentional action captured by the operator [*i*: **istit**] from nonintentional (accidental) action captured by the formula

$$[i\text{: }\mathbf{stit}]p \wedge \neg[i\text{: }\mathbf{istit}]p.$$

That is, "accidentally causing *p*" just means "causing *p* without intentionally causing *p*." Another way to capture the distinction between intentional action and accidental action is by extending STIT logic with modal operators for goal. These operators are called *volitional* modal operators (expressing the idea of intending or willing to act), in opposition to epistemic and doxastic modal operators, which are studied in the context of epistemic logic (the modal logic of knowledge) and doxastic logic (the modal logic of belief), respectively. The generic form of these goal operators is $Goal_i$, where $Goal_i\ p$ means that "the agent *i* wants (or wishes) *p* to be true." Intentional action is then captured by the formula

$$[i\text{: }\mathbf{stit}]p \wedge \mathrm{Goal}_i\ [i\text{: }\mathbf{stit}]p,$$

whereas nonintentional (accidental) action is captured by the formula

$$[i\text{: }\mathbf{stit}]p \wedge Goal_i\ [i\text{: }\mathbf{stit}]p.$$

That is, "intentionally causing *p*" means "causing *p* with the goal of causing *p*," whereas "accidentally causing *p*" means "causing *p* without the goal of causing *p*."

Logicians in the "action as means + result" tradition have been more interested in studying the concept of *intention*. The seminal work in this area is Philip R. Cohen and Hector J. Levesque's article "Intention Is Choice With Commitment." Starting from Michael Bratman's philosophical theory of action, Cohen and Levesque have analyzed intention as a version of PDL in which time is assumed to be linear. On their account, intentions are defined in several steps in relation to the concept (and corresponding modal operator) of "goal"; that is, intention is viewed as a strongly realistic preference: Among the worlds that are (epistemically) possible for an agent, there is a subset that the agent prefers. According to Cohen and Levesque's analysis, a given agent *i* has the intention that *p* if and only if the agent *i* has the persistent goal that *p* and believes he can achieve that goal by an action α of his, where a persistent goal that *p* is a goal that is kept by the agent until it is either fullfilled or believed to be out of reach.

In the article "A Logic of Intention and Attempt," Emiliano Lorini and Andreas Herzig complemented Cohen and Levesque's approach by integrating the concept of an attempt to perform an action. The concept of "attempt" is indeed crucial in order to relate the agent's intention (the mental world) with the performing of the action (the physical world). The central principles here are that "if an agent *i* has the intention to perform a given action α of his, then he attempts (or tries) to perform the action α" and that "if an agent *i* tries to perform a given action α of his and has the capability of doing α, then he will successfully perform the action α."

Models in Science

The *model-oriented stance* in the philosophy of science places models at center stage in our analysis of scientific practice and focuses on issues to do with their multivarious nature(s) and role(s). Many of the relevant examples in this entry have been drawn from the physical sciences, but there are obvious ways in which the discussion can be extended to the social sciences.

The Nature of Models

Models come in all shapes and sizes, as it were. Some are physically constituted, as in Francis Crick and James Watson's famous "tinplate and wire" model of DNA; others are theoretical, as in the Lotka-Volterra model of predator–prey relationships. Within the latter category, some may be quantitative and others qualitative, and combinations of both may feature in scientific investigations. What distinguishes a model from a theory, broadly construed, may not always be clear (and indeed, there are many examples of scientists using these terms interchangeably). However, typically, models incorporate certain simplifications and idealizations that render them more tractable, either computationally or otherwise. Despite the idealized aspects, models *represent* the system concerned. To do so in the relevant respects, and to the requisite degree, the model must be *similar* to the system, in at least some regard.

This focus on the nature of models as representations provides a general framework that is capable of embracing all the very different kinds of models one finds in the sciences. Here we are talking about the nature of models as representational devices at the level of scientific practice. One can then shift up a level and consider ways of representing models (and theories) themselves, at the level of the philosophy of science. At this level, the variety of different kinds of models has often been cited as blocking the construction of any such unitary framework. However, one can regard all such kinds—whether physical, theoretical, or whatever—as instantiating certain kinds of structures, and this structural or model-theoretic approach, then, offers a formal account of representation and also broadens the manner in which models represent, from similarity to the sharing of various kinds of structural features.

Furthermore, this last emphasis on the structural commonalities between models and the systems being modeled helps articulate the various roles that models play with regard to understanding, explanation, and drawing inferences about the system.

The Role of Models

By emphasizing only certain features of the system of interest, a model may then allow certain inferences to be more easily drawn. By drawing such inferences within the model and then transferring these inferences to the system—via the structural commonalities between the model and the system—we perform what is known as *surrogative reasoning*. This ability to support such inferences illustrates the representational power of models, but of course, it would not be possible to make these inferences unless the

appropriate relationship of structural similarity held between the model and the system in the first place.

It is, in part, because of this ability that models have been taken to possess a form of functional "autonomy" in the sense of acting as the locus for knowledge claims, providing the basis for further developments, and so on. A glance at the relevant literature in any particular domain of science will reveal models acting as "autonomous agents" in this uncontentious sense. The stronger claim that models are autonomous by virtue of being constructed independently of theory is more problematic and must be judged on a case-by-case basis.

Furthermore, it is by virtue of such functional autonomy that models act as *mediators* between theory and phenomena. Thus, for a given theory to explain and be confirmed by the relevant phenomena, certain simplifications and idealizations may typically have to be introduced. This mediating function may be extended to accommodate the sense in which models may help relate different kinds of explanation within a field. So with regard to the different levels at which explanations in the social sciences are articulated, assumptions associated with certain models at one level may intrude into another, allowing for interesting interlevel relationships.

Again, shifting to the level of the philosophy of science and of social science itself, this intrusion of models from one level to another, and interlevel relationships in general, can be usefully and formally represented by the model-theoretic approach. The adoption of such a formal framework can then underpin claims about the nature of such interrelationships, both between and within levels as well as between theories, models, and the relevant phenomena.

It is also by virtue of the structural relationships that hold between models and the relevant systems that certain kinds of models can be used in computer simulations, both allowing scientists to explore certain dynamical features of systems that might be difficult or impossible to access otherwise and also suggesting revisions to the model or even alternative models entirely. Given the complex nature of many systems studied in the social sciences, model-based computer simulations offer an attractive option.

And, of course, it is this complexity that raises problems when it comes to capturing the regularities that scientists are interested in via the kinds of laws that one finds in the physical sciences. Here, models may offer a useful substitute, and in the philosophy of biology, for example, a broadly model-theoretic stance is now common. The extent to which such a stance can be extended into the social sciences hinges on a number of methodological issues but remains an open and interesting question.

Models in Social Science

The social sciences use models in order to understand phenomena, to predict trends (e.g., in mortality, morbidity and fertility), and to inform policy actions. For instance, a social scientist may build a model to explain why variations in maternal education are consistently associated with variations in child mortality in developing countries. She may build a model to predict how lung cancer rates

will change if tobacco consumption is considerably reduced. Or she may build a model that supports a policy action on unemployment benefits in order to reduce unemployment rates. Those are empirical models, namely, models that employ data. There are also models that do not employ data and that are instead more theoretical or formal in character. These are more often used in economics and are intended to reconstruct economic processes and behaviors. An example is Thomas Schelling's model of segregation or Milton Friedman's hypothesis of permanent income.

This entry focuses on empirical models used in the social sciences, analyzes their central features, presents central epistemological issues related to them, and shows the relation between models and theories in natural science as well as in social science.

Empirical models can be quantitative or qualitative, depending on the methods used to analyze data. Quantitative models make prominent use of probability and statistics in order to analyze large amounts of data, typically numerically collected; a consequence of this approach is that the larger the size of the sample, the more reliable the analysis. Qualitative models, instead, employ methods for the collection and analysis of data that are independent of statistics and probability. They typically focus on the narrative provided by the chosen interviewees and pay particular attention to their language, background, beliefs, and other contextual aspects.

Another important distinction to be made is the following. In quantitative analysis, models can be associational or causal, depending on their goal. While associational models only aim to provide a faithful description of a phenomenon, causal models go further in searching for the causes of that phenomenon. For instance, an associational model may describe how obesity rates vary according to socioeconomic classes. A causal model, to follow up on the same example, would go further in stating whether and why socioeconomic differences *cause* obesity.

Models are evaluated according to their *validity* or *invalidity*. The locus classicus is the seminal 1979 book by Thomas D. Cook and Donald T. Campbell. There is a vivid debate both in social science methodology and in philosophy about the methods for ensuring the validity of models. There are two main types of validity: *internal* and *external*. Internal validity concerns whether a relationship between two variables is causal, or whether from the absence of a relationship between the two variables we can infer absence of causality. External validity concerns the possibility of generalizing a presumed causal relationship across different times, settings, or populations.

There are also philosophical issues making the notion of validity problematic. For instance, scientists disagree whether internal or external validity is more important; whether external validity is needed or achievable at all in social science; whether validity concerns the results, the model, or the data; and so on. Validity is a notion that certainly needs further investigation and conceptual clarification. Despite all the difficulties that undermine any attempt to provide an account of validity, there is at least one reason to keep the notion. The validity *of a model* allows us to endorse an overarching view where establishing whether *X* causes *Y* depends on the evaluation of the *many* elements of a model: background knowledge, assumptions, data, statistical tests, and so on. This is at variance with the approach typically endorsed in philosophical analyses: saying what makes a causal claim (i.e., *X* causes *Y*) true. Granted, in ordinary language the issue is usually to establish whether the claims we made are true or false based on ordinary causal assessment. For instance, competent speakers would think that it is true that I wouldn't have missed the train had I heard the alarm clock ringing this morning. However, in science, establishing causal relations goes far beyond finding the "facts" or "objects" that make a causal claim true. It instead involves evaluating the whole modeling procedure from beginning to end. This implies that we can challenge the validity of a model at different stages: poor theoretical support, bad data collection, failure of statistical tests, and so forth.

Much debate in the philosophical literature is devoted to the distinction between *models* and *theories*. In social contexts, the distinction has a clearer borderline. Models are used to analyze data and participate in developing general theories. For instance, models on migration that are used to analyze empirical data in different countries and at different times can contribute toward developing a general theory of migratory movements. However, the achievement of general and robust theories in the social sciences is much more difficult than in, say, physics, because human behavior is highly mutable across time, space, and culture. This implies that findings in social

science are highly context dependent. Yet it does not mean that they are not objective or reliable. Typically, (empirical) modeling of phenomena in social science participates in building theories. Economics is perhaps an exception. According to classical economics, economic theory dictates the mechanism (also called the data-generating process) underlying the data, and modeling is just about empirical testing.

Modernity

This entry charts the conceptual and historical unfolding of the notion of modernity, central to the development of both philosophy and the social sciences.

It is customary to locate the origins of *philosophical* modernity in Europe in the period from the middle of the 17th to the end of the 18th century. From René Descartes to Immanuel Kant, scholars posited the individual human being as the knowing subject who, through the combination of freedom and reason, develops an understanding of the world that is radically different from all the earlier ones. In parallel, a particular philosophy of *political modernity* emerged that held that the rules for a peaceful life in common would best—or only—be established through a contract between free and reason-endowed individuals (from Thomas Hobbes's *Leviathan* to the combination of individual freedom and collective self-determination in John Locke). Even though they co-emerged, the foundational philosophy and the political philosophy of modernity proved to stand in tension with each other, which explains much of the relation between such philosophies and the social sciences that were to emerge in the course of the 19th century.

In both its strands, such thinking provided indeed a new and radical expression of the human condition. It would be erroneous, however, to equate it with the understanding of modernity that became dominant in—and characteristic of—Europe and the West, to see it as the philosophy of European modernity *tout court*. Rather, the positing of the autonomous, reason-endowed individual became an extreme point in a tension-rich field of interpretations of modernity.

From the late 18th century onward, the aforementioned modern self-understanding was criticized with regard to its concept of the isolated individual as the knowing and acting subject under conditions of modernity. In response, concepts of intersubjectivity and of situated freedom were proposed to replace the grounding of modern action in the individual. The key contribution came from G. W. F. Hegel at the beginning of the 19th century, and it keeps being referred to as central by contemporary philosophers of modernity such as Jürgen Habermas, Axel Honneth, Robert Pippin, and Charles Taylor.

After the French Revolution, more specifically, political thinkers came increasingly to hold that the founding of the modern polity in the free individual and her capacity for reason alone would be insufficient. The bond of reason and interest, it was argued, was too thin and the extension of social relations in emerging commercial and industrial society too wide to sustain such a polity. In response to this political problem, the recourse to intersubjectivity, however, seemed less convincing than with regard to a basic social ontology. The idea that the social world was created and maintained through interactions between situated persons, and not the least through bonds of communication that would create an action-guiding "public opinion," lost plausibility for large societies like postrevolutionary France and most of her European neighbors.

In turn, a new thinking about social bonds that existed regardless of the will of the singular human beings and had the potential of integrating large collectivities and/or introducing a dynamics of change was proposed, and this in two basic versions. Some authors, maybe most prominently Gottfried Herder, held that cultural-linguistic bonds existed between human beings in the form of shared values and beliefs and commonality of language. Modern polities would be sustainable if they were created by and with speakers of the same language. This thought fed into the national liberation and unification movements and, later, the nationalism of 19th- and 20th-century Europe. Other authors assumed that the rise of commercial and industrial society would extend relations of social interest across large groups, either through mutual dependence in a division of social labor or through the commonality of class position. The latter position was central to Karl Marx's thought, the former to Émile Durkheim's.

This reconceptualization of social bonds stood at the origins both of the social sciences and of the social transformations that went in parallel from the later 19th century onward. Collective concepts such as nation, class, and society became key concepts of the social sciences and referred to social phenomena that were created to deal with the insufficiencies of liberal and instrumental thinking, which as such formed the core of economic theorizing. The social sciences witnessed their disputes on method with foci on the relation between holist (collectivist) and atomist (individualist) ontologies, on the one hand, and abstract reasoning and situated (historicist) reasoning, on the other. Social life witnessed a transformation of restricted liberal modernity into an organized modernity that was based on collective conventions and institutions of various kinds framed by exactly such concepts as nation, class, and society.

In the early 20th century, in particular after World War I, the tensions within these intellectual and political constellations proved unbearable. Politically, the critique of the consequences of political and economic liberalism led to collective existentialisms, of which Nazism, based on a concept of nation, and Stalinism, based on a concept of class, were the most pronounced examples. Philosophically, the critique of modernity and its intellectual tool sets culminated in calls for radical renewal, such as in Martin Heidegger's work or in the early Frankfurt school of Theodor W. Adorno and Max Horkheimer.

After World War II, a less tension-ridden and more inclusive version of liberal modernity, devoid of philosophy and flanked by technocratic social sciences, seemed possible. Our contemporary thinking, however, is marked by a new round of critique, often retrieving older resources, that emerged during the 1960s and culminated toward the end of the 1970s. In their broadest meaning, the terms *poststructuralism* and *postmodernism* stand for a philosophical critique of the "discourse of the human sciences" (Michel Foucault and Jacques Derrida) of the preceding two centuries and for a sociopolitical critique of organized modernity and its claims of having made functional and normative accomplishments unavailable to other societies elsewhere and in the past (Jean-François Lyotard).

These debates and—maybe more importantly—recent transformations of the world that have seen the rise of non-Western capitalisms and the radical critique of Western modernity arising in various forms out of the situation of postcoloniality have reopened the debate about modernity. Most significantly, they have reintroduced a discussion about the ambiguous nature of "occidental rationalism," of which Max Weber had identified the claim of having both local origins and universal significance, thus inviting comparison between the presumed Western and other trajectories of modernity. This has entailed, conceptually, the recognition of a wider interpretative field of philosophy of modernity than has long been assumed and of a plurality of forms of political modernity that may coexist in the current global context.

Modularity of the Mind

The concept of mental modularity plays a prominent role in both philosophy and psychology. As originally articulated by Jerry Fodor in the early 1980s, it characterizes a type of information-processing mechanism that is likely to figure in relatively low-level parts of the functional architecture of the mind. More recent developments of modularity theory, beginning in the early 1990s, loosened this characterization, thereby fostering the idea of the mind as more pervasively modular in organization.

This entry briefly surveys these two phases of thinking about modularity and points to their significance for the philosophy of social science.

Fodorian Modularity

According to the conception of modularity articulated by Jerry Fodor, a module is a component of the functional architecture of the mind that exhibits a cluster of interrelated features. The hallmarks of Fodorian modularity are domain specificity, mandatory operation, limited central accessibility, fast processing, informational encapsulation, "shallow" outputs, fixed neural architecture, characteristic and specific breakdown patterns, and characteristic ontogenetic pace and sequencing. Since each of the features on this list admits of degree, modularity does so as well, but a system will count as modular if it exhibits enough of them to a significant degree. And while each feature is characteristic of modular systems, some features are more central than others, and one of them, in particular—informational encapsulation—is the most central of all.

A system is "informationally encapsulated" to the extent that, in the course of processing its inputs, it has restricted access to information stored outside the system itself. For example, the visual system has limited access to what the perceiver explicitly believes about the character of a visual stimulus, since such information is not stored in a proprietary database. This is suggested by the persistence of visual illusions, such as the Müller-Lyer illusion, in which a pair of equal parallel lines appear to differ in length even after the viewer is convinced of the contrary (see Figure 1).

This particular phenomenon also illustrates the related concept of "cognitive impenetrability."

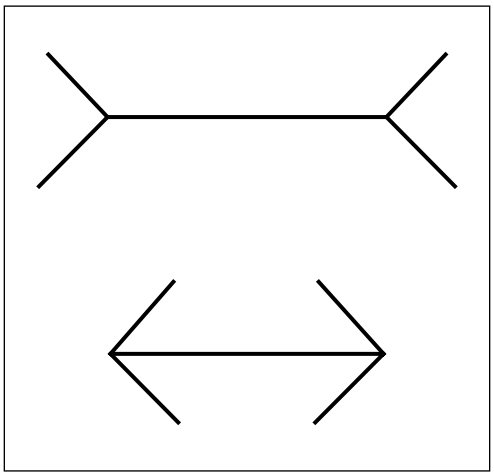

Figure 1 The Müller-Lyer Illusion

Source: Author.

Cognitive impenetrability is a species of encapsulation, namely, encapsulation relative to what the perceiver believes about the world (as opposed to what the deliverances of the visual system might lead her to believe).

Informational encapsulation lies at the heart of modularity, largely because of its explanatory priority vis-à-vis several other features on Fodor's roster. Consider, for instance, the fact that modular processes are typically fast (a half-second or less from start to finish) and mandatory (not under conscious control) and their outputs are "shallow" (computationally cheap and informationally sparse). These features can be seen, at least to some extent, as by-products of a module's restricted informational purview during processing. The same goes for other hallmarks of modularity, such as neural localizability ("hardwiring"), functional dissociability, and innateness.

Is the Mind Really Modular?

With this conception of modularity in play, a natural question to ask is this: How much of the mind is modular in this sense? Fodor's answer is clear: not very much, at least insofar as one thinks of higher cognitive functions, such as decision making, problem solving, and planning, as paradigmatic of the mental. On Fodor's view, only the "sensing and acting" parts of the mind—that is, the relatively low-level systems dedicated to perception and motor control—exhibit much in the way of modularity; the "thinking" parts of the mind do not. This is

due largely to the fact that systems responsible for higher cognition, unlike sensorimotor systems, are *not* informationally encapsulated. Indeed, it seems almost constitutive of higher cognitive operations that they draw freely on widely disparate information stores in the brain. Hence, to the extent that modular systems are explanatorily tractable in a way that nonmodular systems are not, the prospects for a successful science of the mind appear to be somewhat limited. (This *pro tanto* claim is roughly equivalent to what Fodor calls the "First Law of the Non-Existence of Cognitive Science.")

These considerations lead naturally to a second question: Is there some other sense, less restrictive than Fodor's, in which the mind might be said to be modular? The answer from psychology, and *evolutionary psychology* in particular, is a resounding *yes*. On this view, modularity is no longer a peripheral feature of our mental architecture but a pervasive one.

Massive Modularity

The suggestion that the mind might be "massively modular," that is, modular through and through, has relatively little going for it so long as one thinks of modularity along Fodorian lines. The principal reason for this, as noted above, is Fodor's insistence that modularity requires informational encapsulation. Once we relax this requirement, the class of cognitive systems that might count as modular expands considerably.

Accordingly, proponents of massive modularity like Peter Carruthers emphasize other facets of Fodorian modularity, such as domain specificity, automaticity, and inaccessibility of a system's operations to first-person report. Of these features, *domain specificity* tends to get the spotlight. Like encapsulation, domain specificity is a measure of a system's informational reach, but in a different (and logically independent) sense. A system is domain specific insofar as the range of inputs that can turn it on, or initialize its operations, is relatively narrow. For example, the systems responsible for recognizing faces and voices, seeing colors, and analyzing shapes all count as domain specific, since each of these systems is effectively attuned to a particular class of stimulus. That sort of selective attunement, however, does not require informational encapsulation, or conversely.

Much of the enthusiasm for massive modularity stems from the application of *evolutionary* ideas to cognitive psychology. Massive modularists like Leda Cosmides and John Tooby, for example, have argued for the view as follows. First, the human mind is a product of natural selection. Second, selective fitness requires the cognitive ability to solve a range of adaptive problems, such as finding food and shelter, selecting mates, and negotiating social exchanges. Third, adaptive problems can be solved more quickly, efficiently, and reliably by modular cognitive systems than by nonmodular ones. Hence, a modular architecture for cognition (i.e., not just perception and motor control) is more plausible on evolutionary grounds than its nonmodular counterpart.

Lessons for the Philosophy of Social Sciences

The significance of massive modularity theory, and of modularity theories more generally, for the philosophy of social science is difficult to overestimate. For present purposes, two points will have to suffice.

First, given the long-standing debate within social science regarding the relative contributions of nature and nurture to human development (or, as Steven Pinker puts it, the relative plausibility of nativism vis-à-vis empiricism, or the "Blank Slate" model), the affinity between modularity and innateness makes modularity a natural focus of investigation within the philosophy of social science.

Second, insofar as philosophers of social science are concerned with developing an account of psychological explanation—and to the extent that psychological explanation is construed as a species of mechanistic explanation—the distinction between modular and nonmodular mechanisms will likely figure in any such account. This is reflected in recent debates about the functional architecture of social-cognitive capacities such as reasoning about social exchanges (e.g., cheater detection) and reading other minds.

Money

This entry offers a historical and conceptual overview of social scientific and philosophical accounts of money.

Money has long intrigued philosophers and social scientists. Scholars have debated the nature of money at least since Aristotle, who argued in *The Nicomachean Ethics* that money is not natural but a creature of law or convention whose value is subject to alteration. This distinction between the intrinsic value of the monetary medium and the social and legal context on which its definition as money depends continues to characterize present-day debates about the difference between substance- and token-money. It is also important to arguments about the origins of money, central banking, metallism and chartalism, the gold standard, and the role of money in relation to international trade. There are two main schools of thought in monetary theory. On the one side are "chartalist" or "claim" theories of money, which follow Max Weber, Georg F. Knapp, and John Maynard Keynes in arguing that money's value depends on political and legal authority. On the other side are commodity theories, which argue that money's value resides either in its own intrinsic properties as a medium or in its relationship with an underlying commodity, such as gold. In addition, there are "cultural" accounts of money, which suggest that both claim and commodity theories of money underestimate the importance of money's more symbolic properties, which are rooted in the social contexts in which it is used.

In economics, money is defined as a medium of exchange, a store of value, and a unit of account. But the topic demands deeper questioning, throwing up puzzles about the nature of time, number, and space, and for this reason, philosophers, historians, anthropologists, sociologists, political scientists, and geographers have all made major contributions to our understanding of the nature and workings of money. The richest works of monetary scholarship therefore straddle several fields. Perhaps most notably, Georg Simmel's *Philosophy of Money* was a work of sociology as well as philosophy that started out in the early 1890s as an article on the psychology of money. In the book itself, Simmel insisted that "not a single line" of his 600-page book was about economics; indeed, he took a quite different view of the value of money. By his reckoning, money represents an abstract idea of value that is underwritten by "society," depending on a form of trust he likened to religious faith.

Simmel can be counted among a number of modern thinkers—including Karl Marx—who feared that money's increasing use in society would have a corrosive impact on social relationships, emptying them of deeper significance and meaning, reducing qualitative connections to quantitative ones, and rendering our relations to each other increasingly functional and utilitarian. Sociologists and anthropologists who argue that money richly conveys meanings and symbolism that are derived from the social and cultural context of its use have since challenged this view. While anthropologists have debated whether some of this richness is lost in modern economic systems, in sociology the work of Viviana Zelizer is notable for arguing that whenever we use money—whatever the context—we "earmark" it and, thereby, render it distinctive and personal. For anthropologists and sociologists working in this tradition, money is therefore not the abstract and impersonal medium of calculation that classical economic and social thinkers held it to be.

Empirically, scholars have been debating how to define "new" and "alternative" monetary media, such as LETS tokens, Time Dollars, commercial reward schemes, and e-money, alongside the "hybrid" monetary systems that operate in marginal regions of the global economy, such as Melanesia and Africa. Broadly speaking, two countervailing themes stand out in the academic literature. On the one hand, some scholars are focusing on the fact that large-scale currencies like the U.S. dollar are circulating more and more outside the borders of their issuing states and, in some cases, are actually replacing smaller currencies. This process constitutes a trend

toward the increasing *homogeneity* of money. From the perspective of political economy, key drivers of monetary homogenization are state currency competition (dollarization) and regional factors (monetary union). From a Marxist perspective, economic factors, such as the balance of global capital flows, are crucial and account for what the geographer David Harvey calls the "spatio-temporal fix." On the other hand, there are scholars who argue that the range of monetary forms in circulation that are not state-issued currency is expanding, primarily outside the mainstream banking system. This, they claim, constitutes a trend toward increasing the *diversity* of money. The drivers of monetary diversification are connected on one side to financialization and, on the other, to local money and social lending.

The diversification of monetary instruments within the finance industry has been driven by increasingly sophisticated risk management, the efforts of the banks to evade national regulation regimes, and the intense pace of technological innovation in the construction of financial instruments—an increasing tendency to profit from money itself. As for local currencies and social lending networks, monetary diversification is largely driven by economic necessity (financial exclusion), economic advantage (transaction costs), and political commitments to community-related and ecological goals (including more radical programs informed by neoanarchist beliefs). Both trends suggest a decline in the influence of states over the world's money flows; indeed, there is sometimes an observable connection between monetary homogenization and diversification: The widespread use of local currency schemes during the Argentine economic crisis of 1999 to 2002 was an expression of both trends.

The view that states are losing their monopoly over the production and management of money has been reinforced by the development of financial instruments such as derivatives, which some scholars believe demonstrate all the essential features of money. Today's monetary flows connect nodal points such as global cities—with their major financial centers and business districts—along with other major rallying points for money, such as the international art markets. In effect, these centers serve as bottlenecks in the global circulation of money. The major consequence of these flows, according to some geographers, is money's deterritorialization: We are witnessing the end of money's geography. This analysis is central to Michael Hardt and Antonio Negri's *Empire*, which draws on the work of the French philosophers Gilles Deleuze and Félix Guattari to examine the "rhizomatic mobility" of money-capital, whose control is no longer delimited by national borders or by traditional international boundaries. However, the recent financial crisis, which saw governments taking part-ownership of troubled banks, suggests that the argument that states have become irrelevant to the world of global finance is premature. The recent emergence of sovereign wealth funds as a major force in the world's monetary and financial system complicates this picture still further.

Montesquieu and the Rise of Social Science

No theorist of the French Enlightenment contributed more to the development of the social sciences than Charles Louis de Secondat, Baron de Montesquieu (1689–1755). Although the phrase *la science social* was only first used near the end of the 18th century and initially had public policy connotations, it is clear that Montesquieu anticipated developments we now associate with the scientific investigation of human societies.

This entry gives an account of Montesquieu's contribution to the rise of the social sciences qua "sciences" as we have come to know them, as well as of the particular methodological precepts and social scientific axioms he himself formulated to explain both specific government types or the general spirit of nations and the rationality of human social and political action.

In suggesting a linkage between regime types, expanse of territory, and the underlying climatological, geographical, and cultural factors, he demarcated the field of political sociology. In connecting religious beliefs and practices to the underlying social conditions and psychological needs, he anticipated the emergence of the sociology and psychology of religion. In comparing European and Asian practices, he contributed to the founding of comparative law and comparative religion. By focusing attention on a wide range of customs displayed by preliterate cultures, he contributed to the birth of ethnography and anthropology. Moreover, Montesquieu made important contributions to history, political science, sociology, and economics by writing a causal account of the fall of Rome; revising the regime typology inherited from Plato and Aristotle to take account of *how*, rather than *by whom*, power is exercised; constructing ideal types for aiding analysis of governmental form; and analyzing the social and political effects of commerce as well as the diverse sources of the wealth of nations.

Montesquieu understood that *social facts* occupy a realm apart from governmental, psychological, biological, or chemical facts, and he therefore sensed that society presents its own particular subject matter for the social scientist to explore. Moreover, he assumed that certain supposed attributes of human nature cannot explain the enormous variety of customs, manners, and morals that can be observed in various cultures around the world. In addition, like the French sociologist Émile Durkheim substantially later, Montesquieu understood that societies are natural, *organic* entities that by no means originate in an act of social contracting, as so many other political theorists had claimed. Montesquieu also perceived that it is the presence of internalized *values* and *beliefs*—"virtue" for republics, "honor" for monarchies, and "fear" for despotisms—that explains the durability of the social structures underlying governmental forms. Society is *not* the product of individual minds isolated from one another. Rather, society results from *interaction* between individuals and is greatly influenced not only by the principle of government but also by what he termed the "general spirit" (*esprit général*) that, once formed, imposes itself on individual minds and shapes human behavior.

Practitioners of social science assume the *rational* explicability of social phenomena. There can be no science if there are no patterns to discover and if no laws can be devised that describe and predict social behavior. Montesquieu was convinced that rather than acting capriciously, human beings often make rational choices influenced by underlying causes. Thus, he asserted in the Preface to *The Spirit of Laws* (1989), "I began by examining men, and I believed that, amid the infinite diversity of laws, and mores, they were not led by their fancies alone" (p. xliii). Following this train of thought, he remarked in Book I of his treatise that "blind fate" cannot be the cause of "all the effects that we see in the world." He acknowledged that the "intelligent world" displays less regularity than the natural world since human beings possess free will and can err through ignorance, but he believed that the patient observer can nonetheless discern the causes that render human behavior explicable. Thus, he remarked in his notebooks, *Mes Pensées*, "When a law seems bizarre, and

there is no sign that the Legislator has had an interest in making it so . . . , one ought to believe that it is more reasonable than it appears, and that it is based on a sufficient reason" (Montesquieu, 1991, p. 589).

Inspired by the successes of Kepler, Galileo, and Newton in formulating the laws governing matter and the solar system, Montesquieu assumed that similar progress could be made in discovering the constant relations (*rapports*), or *natural regularities*, rendering human social behavior explicable. He concluded that when subjected to a given set of circumstances, human beings will react in predictable ways, and this means that *societal behavior can be studied by the methods we now associate with social science*.

The accuracy of Montesquieu's assertions is less important than their source, namely, his conviction that political, social, and economic practices can be traced to discernible *causes*. It was this viewpoint that encouraged him to formulate a number of now famous social science axioms. He concluded, for example, that despotism arises in countries characterized by extreme heat and vast territorial expanse, where subjects lack energy to resist and where only fear of harsh measures can render subjects on the periphery loyal to a distant central government. Democratic republics will spring up, on the other hand, in extremely small, frugal societies that nourish equality and where direct citizen involvement in lawmaking enables self-sacrificing political virtue to take root. Slavery will be found in hot climates, where labor is burdensome, while polygamy will exist where gender imbalances make women plentiful and men scarce. Even religious phenomena, Montesquieu believed, can be traced to specific, causal influences. Protestantism, for example, flourished in northern Europe because the cold climate there gives the people a spirit of independence and liberty, whereas the people of southern Europe were better suited to Catholicism, which has a more authoritarian structure.

Montesquieu's conviction that social, political, economic, and religious phenomena are explicable in terms of underlying *causes* is apparent in the very title of his posthumously published *Essay on Causes Affecting Minds and Characters*. In this essay, composed between 1736 and 1743, he analyzed the physical causes (*causes physiques*) of human behavior before proceeding to an analysis of the moral, social, and intellectual influences (*causes morales*) shaping societal practices. His list of physical causes included climate, soil, topography, and terrain, while his enumeration of moral causes included maxims of government, laws, education, religion, modes of subsistence, and the customs and manners that shape behavior in a given society.

Foreshadowing Émile Durkheim's later emphasis on the "collective conscience" of a society, Montesquieu believed that every nation develops a "general spirit," or overall disposition, which is the result of all the major influences shaping national character, including climate, religion, laws, maxims of government, precedents, morals, and customs. In sorting out the relative strength of these influences Montesquieu developed what sociologists term a *functionalist* perspective, envisioning social phenomena as part of a larger social totality. The stronger the influence of one particular factor in a nation's overall disposition, the weaker the others are likely to be. For example, when the moral precepts of a religion are strict, the civil and criminal laws will generally be less severe. Montesquieu understood that nations are unique blends of idiosyncratic influences, and he concluded that the general spirits of nations represent a subtle blending of multiple causes that gives each people a distinctive national character. Every nation develops its own "natural genius," which it is best not to alter. Even faults, Montesquieu suggested, should normally be left unaddressed since they are part of an overall blend of influences producing the general spirit, or the common culture to which a nation has grown accustomed.

Montesquieu was by no means a strictly empirical social scientist refraining from *moral judgments*. He combined the descriptive, scientific outlook that prompted August Comte, Émile Durkheim, and Raymond Aron to consider him the originator of sociology with a *normative*, more traditional natural-law perspective that led him to forthrightly condemn evils such as despotism, slavery, torture, religious fanaticism, ruthless colonial practices, cruel and excessive punishments, and legal systems requiring self-incrimination. Much more than the other theorists of his day, however, he set out to discover the reasons why societies develop particular laws, customs, religions, and institutions. Hence, he remarked in his Preface to *The Spirit of Laws*, "I did

not draw my principles from my prejudices but from the nature of things" (p. xliii).

Montesquieu's sociological approach and appreciation of cultural diversity contributed to his belief that there is no ideal form of government that every people should adopt. The right government for a given people, he remarked in Book I of *The Spirit of Laws*,

> is the one whose particular arrangement best relates to the disposition of the people for whom it is established. . . . Laws should be so appropriate to the people for whom they are made that it is very unlikely that the laws for one nation will suit another. (p. 8)

Laws should reflect the particular circumstances present in a society, including "the nature and principles of the government"; "the physical aspect of the country"; the "climate," "terrain," and "extent of the country"; the socioeconomic stage a people has attained; "the degree of liberty that the constitution can sustain"; religious beliefs; wealth, or lack thereof; population size; commerce; mores; and manners (p. 9).

Given Montesquieu's interest not so much in specific laws and legal systems but rather in the underlying influences on laws, which constitute the "spirit of the laws," it is not surprising that Durkheim accorded him a key role in defining the subject matter of social science and that Aron regarded him as not just a precursor of sociology but as the veritable founder of that discipline that seeks to discover the structure underlying human societies. Montesquieu was clearly seeking what Durkheim would later refer to as "social facts" and "the real relations among things." Moreover, like Durkheim, Montesquieu did not perceive society as merely the individual reified. In addition, he grasped that individuals are socialized by the forces and influences that society brings to bear on them. Thus, in the Preface to *The Spirit of Laws*, he referred to "man" as "that flexible being who adapts himself in society to the thoughts and impressions of others" (pp. xliv–xlv). And, finally, through his construction of republics, monarchies, and despotisms as ideal types, he anticipated Max Weber's extensive use of ideal types as aids to sociological understanding.

It is certainly not surprising that François Quesnay and other physiocrats in France as well as numerous other theorists of the Enlightenment—including Jean d'Alembert, A. R. J. Turgot, and the Marquis de Condorcet in France; David Hume, Adam Ferguson, Lord Kames, John Millar, and Adam Smith in Scotland; and J. G. von Herder in Germany—drew much inspiration from Montesquieu for their own scientific investigations of social phenomena. Although Montesquieu lived at a time when the various disciplines of social science had not yet been delineated, he was clearly working on many of the problems that still engage those who seek to explore the behavior of human beings in society in a scientific manner.

Moral Cognitivism

Moral cognitivism is a family of views within the branch of ethical theory known as *metaethics*. Metaethics studies questions about the fundamental nature and status of moral beliefs, judgments, and theories. Rather than taking a stand, say, on the conditions under which actions are morally required or permitted, or states of affairs morally good or bad, metaethical views instead focus on whether such substantive ethical claims can be true, whether and how they can be known, whether they are in some way rationally compelling, and whether and how they motivate us.

The defining features of any version of moral cognitivism are (a) its commitment to the *truth-evaluability* of moral propositions and assertions and (b) its view of *moral assertions* as intended primarily to accurately represent the moral truth. The first commitment is straightforward: All moral cognitivists think that moral claims can be assessed as either true or false. But this is not enough to define one as a cognitivist, since a number of sophisticated noncognitivists nowadays share this view.

Where cognitivists and their counterparts disagree is with regard to what is happening in central cases of moral judgment. Cognitivists claim that moral agents are ordinarily attempting in their moral judgments to make factual assertions that seek to depict a world in which things exemplify a variety of moral features. On the cognitivist view, moral judgments are attempted reports of the moral facts. Of course there are nonstandard cases of moral utterances, in which agents are lying or insincerely parroting the views of others. But the cognitivist says that most moral judgments, and all central cases of moral judgment, amount to *assertions* of the putative truth about what is right, good, admirable, and so on.

This view is opposed to *noncognitivism*, which holds that moral judgments are centrally judgments in which a person expresses some nonrepresentational attitude toward some nonmoral state of affairs. The core idea in noncognitivism is something like this: *There are no values in the world*, really. There is, roughly, the world that science tells us about, and our emotional or affective responses to that world. Our moral judgments enshrine those responses and use moral vocabulary to convey our sentiments. Moral judgments are not really in the business of describing the way the world is. They are rather in the business of expressing our emotional responses to a value-free world.

Moral cognitivists believe that people are attempting to speak the truth when they issue their moral judgments. But some cognitivists deny that there is any truth to be had in morality. These cognitivists are known as *error theorists*. According to error theorists, try as we might to get things right in our moral claims, we invariably fail, since nothing is morally right or wrong, good or bad. The basic idea behind error theories is that there is some fundamental assumption underlying all moral views—different error theorists may disagree about just which assumption this is—and that this assumption is false. People try to state the truth when making moral judgments. And they always fail, hence the error.

Error theorists are the pessimists within the moral cognitivist family. By far the greater number of cognitivists have instead endorsed the idea that some moral claims are true and that we can know that they are true. We can cognize about—that is, think and reason about—morality and sometimes come to correct moral answers in the correct way, backed by the correct reasons and arguments. This optimistic assessment is shared by all moral cognitivists except error theorists.

If we leave error theories aside, all other forms of moral cognitivism can be classed as versions of either *moral constructivism* or *moral realism*. Constructivist theories are defined by their commitment to the view that fundamental moral truths are in some way constructed from the attitudes or responses of a duly specified agent or set of agents. Realist theories deny this constructive role—realists are united in their view that fundamental moral truths are not made true by virtue of having been ratified, endorsed, or implied by the attitudes or responses of any given individual or set of individuals.

Constructivist theories range from various forms of relativism all the way to ideal-observer theories. Starting on the more "subjective" end of the spectrum, different versions of relativism insist that what counts as the correct moral theory—the correct theory that specifies the necessary and sufficient conditions for an action's being morally right or good—may properly differ from person to person, or from society to society. At the more "objective"

end, ideal-observer theories will claim that the fundamental moral truths are those that reflect the choices or attitudes of agents who are far smarter and more rational than any actual agent. Different versions of ideal-observer theories can be developed, each distinguishing itself from the others on the basis of which characteristics (and conditions of choice or response) are part of the idealization.

Realist theories are primarily divided between *nonnaturalist* and *naturalist* versions. Naturalist moral realists think of ethics as continuous with the natural sciences and think that a posteriori, empirical investigation is the proper way to discern all the substantive moral truths there are. Nonnaturalists reject this picture and resist the assimilation of moral inquiry to scientific inquiry. Nonnaturalists regard moral properties as sui generis, fundamentally unlike those that are the subject matter of the natural sciences. Being morally required, for instance, is essentially a normative feature of actions, and its normativity distinguishes it from the sorts of properties—such as being round or being red—that are the proper subject matter of the sciences. Or so nonnaturalists will argue.

In sum, all moral cognitivist theories share a commitment to the view that people are standardly trying to speak the *truth* when issuing moral judgments. Error theorists claim that everyone fails in such efforts, since, as error theorists see things, no moral claims are true. Constructivists and moral realists reject the attribution of fundamental error to morality, and each offers his or her own distinctive take on the status of the ultimate standards of morality.

Multi-Agent Modeling

This entry explains the importance and application of multi-agent modeling in social explanation and contrasts it with the kindred but distinct field of *cognitive architectures*. It also draws a parallel with the traditional sociological approaches, like those of Max Weber or Alfred Schütz, which can be further illuminated by these recent methods of computerized social simulation. Multi-agent modeling and social simulation have become an increasingly important research methodology for the social sciences.

Computerized Social Simulation of Agency

The notions of "agent" and "agency" have had a major role in framing research in the social and behavioral sciences. Influenced by computer science (including distributed artificial intelligence, computer networking, etc.), multi-agent modeling or *social simulation*, that is, simulation of social processes and phenomena on the basis of models of multiple autonomous individual agents, has become a significant aspect of the social sciences.

In this context, agents are *computational entities* each of which presumably represents an individual person. From their interactions, complex patterns may emerge, leading to various representations of social phenomena. Thus, the interactions among multiple computational agents provide potential explanations for the corresponding social phenomena.

Multi-Agent Social Simulation

Multi-agent social simulation has seen tremendous growth in recent decades. Researchers hoping to go beyond the limitations of traditional approaches to the social sciences have increasingly turned to agent-based social simulation for studying a wide range of theoretical and practical issues.

Traditionally, two approaches dominate the social sciences. One approach centers on the construction of mathematical models of social phenomena, usually expressed as a set of closed-form mathematical equations. Such models may be mathematically elegant but with limited expressive power. Deduction may be used to find the consequences of assumptions. The other approach may be more *qualitative* and *conceptual*, with which insights are obtained

by generalizations from observations in an informal (nonmathematical) way.

The new approach of multi-agent modeling (social simulation) has emerged relatively recently. It involves computational modeling and simulation of social phenomena based on multiple interacting agents. It starts with a set of detailed assumptions (in the form of rules, mechanisms, or processes) regarding agents and their interactions. Simulations lead to data that can be analyzed to come up with useful generalizations. Thus, simulations are useful as an aid to developing theories, or even as theories themselves.

One of the first uses of multi-agent models in the social sciences was by Robert Axelrod, in his study of evolution of cooperation. In this early work, computational simulations were used to study strategic behavior in the iterated Prisoner's Dilemma game. Even today, this work is still influencing research in various fields. In the mid-1980s, artificial-life modeling emerged, the idea of which was to simulate life to understand the basic principles of life. This led to the application in social simulation of many interesting ideas, such as complexity, evolution, self-organization, and emergence. These ideas influenced social scientists in developing and conducting social simulations. Recently, another topic area appeared dealing with the formation and the dynamics of social networks (i.e., social structures connected through social familiarities ranging from casual acquaintance to close familial bonds).

Cognitive Architectures

Related to social simulation but separately, psychologically realistic computational models of agents have been developed in cognitive science. In cognitive science, they are often known as *cognitive architectures*, that is, the essential structures and processes of cognition/psychology in a broadly scoped, domain-generic computational cognitive model. There are reasons to believe that computational cognitive architectures can play a significant role in multi-agent social simulation. Social simulation can benefit from incorporating cognitive architectures, because they provide a realistic basis for modeling individual agents.

For the field of multi-agent social simulation, the use of cognitive architectures leads to an interesting kind of explanation of social phenomena—*cognitively based explanation* of social phenomena. Social processes ultimately rest on the actions and decisions of individuals, and thus understanding the mechanisms of individual cognition/psychology can potentially lead to better theories describing the aggregates of multiple individuals. In traditional, early treatments of social explanation qua "understanding," the central desideratum was to try and understand the social agents' own conception of "meaningful behavior" and, more generally, the contextual meaning. Getting to know cognitive structures of agents' mental make-up was thus already on the agenda—even if in a different terminology. Max Weber, for example, pointed out that being different from the physical sciences, the social sciences need to gain an "empathetic understanding" of the "inner states" of social actors (their psychology/cognition), thus gaining an understanding at both the level of causation and the level of "meaning" (i.e., cognition/motivation). Alfred Schütz, for another example, attempted to understand the construction of social reality from the point of view of an individual, in terms of meaningful actions, motivations, and social relationships. Thus, a realistic agent model, incorporating realistic tendencies, inclinations, and capabilities of individual agents on the basis of contemporary cognitive sciences, can serve as a solid basis for understanding the interaction of individuals and social processes. What this boils down to is cognitive social simulation (as termed and argued for by Ron Sun), as opposed to mere agent-based social simulation. Cognitive architectures may be an important centerpiece of this enterprise.

So far, however, the two fields of multi-agent social simulation and cognitive architectures have developed rather separately from each other, with some notable exceptions. Much of the work in social simulation, for the sake of ease of programming and running simulation, assumed rudimentary cognition on the part of the agents.

Issues addressed thus far by multi-agent modeling have been diverse. They include, for example, social beliefs, norms, language evolution, resource allocation, traffic patterns, social cooperation, tribal customs, culture formation, stock market dynamics, group interaction and dynamics, organizational decision making, organization design, and countless others.

In all, multi-agent modeling and simulation have become an increasingly important research

methodology for the social sciences. They are now widely used for testing theoretical models (e.g., for investigating their properties when analytical solutions are not possible). A simulation may serve as a theory (or an explanation of a social phenomenon) by itself.

MULTICULTURALISM

Multiculturalism has a number of meanings within and beyond social science. For some it refers to the sociological fact that different ethno-cultural groups are present in a single society. For others it refers to a society where individuals are presented with a smorgasbord of cultural choices and pick and mix as they choose, while no distinct groups are dominant. One should particularly beware of texts that define multiculturalism without reference to any of the work of its advocates, as is now common in public and even academic discourse, as this usually means that a caricature is being presented—typically, "cultural separatism" and "cultural relativism," neither of which has ever or rarely been argued for by multiculturalists.

Thus, multiculturalism is a site where two principal epistemological issues in the social sciences take on tangible forms: On the one hand, the individualism/holism divide is tested in concrete ways, while, on the other, the multifarious ways in which multiculturalism is defined reenact the essential contestability and definitional multiplicity of social and political concepts.

This entry focuses on one of the core meanings: The political accommodation of cultural minorities, a movement in the latter part of the 20th century, which filled some of the space that accommodation of the working classes had previously occupied for a century or more. Even within this restricted scope, in both theoretical and policy discourses, however, multiculturalism has different meanings in different places—and this is crucial for the social sciences. For example, in North America, its referents include groups with territorial claims, such as Native Peoples and the Quebecois, even though these groups want to be treated as "nations" within a multinational state, rather than merely as ethnocultural groups in a mononational state. In Europe, groups with such claims, like the Catalán and the Welsh, are thought of as nations, and multiculturalism has a more circumscribed meaning, referring to a postimmigration urban mélange and the politics it gives rise to. While in North America, language-based ethnicity is seen as the major political challenge; in Western Europe, the conjoining of the terms *immigration* and *culture* usually invokes the large, newly settled Muslim populations. Sometimes, usually in America, political terms such as multiculturalism and "rainbow coalition" are meant to include all groups marked by "difference" and historic exclusion, such as women and gays.

This coalitional meaning derives from the fact that the ethnic assertiveness associated with multiculturalism has been part of a wider political current of "identity politics" that emerged in the 1960s and transformed the idea of equality as sameness to equality as difference—or, in a related conceptualization, adding the concept of respect or "recognition" of a group identity to the older concept of equality as the equal dignity of individuals. Black power, feminist, and gay pride movements challenged the ideal of equality as assimilation and contended that true equality was when stigmatized groups could define themselves in positive terms, thus challenging an individualist ideal of color-blind, culture-neutral politics with the critique that ethnicity and culture

cannot be confined to some so-called private sphere but shape political and opportunity structures in all societies. It is the theoretical basis for the conclusion that allegedly "neutral" liberal democracies are part of a hegemonic culture that systematically de-ethnicizes or marginalizes minorities—hence the claim that minority cultures, norms, and symbols have as much right as their hegemonic counterparts to state provision and to be in the public space, to be recognized as groups and not just as culturally neutered individuals.

The prominence of political theory in multiculturalism is also partly to be understood in terms of the internal dynamic within the discipline. John Rawls's *Theory of Justice*, published in 1971, is the founding text in the modern revival of normative Anglo-American political theory. It promised a philosophically grounded, systematic answer to questions of distributive justice in societies such as the contemporary United States, which were assumed to be characterized by value pluralism. Subsequent debate, including Rawls's reformulation of his own position, focused not on his conclusions about distribution but on his assumptions about rationality and value pluralism. The generation of political theorists following Rawls thus have come to define their questions more in terms of the nature of community and minority rights than in terms of distributive justice, no less than their social-theory peers defined it in terms of difference and identity rather than class conflict, and in each case the intellectual framework lent itself to multiculturalism, even when the term itself was not favored. While for most political theorists academic liberalism has been the primary reference point, Bhikhu Parekh has offered a philosophical multiculturalism grounded in an analysis of human nature and culture and elaborating the intrinsic value of diversity as more fundamental than the accommodation of minorities.

One of the most fundamental divisions among scholars concerns the nature of "cultural groups." In sociocultural studies, groups are seen as having internal differences, hierarchies, gender inequality, and dissent; and culture is always fluid and subject to varied influences, mixtures, and change. To think otherwise is to "essentialize" groups such as Blacks, Muslims, Hispanics, and so on. Political theorists, on the other hand, continue to think of cultural groups as socio-political actors that may bear rights and have needs that need to be institutionally accommodated. This approach challenges the view of culture as radically unstable and primarily expressive by putting moral communities at the center of a definition of "culture." Empirical studies, however, suggest that both these views have some substance. For while many young people, from minority and majority backgrounds, do not wish to be defined by a singular ethnicity but wish to actively mix and share several heritages, there is simultaneously development of distinct communities, usually ethno-religious and sometimes seeking corporate representation.

Since the events of 9/11 and their aftermath, it is Muslims who have become the focus of discourse about minorities in the West. This is partly an issue of security, but more generally, it is accompanied by a "multiculturalism is dead" rhetoric and is found mostly in Western Europe. Muslims, it is argued, are disloyal to European states, preferring segregation and sociocultural separatism to integration; they are illiberal on a range of issues, most notably the personal freedom of women and homosexuality; and they are challenging the secular character of European political culture by thrusting religious identities and communalism into the public space. The prohibiting of Muslim identity in public space has so far been taken furthest in France, where, in 2011, Parliament banned the wearing of the face veil in public places.

Thus, if multiculturalism was initially about indigenous peoples, Black pride, and bilingualism, it is currently challenging ideas about the place of religion in public life, and so an interrogation—sometimes a reassertion—of a secularism that most western Europeans thought was settled and hegemonic. What unites the earlier and the current phase of multiculturalism is the aspiration to create new forms of internally plural national identities that nurture a sense of belonging among minorities as well as historic majorities. While the appeal of multiculturalism as a public policy has suffered considerable political damage, the intellectual and policy argument that multiculturalism is a valuable means of remaking public identities in order to achieve an equality of citizenship that is neither merely individualistic nor premised on assimilation remains powerful and is unlikely to be erased. It is in this way that multiculturalism appears, again, to be a privileged

site within which the individualism/holism divide at the center of the social sciences takes various yet concrete forms.

Mutual Beliefs

The notion of mutual belief (also called *common belief*) has been extensively studied in the past four decades. It plays a central role in several areas of research, ranging from social philosophy and linguistics to game theory, theoretical computer science, and distributed artificial intelligence. This entry gives an account of the essential (formal and substantive) features of mutual belief and the crucial role it plays in analyses of joint action, group activity, cooperation, conversation, and other such social contexts in which *collective* items (collective agency, collective reasoning, collective intentionality, etc.) are the defining features.

Formally, *mutual belief* is distinguised from *shared belief* in the following way. We say that the agents in a set of agents G *share the belief* that a certain fact p is true if and only if each of the agents in G individually believes that p is true. We then say that the agents in G have the *mutual belief* that p is true if and only if the agents in G share the belief that p is true for every order k. That is, the agents in G share the belief that p is true, the agents in G share the belief that the agents in G share the belief that p is true, and so on ad infinitum. This is also called *iterative definition* of mutual belief and has been distinguished from the *fixed-point definition*, which can be stated as follows: The agents in G have the *mutual belief* that p if and only if every agent in G believes that p and every agent in G believes that the agents in G have a mutual belief that p. It can be proved that the two definitions are equivalent in the so-called Kripke structures (after Saul Kripke), the state space models that are traditionally used by logicians to model belief and knowledge.

The seminal work on the analysis of mutual belief is David Lewis's philosophical theory of *convention*. The economist Robert Aumann was the first to provide a mathematical characterization of a similar concept using set theory. More precisely, Aumann formalized the concept of *mutual knowledge* (also called *common knowledge*), which, contrary to mutual belief, has the property of being truthful. That is, while having the mutual belief that p is true does not necessarily imply that p is true, this is the case for mutual knowledge. More recently, formal accounts of mutual belief and mutual knowledge were proposed using the tools of epistemic logic by Ronald Fagin, Joseph Halpern, Yoram Moses, and Moshe Vardi; by Luc Lismont and Philippe Mongin; as well as by other logicians.

The concepts of mutual belief and mutual knowledge were widely employed to explain group activity, coordination, and communication. For instance, it was proved that mutual knowledge justifies the plausibility of equilibrium notions in game theory such as backward induction. An example of this is the well-known theorem proved by Aumann, which states the following: "For any non-degenerate game of perfect information in extensive form, mutual knowledge of rationality (i.e. the players have mutual knowledge that every player is an expected utility maximizer) implies the solution prescribed by backward induction," where backward induction is the process of reasoning backward in time, from the end of the game to the beginning of the game, to determine a sequence of optimal actions. Backward induction proceeds as follows. The first step is to determine the

optimal choice of the player who makes the last move of the game, where "optimal choice" means "a choice that maximizes the player's utility." The second step is then to turn to the second-to-last player and, taking the last player's choice as determined in the first step, to determine the optimal choice of the second-to-last player. And so on.

Moreover, mutual belief has been used to define the concept of "common ground" in a conversation, which is fundamental for discourse understanding and definite reference. Language use in conversation is a form of social activity that requires a certain level of coordination between what the speaker means and what the addressee understands the speaker to mean. Indeed, any utterance of the speaker is in principle ambiguous because the speaker could use it to express a variety of possible meanings. Common ground—as a mass of information and facts *mutually believed* by the speaker and the addressee—ensures coordination by disambiguating the meaning of the speaker's utterance. For example, suppose two different operas, *Don Giovanni* by Mozart and *Il Barbiere di Siviglia* by Rossini, are performed in the same evening at two different theaters. Mike goes to see *Don Giovanni* and the next morning sees Mary and asks, "Did you enjoy the opera last night?"—identifying the referent of the word *opera* as *Don Giovanni*. In order to be sure that Mary will take "opera" as referring to *Don Giovanni* and not to *Il Barbiere di Siviglia*, Mike has to believe that the night before Mary too went to see *Don Giovanni*, that Mary believes that Mike too went to see *Don Giovanni*, that Mary believes that Mike believes that Mary too went to see *Don Giovanni*, and so on.

Furthermore, common belief has been considered a fundamental constituent of joint activity and of shared and group intentions. For instance, according to Robert Bratman's well-known definition of shared intention, we can say that two agents share the intention of "painting the house together" only if they mutually believe that they both intend to paint the house together.

In computer science, mutual knowledge and mutual belief are central concepts in the analysis of properties of distributed systems. One of the results in that field is that mutual belief between two agents can only be attained if the communication channel is reliable (i.e., when an agent sends a message to another agent, then the latter will certainly receive the message, and the two agents have mutual belief of this), as noted by Ronald Fagin and associates.

Raimo Tuomela, Margaret Gilbert, and other philosophers working on social ontology have opposed mutual knowledge and mutual belief to other forms of collective attitude, such as the notion of *collective acceptance*. A property that clearly distinguishes mutual belief from collective acceptance is that mutual belief implies shared belief, while collective acceptance does not: When there is a mutual belief in G that p is true, then each agent in G individually believes that p, while it might be the case that there is a collective acceptance in G that p is true, and at the same time one or several agents in G do not individually believe that p is true. For example, the members of a parliament might collectively accept (qua members of the parliament) that launching a military action against another country is legitimate because by majority voting the parliament decided so, even though some of them—who voted against the military intervention—individually believe the contrary.

Narrative in Historical Explanation

The topic of narrative in historical explanation excites controversy because of deep disagreements regarding what makes such narratives genuinely explanatory. This entry reviews two areas of philosophical controversy regarding the status of narrative in historical explanation: epistemological and metaphysical issues.

In this context, "narrative" connotes a presentation in a story-like fashion of presumably related events that result in a particular outcome. Two sets of philosophical issues have dominated debate about narratives qua explanations. One concerns formal and epistemological issues, the other metaphysical ones. (1) Formal and epistemological concerns typically ask after theoretical articulations of assumed connections and so impose justificatory demands on relationships cited as explanatory. (2) A fundamental metaphysical issue with regard to narrative in historical explanations centers on narratives per se as a form of representation of the reality of the past.

1. Regarding the first set, a standing concern has been that what narratives often suggest as *causes* involve un- or undertheorized connections, such as *reasons* of various sorts. Relatedly, a narrative might appear to explain by providing information unique to a period and its thought. But then, the very reasons presented as explanatory seemingly count against integrating such an explanation with those generalizing and integrative models of explanation familiar from the natural sciences. So questions remain about how narratives explain.

In the heyday of logical positivism, when an assumption regarding a common logical form to properly scientific explanations reigned supreme, narratives were explanations in some derivative sense, one that depends on a received account of scientific explanation. Formally, narratives were stigmatized as at best "explanation sketches" (a term used by Ernest Nagel). To vary a bit C. G. Hempel's famous example, suppose that someone narrates that the water in his car radiator froze and then the radiator burst. The person concludes by saying, "I forgot to put in antifreeze." But this brief story only explains because it can be "converted" into an account that justifies the connections—for example, the temperature at which water freezes and the tensile strength of the radiator. By contrast, when Raul Hilberg summarizes a key thesis of his magisterial narrative of the Holocaust, *The Destruction of the European Jews,* he pointedly denies that acts eventuating in the creation of death camps followed from one another in any predictable or preordained way. Rather, such a narrative explanation can only chart, in Karl Schleunes's phrase, the "twisted road to Auschwitz." This typifies a historian's sense of a narrative, at least insofar as it denies that a narratively presented sequencing of events even possibly "converts" to some more generalizing form of explanation such as those found in the natural sciences.

Questions regarding form—what elements a proper narrative explanation must contain—and epistemology—what theory underwrites the imputed causes—generated a division of views that persists

unabated. Epistemologically, some defend narrative explanations as a distinctive format for teleological or purposive explanations. Another epistemological approach construes narratives as a sui generis form of explanation. On this view, narratives either represent a special cognitive act, as Louis Mink holds, or achieve their "explanatory effect" because, in a view famously advocated by Hayden White, such story forms play a special role in our cognitive economy.

Mink's influential account emphasizes narrative as a mode of comprehension that differs categorically from the type of explanations that the natural sciences offer. Mink's position can be distinguished from those who, following Hayden White, emphasize narrative as an imposition of order by means of cultural poetics. For White, the writing of history should be understood as just a special case of literary creation and thus should be analyzed in that spirit. Mink, in contrast, emphasizes that the key formal characteristic of historical narrative as a type of explanation resides in the fact that it consists of a special form of *retrospective* of sense making. For an important feature about knowledge of the past, as Arthur Danto's work establishes, involves the fact that statements true of the past could not be known as true (or known at all) at that time. Danto's canonical example is "The Thirty Years War began in 1618." Although now true of what happened in 1618, this statement became true of events in 1618 some 30 years after the fact. What happens later creates truths of times past that yet were not true or knowable at just those times. And while Mink's position does not exclude consideration of cultural poetics, its emphasis falls on historical narratives as retrospectively fashioned accounts of events already lived.

2. A second currently debated question flows directly from the formal considerations urged by White and by Mink and parallels the realism/anti-realism debate in the philosophy of science, at least in the following respect. For both White and Mink emphasize histories as human fashionings—that is, narratives as *constituting* historical events. But the question then arises whether this implies that narratives per se (and not just their individual statements of fact) cannot be true, in the sense of correctly representing *the* past. (Use of the definite article is key here.) What happens to the realist intuition that narrative histories could possibly represent the past *wie es eigentlich gewesen* ("as it really was")?

Indeed, such metaphysical/representational questions about historical narrative explanations have now come to the fore in philosophical debates about the reality of the past and narrative as a form of representation of this assumed reality. Mink anticipated the unsettling implications of what happens to an understanding of human history in the absence of a belief in any "master narrative" or "universal history." Once a belief in a universal history goes, no single narrative can claim metaphysical precedence. As a result, history cannot be imputed a determinate structure perceivable *sub specie aeternitatis*. In sum, debates about narrative in historical explanation begin as ones of form or epistemology. But the sharpest philosophical challenge that emerges from these discussions has been to the metaphysical assumptions underlying belief in the reality of the past—in other words, to the idea that human history has any independent determinate form.

Naturalism in Social Science

Naturalism in the social sciences—namely, that the subject matter of the social sciences should be seen as an element of the natural world and could be explained accordingly—has an ontological face and a methodological face: that social institutions

or human phenomena in general can be reducible to natural ones or that they are explainable naturalistically. This entry discusses critically each version of naturalism in turn.

Ontological Naturalism

Ontological naturalism holds that the objects and phenomena of interest in the social sciences are part of, or aspects of, the natural world. As biological entities and phenomena are part of, or aspects of, the physical world, so also is the subject matter of the social sciences a part of the natural world. Culture is natural for humans. The parallel with biological phenomena is instructive for the naturalist. Biological systems are relatively complex physical systems. They have interesting and somewhat distinctive properties. Examples include the capacity for reproduction, for certain forms of homeostasis, and for assimilation of nutrients. Such capacities, or properties, are commonly not instanced in the nonbiological components of the physical world. They make for a distinctive biological subject matter—though clearly it remains a dependent part of the physical world. Thus, a biological entity's capacity for self-replication is based in (or is reducible to) the simpler dispositional capacities of complex molecules and ultimately in the behavior of sequences of atoms in molecules. Plants are a class of system with the capacity for converting incident solar energy into stored chemical energy. Living things generally have the capacity for reproduction. In all such matters, there is no suggestion of anything "supernatural"—no suggestion that there might be some force that eludes physics. This is not to suggest that such systems can only be understood at the level of physics—for typically, they can be understood in terms of regularities involving biological features or properties. It is to say that they are ultimately complex physical systems, and thus natural systems.

Ontological naturalism extends this picture to psychological phenomena and to human groups and group phenomena. These are yet more complex phenomena within the natural (and physical) world. Again, these phenomena may turn on features and regularities that are not features of the simpler physical/natural systems at lower levels of organization. There is no transcription, and no transcription errors, mutation, mutation repair, and the like, within atoms—as these are features or properties of cells and cellular phenomena. There are no beliefs within atoms, as there are within humans or like creatures. There is no norm formation and conformity and no elections and victories within atoms—just within various social groups. Yet such higher-order phenomena and features plausibly arise out of organized lower-order phenomena and properties. To capture the resulting dependency of the higher order on a basis in the natural, ultimately physical, world of which it is then a composed part, many ontological naturalists write of a *supervenience* of the one on the other. A set of properties, *S,* is said to supervene on another set of properties, *B,* just in case were a system alike with respect to the *B*-properties, it would be alike with respect to the *S* properties (how things are with respect to the *B*-properties determine how things are with respect to the *S* properties).

Properties with a historical aspect seem to call for special comment. For example, on the phylogenetic species concept, a species is understood as a location on the phylogenetic (evolutionary) tree. On this concept, a molecule-for-molecule parallel of a population of *Canis lupus* engineered in a lab (and thus not resulting from the standard evolutionary mechanism) would not count as a population of *Canis lupus*. However, it would remain a part of the natural world—relevantly understood. Similarly, duplicates of U.S. Treasury notes are not U.S. Treasury notes. Yet the notes, and the various human institutions, are here thought of as a part of the natural world. (Think also of various geological epochs or periods—the Carboniferous, for example—and historical periods—the European Middle Ages. While historically specific, each one is a part of the natural world.)

Methodological Naturalism

Methodological naturalism is the position that, as a part of the natural world, social phenomena are best studied using methods that have borne fruit in the study of the rest of the natural world.

Such study has commonly turned on careful attention to regularities—to generalizations that can be refined under test and that can be deployed to understand the patterns of counterfactual dependencies holding with respect to particular episodes or classes of events. The systems, or classes of cases so understood, commonly are local and limited—so that the relevant generalizations would also be limited. That there are such systems—for example, in ecology—is

a contingent matter. Ecosystems (or more specifically tundra or limnological ecosystems) are local and contingent—that is, systems thrown up by the contingencies of evolution within a limited planetary system. However, there are generalizations that hold for such systems. Ecology advances by coming to understand such regularities in terms of generalizations with a limited degree of invariance. Often, the understanding one has of such natural systems comes by way of deploying generalizations treating interrelated processes at various levels. Ecology has fairly weak generalizations to call its own but borrows heavily on generalizations from a range of related fields.

Methodological naturalists project parallel developments within fruitful social science. For example, suppose one sought to understand the prevalence of certain social norms in a certain cultural context. According to the methodological naturalist, one will be in a position to do so when one has developed and empirically refined a range of generalizations. Plausibly, some generalizations might have to do with the social transmission of cultural ideas—perhaps generalizations treating a replicator dynamics having limited analogies with genetics (as in evolutionary approaches to culture). Some generalizations might have to do with human psychology, particularly generalizations having to do with characteristic human social preference. Some generalizations might originate within general cognitive psychology and suggest ways in which norm representations might be stored and activated (as accounts of the dynamics of social norms suggest). In all cases, the generalization in question should be subject to refinement either in the lab or in other experimental settings, and with careful cross-cultural investigation.

While ontological naturalism has few natural enemies today, methodological naturalism is opposed by a form of methodological separatism that insists (a) that social phenomena are best appreciated by way of "interpretation" and (b) that the interpretation operates by a kind of logic that is unlike any in the natural sciences. This is reflected in the *hermeneutical* tradition. A recent, distinct version of interpretivism, originating from within analytic philosophy, takes inspiration from Donald Davidson's views on interpretation: He understands interpretation as essentially conditioned by a normative—nondescriptive—presumption of rationality. Some find this line of thought untenable, while others advance a moderate naturalist account of interpretation.

Naturalized Epistemology

Naturalism in its 20th-century American incarnation seeks to align philosophical inquiry with scientific inquiry generally. In this form, naturalism rejects a priori claims to knowledge (i.e., it rejects a view of knowledge as not explicable as part of the natural world) and links justification to the methods of science, broadly understood. Unlike positivism, naturalism offers no rigid demarcation criterion

regarding what defines a science. In post-positivism, questions arise on how to delineate what counts as a science, and this creates a lingering strain with naturalism as originally conceived.

Since much of the discussion of naturalized epistemology emanates from Willard Van Orman Quine's landmark essay on the topic, debate on this topic might be presumed to also inherit Quine's holism with regard to theories and his extremely liberal notion of what constitutes a science. But this has not turned out to be the case. Broadly specified in a Quinean spirit, naturalized epistemology could incorporate methodologically much beyond any list of methods native to the natural sciences and so includes those of, for example, any of the social sciences and history. As a naturalist, Quine assumes no fixed methodological essence that serves to demarcate disciplinary kinds. Read less in the spirit of American naturalism, naturalized epistemology can be taken to imply a reductionist program, with the natural sciences supplying the licit elements of any proposed reduction. But inasmuch as such readings beg the question of how to establish what to count as a science, they will not be considered further here.

Disagreements regarding what the term *naturalized* implies in consequence typically turn on ambiguities regarding what a science is, since explications of "naturalism" invoke some notion of science. It might be thought that agreement on the purview of the notion of epistemology would prove unexceptional no matter how contentious the interpretation given to the modifier "naturalized." But it turns out that using this modifier generates uncertainty with respect to epistemology so modified. Even supposing that everyone agrees that epistemology covers the philosophical analysis of knowledge, such apparent agreement would only mask a core philosophical controversy. For what knowledge is, and so what epistemology in fact examines and encompasses, will depend on how the term *naturalized* functions to modify *epistemology*. Thus, the topic of naturalized epistemology elicits controversy not only with regard to what to accept as a *naturalized* epistemology but also as to how to construe "epistemology" so modified. In short, determining what sets the scope of the term *knowledge* has emerged as a key point of contention with respect to providing any account of naturalized epistemology.

The "Autonomy of Knowledge" View

Two antithetical answers to the question of what knowledge is dominate contemporary epistemology. One answer, claiming a heritage to Thomas Reid and G. E. Moore, premises its approach to epistemology and a determination of its subject matter on what could be termed the "autonomy of knowledge" assumption. Knowledge so conceived constituted a domain prior to philosophy ever arriving on the scene. On this assumption, there exists a pretheoretic ("commonsense") notion of knowledge that any analysis of knowledge must respect. From this perspective, tests of philosophical analyses of knowledge then proceed by holding them hostage to "intuitions" regarding a fit between these analyses and a prior sense of what belongs in the domain.

On this "autonomy of knowledge" view, then, epistemology begins with an established subject matter—some pretheoretically ascertained domain of the known—prior to, and independently of, modifiers such as "naturalized." The modifier thus only signals a particular approach with respect to an independently established category, as in "Italian cuisine." But the category has independence and a breadth apart from its modifier.

Further, by assuming the "autonomy of knowledge" view of epistemology, any efforts to bring science to bear on knowledge claims will be circumscribed by knowledge pretheoretically understood. People pretheoretically have a great deal of knowledge, and they always already know (more or less) what propositions count as instances of knowledge. Philosophical analysis contributes just self-awareness in the form of a specification of the conditions (i.e., the analysis) of knowing. The object of analysis—knowledge—exists prior to, and independently of, any science. From this perspective, a naturalized epistemology only contributes whatever resources the sciences might offer that abet this task of making explicit already existing conditions of knowledge. Science then plays the handmaiden to philosophy.

The "Autonomy of Naturalized Epistemology" View

A second and very different view of naturalized epistemology emerges, however, on the assumption that pretheoretic views have no particular standing to determine or adjudicate what passes for knowledge. On what may be termed the "autonomy of naturalized epistemology" assumption, whatever falls within the scope of a naturalizing process determines the domain of epistemology and so defines knowledge. Rather than assuming, that is, an autonomous domain of knowledge before philosophy comes on

the scene, this approach to naturalized epistemology defines knowledge in naturalistic terms and proceeds from there. Here, the subject matter of epistemology can only be determined in conjunction with what current sciences endorse. People of course belong to linguistic communities that already use terms such as *knowledge, justification, good reasons,* and so on. But once in place, science sets the standard for what passes as knowledge. So even on the assumption that science evolves from ordinary understanding, the sciences ultimately come to constitute the domain of knowledge properly so called.

Quine argues for this view specifically, maintaining that with the collapse of foundational programs epistemology loses any standing to prescribe to science a standard of knowledge apart from whatever the sciences collectively endorse. For in the absence of foundationalism, there exists no extrascientific gold standard for adjudicating knowledge claims. And with the standards of the various sciences in hand, it can then be decided which candidates for knowledge meet them. Since standards come bundled with theories generally, knowledge then consists of all that these theories imply.

Framing the Debate

Although it might seem as if intermediate positions between these two extremes—the "autonomy of knowledge" and the "autonomy of naturalized epistemology"—should be possible, further consideration indicates otherwise. The chief sticking point arises with regard to what will count, in any approach, as knowledge. Either there exists an identified nonscientific standard of knowledge, or there does not. Naturalizers say that there does not. A consistent naturalizer cannot canonize both common sense and science; for that would be to certify as epistemologically appropriate methods not licensed by science. Nonnaturalizers hold to their Moorean sensibilities and so assign philosophical primacy to a pretheoretically determined knowledge domain.

Either pretheoretic intuitions about knowledge trump science or vice versa. For a nonnaturalist, invoking science as an aid begs all the critical philosophical questions. Assigning science an epistemological role must appear inexplicable or arbitrary. For if science sets a (rather than "the") standard of justification, what reveals this? Certainly, nothing related to "common sense" or pretheoretic intuitions about knowledge. So science on the nonnaturalist view awaits justification; it cannot plausibly function as a touchstone, however modest, of knowledge. Conversely, to endorse science would be to endorse a standard with no ultimate necessary connection to whatever informs commonsense intuitions about knowledge. Philosophically, one cannot have it both ways. Thus, as noted above, one will be pushed to the extremes represented by one or the other of the autonomy views.

Two red herrings often further cloud the debate with regard to naturalized epistemology. One, already mentioned, insists that a naturalized epistemology entails a reductionist program, with the terms of reduction having to come from the physical sciences. While it is not clear whether or not positivism even in its heyday mandated such an approach to epistemology, post-positivism, no such implication can be said to follow from naturalism. In the absence of a demarcation criterion, what to call a science can plausibly be said to include all disciplines that seek to provide an integrated and systematic account of their subject matter. A naturalized epistemology uses all the tools of the various sciences to study how the subject matters of these sciences (and so what can pass for knowledge) come to be, including how those sciences themselves as theories of these subject matters come to be. No necessary or sufficient conditions exist for separating sciences from nonsciences, but this hardly matters. Indeed, the disunity of science has emerged as a working hypothesis for understanding the sciences as we find them. Inevitably, a naturalized epistemology will depend on what a society recognizes as legitimate science.

A second red herring issue that also often surfaces in debates with regard to naturalized epistemology concerns the role of so-called normative factors with respect to an analysis of knowledge, for example, what makes for the goodness of reasons. The charge goes that science, and so by extension any naturalized epistemology, can only focus on descriptive/causal aspects of cognition. Nothing in science permits an analysis of evaluative practices, for evaluative practices can never be caught in a descriptive/causal net; they are items of another sort. Hence, according to this criticism, the very term *naturalized epistemology* constitutes an oxymoron; to the extent that the subject matter allows of naturalization, to that extent it cannot address the primarily normative concerns of epistemology.

Of course, those making this criticism cannot deny that many social sciences study the genesis,

evolution, and change of norms within groups. The complaint only has a point if the norms at issue cannot be identified with those "transitory" or "merely social" norms that have their lineage analyzed in this way. The investigation then must be in primary part conceptual, not empirical, since it asks after the appropriateness or rightness of a type of judgment, not how this or that rule came as a matter of fact to be taken for a norm. Only a mode of philosophy not fully or at all naturalized stands ready to undertake such inherently conceptual investigations.

Here, the debate seems to end. A naturalist can only dig in her heels and question why it must be the case that any norm has a more exalted status than whatever reasons led a group in the first place to adopt it. Does this imply that all norms receive a functional explication? No. It merely points to the fact that disciplines tend to settle over time what their norms are. These can be studied, explained, and, yes, critiqued by examining through various means—historical, sociological, economic, and so on—how norms come to be and pass away.

Naturalized epistemology denies what traditional philosophy took it to be the purpose of first philosophy to provide, namely, a metaperspective from which to adjudicate the "really best" from among those norms that wash up on a society's shores in the ebb and flow of history. But a naturalized epistemology offers no such promise of an atemporal or absolute perspective on cognitive standards. A naturalized epistemology can help one learn how what now passes for knowledge came to so pass, and by doing so possibly suggest what may have been problematic in that process. In this clear respect, a naturalized epistemology, qua epistemology, does contribute to the eternal philosophical project of increasing self-understanding. But *qua naturalized* epistemology, it promises no more than that, that is, a bringing to self-awareness through science how beings like us come to possess the sciences that we do.

Naturwissenschaften Versus *Geisteswissenschaften*

This entry presents the celebrated contrast between the natural and the human sciences as it developed historically in the 19th century around the core ideas of Wilhem Dilthey. The entry focuses on Dilthey's thought and discusses the various epistemological theses characterizing the distinction between the sciences of nature and the human sciences. It also presents the Neo-Kantian distinction between "nomothetic" and "idiographic" methods.

Introduction

The distinction in German between the *Naturwissenschaften,* or natural sciences, and the *Geisteswissenschaften* received its classical definition in the writings of the German philosopher and historian Wilhelm Dilthey (1833–1911) and has continued to shape our thinking about the sciences. The term *Geisteswissenschaften* is difficult to translate.

The literal translation "sciences of spirit" points back to the Hegelian view of philosophy as the one and only science of spirit (*Wissenschaft des Geistes*). Dilthey, however, conceives the *Geisteswissenschaften* pluralistically and in empirical terms, which makes the literal translation misleading. *Geisteswissenschaften* is therefore commonly and more appropriately translated as "human studies" or "human sciences."

Origins and Legacy

The plural use of *Geisteswissenschaften* already occurred in the writings of the Romantic natural philosopher Lorenz Oken in 1817 and the historian Johann Gustav Droysen in 1843. But it was not until it was used to translate John Stuart Mill's use of the term *moral sciences* in 1849 that the *Geisteswissenchaften* began to be conceived more empirically and in terms of the methods that are appropriate to them. This was then programmatically worked out by Dilthey in his *Introduction to the Human Sciences* of 1883 and his *Formation of the Historical World in the Human Sciences* of 1910.

The human sciences include both the humanities and the social sciences. For that reason, the twofold *Natur-Geisteswissenschaften* distinction found in German universities is now also expanded into the threefold *Natur- Geistes-und Sozialwissenschaften* distinction. One of the important contributions of the twofold distinction is that it brings reflective and disciplinary considerations to bear on the humanities by not sharply separating them from the social sciences. Social scientists have been more eager to emulate the explanative and statistical methods of the natural sciences. The more inclusive notion of the human sciences has led to the development of methods of *understanding* and *interpretation* that are applicable to both more humanistic disciplines such as literary history and more systematic disciplines such as sociology. The sociologist Max Weber (1864–1920), for instance, claimed that it is necessary to understand the Protestant work ethic to explain why capitalism first emerged in countries such as The Netherlands, England, and the United States. Weber and philosophers such as G. H. von Wright (1916–2003) consider *understanding* a preliminary to *explanation*. Dilthey and many phenomenologists, however, conceive understanding to be more comprehensive than explanation.

Wilhem Dilthey

Dilthey's *Introduction to the Human Sciences* examines the relation between the natural and human sciences in two ways. The first way is to consider how the human sciences supplement the natural sciences and to what extent their goals differ. This is the general approach of Book One. The second approach takes stock of the way the human sciences have emerged from human self-reflection and is most fully developed in the drafts for Books Four to Six. What Dilthey calls self-reflection or anthropological reflection is both theoretical and practical and establishes its own parameters.

These two approaches to the sciences are developed in the following two sections; the third section deals with subsequent developments.

Human Sciences and Natural Sciences

In Book One of the *Introduction to the Human Sciences,* Dilthey differentiates the human sciences from the better-established natural sciences. He points out that whereas the natural sciences provide causal explanations of the phenomena of outer experience, the human sciences attempt to understand the *meaning* of both inner and outer experience. Acknowledging that mental processes are influenced by physical processes, he nevertheless argues that this involves a functional rather than a causal relation, which entails that mental life can have a relative independence. There are aspects of the life of the human spirit that cannot be explained by the natural sciences, and throughout human history different disciplines have arisen to deal with the issues faced by human beings in their social and cultural life. According to Dilthey, the human sciences, as they have evolved over time, contain three classes of assertions. One class describes reality as perceived, the second class explicates the uniform behavior of partial contents of this reality, and the third class expresses value judgments and prescribes rules. In the human sciences, descriptive-historical accounts of what is singular and individual are as important as the explication of theoretical uniformities. And both are governed by a normative system that connects values, ideals, and the aim to shape the future.

This interdependence of the theoretical and practical in the human sciences makes them less hierarchical than the natural sciences. Initially, Dilthey

did consider psychology to be the first of the human sciences, similar to how physics had become the foundational explanative natural science. But he always made it clear that psychology can only serve an analogous role if it stays within the limits of a descriptive discipline and renounces the hypotheses of explanative psychology about the underlying elements of mental life, most of which cannot be tested. Descriptions of psychic processes can delineate general structural regularities, but they cannot be abstracted from the rest of reality. Thus, a psychological trait such as thrift cannot be understood apart from the economic and social context within which individuals find themselves. Later, as Dilthey's thought became more hermeneutical, psychology would be stripped of even this limited foundational role. But he never doubted that psychology had a place among the human sciences and their efforts to understand the spiritual aspirations that are manifested in human history.

The Baden School of Neo-Kantians: Reaction to Dilthey

Dilthey's claim that psychology is a human science was rejected by the Baden-school Neo-Kantians Wilhelm Windelband (1848–1916) and Heinrich Rickert (1863–1936), who considered it to be a natural science. Insisting on a sharp distinction between psychological and epistemological accounts of consciousness, they restricted psychology to the search for empirical causal laws linking physiological and psychological states. Only the transcendental standpoint of epistemology can disclose the spontaneity of consciousness. And to do justice to the historical developments of the human spirit, they turn to what they call the cultural sciences (*Kulturwissenschaften*). However, Marburg Neo-Kantians, like Ernst Cassirer (1874–1945), were willing to speak of both cultural and human sciences.

Windelband attacked Dilthey's distinction of the natural and human sciences for focusing too much on differences of subject matter and proposed that the formal distinction between *nomothetic* and *idiographic* methods is more appropriate. According to Windelband the natural sciences are nomothetic in developing lawful uniformities, and the cultural sciences are idiographic in focusing on unique historical patterns. Dilthey rejects this sharp division as invalid for both kinds of science. The natural sciences are not exclusively nomothetic. He points out that biology involves both a general theory of animal functions and a descriptive classification of animals. Moreover, there are many human sciences, such as economics and sociology, that have established uniformities within certain systems of interaction and cooperation that have come to be differentiated and institutionalized over the course of historical life. The understanding of individuality that characterizes the human sciences is not merely the appreciation of ideographic singularity but requires that we consider the uniformities that provide the background for individuation. These uniformities may be causal or structural in nature.

Lived Experience and Self-Reflection

In Book Four of the *Introduction to the Human Sciences,* which was published posthumously, Dilthey observes that everything real is a fact of consciousness and subject to the conditions of consciousness. Reality is already there for us or present before it is represented cognitively or scientifically. Our lived experience is reflexively given to us in a way that precedes psychological description and the theoretical analysis of epistemology. For reflexive awareness, which is prereflective, there is no distinct self to be described. Only gradually does the continuum of lived experience differentiate itself into inner and outer experience, a reflective self and an objective world. And when the overall nexus of lived experience is reflected upon, it provides the context for both theory and practice. Dilthey makes "self-reflection" about this context, not merely epistemology, the foundation of all the sciences. Reflection's most basic task is to analyze what is given and to relate the partial contents of experience in accordance with the forms and rules of logic. The human sciences must analyze the givens of experience without losing sight of their larger life context, and experience itself must be probed for the ways we engage the world in terms of thought, feeling, and volition. The natural sciences analyze the givens of experience precisely to the extent that we do not contribute to them. Their results are thus more abstract and primarily theoretical. They deal with fewer variables and can thus be more successful in testing explanative hypotheses.

From this perspective, the natural sciences are more derivative than the human sciences. To be sure, the understanding aimed at by the human sciences

must incorporate the empirical findings and causal uniformities of the natural sciences when describing human behavior and historical events. But it is the *meaning context* defined by the human sciences that guides the judgment on where to look for causal conditions relevant to human behavior. Similarly, the goals set by human agents codetermine how nature as a system of means applies.

Dilthey argued for a radically pluralistic theory of the human sciences. Just as there cannot be an explanative foundational human science such as physics, there should not be a monolithic, overarching discipline like Hegel's philosophy of history or Auguste Comte's sociology. There are no laws of history at large, and sociology cannot do justice to all aspects of human interaction. History can only be understood by analyzing it into the specific systems of interaction that have developed over time. Dilthey divides them into what he calls voluntary productive systems of cooperation, such as economic and political organizations, and the institutional formations in which individuals find themselves. It is only within these more defined sociocultural systems that we can expect to arrive at uniformities and laws.

Further Developments

Although nature has become alien to us since the rise of modern science and must be explained in hypothetical intellectual terms, Dilthey thinks that much of our psychosocial life can be understood nonhypothetically from within. We participate in the life of history, which means that its understanding (*Verstehen*) engages not only our intellect—what Immanuel Kant had called the faculty of understanding (*Verstand)*—but all the cognitive, affective, and volitional powers of the mind. In his "Ideas for a Descriptive and Analytic Psychology" (1894), Dilthey asserts that the inner connectedness of lived experience already provided an indeterminate understanding, which could then be further explained in detail by means of specific and testable hypotheses. But in the essay "The Rise of Hermeneutics" (1900), he comes to the realization that the inner intelligibility of lived experience does not yet constitute understanding. The way we express ourselves, whether in communication or in action, is a crucial intermediary in defining ourselves. Understanding can only be reliable if it proceeds through the interpretation of human objectifications.

In the *Formation of the Historical World in the Human Sciences* (1910), Dilthey provides a final delineation of the relation between the natural and human sciences. They cannot be distinguished merely as two spheres of facts. They often treat the same facts, such as language: one in terms of the physiology of the speech organs, the other in terms of syntax and semantics. But it would be a mistake to think that the natural sciences deal with the external aspects of language and the human sciences with the inner core. The human scientific approach to language must take into account not only the physiological conditions of speech formation but also the physical manifestations of the way language is used. This leads Dilthey to point to the physicality of linguistic expressions as a means of understanding. It is through the interpretive path from without to within that understanding begins to define itself. Everything that confronts us in the human historical world—whether it be an individual linguistic expression, a human action or deed, a social interaction, or the practice of a public institution—is an objectification that must be referred back from its outer, sensory aspect to one that is withdrawn from the senses and therefore inner. This inner aspect is in the first instance not mental but normative. Thus, what we see happening in the courtroom, where criminals are brought to justice, is the expression of a purposive system of legal norms and functional rules. Here, interpretation finds an inner meaning that is not some psychical content but points to a historical formation that has its inherent structure and lawfulness. Even in the case of an individual creation such as a novel, what is expressed is not some complex of the novelist's mental states but a structural nexus consisting of motifs, plot, and characters created on the basis of those states. The understanding of this literary nexus need not appeal to psychology except if there are sharp deviations from the conventional ways in which characters are portrayed or shown to interact.

The natural sciences relate the objects of experience to each other and thus constitute an external natural system. The human sciences relate those objects that can be considered human objectifications to historical systems that can be called "inner," not because they belong to us but because we participate

in them. The understanding of these inner structures is always indirect and requires interpretation.

Concluding Remarks

Dilthey contrasted the human sciences to a classical, law-based conception of natural science. Today, the natural sciences show many interpretive features as well, which has led some to speak of a universal hermeneutics. But interpretation is only hermeneutical if meaning is assessed normatively in relation to values and purposes.

Neo-Kantianism

Neo-Kantianism broadly refers to a philosophical movement mainly in Germany and France beginning in the second half of the 19th century, peaking between 1880 and 1910 and declining after World War I. As the name of this movement suggests, the members of this movement intended to revive the spirit (not the letter) of Immanuel Kant's philosophy in various manners.

This adherence to Kant is remarkable, for three reasons. First, different philosophers picked out different, and in part contradicting, moments from the Kantian oeuvre, so as to make it nearly impossible to indicate one main tendency of this broad movement, other than the general label of "philosophizing in the Kantian spirit." Second, Kant was hardly the only philosopher who was invoked in this movement; other theorists of influence for the Neo-Kantians were Johann Gottlieb Fichte and even G. W. F. Hegel. Third, some thinkers of crucial influence, especially in the early phase, were not philosophers but scientists who were pushed to more general philosophical musings through their experiments and discoveries in laboratories and found, to their surprise, an ally in Kant. Ironically, it was the scientistic and positivistic spirit of the time that renewed the urge on the part of many scientists to return to the sober spirit of Kant and also to renew a new sense of idealism or criticism. The close connection to cutting-edge science, however, remained a staple of Neo-Kantian practice.

Reception and Recent Revival

Before going into the philosophical details of the movement, it needs to be emphasized that, despite their falling into near-total oblivion by the second half of the 20th century, the Neo-Kantians were the most influential and most highly regarded thinkers in Germany and France around 1900, which has led Jürgen Habermas to characterize their stance in

academia and culture at large at the time as "imperial." This also explains why the philosophers to critically reject them—most notably the members of the emerging phenomenological movement and the Vienna Circle—bashed the movement of Neo-Kantianism as a whole with such force. It seemed that no progress could be made in philosophy without rejecting wholesale the philosophical establishment of the time.

More nuanced analyses reveal, however, to what extent thinkers such as Edmund Husserl, Martin Heidegger, and Rudolf Carnap were heavily influenced by their Neo-Kantian colleagues. And yet deeper reflections quickly show how much the Neo-Kantian movement as a whole has shaped 20th-century philosophy and beyond. There is currently a revival of Neo-Kantianism, both in philosophical historiography as well as in systematic fields such as epistemology, ethics, and social and political philosophy, which corrects this skewed image. Especially, the work of Michael Friedman on the philosophy of science and its history has been a great force in reviving a central Neo-Kantian project: a priori cognition. Friedman, like no other contemporary philosopher, has enforced the need for a renewed form of transcendental philosophy to meet the challenges of contemporary science. In this intent, he has fruitfully taken up the original concept of the "a priori" developed in the Marburg school for his conception of the "dynamic *a priori.*" Finally, due to the contemporary dearth of historical knowledge of Neo-Kantianism, it is astonishing how many ideas that are currently floated are simply reinventions of the Neo-Kantians' work, such as the topic of normativity, up to current interpretations of Kant's philosophy, which was perhaps the most visible trademark of the Neo-Kantians.

Main Tenets

Despite the heterogeneity of Neo-Kantianism, one can venture some general definitions and indicate some main philosophical paradigms guiding the philosophers who defined themselves as working under the banner of "Kantianism." A general definition of Neo-Kantianism, which is equally utilized by any philosopher today who calls himself a "Neo-Thomist," "Neo-Aristotelian," or the like, is to philosophize in the spirit of Kant but in an updated version of the revered person. This implies rejecting some elements of the orthodoxy in order to salvage certain other aspects that are deemed central and timeless in Kant's work. To be sure, disagreement about what exactly is central in Kant is part of such an adherence to him.

Nevertheless, a more specific definition may be attempted: The Neo-Kantians intended to update the Kantian critical project in light of newer findings, first and foremost in the natural sciences, where the Kantian project is understood as a justification of the *factum* of reason, which is now construed as the undeniable *factum* of the sciences. Furthermore, the main paradigm under which they operated, in the Kantian spirit, can be called *critical* and *idealistic:* critical insofar as the critique is a justificatory enterprise with respect to existing findings (the *facta*) in different spheres of knowledge and idealistic insofar as any realistic scenario in the experience and cognition of anything worldly is rejected. Instead, nearly all problems the Neo-Kantians deal with operate under the basic assumption that there is no direct access to the world as a thing in itself but that all knowledge about the world is mediated by our experience of the world and the conceptual capacities that we have of it. This stance concerns the main topics of inquiry, be they science, cultural artifacts and contexts, or values.

Since it is impossible to give a comprehensive overview of Neo-Kantianism in the space provided, it is best to present this movement in its two main schools in Germany and their general tendencies, respectively. This account will have to pass over the French scene with its main representatives, Émile Boutroux, Léon Brunschvicg, and Jules Lachelier. Suffice it to say that they, too, took the Kantian inspiration to move beyond a materialistic or positivistic worldview, though the French movement was remarkably different due to the tendency on the part of some of its representatives to move in the direction of a spiritualism that would have been quite implausible to its adherents on the eastern side of the Rhine.

The Marburg School

Undoubtedly, the most influential and compact school to emerge was the school centered at the University of Marburg, appropriately called the Marburg school. It included, essentially, Hermann Cohen, Paul Natorp, and Ernst Cassirer, though the latter is sometimes believed to have left the school confines with his original philosophy of symbolic formation. Their main achievement was to work out what they called, in vague adherence to Kant, the transcendental method. This method, first employed by Cohen with respect to the Newtonian sciences, with the added thesis that it was they that Kant had

in mind when he drafted his critical system, intends to reconstruct the cognitive activities of the scientist as she constructs her theories. This is not psychology, however, quite to the contrary; the transcendental philosopher extracts the logical laws that went into the construction of the respective theory; it is a method of "purification" of the work of the scientist to reduce the latter to its bare logical and conceptual elements. If, as the Marburgers claim, "true" reality is found in the theories about nature, transcendental philosophy is equally constructive in grounding the applied theories in a space of pure thought—that is, purely logical structures and a web of logically interconnected concepts. This nexus of logic expands, however, as science progresses, causing Cohen to construe transcendental philosophy as a discipline of grounding cognition in the form of an expanding nexus of categories, which evolve as our knowledge of the world evolves. This way, the Marburgers wanted to preserve Kant's project of a synthetic a priori while acknowledging a progress in the sciences that demands ever new conceptual groundings. The *factum,* in this case of the sciences, thus, was reinterpreted as a *fieri,* a constructing on the part of reason. As mentioned, Friedman has taken up this trope in what he calls "dynamic *a priori.*"

Philosophy, then, has no special space carved out for its own, but it works in close conjunction with the science it concretely justifies. What was exemplified by Cohen, however, in the realm of science was also carried out in other *facta* that make up our culture, namely (following the Kantian architectonics), ethics, art, and religion. Although Cassirer relaxed Cohen's rigidly logical look at reality, he, in keeping with the spirit of Marburg, characterized this project as a move from Kant's critique of reason to a critique of culture. Natorp expanded Cohen's project to also include psychology as a science in the critical purview of this method. In Cassirer, the critique of culture pertained to the plural of "logics" that comprise the different forms in which the human being, as "animal symbolicum," encounters the world as a universe of symbolic formation.

The Baden School

Much less unified was the so-called Southwestern or Baden school, which included Wilhelm Windelband, Heinrich Rickert, and Emil Lask. Their main efforts may be seen as focused on two related issues: (1) a comprehensive theory of science, which included both the human and the natural sciences, and (2) a theory of values, where Plato was just as influential as Kant. As regards the former, especially Windelband and Rickert were focused on the object of cognition, which was to be determined not ontologically but methodologically by focusing on the object either in its lawful generality (nomothetically) or in its individual singularity (idiographically). Depending on the direction of research, the object of cognition is located somewhere between these two ideal poles.

With respect to the much discussed status of values, it was especially Rickert who opted for the values' own sphere of existence, which he called (following Hermann Lotze's interpretation of the Platonic forms) "validity." Perhaps the most promising Southwest Neo-Kantian, Emil Lask died prematurely in the trenches of the Great War but was on the way to working out a category system for philosophy itself (a philosophy of philosophy), which, if completed, could have been hugely important for philosophy in the 20th century.

Concluding Remarks

In this overview are mentioned only the "idealistic" representatives of Neo-Kantianism. This means that there were also some (like Alois Riehl) who favored a realistic reading of Kant's critical philosophy. But given the relative outsider status of Riehl, one can conclude that the main target of the Neo-Kantians was a materialistic worldview as proposed by the experimental sciences, which was seen as reductionistic and ultimately relativistic. They were in favor of an idealistic one, while at the same time remaining close to the actual work in the sciences, critiquing them. In both senses, as making a sustained case for an idealistic and critical philosophy, the Neo-Kantians may be seen as heirs of their namesake.

Neo-Marxism

Neo-Marxism is a term that has been used since as far back as 1918. Here, it is taken to mean Marxism as it has survived and developed since the fall of the Soviet Union. This entry discusses the background situation and the main theoretical areas currently discussed.

Marxism was widely thought to have been consigned to the dustbin of history by events around 1989. These included the fall of the Soviet Union, the ending of communism in Eastern Europe, the breakup of Yugoslavia, and the ongoing spread of capitalism in China. In parallel with these developments, communist parties in Western Europe tended to convert themselves into left-wing social democratic parties that accept "bourgeois democracy," meaning that any advances toward communism are susceptible to being reversed by subsequent elections. Intellectual fashion likewise veered away from Marxism, the postwar heyday of which came in the late 1960s and early 1970s, following the events of May 1968 in which France came close to experiencing a socialist revolution. The dominant trend was now postmodernism, with its doctrine that grand theories such as Marxism had died.

However, although initially Marxists were relatively isolated, there has been a growing stream of Marxist theory. This has been particularly spurred on by the virtually worldwide spread of capitalism, which has recently taken a purer form than the Keynesian welfare states that arose following World War II. In the advanced countries, there has been a serious growth of inequality, and in the Third World, the imposition of the so-called Washington Consensus has exacerbated the condition of the poor and widened the gap between rich and poor nations. The fall of the Soviet Union and the intellectual isolation of Marxism has meant that splits between Trotskyists, Stalinists, and Maoists have tended to die away. Enthusiasm for a violent "big bang" revolution has also waned: Extensive bloodshed in order to achieve a reversion to communism in due course does not seem a price worth paying.

A wide range of topics are discussed, as can be seen from the pages of journals such as *Historical Materialism,* an outstanding new initiative in creative Marxist thinking, and *New Left Review.* A particularly widely discussed theme is *justice.* There is much debate as to whether or not Marx had an implicit theory of justice despite his frequent avowals that justice is not a conception he accepts. There is more of a consensus that "scientific socialism" does not actually work very well in various respects. Notably, aspects of Marx's *economics* such as the transformation from value into price and the declining rate of profit are generally held not to work. Linked to this, and to what has actually happened since Marx's day, there is scepticism about the inevitability or even likelihood of revolution, particularly in advanced capitalist states. While it is accepted that an important cleavage in society is that between capital and labor, there is skepticism about the unity of the working class, when those on the minimum wage in the United States earn more than 50 times as much as workers in Third World sweatshops. Much of the workforce in the advanced capitalist countries is, of course, paid well above the minimum wage. Moreover, it can be argued that workers are not as poor as, for example, most carers.

For all these reasons and more, many theorists argue that even if Marx did not have a theory of justice, those working in the Marxist tradition today need one. The question then is what would a Marxist theory of justice look like? It is difficult to answer this. Marx himself says that in a communist society the slogan "From each according to his abilities, to each according to his needs" applies. However, if "needs" is interpreted to mean basic requirements of food, shelter, and other essentials, these are by and large already met in advanced capitalist societies. If it means "anything you want to do," there

are several problems. It is doubtful that the planet's resources will sustain an affluent American lifestyle for everyone. Activities such as making epic films, altering the climate of Australia, or drinking vintage champagne are manageable for some people but not for everyone. Some needs, such as the need for personal care, are indefinitely large.

One of the stronger points of Marxism is its account of the tendency of capitalism to spread itself worldwide, as this is exactly what capitalism is tending to do today. There is then some debate as to the implications of this tendency, notably whether some kind of theory of imperialism is appropriate for them. One much debated theory developed from Marxism juxtaposes the multitude of those who work to the ubiquitous empire of capitalism. However, as seen above, the workforce is too diverse for this to really be plausible.

Not surprisingly, there is debate about issues that have arisen since Marx's day. One of these concerns human nature: Apart from asking whether the young Marx's theory of human nature can be rendered compatible with differences of gender and ethnicity, some theorists ask whether it is valid for cyborgs. The role of the Internet and of an economy based increasingly on the processing of knowledge rather than on straightforward material production is also discussed. More immediate questions such as what is really involved in the war on terror or the invasion of Iraq are of course debated.

Debate continues on a range of issues that were already under discussion back in the 1960s, but with additional aspects that have arisen since then. These include the question of the extent to which various interpretations of historical materialism are compatible with the way societies actually function; the question of whether a Marxist theory of class can be made to fit with social groupings today; the extent to which anything can be salvaged from Marx's economics; the question of whether Marxism works better with its Hegelian heritage emphasized or expunged; related to this, the issue of whether or not Marx's theories really benefit from some version of a dialectic; and the relative quiescence of working people, which in turn points toward the role of ideology and the idea of a labor aristocracy.

Neural Hermeneutics

The term *hermeneutics* originally referred to the art of interpreting complex written texts, in particular holy scriptures, which demand considerable skill to reveal their meaning. Hermeneutics is especially relevant to the problem of translation, which, of necessity, requires interpretation of the original text. The major problem for hermeneutics concerns how to develop criteria for deciding when an interpretation is correct.

Modern practitioners of hermeneutics recognized that this problem applies, more generally, to any situation in which messages have to be interpreted. The philosopher and theologian Friedrich Schleiermacher (1768–1834), among others, suggested that the problem for the interpreter is to reveal the message intended by the speaker—that is, what the author had in mind when she wrote the text (*mens auctoris*). However, this criterion, that the interpretation matches the intention, is problematic since the author might be dead or otherwise unavailable. So all we typically have is the text and some knowledge of the context in which it was written.

This difficulty is not confined to the interpretation of ancient texts. Even if I am talking with you face-to-face, I cannot access your mind to check whether my interpretation of what you have just said corresponds to what you intended me to understand. I can create a coherent story, but I can never get independent evidence about the correctness of my interpretations. Nevertheless, in spite of this apparently insurmountable difficulty, most of

the time people seem to be able to understand each other very adequately. How is this achieved?

Neural hermeneutics is concerned with the mechanisms, instantiated in the brain, through which people are able to understand one another. Such mechanisms, although they might now be specialized for understanding, will have evolved from earlier mechanisms with other purposes. Two such extant mechanisms seem relevant to the problem of understanding. The first is *predictive coding* (or Bayesian inference), which explains our perception of the physical world. The second is that of *simulation* and *alignment,* which aids our perception of the social world.

We perceive an object, such as a tree, on the basis of signals from our senses. This process is not linear, since no sensation can unambiguously indicate the presence of a tree. Rather, a computational loop is required, circling from sensation to inference and back again. Our brain infers the most likely cause of the sensations and then tests this inference by collecting more sensory evidence (e.g., by moving the eyes or touching the object). If the evidence is not what was expected on the basis of the inferred cause of the sensations (a prediction error), then the inference has to be updated. Only when the fit between sensations and inferred cause is sufficiently good is the object unambiguously perceived.

In principle, the same mechanism can be applied when trying to understand the mental world of others. The major difference is that, unlike with trees, the process goes in both directions: While I am trying to understand you, you are trying to understand me. Here, the sensory evidence might be the words I hear, from which I infer the idea you are trying to convey. I can test my inference not only by predicting what else you are likely to say but also by saying something myself and predicting how you will respond. Meanwhile, you will be applying the same strategy to what I say. When our prediction errors become sufficiently low, then we have probably understood one another. In this account, the error we are minimizing is not the difference between my idea and your idea, since we have no direct access to each other's ideas. Rather, it is the difference between my idea and my representation of your idea (see Figure 1).

One advantage of the formulation in terms of predictive coding is that it elegantly captures the concept of the *hermeneutic circle,* originally developed in classic hermeneutics, whereby the whole cannot be understood without reference to the parts, while, at the same time, the parts cannot be understood without reference to the whole. In the same way, in the predictive coding loop, the inferred cause (the idea, *the whole*) predicts the evidence, while, at the same time, the evidence (the words, *the parts*) modifies the inferred cause.

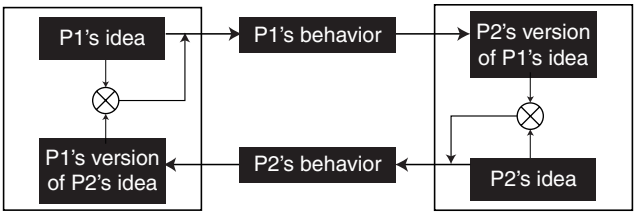

Figure 1 | If there is a discrepancy between P1's idea and P1's version of P2's idea, then P1 will modify her behavior. The two people reach an understanding when they both minimize the difference between their idea and their version of the other's idea.

Source: Chris Frith.

The predictive coding model outlined here does not explain how the link is made between the words and the idea, that is, how the initial inference is made. One possibility is to use *simulation;* that is, I can predict what words you will use on the basis of what I myself would say in the same situation. This is by analogy with motor simulation, in which I predict the movements of others on the basis of my own motor system, a mechanism for which there is now considerable evidence. A necessary consequence of the application of simulation to understanding others is that understanding will be more difficult to achieve if you are in some way different from the person you are trying to understand. This problem may be mitigated through *alignment* (or *mirroring*).

We all have a strong and automatic tendency to imitate each other: the *chameleon effect*. This imitation or mirroring occurs in many domains, including gestures, emotions, and aspects of speech, such as intonation, grammar, and vocabulary. Such mirroring makes us more similar to the person we are interacting with and thereby makes motor and mental simulation more efficient. Direct evidence that understanding is improved by alignment comes from a study showing that communication improved when participants deliberately imitated the accent of the person they were talking to.

The interactive mechanism described above implies that understanding is, in part, a collaboration between the partners engaged in the discourse. Thus, I learn more about my own ideas through interacting with someone else. This relates to Schleiermacher's suggestion that by taking the context into account, the translator can achieve a better understanding of the text even than the original author. By the same argument, a listener can have a better understanding of the speaker than the speaker herself. This is because the listener will not only understand the message that the speaker intends to convey but can also take account of signs, such as body language, indicating aspects of the message that the speaker was unaware of. This better understanding will be fed back to the speaker in the course of the conversation. Thus, through interactions with others, we can achieve a better understanding of ourselves.

Neurath's Unity of Science and the Encyclopedia Project

This entry gives an overview of Otto Neurath's thought and, in particular, his vision of a specific variety of unity of science and his famous project of an encyclopedia. The entry first presents Neurath's project, also indicating his political vision behind it; goes on to unravel the general doctrine of the unity of science in its various forms; and ends by explaining Neurath's own distinctive conception of scientific unity. Neurath's ideas were specifically concerned with the social sciences and their relation to the natural sciences.

Historical Background

The doctrine of *the unity of science* was the mainstay of the philosophical movement known as logical positivism and/or logical empiricism. According to this doctrine—and contrary to Neo-Kantianism, Phenomenology, and Neo-Wittgensteinianism—there is no sharp, categorical distinction to be drawn between the natural sciences on the one side and social science or the human sciences on the other. Often understood to be reductive in its intent and caricatured as aiming to replace social science by a future physics, the doctrine took a particularly interesting and decidedly antireductivist form in the hands of Otto Neurath, who anticipated in some respects the criticisms of contemporary opponents of the unity of science doctrine.

Neurath's Project

Otto Neurath (1882–1945) was a member of the Vienna Circle group of philosophers that met between 1924 and 1936 (other members included Moritz Schlick, Rudolf Carnap, Philipp Frank, and

Hans Hahn) and that became famous for its opposition to metaphysics as cognitively meaningless (they conceded that it served other psychic needs). In this group, Neurath consistently opposed phenomenalist epistemologies and stressed the ever hypothetical and holistic character of our knowledge. For him, philosophy became science in a critical self-reflective mode aiming for its systematic development. The goal was the *unification,* and later the "orchestration," of its multiple branches, which, in turn, was to be documented by the multivolume project of the *International Encyclopedia of Unified Science* (IEUS). (The 20 monographs that appeared between 1938 and 1970 have since been collected as the two-volume *Foundations of the Unity of Science.*)

A social scientist by training and an ardent social reformer by conviction, Neurath wanted social science to contribute to the *reshaping of society.* Concerned with its applicability, he made *empirical testability* the hallmark of its theories. What he primarily opposed as metaphysics was high-flown obfuscation serving to mask social inequality and exploitation. The unity that he aimed for has aptly been characterized by Nancy Cartwright as "unity at the point of action." In this, as in his understanding of other doctrines characteristic of the movement, Neurath's views were increasingly at odds with the emerging orthodoxy of logical empiricism. The latter's strictly formalist orientation toward philosophy of science cared little for the complementation of the study of the logic of science (the logic of scientific representation) with the study of the pragmatics of science (its conditions and exigencies as a social activity), which Neurath thought essential.

The Rise and Fall of the Unity of Science Doctrine

Different versions of the doctrine of unified science were affirmed by different protagonists at different times, reflecting the extremely rapid development of the theories proposed by the logical empiricist movement in its first two decades—before, that is, a certain stasis set in after the end of World War II, with its reputed establishment as the dominant form of Anglo-American philosophy of science. It is notable that one of the most reductivist forms of the doctrine was propounded by the contemporary American philosopher Hilary Putnam in 1958 (a stepwise reduction of theories all the way down to physics), at a time when Carnap had already abandoned the ideal of a reductive hierarchy of laws of different scientific disciplines. Yet even what Carnap retained—the unity of method and the unity of language—was still too ambitious for the historicist opposition to logical empiricism that gained ground in the aftermath of the publication of Kuhn's *The Structure of Scientific Revolutions* in 1962. (It should be stressed that Kuhn's work was published in precisely the IEUS that Neurath had started.) What is clear is that by that time Neurath's alternative conception of the unity of science had been lost from view. What remains unclear is whether, had it been known, it would have made a difference, given the antipositivist fervor that has since held sway.

Then, as now, opposition to the unity of science thesis tended to be motivated at least in part by concern for retaining the distinctly human dimension of the nonnatural sciences. Yet this concern had also already strongly motivated the separatist doctrines that were propounded with particular intensity in the German-speaking parts of Europe when the logical empiricists opposed them (as then also supporting reactionary political ideologies). This concern focused attention on the diversity of the types of objects of the natural and the social sciences (nonminded vs. minded, i.e., physical events vs. human beings), on the diversity of their epistemic aims (nomological explanation vs. understanding of singular cases), or on the diversity of the methods of investigation they used (experimental testing vs. hermeneutical interpretation)—or on a combination of these—stressing that one account of science would not fit all. Given the difficulty of denying any differences between the natural and the social sciences on these accounts, the question arises how a unity of science thesis can accommodate them.

Neurath's Conception of the Unity of Science

Neurath's answer emphasized the aspects of the unity of the method of science and the unity of the language of science but discounted that of the unity of its laws. Instead of aiming for the successive reduction of the laws of the special sciences to those of fundamental physics, Neurath stressed that all that was needed were cross-connections between the sciences, allowing for the explanation

(and, where possible, prediction) of individual or types of events by the combination of the resources of different sciences. (He was not disturbed by the limits of predictability in the social domain and later even stressed that the occasional unpredictability in principle held across all sciences.) In addition, he pointed out that the generalizations of the social sciences often failed to amount to the universal ones familiar from physics, holding instead only for particular historical periods and cultures or types of societies. Importantly, unlike his more orthodox colleagues and opponents, like Karl Popper, he defended this limitation as legitimate and opposed the tendency to use the universal laws of physics as the deciding measure. Most significantly, Neurath opposed the idea of unified science as a deductively closed system of axiomatized theories as an impractical and misleading ideal and instead championed the model of an "encyclopedic," case-by-case integration of the sciences where possible. (Needless to say, not all contributions to the IEUS shared this vision.)

The *autonomy of the social sciences* was further secured by Neurath's conception of the unity of the language of science. For him, this unity did not consist in the eliminative reducibility of all scientific predicates to those of mathematical physics or even to those of the "intersubjective thing-language" but in the fact that all scientific statements had to be checked for their logical compatibility with so-called protocol sentences. Unlike Carnap's bare observation statements, Neurath's protocol sentences were canonically regimented statements of scientific testimonies, indicating sets of conditions for the acceptance of the testimonial claims made. All that was therefore required of the language of legitimate social sciences was that their claims could be checked in this way. Of particular importance here was that Neurath, unlike Carnap, also allowed these protocols to contain predicates that were intersubjectively confirmable (by indirect means) but not intersubjectively testable (by direct means). This allowed protocols to feature reports of psychological states and thus allowed for social-scientific theories that dealt in the beliefs, preferences, plans, and intentions of individual agents to be checked in practice—without, that is, reliance on questionable logically behaviorist definitions or unknown neurophysiological identity conditions for the referents of those intentional locutions.

In consequence, Neurath's conception of the unity of method was very liberal. When he rejected the empathy-based conceptions of a separatist *Geisteswissenschaft,* he rejected the claim that empathetic understanding was necessary in general and ever sufficient for social-scientific knowledge, but he did not deny that empathy could be used as a heuristic of discovery as long as it was recognized that its findings required independent justification. Also, interpretation in a more general sense (attribution of intentional states to agents) was a legitimate social-scientific method by Neurath's lights. What he opposed as Max Weber's metaphysical leanings was not Weber's interpretive sociology but his attempt to reverse the order of explanation postulated by historical materialism. That is, Neurath felt that Weber's insistence on meaningful behavior as an explanation of human action in the social world was alright up to the point that it did not undermine the robust material causal mechanism postulated by Marxism.

The unity of scientific method that the social sciences had to hew to thus consisted in a variation of Carnap's conventionalist take on the principle of empiricism: to formulate the findings of social science in such a way that they are intersubjectively confirmable by means of scientific testimonies.

Conclusion

Whether Neurath's own conception of the unity of science can overcome or undermine all the qualms of contemporary theorists of the disunity of science cannot be decided here. It may be noted, however, that the latter's objections to the traditional conception of the unity of science mostly bypass Neurath's version.

Neuroeconomics

Neuroeconomics is an emerging interdisciplinary field combining economics and neuroscience. Neuroeconomics investigates various problems, combining economics with diverse neuroscientific studies. In particular, neuroimaging technologies such as positron emission tomography and functional magnetic resonance imaging have played an important role in the development of neuroeconomics, although other studies, such as lesion studies and physiology, are also indispensable for neuroeconomics. These neuroimaging technologies enable us to noninvasively investigate how human brains work when human beings are asked to do some task. This entry presents the novel field of neuroeconomics and reviews the two dominant approaches in it. Both approaches raise a number of epistemological issues.

Some might think that neuroeconomics is a unified field of economics and neuroscience, but economists and neuroscientists take different approaches to neuroeconomics. The first approach performs behavioral economic experiments using neurologic imaging studies to criticize standard economics. The second approach uses standard economics to develop algorithmic models of neural structures. This difference of attitude toward standard economics reflects the fact that economists and neuroscientists have different interests in neuroeconomics, and thus this could potentially affect the future of neuroeconomics as a field.

The Behavioral Economic Approach to Neuroeconomics

Some prominent behavioral economists, such as Colin Camerer and Ernst Fehr, take this approach to neuroeconomics. Their findings have generated much of the current interest in neuroeconomics. They employ game-theoretic situations, such as prisoner's dilemma games, ultimatum games, and trust games, and investigate how subjects' brains work. For instance, Dominique de Quervain and his colleagues in Fehr's research group have investigated whether there is any neural basis for altruistic punishment of defectors in the trust game. According to this experiment, when subjects are asked whether they would spend money to punish defectors who betray trust, the subjects' dorsal striatum, an integral part of the brain's reward system, is activated. Furthermore, subjects with greater activation of the dorsal striatum spend more money for punishment. This suggests that the punisher derives satisfaction from punishing the defector who violates social norms. Such a finding is expected to reveal the neural underpinnings of human cooperative behavior.

Neuroeconomists in the first approach share a motivation with behavioral economists. They intend to reveal how real human behaviors differ from theoretical assumptions and, thus, to criticize the idea of homo economicus, or economic man. Although it is well-known that the idea of homo economicus differs from flesh-and-blood human beings, it has been used as the main assumption in standard economics for many years. By criticizing the idea of homo economicus, neuroeconomists using this approach aim to modify standard economics. But scholars such as Herbert Simon have already pointed out the discrepancy between theory and reality and proposed some alternatives to overcome it, so the idea of neuroeconomics is not entirely new. Armed with the latest developments in neuroimaging technologies, neuroeconomists hope to provide a better alternative to standard economics.

The Neuroscientific Approach to Neuroeconomics

According to the second approach, neural tissues *economically* evaluate what reward would be obtained from a behavior, based on information such as internal states and/or external stimuli. This process is necessary for our decision making because our resources are limited. To see neural tissues in such a way is to *regard neural activities as an object of economic analysis*. This is why some neuroscientists become interested in economics, and thus they are led to neuroeconomics. But those who are interested in this second approach do not necessarily intend to criticize standard economics. Rather, researchers such as Paul Glimcher positively use standard economics in their studies of neural activities. Among others, they try to develop a mathematical model of the brain's reward system, in particular the role of dopaminergic neurons in predictive valuation and learning. Based on such a study, they aim at constructing a comprehensive algorithmic model of the brain. True, such a model may be just a model, because neural activities do not necessarily follow theoretical assumptions. But contrary to neuroeconomists in the behavioral economics vein, neuroeconomists in the second approach do not find this problematic. In their view, the mathematical model helps understand how reality differs from theory. In this sense, we could say that neuroeconomists using the second approach regard the mathematical model as an ideal type. Such a stance toward standard economics differs from the behavioral economic approach.

Quo Vadis Neuroeconomics?

As described above, there are two different approaches to neuroeconomics. Although major neuroeconomists know that this is a problem, they hope to arrive at some convergence. But the future of neuroeconomics is not clear for reasons other than the reason suggested above. One is that the results of noninvasive neuroimaging technologies on which many neuroeconomic studies rely are correlational. To do a causal explanation, neuroeconomists need to use noninvasive brain stimulation technologies, such as transcranial magnetic stimulation, which can activate or inactivate particular parts of the brain. But because of the risk of possible damage to the brain, Leslie Sargent Jones warns against the use of brain stimulation technologies on human subjects. This would affect the behavioral economic approach, because it is mainly interested in *human* behaviors in economic situations. The neuroscientific approach, however, performs experiments not only on human subjects but also on animals. Thus, the latter may be more productive than the former. But given the European Union's recent legislations on animal experiments, this might be too optimistic. We are yet to see how this new field develops and whether there can be any convergence between two different approaches.

Neuroethics

Neuroethics is a newly emerging branch of philosophy, with two main focuses: (1) ethical issues arising out of the sciences of the mind (especially, but not only, neuroscience) and (2) the ways in which these same sciences illuminate traditional philosophical issues such as the existence of free will, the nature of personhood, and the features of morality. Neuroethics is a heavily interdisciplinary area of inquiry, bringing together researchers from the humanities and the natural and social sciences.

This entry presents these two areas of neuroethics, explains the role of technology, highlights new findings from experimental social science challenging the received view that moral judgments are rationally arrived at (based on a supposedly universal rational intuition all humans have), shows how this approach brings neuroethics close to so-called experimental philosophy, and, what is more important, underlines the increasingly dominant role of various branches of social science in transforming how philosophy looks at moral judgments (the second area of neuroethical concern).

Beyond Bioethical Issues

Much of the subject matter and approach of neuroethics is closely akin to the subject matter and approach of bioethics. Whereas bioethics is concerned with ethical issues arising out of the biomedical sciences and their application, ranging from the permissibility of abortion to whether life support may ethically be withdrawn, much of neuroethics concerns the applications of our growing knowledge of the brain. Neuroethicists consider questions such as the permissibility of the use of cognitive enhancements, the potential loss of privacy from the development of neuroimaging-based systems of "brain reading," and the manipulation of memory using psychopharmaceuticals. These questions are urgent and intrinsically interesting, but they are not in themselves of particular interest to social scientists.

Technology

However, an adequate analysis of the ethical issues with which neuroethics deals requires a detailed knowledge of the powers and limits of the technologies whose application is under consideration, and that requires that these technologies be understood. The technologies are typically developed by researchers in the natural sciences, such as neuroscience and biochemistry, but the theories these researchers draw upon stem largely from psychology. Furthermore, assessing the permissibility of neuroethical technologies often requires expertise in other social sciences, such as sociology and economics. For instance, assessing the common claim that neuroethics raises issues of social justice requires that we be able to gauge the likelihood that cognitive enhancements will be available only or mainly to the already better-off individuals or whether they are likely instead to rapidly become cheap enough to be available also to individuals of lower socioeconomic status. An understanding of the mechanisms whereby other technologies, such as cell phones, have diffused across societies may enable us to make better-informed predictions with regard to this question.

Experimenting on Moral Judgments

Expertise in the social sciences, and especially in psychology, is also required for engagement in the other branch of neuroethics, the understanding of the ways in which the sciences of the mind illuminate traditional philosophical concerns. In a number of areas, philosophers have relied upon intuitions to understand the structure of the concepts they deploy; that is, they have consulted their gut reactions or a priori judgments when trying to delineate concepts. This way of proceeding has often been justified by the claim that competent speakers of a natural language have an implicit understanding of the extension of their concepts. However, work in linguistics and in psychology casts doubt on this justification. Many linguists believe that concepts are not structured as sets of implicit necessary and sufficient conditions; rather, conceptual classification is achieved by reference to a prototype (e.g., what it means to be a "foetus"). If that is the case, then there may be no determinate answer to whether a certain entity falls within the extension of a concept (thus altering the way moral judgments concerning its treatment are to be accepted or not). Furthermore, a wide range of work in psychology suggests that many intuitive or a priori judgments are the product of cognitive biases or of heuristics, which, while normally reliable, may misfire in particular cases. Neuroethicists have therefore turned to evidence from the social sciences to explore when our intuitions about ethical issues should be disregarded as unreliable.

Experimental Moral Cognition: Some Recent Challenges

Recent work on moral cognition has proved a fruitful source of inspiration for neuroethicists pursuing this agenda. Consider Jonathan Haidt's work, for instance. Haidt argues that his experimental evidence supports the view that moral judgments are generated by subjects' emotional responses to cases and that the role of reasoned argument is merely to offer support to our judgments. It follows that

moral judgments will be relatively impervious to being undermined by reason. Haidt's evidence for this claim consists in the fact that his subjects do not typically back away from their moral judgments when they cannot offer adequate grounds for them and that judgments can be manipulated by manipulating emotional responses (e.g., by post-hypnotic suggestion). On the assumption that Haidt has demonstrated that moral judgments can be caused by irrelevant features of cases, we might hope to show that particular classes of intuitions should be rejected as unreliable, on the ground that they respond to irrelevant features of cases. Alternatively, we might conclude that the evidence from social psychology shows that we cannot rely on intuitions at all and must, instead, generate moral judgments by applying an algorithm. Some consequentialists have responded to Haidt's claims in that kind of way.

Of course, Haidt's work represents just one source of inspiration for neuroethical work on moral judgment; other sources include the rich vein of work on alleged *moral modules,* older work in the heuristic and biases traditions detailing particular ways in which judgments may go wrong, and work in the *situationist* tradition in psychology. Other work in psychology promises to illuminate other neuroethical concerns. There is a large body of work in social, cognitive, and developmental psychology on *self-control,* which has been thought by some neuroethicists to be essential to a better understanding of weakness of the will; other work bears importantly on the nature of the sense of self, the possibility of self-knowledge, and even the existence of free will.

The Ascending Role of Social Sciences

It should be noted that neither the topics just mentioned nor the conviction that they should be approached with at least one eye on the social sciences are the exclusive concern of thinkers who describe themselves as neuroethicists. Philosophers of mind, moral philosophers, and philosophers of biology, among others, make use of this kind of data for similar ends. Neuroethics fades into what has been called by some thinkers *empirical philosophy* and even into the new movement of "experimental philosophy," which actively generates empirical results for further reflection; insofar as it can be distinguished from these approaches, it is by the degree of concern that workers in neuroethics evince for the moral and social implications of the work they perform.

Neuroscience and Politics

This entry addresses the application of methods and models from cognitive neuroscience to political questions and problems. The majority of these examinations have looked at the differences between political liberals and conservatives or have sought to provide less biased means to study socially sensitive topics such as race. Most of these studies involve the application of functional magnetic resonance imaging (fMRI) to understand more about the human brain, but neuroscientific methods also encompass hormonal, physiological, and genetic explorations.

The following section discusses fMRI technology and provides some examples of work that has used it to investigate political topics. The entry concludes with a brief overview of other neuroscientific methods that have been employed to study political topics.

Functional Magnetic Resonance Imaging

Neuroscientific methods allow the possibility of exploring some aspects of brain functioning that were not possible prior to the advent of more advanced technology. Brain imaging uses differences in the level of blood oxygen to impute regions of relative brain activity. This analysis allows observers to determine with great accuracy the geographical region in which the greatest activity takes place during a given task. However, this technology cannot provide as accurate a temporal record of when this activity takes place as other methods, such as the use of the electroencephalograph, which typically employs a cap on the head to record the speed of neural activity. Morever, while fMRI has provided untold information regarding the anatomy of much brain activity, it cannot alone explicate the pathways and mechanisms involved in any given activity. In fact, many individuals may use different brain regions to solve the same task, just as many others may use the same regions to respond to different challenges. In this way, brain imaging can provide a more direct measure of response. Finally, it is not necessarily the case that such studies provide more useful or valid information than that derived from psychological studies that involve the use of other methods. As with any other methodology, the utility of fMRI technology depends in part on the question being asked and the kind of evidence sought in order to answer it.

However, fMRI technology has been used to examine some important aspects of *political preferences* and *behaviors*. Work in this area has shown, for example, that political conservatives and liberals appear to have different brain structure. Other work has shown that liberals and conservatives differ in their evaluative processes in risk taking as well. Most of this work implicates the *emotional centers* of the brain as central to the processing and interpretation of political information, including the evaluation of political candidates and policy issues.

Much of the work in this area has examined how individuals respond to political candidates. Influential work has demonstrated that negative attributions appear more important than positive ones in mediating the effect of appearance on voters' decisions. While attractiveness typically enhances a candidate's appeal, this characteristic does not appear to be able to overcome assessments of competence or threat.

In addition, fMRI technology has been used to examine how people respond to sensitive topics such as *race,* where individuals may prove either unable or unlikely to tell the truth about how they feel. These studies have shown that people process facial emotions differently based on the race of the viewer and the subjects. One of the most provocative of these studies showed increased activation in the amygdala, a part of the brain understood to be involved in emotional learning, processing, and evaluation, when White subjects looked at pictures of Black faces. However, this effect disappeared when subjects looked at the faces of famous or positively regarded Black figures.

Other Neuroscientific Analysis

Tremendous advances have been made recently in studying the basis of political preferences and behavior using *genetic* methods and models. These studies can use a variety of techniques to examine the nature of individual variance in the outcome of interest. Genetic studies often involve the genotyping and in-depth interviewing of related family members, including twins, nontwin siblings, parents, spouses, and children. Such work can also involve the intensive investigation of the relationship between genetic variance on specific genes or genetic pathways, and particular outcomes of interest. Scholarship in this area has demonstrated, for example, that more than *half the variance in political ideology can be attributed to genetic causes.*

Additional work has examined the relationship between *hormonal* factors and political outcomes. Early work in this area explored the role of serotonin in dominance behavior, while more recent work has examined the influence of testosterone on aggression or of cortisol on voting behavior.

Other methods designed to assess the neurological responses of individuals to political topics include tests such as the implicit association test, which is designed to examine small differences in reaction time between positive and negative associations to key concepts or triggers, such as race. Studies that use reaction time alone have also produced influential results, showing, for example, that 1-second judgments of competence based entirely on facial appearance can predict the outcome of senatorial races better than chance and can directly track the margin of victory in such races.

Physiological measures, using strategies such as rapidity of eye blink in the face of threat, have also been used to examine the differences between political liberals and conservatives. Other physiological

measures include galvanic skin response, which measures small changes in the secretion of sweat on the skin, or eye-tracking technology, which examines the areas that individuals look at in a given image, how long they spend looking at that region, and how often they return to examine it further. Work in these areas has often found systematic differences in the response patterns of political liberals and conservatives.

New Wittgensteinians

"New Wittgensteinian" is a moniker used to pick out the members of a particular set of readers of Wittgenstein. Commentators on Wittgenstein's philosophy generally speak of a dramatic rift between his early and later conceptions of the workings of language. In contrast, some of the philosophers who are referred to as New Wittgensteinians claim that there are fundamental *continuities* between his earlier and later accounts of linguistic phenomena. While, on the one hand, these philosophers emphasize that there are fundamental similarities between Wittgenstein's philosophical preoccupations at different periods, on the other, they hold that there are certain telling differences and that his thought about language receives its most compelling treatment later on. Their claims about Wittgenstein's later view of language, even when considered in isolation from their claims about the evolution of his thought, represent a point of substantial conflict with the more widely received interpretations. Interest in the basic view of language in question is what unites the work of the different philosophers who get dubbed New Wittgensteinians, some of whom have little or nothing to say about Wittgenstein's early work. At issue is a view of language that, if sound, would have significant implications for how we approach central questions of philosophy and the social sciences, including, first and foremost, questions about the logical character of the resources available to us for critically assessing social practices.

This entry briefly describes the relevant view of language, distinguishes it from superficially similar views sometimes attributed to the later Wittgenstein, and discusses its bearing on these questions.

New Wittgensteinians: Realism and Anti-Realism

Wittgenstein is frequently read as having espoused a form of philosophical realism at the time of the writing of his early work, the *Tractatus,* and as having exchanged it for a form of anti-realism later on. When depicted as championing philosophical realism, the author of the *Tractatus* is interpreted as favoring a conception of discourse on which the meanings of expressions are determined by ties to objects in a prior reality. When portrayed as trading in a realist outlook for a species of anti-realism, the later Wittgenstein is taken not only to be rejecting the thought that meaning is determined in this way but also to be claiming that there can therefore be no such thing as objective agreement between language and the world. The point is that meaning is fixed not by links to an antecedent reality but by our public practices with expressions and, moreover, that, because meaning is thus a function of what we do, there can be no question of its attaining our ideal of objectivity.

While not all the philosophers who have been labeled New Wittgensteinians discuss the *Tractatus,* those who do are committed to disputing this narrative about Wittgenstein's philosophical development.

They take Wittgenstein to be, in the *Tractatus* as well as in later writings, concerned with repudiating a presupposition *common* to the sorts of realist and anti-realist doctrines that are attributed to him at different periods. Read as a realist, the author of the *Tractatus* is taken to be presupposing that we have the sort of transcendent perspective on language from which to determine that any objective authority it possesses is a matter of grounding in an antecedent reality. And an important claim of the "new" body of work on the *Tractatus* is that its author not only doesn't make this presupposition but sets out to expose it as confused. Furthermore, according to the pertinent New Wittgensteinians, Wittgenstein's early writings anticipate his later philosophical efforts in this respect.

Different anti-realisms are often depicted as anti-metaphysical enterprises, so it might seem as though the idea of hostility to transcendent metaphysics is unthreatening to familiar anti-realist readings of Wittgenstein's later work. But the anti-realist posture ascribed to the later Wittgenstein resembles the realist posture ascribed to him at the time of the *Tractatus* in making the following metaphysical presupposition, namely, that whatever objective authority, if any, language has is a matter of a foothold in a prior reality. Admittedly, the supposedly Wittgensteinian anti-realist differs from her realist counterpart in denying that there are transcendent objects underwriting our modes of thought and speech. But this thinker represents our claim to objective authority as turning on the existence of such objects, and she accordingly presupposes that we can grasp the notion of an external vantage point on language, at least well enough to understand what the—in her eyes unachievable—ideal of objectivity is like. This is the metaphysical presupposition, common to realism and anti-realism, that some New Wittgensteinians take Wittgenstein to be challenging both in his early and in his later writings.

What unites the work of all New Wittgensteinians, those who do as well as those who do not discuss the *Tractatus,* is a sympathetic concern with Wittgenstein's later efforts to arrive at a conception of our lives with language that is not beholden to the presupposition of a transcendent perspective. Wittgenstein is taken to be treating the idea of such a perspective on language as utterly confused, so that now there can be no question of regarding its forfeiture as threatening our entitlement to the ideal of objectivity. By the same token, he is taken to be representing sensitivities characteristic of us as people who have mastered a set of linguistic practices as contributing internally to our ability to think rationally about the world and bring it accurately into focus.

Implications for the Philosophy of Social Sciences

It is insofar as "new" readings of Wittgenstein develop this image of our rational capacities that they have a significant bearing on philosophical debates about our resources for critically assessing the actions, practices, and institutions that are the objects of the *social sciences*. It is an, at least, implicit assumption of many contributions to these debates that we are obliged to accept some version of one of the two following basic positions.

The centerpiece of the first position is the view that there are universal standards for rationality and, further, that these standards are such that our ability to recognize their correctness and apply them does not depend on our having an appreciation of the social practices at issue. This view is attractive insofar as it seems to equip us to offer wholeheartedly rational assessments of social practices. Yet it is unattractive insofar as it also seems to enable us to do so from outside, in what some would impugn as a hopelessly paternalistic manner.

The second basic position that figures in debates about our resources for criticizing social practices pivots on the view that standards for the assessment of given practices are *internal* to the particular practices themselves. This view is attractive insofar as it makes assessment inseparable from a close study of particular practices. Yet it is unattractive insofar as it excludes the possibility of rationally authoritative assessment, thereby ushering in an extreme form of cultural relativism.

What gives the image of our rational capacities characteristic of New Wittgensteinians interest in this context is the fact that it suggests the possibility of combining the virtues of the two foregoing positions while also eliminating their vices. Now it appears possible consistently to say both that grasping standards appropriate to assessing a practice necessarily involves entering into the concerns and interests that shape it and, additionally, that this does not disqualify the standards we thereby pursue from being fully rational. There appears to be a possibility here because, against the backdrop of the image of our rational capacities favored by New Wittgensteinians,

there is no question of a transcendent standpoint from which any interests or concerns we explore have a necessary tendency to obstruct our view of what a practice is really like. The upshot is that New Wittgensteinians' notion of a shared understanding of our rational capacities holds forth the promise of radically reshaping the conceptual space in which debates about rationality within the philosophy of the social sciences take place.

Distinguishing New Wittgensteinians From Older Approaches

These issues have to some extent been obscured by disputes about the legacy of Peter Winch. The disputes in question surround Winch's widely discussed 1958 monograph *The Idea of a Social Science and Its Relation to Philosophy.* In this book, as well as in various later reflections on it, Winch presents himself as drawing his chief inspiration from Wittgenstein's later reflections on language. There is a general consensus among readers that Winch is rightly read as favoring some version of what is described above as an anti-realist reading of Wittgenstein's later philosophy and that Winch's work therefore falls squarely on the relativistic side of familiar debates about our resources for criticizing social practices. This consensus has contributed to an intellectual climate in which a friendly interest in Wittgenstein's later view of language is sometimes regarded as inseparable from a commitment to cultural relativism. The existence of such a climate represents an obstacle to registering the significance of the writings of New Wittgensteinians. But it remains the case that this body of writing has the potential to reconfigure key conversations in the philosophy of the social sciences.

Newtonianism in Adam Smith's Social Science

Isaac Newton's influence on Adam Smith has been widely acknowledged, but its real nature is still a matter of debate. Within the generally accepted view, Adam Smith would have applied Newtonianism to social science, setting the ground for neoclassical and modern mainstream economics. But the reality of this assertion is disputable.

This entry reviews and assesses the thesis that Adam Smith's conception of social science was influenced by, or was a direct descendant of, Newton's scientific method.

Newton and Newtonianism

In 1687, Isaac Newton, the father of modern physics, published *Philosophiae Naturalis Principia Mathematica* (*Principia*). In 1704, a year after the death of his rival Robert Hooke, Newton published in English his *Opticks: or, A Treatise on the Reflexions, Refractions, Inflexions and Colours of Light*. The irrefutable character of *Principia,* with its laws of motion and the universal law of gravity "derived from phenomena," became paradigmatic during the 18th century. And the spectacular nature of Newton's *Opticks,* with its experimental results and its many speculations, influenced the way modern philosophers would think about the world. To assess Newton's monumental influence, we must simply recall Alexander Pope's intended epitaph for Newton: "Nature and nature's laws lay hid in night: / God said, Let Newton be! And all was light" (1730).

Newton's impressive discoveries in natural philosophy influenced a long intellectual tradition. As Newton found the key to understanding nature with his "experimental philosophy," many intellectuals relied on his method to uncover the nature of social

sciences. During the Enlightenment, philosophers would rely on Newton, assuming that social phenomena could be understood using his methodology. In Query 31 of his *Opticks,* the father of modern science declared, "And if natural Philosophy and all its Parts, by pursuing this Method, shall at length be perfected, the Bounds of Moral Philosophy will also be enlarged." This statement was taken seriously in the 18th century.

But the image of Newton as the father of the Age of Reason is biased. The economist John Maynard Keynes, after reading some of Newton's manuscripts, wrote his essay "Newton, the Man," challenging the glorified image of the father of modern science. In the past decades, a renewed interest in the figure, the discoveries, and the methodology of Newton has developed. If *Principia* and the *Opticks* are the most important "public" sources for understanding Newton's method, today we know that Newton also conceived his speculations by relying on his alchemical, theological, and ancient-wisdom knowledge.

Newton's methodology is more complex than the generally accepted view of an axiomatic deductive or positivistic interpretation. Within Newton's method of resolution (analysis) and composition (synthesis), induction plays a crucial role. The first four "rules for the study of natural philosophy" in *Principia* have become emblematic to understand Newton's "experimental philosophy." In particular, the controversial Rule 4, which was added for *Principia*'s third edition (1726), states that "in experimental philosophy, propositions gathered from phenomena by induction should be considered either exactly or very nearly true notwithstanding any contrary hypothesis, until yet other phenomena make such propositions either more exact or liable to exceptions." Besides the method of analysis and synthesis, Newton developed his conception of a potentially open-ended process of successive approximation to reality similar to that of critical rationalism's verisimilitude.

The Scottish Enlightenment and Adam Smith

The Scottish Enlightenment rapidly assimilated Newton's discoveries and his methodology, spreading Newtonianism first in Britain and then in the Continent, where it was received more reluctantly. The Cartesian tradition could not accept the notion of a void, insisting on mechanisms and contact between bodies. Newton's notion of universal gravitation as a force operating universally and independently of any direct mechanical contact was difficult to accept in France. René Descartes had defined matter as an infinitely extended *plenum,* but Newton formulated his concept of universal gravitation operating in bodies *in vacuo*. G. W. Leibniz, the most capable representative of mechanical philosophy, who discovered calculus at the same time as Newton, argued that a contact mechanism was needed to explain gravity. And if Newton had to appeal to God in the *General Scholium* to explain gravity, his realism is explicit when he declares that gravity "simply exists."

According to Dugald Stewart, Adam Smith's lectures in moral philosophy at Glasgow University (1752–1764) were divided into four parts: Natural Theology, Ethics, Jurisprudence, and Political Economy (*expediency*). Based on it, Smith developed a system of social science that comprised ethics (*The Theory of Moral Sentiments,* 1759), economics (*An Inquiry Into the Nature and Causes of the Wealth of Nations,* 1776), and his unaccomplished project of jurisprudence.

Naturally, Adam Smith reflects the 18th-century admiration for Newton's discoveries. In his essay *The Principles Which Lead and Direct Philosophical Enquiries; Illustrated by the History of Astronomy,* the father of economics analyzes "the superior genius and sagacity of Sir Isaac Newton," which "made the most happy, and, we may now say, the greatest and most admirable improvement that was ever made in philosophy." In addition, paraphrasing Query 31 of *Opticks* for extending Newton's methodology to the realm of moral philosophy, Smith is reported to have lectured that "the Newtonian method is undoubtedly the most Philosophical, and in every science whether of Moralls or Naturall philosophy." This is textual evidence that Smith relied on Newton, but the crucial question is about the real nature of Smith's Newtonianism.

Based on some references to Newton and his system, and a narrow understanding of Smith's notion of human beings as a simple homo economicus, it has been generally accepted that Smith attempted to build his system of social science on a Newtonian basis. If the French early reception of Newton's legacy finally led to neoclassical and modern mainstream economics, Smith had a different interpretation of Newtonianism. The Scottish Enlightenment not only promoted Newtonianism but also understood its methodology. Therefore, Adam Smith was well aware that we approximate to the real nature of social science using a progressive

process of approximation. In this sense, the real legacy of Newton's methodology was developed by the Scottish Enlightenment. And Adam Smith, the father of economics, was a key inheritor of this tradition.

Nihilism

Nihilism is derived from the Latin term *nihil,* meaning nothing. At its core, nihilism is the claim that existence has no meaning. This entry charts the history of the notion of nihilism and shows its importance both for philosophy and for social inquiry.

The most influential version of nihilism is *existential nihilism,* the claim that there are no ultimate values. Ultimate values are those values that give life, and existence itself, meaning. The claim that existence is meaningless is sometimes taken to be the central premise of existentialism of this sort. The term *nihilism* can also be used in an *epistemological* and a *moral* sense. Epistemological nihilism is a form of radical scepticism that denies that anything can be known. Moral nihilism is the metaphysical claim that there are no objective moral values. The nihilistic claim that life has no meaning is often twinned with one of two normative responses: either that one should withdraw from life and active engagement in it or that one should defy life by adopting a form of violent protestation against its absurdity, as suggested in the French existentialist writer Albert Camus's *The Myth of Sisyphus*.

At the end of the entry, we shall mention two forms of nihilism in recent analytic philosophy, *mereological nihilism* and *metaphysical nihilism*.

The concept of nihilism plays a prominent role in many philosophical and literary works from the middle of the 19th century onward and may be regarded as one of the distinguishing traits of modernity. In particular, nihilism is often regarded as one of the perceived effects of secularization on European culture. Nihilism's prominence in social thought owes as much to literary and cultural criticism as it does to systematic theorizing. This in part explains the concept's heterogeneity.

History

The German philosopher F. H. Jacobi, in an open letter to J. G. Fichte in 1799, claims that Fichte's philosophy of Absolute Idealism is "nihilistic" because it denies the existence of anything outside the transcendental Ego. As God (according to Jacobi) cannot be posited by Fichte's "I," Fichte's philosophy denies God and is therefore a kind of nihilism. Jacobi concedes that Fichte's system is intellectually rigorous; his concern is with the potentially deleterious

effects that belief in such a philosophical system may have on its proponents. His critique of nihilism as reason pushed to destructive limits was a recurring theme in its subsequent development. However, the term *nihilism* really gained widespread recognition through its use in the Russian author Ivan Turgenev's *Fathers and Sons*. Bazarov, the main character of the novel, exemplifies an extreme form of critical positivism (scientism), subjecting all beliefs and received opinion to critical scrutiny and doubt. Turgenev's ambivalence toward Bazarov is partially determined by his reaction to the Russian anarchist and Young Hegelian thinker Mikhail Bakunin, whom Turgenev met in Berlin in 1840. Bakunin had attained great notoriety for extolling creativity through destruction. The perceived link between nihilism and the social and political movement of anarchism (and to some extent socialism) was strengthened by another famous Russian, Fyodor Dostoevsky, whose work *The Devils* (1872) drew inspiration from the activities of the revolutionary nihilist Sergei Nechaev. Nechaev's notorious *Catechism of a Revolutionary,* published in 1869, called for the complete destruction of both the state and society. Peter Verkhovensky, the main character of *The Devils,* participates in various assassinations and other acts of political violence. Dostoevsky's critical appraisal of the nihilistic spirit as bound up with violent and destructive acts of rebellion against society had a crucial impact on the development of Friedrich Nietzsche's understanding of nihilism.

Nietzsche

Friedrich Nietzsche (1844–1900) is the most influential figure in the subsequent understanding and elaboration of nihilism at the end of the 19th and for much of the 20th century. Despite the fact that Nietzsche published very little on nihilism, many of his numerous notebook entries dealing with nihilism appeared in a posthumously published work, *The Will to Power,* put together from his notes by his sister and others. This volume proved extremely influential in the subsequent understanding of both nihilism and Nietzsche's own philosophy.

For Nietzsche, modern nihilism is the absence of all overarching (ultimate) values and is the inevitable outcome of a thorough recognition of the death of (the belief in) God. For Nietzsche, modern moral systems such as Kantian deontology, utilitarianism, socialism, and Marxism merely carried on what he called the Judaeo-Christian "morality of compassion" in a secular form. They, like Christianity, are moralities of compassion in that they are essentially concerned with alleviating the suffering of humanity. Nietzsche argued that without the authority of God's command these moralities of compassion will eventually lose their grip on us and we, modern Europeans, will be left without any overarching values. This may aptly be called the "nihilism of disorientation." It is the kind of disorientation that has often been noted (e.g., by Sigmund Freud) to accompany the great conceptual revolutions instituted through the discoveries of Copernicus (the earth is not the center of the universe), Charles Darwin (humankind is not the product of, and hence the center of, divine creation), and Freud (man's conscious ego is not his ruler and the center of his being). It is this disorientation, the lack of ultimate overarching, centring values, that Nietzsche presciently pronounces as "the history of next two centuries." The emphasis on overarching values is crucial, for, as Nietzsche himself claims, life inevitably involves values. For instance, in reading this essay you are expressing a value; you are, at the moment, valuing reading it above, say, watching television. In his *Thus Spoke Zarathustra,* Nietzsche paints a vivid picture of the "last men," who value their families, their careers, and their small happiness but ask, "What is a star?" and blink. If nihilism really involved the absence of all values, as opposed to only the absence of overarching values, it would be incompatible with life (but see Nietzsche on affective nihilism, below). The basic Nietzschean argument that life inevitably involves values is that life itself is nothing but a collection of drives, and each drive, through its aims, assigns instrumental values to things, according to the thing's ability to satisfy the drive's aim. Thus, our hunger drive places a high value on food, say the croissant before us, and little value on, for instance, the pretty curtains in our study. What the nihilist lacks are overarching values that give meaning and provide a narrative structure to all existence. This Nietzschean idea was influential in works such as Oswald Spengler's *The Decline of the West.* The post-Christian West, "disenchanted" in Max Weber's words, is arguably a culture in decline as its members have lost belief in the central organizing values that fortified and gave vitality to their culture.

However, beyond this modern nihilism of disorientation, Nietzsche recognizes a deeper form of nihilism. This is evidenced by his repeated claim that Christianity itself is nihilistic. The Christian after all does not suffer from disorientation. Existence for him has great value as it is God's creation and, for the righteous, a gateway to the infinitely valuable external bliss of heavenly existence. Nietzsche argues, however, that this very proclamation of the value of the world to come serves to disvalue this, our worldly, existence. Christianity tells us that our natural worldly inclinations, our sexual drives, and our drives for power and dominance are affronts to God and need to be repressed if not extirpated if we are to gain entry to heaven. Now if we, like Nietzsche, equate life with our drives, we will see Christianity's rejection of the drives as a turn against life itself, what Nietzsche calls "the will turned against life." For Nietzsche, the desire to quieten the drives is in fact the desire to be nothing, to not exist, akin to what Freud would later call the *death drive*.

This phenomenon of the will turned against life we might call *affective nihilism*. Unlike the nihilism of disorientation, it does not involve an endorsement of some proposition, for instance, the proposition that there are no ultimate values. It involves a psychological component: wholesale repression of the drives. This captures the *nihil* (nothing) of nihilism, since the drive to suppress or extirpate the drives is a kind of drive to nothingness; for, as we have observed, for Nietzsche, life is itself a collection of drives; thus, to eliminate the drives is to eliminate life itself. When Nietzsche heralds nihilism as the history of Europe for the next 200 years, what he is prophesying is that the affective nihilism of Christianity will come to be consciously expressed in the embracing of claims such as that of the nihilism of disorientation—that there are no ultimate values.

Other Senses of Nihilism

As well as its existential sense, nihilism can also be used in an *epistemological* and a *moral* sense.

Epistemological nihilism is a form of radical skepticism that denies that anything can be known. Taken literally, this appears to be paradoxical; if literally *nothing* can be known, then presumably this includes the claim that nothing can be known. So if epistemological nihilism is true, we cannot know that it is true. In the social sciences, epistemological nihilism is often closely associated with extreme forms of relativism, for instance, the claim that truth is always relative to a theory. Such claims face a similar philosophical problem, namely, that they are self-undermining. As the old joke has it, "Relativism is not true, relative to my theory." A common, though disputed, charge (as leveled, e.g., by Jürgen Habermas) against philosophical postmodernism (as in Jacques Derrida), with its celebrated "incredulity toward meta-narratives" (as Jean-François Lyotard urged), is that it leads to relativism and nihilism.

Moral nihilism is the claim that objective moral values do not exist. One version of this view was given by the 20th-century Australian philosopher John Mackie, who argued that moral properties do not exist. The world as revealed to us by science does not give any grounds for attributing such properties to things, despite what our moral language would suggest. Ethical language is thus in systematic error, according to Mackie, and hence this variety of moral nihilism is called an *error theory*.

Finally, in contemporary discussions in metaphysics, there have been two areas in which the notion of nihilism has been employed but in a different way from the ones we have presented so far. Whereas the first of these metaphysical theses is explicitly non-intuitive, the second is not. First, there is the thesis of *mereological nihilism,* advanced by philosophers who reject the existence of any proper parts; that is, it amounts to the thesis that there are no composite objects or, in other words, objects with proper parts do not exist. Advocates of mereological nihilism assert that there exist only the smallest building blocks of reality, *simples,* which, however are, and remain, independent, forming no composite wholes. So strictly speaking, there are no composite things, such as, for instance, houses, but only material simples (subatomic particles) "arranged housewise." Some nihilists of this sort, like Peter van Inwagen, admit living organisms as the only exception, allowing them to be composite wholes of parts that contribute to the organism's life. Second, there is the (quite intuitive) thesis of *metaphysical nihilism,* according to which it is possible that there could be no concrete object or that it is a possibility that nothing concrete existed. The thesis asserts a metaphysical possibility; it does not claim that there are no concrete things. Metaphysical nihilists support the thesis that an empty world is a possibility

by an argument, the so-called subtraction argument (originally put forward by Thomas Baldwin).

Nonconceptual Content

The issue of nonconceptual content revolves around two related questions. First, are there mental or cognitive states that represent some entity, without the subject of those states having to possess and/or employ any concepts of that entity? Second, what is the nature of the contents that such cognitive states possess? Answering either question is extremely difficult. For one thing, *nonconceptual content* designates something in terms of what it is not, and there may be many distinct kinds of content that conceptual content is not. Just as "nonhoofed animal" does not designate a theoretically interesting biological kind, there is no guarantee that "nonconceptual content" designates a theoretically interesting psychological kind. For another, any argument for the existence of states with nonconceptual content, and any account of their nature, depends on a conception of conceptual content. Unlike the property of being a hoofed animal, there is a wide range of opinion regarding what conceptual content is and under what conditions a subject possesses it; and the importance and the plausibility of the claim that nonconceptual content exists depends on just how robust or deflationary one's notion of conceptual content is.

Content

As the term is used today, the claim that a mental state "has content" often just amounts to the claim that it represents something as being a certain way. Historically, this was not so. Bertrand Russell, criticizing the views of Alexius Meinong—and by extension Kasimir Twardowski—explicitly denied the existence of mental content. In contemporary discussions, a distinction between content and object is often not explicitly drawn, so whether the "content" that a mental state "has" is the object represented or something that itself represents that object—such as a Fregean thought—is an issue on which there is some disagreement. Some authors appear to use the term *content* for both sorts of things. For instance, Christopher Peacocke uses the phrase "the content of experience" to refer not only to the objects, properties, and relations perceived but also to the ways they are perceived. Some philosophers use the term *content* to designate what a mental state represents. Other philosophers expressly use the term *content* for the way or manner in which an object is represented. As David Woodruff Smith expresses it, the content is "the 'mode' of presentation"—that is, the conceptual or presentational structure of the experience.

The ambiguity of the term *content* has a significant impact on the shape of the debate. For those who identify a mental state's content with its object—what it represents—the claim that certain mental states have nonconceptual content can be taken to mean that such mental states represent different sorts of objects than do states with conceptual content, such as beliefs. This position is the "content view," or *absolute nonconceptualism.* It can also be taken to mean that nonconceptual and conceptual states differ not in their objects but qua states. This is

the "state view," or *relative nonconceptualism,* and is compatible with the claim that conceptual and nonconceptual states can represent the same kinds of objects. For those who distinguish a mental state's content from its object, the claim that some mental states have nonconceptual content is also compatible with the claim that those states represent the same objects as do states with conceptual content. All that follows is that they represent those objects in a different manner. So, for instance, one might explain the difference between thinking about a tree and seeing a tree as a difference not in the tree but in the contents of the respective states. On any version of nonconceptualism, there exist mental states such that the subject of such a state need not possess or exercise concepts of the objects (or "contents") the state represents in order to be in that state.

What sorts of states might have nonconceptual content? The most commonly discussed candidates are (a) perceptual states, (b) the states of animals and prelinguistic humans, and (c) subpersonal cognitive states.

Perceptual States

Nonconceptualists have specified a number of features that, allegedly, belong to perceptual states and that, allegedly, do not belong to conceptual states. The most widely discussed feature in the literature is the fineness of grain of perceptual states. For example, a table may exhibit a variety of shades of brown that are perceived, while the perceiver has no names for them. The argument, then, is that if we can be conscious of certain objects or features but lack concepts of those objects or features, then the states in which we are conscious of them must have nonconceptual content. Since perceptual states sometimes make us aware of certain objects or features, such as determinate colors, for which we lack concepts, those states have nonconceptual content.

The standard conceptualist response is to claim that we do have concepts fine-grained enough to characterize such properties, namely, demonstrative concepts, and that such demonstrative concepts are exercised in perception. As John McDowell (1994) put it,

> In the throes of an experience of the kind that putatively transcends one's conceptual powers . . . one can give linguistic expression to a concept that is exactly as fine-grained as the experience, by uttering a phrase like "that shade." (pp. 56–57)

One nonconceptualist response to this position is that having the concept *C* entails having the ability to reidentify the object or property falling under *C,* but perception discrimination of a property does not require having the ability to reidentify it. Another response is that the perceptual experience of an object is what causally explains one's ability to refer to it demonstratively, in which case exercising the demonstrative concept cannot partially constitute one's perceptual experience of the object.

Many advocates of nonconceptualism, including some who reject the demonstrative strategy, express reservations about the fineness-of-grain objection, at least if that objection amounts to the claim that perceptual experiences represent more determinate properties than can be represented conceptually. There is another way of understanding the fineness of grain of experiences, however, according to which it is not that the objects of experience are more fine-grained or determinate than those of conceptual states. Rather, it is that the states represent objects and properties in a more fine-grained *way.* According to Sean Kelly, the nature of one's experience of color is partially determined by the lighting conditions in which it is perceived—the same color can appear differently in different contexts without appearing to be different. Since a demonstrative such as "that color" does not distinguish between the same color as experienced in different conditions, the experience has a sort of content that cannot be captured conceptually. Chistopher Peacocke makes the related point that the visual perception of a square differs from that of a regular diamond, despite their having identical objects and despite the fact that the demonstrative "that shape" would, if employed in both experiences, refer to the same shape. (The French phenomenologist Maurice Merleau-Ponty spoke, in the same vein, of the "paradox of symmetrical objects.") As we saw above regarding how the "content" of experience should be construed, Peacock insists that when we describe cases of fine-grained phenomenology, we employ the "notion of the *way*" a property or a relation is given in experience.

Another feature of perceptual states cited by nonconceptualists is that their contents are context and object dependent. The phenomenon of perceptual constancy shows that a given property

(shape, color, size, etc.) can appear to be the same in experiences that are phenomenologically different. What accounts for this is that perceived properties are always presented in a wider context. Kelly also argues that perception does not reveal abstract properties but "dependent aspect[s]" of the perceived objects. The blue of a woolly blue carpet and the blue of a shiny steel ball might be the same, but they show up differently in perceptual experience.

A related argument that perceptual states have nonconceptual content is that conceptual contents can be entertained when one is not confronted with the objects or states of affairs those contents represent, whereas the contents of perceptual states cannot. Conceptual content, as Susan Hurley said, is not "context-bound." Edmund Husserl had also argued that perception is not a "carrier of meaning," since on the basis of exactly the same perceptual experience one can think, "There flies a bird!" "That is black," and countless other propositions. And one can think, "There flies a bird!" while one's perceptual experience of the bird varies, and even when one is not perceiving any birds at all. More generally, for any perceptual experience *E* and any conceptual content *p,* undergoing *E* does not entail that one is entertaining *p,* and entertaining *p* does not entail that one is undergoing *E*.

Another argument that perceptual experiences have nonconceptual content is that their contents are not structured in the way those of conceptual states are. As Jerry Fodor argues, the concepts "John," "Mary," and "loves Mary" are *constituents* of the thought that John loves Mary. "John loves," however, is a *part* rather than a constituent, since it does not figure in the "canonical decomposition" of the thought that "John loves Mary." Perceptual contents, however, are iconic representations, which do not have any canonical decomposition. Such representations have parts but not constituents. Furthermore, according to Gareth Evans's Generality Constraint, a thinker capable of thinking both *Fa* and *Gb* is also capable of thinking *Fb* and *Ga,* provided that doing so does not involve any category mistakes. Perceptual contents, however, cannot be combined in this way. One might perceive that a cat is running and that a building is tall, but one cannot thereby perceive that the building is running.

Other advocates of nonconceptual content, finally, have emphasized the intimate connection between perception and action. Conceptually, one might present one's speed on a motorcycle as "55 miles per hour." That, however, is neither necessary nor sufficient for the sort of "embodied and environmental" knowledge one possesses while actually going that fast. Furthermore, nonconceptualists have argued that there is a constitutive connection between perceptual states and actions, while connections between conceptual states and actions are contingent.

All of these arguments depend on rather substantive claims about the nature of conceptual contents and their possession conditions, and it is open to the conceptualist to dispute them. Alva Noë (2004), for instance, writes,

> Perceptual experience presents the world as being this way or that; to have experience, therefore, one must be able to appreciate how the experience presents things as being. But this is just to say that one must have concepts of the presented features and states of affairs. (p. 183)

If employing concepts is just a matter of being able to represent something as being a certain way, then plainly none of the arguments for nonconceptual content above are sound.

Conceptualists, for their part, have defended their position in a variety of ways. One of the most notable arguments, by McDowell or Bill Brewer, for instance, is that since only states with conceptual content can justify beliefs and since perceptual states plainly do justify beliefs, experiences must have conceptual content. Against this, Tyler Burge has criticized such views for overintellectualizing perception and for treating perceptual belief as a form of reasoning, and Walter Hopp has argued that the special epistemic role of experience cannot be accounted for in any conceptualist view.

Animals and Children

Another argument for nonconceptual content is that animals and children are aware, and consciously aware, of objects in the world but lack concepts of many, most, or even all of the objects of which they are conscious. Sandfish, to use Andy Clark's example, detects vibrations caused by its insect prey. But it does not represent the features and occupants of its environment by employing the concepts we use to describe them, such as "vibration" or "insect." Furthermore, animals need not satisfy the Generality Constraint. A frog might represent that there is a

fly over there, without being able to be in any other sorts of states directed at flies. Similar remarks go for prelinguistic humans.

Conceptualists counter such arguments either by denying the theory of concept possession underlying them or by disputing the claims made about animals and children. Alva Noë argues that while animals surely do perceive and act in their environments, they also seem to demonstrate a number of conceptual and inferential capacities differing from our own only in degree. A monkey can recognize another "as of high status," for instance. That we treat our conceptual abilities as different in kind from those of animals is likely due to the fact that we have a much more exalted conception of our own conceptual abilities. When we examine how we recognize something as red, or an argument as invalid, we find that we can apply the relevant concepts without any ability to articulate why or how we can and that our abilities, too, are highly context-bound.

McDowell (1994a), by contrast, does not lower the bar on concept possession but insists that our conceptual and perceptual abilities differ from those of animals in kind. We do share something in common with animals. However, this does not mean that we can "isolate what we have in common with them by stripping off what is special about us" (p. 64), leaving perceptual states as a common factor in the lives of both persons and animals. Drawing on the hermeneutics philosopher Hans-Georg Gadamer, McDowell claims that animals inhabit an environment (Umwelt), while we inhabit a world (Welt). Animals are merely sentient; solely biological imperatives structure their lives rather than deciding what to do and think. Because of this, we should not ascribe full-fledged subjectivity to animals.

Subpersonal States

Finally, some philosophers have argued that subpersonal representational states have nonconceptual content. The argument is that such states have content but since the subject of those states need not possess the concepts required to specify that content, the content is nonconceptual. To borrow an example from Jose Bermúdez, David Marr's theory of vision involves a subpersonal, unconscious 2½-D sketch that represents depth and orientation. But the subject of such a state need not possess the concept "2½-D sketch," or indeed any of the concepts that figure in Marr's complicated theory. Bermúdez argues that such subpersonal states have *content* insofar as they serve a role in explaining behavior, can be integrated with other cognitive processes, are compositionally structured, and can possibly misrepresent their objects.

A conceptualist might argue that such states do not bear intentional content at all but simply manipulate syntactic items. McDowell, for instance, argues that subpersonal systems merely have "as-if" content and are "syntactic" rather than "semantic" engines. Another possible response is that the argument relies upon a flawed conception of conceptual content. An alternative view is that a content is conceptual just in case it is composed of concepts, and Bermúdez's arguments do not establish that the contents of subpersonal states are not composed of concepts.

Conclusion

Clearly, the debate over nonconceptual content is far from settled. There is no consensus over just what contents are, what concepts are, and what their possession conditions are. There are, in addition, substantive and controversial philosophical, phenomenological, and psychological premises in almost every argument for or against nonconceptual content. What should be clear, however, is that the current debate has generated a great deal of important insights into the nature of a wide variety of mental states.

Norbert Elias: Process of Civilization and Theory of Sciences

On the Process of Civilization (alternatively and mostly known by the misleading title *The Civilizing Process*) is the English title of the most famous book, *Über den Prozess der Zivilisation,* written by the German-born sociologist Norbert Elias (1897–1990). In this book, Elias investigates in a non-normative way the interconnected development of manners and social structures in Europe from the end of the Middle Ages. The "process sociology" (alternatively, "figurational sociology") that his work inspired is characterized by a long-term historical approach, with an interest in the multiple aspects of social life. Crossing disciplinary borders, the study of social processes is also based on cross-cultural comparisons. Process sociology consequently challenges all forms of reification, notably the fictive methodological opposition between society and the individual that is at the foundation of individualist and holist approaches. In addition, the theory of knowledge advocated by Elias and his followers poses questions about the development of the social sciences.

The Book

Über den Prozess der Zivilisation was first published in German in Basel in 1939, when its author was in exile in London. Based on European writings on manners, the first volume examines the changes in the behavior of the upper classes in the West through the centuries, for example at table. Elias demonstrates that disgust and reserve are not innate

or invariant. Behavior and sensibility have been continuously shaped according to what was socially expected, till a point where modeling became unconscious for individuals. The second volume links the long-term social process toward civilization with the dynamics of state formation in Europe.

The Western civilizing process thus involves at the same time "psychogenesis" and "sociogenesis." The influence of Sigmund Freud is evident, but Elias is more interested in showing the sociohistorical nature of any superego formation process, by inquiring into how social constraint progressively mutates toward self-constraint. For instance, the end of the age of feudal warriors and the progressive establishment of the state's monopoly of the legitimate use of violence, along with the greater development of economic interdependencies, consolidated the constraints imposed on the aggressive drive.

Unnoticed in 1939, Elias's book and the idea of a "blind" and unplanned but directional process were later subjected to many criticisms, aggravated by the context of World War II and the consequent contestation of the very possibility of talking about "civilization." Nevertheless, Elias's enquiry had little to do with the ethnocentric and unilinear progress theories that marked the emerging social sciences in the 19th century, even though he recognized August Comte and Karl Marx in particular as pioneers of process theories. But the Eliasian approach has even less in common with the radical right-wing, antidemocratic and pessimistic visions that flourished in the early 20th century, such as Oswald Spengler's thesis expounded in *The Decline of the West*.

Process Sociology

Not only did Elias never suggest that there was only one, European, process of civilization, but he invited challenges to his model by comparing the Western process with that of other societies, such as Asian court societies. Moreover, he pointed out that civilization has to be considered as a *process* that is neither good nor bad. For example, civilization does not mean the disappearance of violence from social life but rather a shift toward state military institutions and into an inner struggle that takes place *inside* highly self-controlled individuals. Elias also showed that state formation unleashed increased violence in the relations *between* states.

Civilizing processes are plural, reversible, and often go hand in hand with "de-civilizing" processes. This idea is central in the essays Elias devoted to Germany and to the Nazi period. In his *Studies on the Germans,* he tried to advance a valid explanation of what he called "the breakdown of civilization," without giving up the principles of process sociology.

Norbert Elias's sociology often depicts itself as "reality congruent." It implies first of all an interest in how societies change to become what they actually are. It also forces the recognition that a society, or "figuration," is always a society "of individuals." It means that there is no society existing apart from networks of interconnected individuals. At the same time, there is no *homo clausus* or isolated individual preexisting social life, as people are irreducible to the "thinking statues" depicted by the classical philosophy from Descartes to Kant. Individuals "depend" on each other in the various aspects of their life and inherit their institutions, ideas, manners, behavior, and mode of thinking and feeling from precedent generations, although they continuously transform them. The different areas of social reality, from politics to sports or emotions, are indeed linked through individuals, instead of being separated, as they seem to be for the hyperspecialization that occurred in the social sciences and that Elias denounced, as well as "the retreat of sociologists into the present."

Reality congruence thus imposes a great interdisciplinary openness and a long-term historical approach, as some of the features of societies are transformed on the scale of centuries. Process sociology is far from according with a certain vision of figurations as stable or harmoniously evolving systems. While avoiding any kind of determinism, it rather seeks in the changing balances of power between groups the ways figurations are potentially changing in their various aspects.

Avoiding the structuralism and functionalism that dominated sociology in the second half of the 20th century, Elias did not really found a unified school of thought. Yet his work became particularly influential in the Netherlands and eventually in Britain, two countries where he taught and lived. In France, his sociology has renewed interest in a diachronic sociological approach, notably because of a certain proximity with the historians of the

Annales school and with Michel Foucault's themes. Pierre Bourdieu contributed too to popularize the concept of *habitus,* which Elias had used much earlier to describe embodied social knowledge.

Theory of Knowledge

Elias was quite suspicious of any form of idealism. He first gained a doctorate in philosophy, but he had a major dispute with his teacher, the Neo-Kantian Richard Hönigswald, about the Kantian idea that some a priori elements of thought exist that do not derive from experience but are permanent and universal. Process sociology is particularly concerned about balancing empirical observations against theory. In Elias's view, *what* sociology unveils (i.e., discovery) in a sense prevails over *how* it does it. Elias totally disagreed with Karl Popper. First, the sociologist contested the preeminence of methodology in itself. Second, his writings are very critical of the predominance of the methods imported from physics and the natural sciences. Given their historical character, processes that constitute social reality are in fact too complex to be comprehended by means of only quantitative and analytic tools, observation, and measurements. On that point, Eliasian process sociology inherits the questions raised by German epistemology, which, from Wilhelm Dilthey to Max Weber, feed a fundamental distinction between *Kulturwissenschaft* and *Naturwissenschaft,* as expressed by Heinrich Rickert in 1899.

Nevertheless, the process approach tries to avoid all reifying oppositions of that kind. Sociology is a particular standpoint focused on people living together, while psychology interests itself in people as individuals. And a human being also is, or has, a body, that is within the scope of biology. In other words, sciences are linked to each other through their common human subject. Not only do the humanities and social sciences depend on the natural sciences and physics, but the latter are also social products that historically vary—which made them subjects of investigation by the former.

This perspective of continua rather than dichotomies remains present in Elias's reflections on the dynamics of "involvement and detachment." The main issue here is that of the situation of the researcher, and it is irreducible to the problem of objectivity. The social scientist in particular is evidently part of the social life. Elias seeks to ask how this involvement varies and to what extent it is necessary to perform his role or, at the opposite, the extent to which it may blind him to certain observations. He thus enlarges Max Weber's question about the usefulness of a social scientist's commitment to certain social or political beliefs. Process sociology also proposes a reflection on how a certain amount of self-detachment can be reached. Finally, it reopens the debate on the conditions in which sociologists may, or should, face the problems of their times.

Normativism Versus Realism

This entry introduces the positions of normativism and realism or descriptivism in explaining an agent's thoughts and actions and presents in detail the various versions of those positions as well as the arguments and counterarguments used by each. Normativism and realism are two very general, conflicting approaches to the explanation of what is thought and done.

Normativism seeks to explain by showing that the thought or action in question was normatively appropriate. It is thought that one explains better, more satisfactorily at least, if one exhibits the normative propriety of what is thought and chosen. Exhibiting rationality, for example, is commonly taken to be central to good explanation.

Realism/descriptivism seeks to explain by showing that the thought or action in question was the result of facts about the agents, societies, and environments, where such facts include regularities in the processes that are in play. Thus, at the level of individuals, one explains by understanding the cognitive processes in play—whether or not these are rational. Or one explains by understanding the conative commitments and preferences of the people involved. Of course, people are in various ways both rational and irrational—what is important in explanation is how they are, not how they should be.

Each approach has found adherents in the social sciences and among philosophers of the social sciences. Later in this entry, a related, but different, way of drawing the normativism/realism distinction will be presented.

Explanation

Influential thinkers such as the sociologist Max Weber have been interpreted as seeking explanations that work in both ways—finding rationality at the level of meanings yet uncovering causes that turn on mental processes, and allowing for some idealization on both counts. Normativism has constrained thinking in some paradigmatic social science. Thus, rational choice models have been influential in economics—commonly with little attention to the plausible limits of human rationality (or to the limited information commonly possessed by agents). On their face, such explanations apply normative models—decision-theoretic models of how folk ought to think and choose—to account for what is done and its aggregate consequences. Some political science and other related social sciences have followed suit. The influential philosopher Donald Davidson once insisted that rationalizing explanation is the only model of explanation with clear application to "the mental." Yet Davidson also insisted that explanations of why someone did or thought as they did could only be understood as a form of causal explanation, and causes are apparently real events in a real process. Covering-law models of causal explanation obviously incline one to realism—as reflected in Carl Hempel's classic discussion of covering laws in history. More recent general views on explanation within philosophy of science repudiate central elements of Hempel's deductive-nomological account, while yet generally supporting descriptivism.

A general idea shared by most approaches to explanation is the following: Explanations provide answers to why-questions—or (relatedly) to how-questions or what-if-things-had-been-different-questions. To explain why someone did something is to note what it is about them (or their conditions) that eventuated in their doing that rather than doing alternatives. Accordingly, to explain is to exhibit or allow one to appreciate a pattern of counterfactual dependencies. To understand the pattern of counterfactual dependencies is to understand what would have obtained had things been different with respect to the matters pointed to in one's explanation.

The conflict between realism and normativism then boils down to a question of whether, for actual thoughts and actions of actual humans, the pattern of counterfactual dependencies traces the nuances of rationality (or some similar normative matter) or, instead, follows the intricacies of actual cognitive processes and social processes, whether rational or not.

"Oughts"

It will be useful to draw a distinction between two conceptions of what is normatively appropriate—as those who suppose that one can explain by showing normative correctness may have either in mind. This allows for importantly different forms of normativism. On the one hand, there are *qualified oughts*, having to do with how people situated in a society

with certain norms ought to behave—among the *X*s (or as an *X*), one ought to *A*. On the other, there are *unqualified oughts,* thought to hold of any agent, *qua agent*—flatly: One (or all) ought to *A*. The qualified oughts would seem to be an interesting hybrid—as they would seem to be oughts that depend in part on descriptive matters holding within a group of people (their shared understandings, preferences, etc.) and in part on some unqualified oughts.

The distinction can be illustrated by thinking of how one thinks about correct moves in choice situations of the sort characterized by certain kinds of economic games. Consider the ultimatum game. In this two-person game, one player, the proposer, is conditionally provided a stake and must propose a division of that stake between the two players. The second player, the responder, can only accept or reject the proposal. If the proposal is accepted, the stake is divided accordingly. If it is rejected, neither player gets anything. Among folk in societies that have significant involvement with modern market economies, it is common to find proposals of 40% to 50% of the stake. Apparently, in those societies, there is a norm that prescribes roughly equal distributions. There is an idea in such societies that this is how one ought to play that game—perhaps provided that enough others also conform to the norm. There also seems to be a norm that the responder should punish proposers who offer 20% or less—they should decline the proposal at a cost to themselves as well as the proposer. This is how people in such societies tend to play such games—it was what, in those social contexts, is *counted as* how one ought to play. These patterns of play are pretty robust across the societies in which the ultimatum game was first studied (e.g., educated populations in the United States, Europe, Japan, and Indonesia).

However, when Joseph Henrich (and then others) ran ultimatum (and related economic) games in relatively isolated small-scale societies, they found much cross-cultural variation in play. Apparently, there are variations in the norms applied when encountering such games or situations. Somewhat provocatively, Henrich and associates distinguished Western, Educated, Industrialized, Rich, Democratic (WEIRD) societies, from others. It seems that what is normative for WEIRD people may not be normative for non-WEIRD people—as the norms for economic play may vary. Fitting to different settings and resources, different peoples have coordinated around different norms providing solutions to the choice situations they face. Arguably, we WEIRD folk ought to play as we commonly do, while the Machiguenga ought to play as they commonly do. Of course, in each social setting, there is a good deal of variation across members in the degree of norm conformity and norm violation. Normativists who envision explanation by exhibiting conformity with such qualified oughts might be termed *local normativists*.

On the other hand, there are those who imagine that there are objective oughts—holding for all people, no matter what their personal or social normative commitments. One might find such an unqualified normative principle lurking in or across the various social responses to the ultimatum game—as it might be argued that these different norms are satisfactory solutions to social problems faced in their respective settings. This is to envision a kind of universal game-theoretic normativity—and one might insist that this unqualified normativity is what makes for explanations. Indeed, some level of practical rationality and epistemic rationality commonly has been espoused by normativists as the unqualified normativity to be exhibited in explanations of thought and action. Normativists who envision explanations that work by exhibiting such unqualified oughts may be termed *imperial normativists*.

Imperial Normativism

Let us focus first on imperial normativism. On the epistemic side, it is said that all should accommodate base rates when making inferences about probabilities. But, famously, not everyone does, and perhaps no one does so consistently. Plausibly, perhaps, all should conform to socially salient norms that afford solutions to social choice problems, when one expects that others will conform. Again, not everyone does. Realists/descriptivists have a reasonably straightforward argument against imperial normativists that takes its departure from this mixed record of rationality and irrationality (or normative correctness and violations). Start with these uncontroversial points:

1. Sometimes folk do what they ought. Sometimes they do not. (Actually this is true, whether one uses qualified or unqualified oughts. So the argument rehearsed here will also have some force against local normativism.)

2. When folk do what they ought, there are facts about them—their actual training and resulting cognitive processes thus shaped—that are such that, in their environment or setting, tend to yield decisions/thoughts that (at least on the limited matter in question) conform to the relevant normative principles.
3. When they do not do what they ought, there are facts about them that are such that, in their environment or setting, tend to yield decisions/thoughts that (on the limited matter in question) fail to conform to the relevant normative principles.

Consider then the two classes of cases:

4. Obviously, when folk do not do what they ought, only the descriptive/realistic explanation has application. They do what they do, which is to fail to do what they ought, because of the facts about them that yield the normatively inappropriate result. The answers to why questions about their thought or action—and patterns of counterfactual dependency—all turn on the processes actually in play in them.
5. When folk do what they ought, it is no less true of them that the descriptive/realistic explanation of their action has application: In those cases, they do what they do because of the facts about them that yield at least these (limited range of) normatively appropriate results. The answers to why questions about their thought or action—and patterns of counterfactual dependency—all turn on the processes actually in play in them.

So, in either case, it is descriptive facts about the agents in their setting that explain what they do and think. These facts give rise to the patterns of counterfactual dependency the understanding of which makes for an explanatory answer to a why- (or a related) question.

6. The patterns of counterfactual dependency obtaining in any case are governed by the relevant descriptive facts—the actual processes actually in play—rather than by any general principle that the imperial normativist might adduce.

Understandings of cognitive/connotative processes, of background shaping of such cognitive processes, and of the resulting dispositions can enable one to answer why-, how-, and what-if-things-had-been-different questions. That some act or thought is flatly normatively appropriate cannot. Were one to attempt to explain what is done by noting that it is normatively appropriate in this unqualified sense—perhaps by saying flatly that it was rational—this would project a pattern of counterfactual dependencies that just does not obtain.

Here is a tractable toy illustration: Suppose that Agent A is given information about B. B was given a test for some condition, C; this test is 90% accurate, and B's test was positive for C. A then forms the belief that B has a 90% chance of having C. Suppose further that A's extant processes for working with probabilities are pretty minimal and that A would judge the same way were C a very rare condition or a very common condition. We may suppose that A was told (and believed) that there was no information to be had about how common Condition C was in the population. However, we have just stipulated that A is insensitive to base-rate information—such being A's extant processes. A would have neglected base-rate information had it been provided.

Of course Bayes's Theorem is a theorem of the probability calculus—the sort of principle that is generally loved by imperialist normativists. It says that such differences in base rates should be accommodated, at least when available. But, lacking such information, arguably, A's simple inference is rational in that it conforms to an application of Bayes's Theorem that is acceptable, given the ignorance of base rates stipulated.

To explain A's conclusion in terms of A's simple processes seems fitting—as the counterfactual dependencies obtaining here would be just those occasioned by the inferences that those processes would generate. Some of these inferences conform to Bayes's Theorem and would be normatively appropriate. Many do not. Understanding A's processes allows us to appreciate that, had A been told that C was a rare condition, A would still not have reached a different conclusion. Counterfactual dependencies follow actual processes, and what is explicable are the effects of actual processes.

In contrast, to explain A's simple inference as rational (and thus as fitting in light of Bayes's Theorem, taken as a putative explanatory principle of imperialist normativism) would entail that, had various information about base rates been provided

to A, A would have made correspondingly different inferences. But that is not so.

There is nothing special about this toy example. This problem for imperialist normativism will arise as long as (a) there are principles of practical or epistemic rationality expressing unqualified oughts and (b) people's dispositions deviate from what are taken to be such unqualified oughts. Whenever this obtains, and it seemingly is pervasive among actual cognitive systems, among actual creatures, the patterns of counterfactual dependency obtaining in any given case will follow the actual cognitive processes of flesh-and-blood agents, not the normative principles to which the imperialist normativist is committed. Bayes's Theorem simply served in the toy example as a possible illustration of one such principle of rationality. Provide a substitute if you prefer. The lesson will remain the same.

Local Normativism

Do social norms and local normativity help the normativist?

The kind of qualified normative principles called for by local normativism are social norms around which people have somewhat coordinated their actions or thinking. Thus, while members of diverse groups apparently respond to economic games differently, it seems that in each society their respective typical responses are informed by their respective social norms for the distribution of goods. WEIRD folk deploy a norm or set of norms that they have learned and adopted. Others deploy other norms. In each case, the character or content of a folk's norms may be largely implicit and difficult for folk to articulate. But among a folk, there is commonly some set of normative commitments that are learned and adopted. More or less coordinated around the application of these norms, people come to rely on each other, evaluate each other, and punish or reward each other in somewhat coordinated ways. Of course, the coordination, evaluation, conformity, and punishment are "uneven" or variable within the group.

Local normativism supposes that there is some sense in which people in such a setting *ought* to do as their norm requires. It is important that this is understood as a "real" normative ought and not some descriptive ersatz for oughts. Of course, such local oughts might be thought of as arising from the local application of some unqualified normative principles—such as principles of practical rationality. If so, then local normative principles amount to special-case applications of imperialist normativism. Local normativism would then face the objections to imperialist normativism mentioned above. If it is not understood in this fashion, it would seem to require that one be able to derive an "ought" from an "is": Local normativism seems committed to local oughts falling out of a descriptive state of affairs—the state of affairs that constitutes people's holding to some norm. In either case, local normativism itself faces daunting objections.

It is perhaps worth noting that normativists generally have resisted the idea that real oughts could arise merely out of some local descriptive facts-on-the-ground. The point is pressed by Richard Brandom, who insists that there must be a distinction between something being correct and its merely seeming correct. As Brandom argues, it does not help socialize the matter, as there is a distinction between something being right and people thinking, or acting as if, it is right. Without this difference, it is hard to see what normativism comes to or how it differs from a form of realism/descriptivism that emphasizes that one need attend to people's normative beliefs and attitudes. With this difference, it is hard to see what makes for the normative statuses that are envisioned—unless it is what the imperialist imagines. And even these can seem spooky. Such issues are pursued by Stephen Turner.

Social Norms

What it takes for there to be a social norm in some group can be understood in descriptive terms—for example, in terms of the preferences among some folk who have learned some action-directing content. For purposes of illustration, we can here draw on an account that seems as good as any presently on offer.

Cristina Bicchieri understands norms as rules that allow folk to coordinate behavior in the face of a class of choice situations (as solutions to some decision-theoretic game). On her usage, social norms are a special class of norms, having to do with situations in which individuals have some temptation to defect from the coordination (with "mix-motive games"). Descriptive norms are another class of norms, having to do with situations in which, once people have achieved a coordination by way

of the norm, there is no temptation to defect (with "coordination games"). In either case, the rules in question need not be articulable by agents, and how they are represented in individual agents is somewhat indeterminate. On Bicchieri's account of social norms, a rule is a social norm in a population facing a mixed-motive game just in case sufficiently many agents within that population (a) "know" the rule (to some approximation) and (b) have a conditional preference for conforming to it, provided (i) enough others conform to it and (ii) enough others have a tendency to evaluate performance according to the rules (and perhaps also to punish violations). A rule is a descriptive norm within a population just in case sufficiently many agents (a) know the rule (to some approximation) and (b) have a conditional preference for conforming to it provided enough others do. The extra demands on social norms are there to get over the mix of motives. In either case, provided one expects that enough others satisfy the conditions featured in one's conditional preferences, one likely conforms to the rule in question.

For our purposes, it is crucial to see that such characterizations of norms are wholly descriptive. It simply requires that a bunch of agents in the population (a) have some manner of mental representation of a behavioral rule and (b) have conditional preferences for conforming to that rule. Conformity then results when enough of those who hold the norm also have expectations for others conforming and evaluating according to that rule. One could be a skeptic about all normativity and yet have no difficulty applying this account of norms. Something along these descriptive lines is the "is" from which local normativism would need to derive its "oughts."

Realist/Descriptivist Responses and the Normativist Rejoinder

But the descriptivist/realist will certainly have reason to wonder what talk of normativity could add to the explanation afforded by a descriptive understanding offered by a descriptive account along the lines just sketched above. All patterns of counterfactual dependencies would seem to fall out of the cognitive representations and preferences just sketched—together with an understanding of the cognitive processes common with this set of agents. To the extent that one understands the content of the agents' representations of the norm, to the extent that one understands their conditional preferences, and their expectations for the satisfaction of those conditions (all matters to be described), and to the extent one understands the character or tendency of the agents' cognitive processes, one is wonderfully placed to understand why individuals do or think as they do and how they would act or think were they to be situated in different but related ways. Indeed, it is hard to see how one could be better placed to explain. Normativity, mysterious in its relation to these descriptive matters, seems to add nothing to one's ability to explain.

All the above discussion has presupposed one thing that the normativist will want to challenge: It has supposed that what is to be explained—the what is thought and done—is itself understood as descriptive matters of fact. This is at the heart of the disagreement between the normativist, exemplified by Brandom, and the descriptivist, exemplified by Turner. The normativist insists that some fitting topics of explanation have ineliminable normative elements. To appreciate what is at issue, at least to a first approximation, consider a case in which some agent, A, wants to go to the shop directly across the street from her, midblock. Suppose that A then walks down the street to the intersection and crosses there, before walking back up the other side of the street. In so doing, A conforms to the law prohibiting jaywalking in the area. And, indeed, we may suppose that A took the indicated route in part because she wanted to conform to the law and believed that the law prohibited jaywalking there. Of course, the descriptivist/realist can explain why A took the route described. Her desire to get to the shop, her understanding of its location relative to her and the block, her desire to comply with the law, and her belief about what the law prohibited, and an understanding of some rudimentary cognitive processes in A, should jointly afford the descriptivist an explanation. Indeed, the law in A's locality might not prohibit jaywalking, it would not matter—A would yet take the route indicated. The law may prohibit crossing at that intersection; again, it does not matter so long as A's beliefs are as indicated above. A may irrationally believe that she would be struck dead by the traffic gods, so that the explanation really involved irrationality, not rationality—again, this is fine with the descriptivist, who readily explains A's taking the route taken.

But the normativist will insist that there are things that the descriptivist cannot explain, and that one

wants explained—notably, why A conformed to the law. Of course, if "the law" is simply some descriptive matter, the descriptivist has no problems. Thus, if, crudely, the law in question is a matter of a social norm that a group of people have organized (with other social norms) to enforce, then the descriptivist can describe the relevant social norms and how A came to share in them, and the descriptivist can then explain A's conformity with the norm. However, some normativists insist that law—real law, and thus real conformity to law—requires a *legitimate* government and requires that a certain substantive principle be the result of actions by that government that are such as make a prescription or proscription into a law. They will insist that there is a difference between people—even all the people—thinking that such is a government and its being a government. They will insist that there is a difference between people—even all the people—thinking that something is the law of the land and its indeed being the law. This difference, they insist, makes a difference for the social sciences. To explain A's conforming to the law requires registering this difference, and it is a normative difference. The descriptivist/realist may counter that the normativists may not be up to their own challenge here.

Normativity

Normativity is a property possessed by propositions. A proposition is normative just in case it is either an evaluative or a directive, or an appropriate function—such as negation, conjunction, or universal generalization—of evaluatives and directives. A proposition is an evaluative just in case a person who asserts it commends or "discommends" something; examples include the propositions that Alfred is a good person, that Barbara is a better parent than Carol, and that David is greedy. A proposition is a directive just in case a person who asserts it claims that someone or something is called on, or required, to behave in a certain way; examples include the propositions that Ellen should apologize to her brother, that Frank ought to help George, and that Harriet must stop hitting her sister.

1. It is intuitively very plausible that directives are in some way related to evaluatives. On many views, directives are analyzable into evaluatives. Objective consequentialists say that for it to be the case that Frank ought to help George is for it to be the case that the consequences of his doing so would be better than the consequences of his not doing so. Subjective consequentialists say that for it to be the case that Frank ought to help George is for it to be the case that Frank believes that the consequences

of his doing so would be better than the consequences of his not doing so. According to a more complex analysis: for it to be the case that Frank ought to help George is for it to be the case that if Frank knew what would happen if he did, and what would happen if he didn't, then he would be in a measure defective if he didn't.

2. The examples so far mentioned are all moral propositions, that is, propositions such that to assert them is to make a moral judgment. All moral propositions are normative. All aesthetic propositions are also normative, for they too are either evaluatives or directives, or appropriate functions of evaluatives and directives. (On some views, there are no true aesthetic directives, and thus all true aesthetic propositions are evaluatives or appropriate functions of evaluatives.)

But *are* there any such propositions? In virtue of finding it unclear what could make a moral proposition true, some moral philosophers conclude that there are no moral propositions. Thinking it equally unclear what could make an aesthetic proposition true, and taking it for granted that the moral and the aesthetic exhaust the normative, they conclude that there are no normative propositions at all. On their view—currently called *expressivism*—to say the words "Alfred is a good person" is merely to display a favorable attitude toward Alfred *qua* human being; to say the words "That statue is beautiful" is merely to display a favorable attitude toward the appearance of the statue referred to by *That statue;* to say the words "Harriet must stop hitting her sister" is merely to display an unfavorable attitude toward Harriet's hitting her sister. A substantial literature has been devoted to efforts to refute or refine that view.

3. Assuming that *expressivism* is false, and thus that there are such things as normative propositions, it is intuitively plausible that the true ones divide into (1) those that are made true by (1a) formal social arrangements or (1b) informal social conventions, and would not have been true if there had been no such arrangements or conventions, and (2) those that are true whether or not there are formal social arrangements or informal social conventions that also make them true.

Consider moral propositions. Suppose Alfred plans to kill Bert, though Bert has done no harm and doesn't plan to do harm. Suppose Carol therefore asserts that Alfred ought not kill Bert. Then she asserts a moral proposition of kind (2): it is true, and its truth is overdetermined since it is also made true by a law, thus by a formal social arrangement, but would have been true even if there had been no such law. (The question what makes moral propositions of this kind true lies at the heart of moral theory.)

Suppose, by contrast, that we tell people that when in America, they ought to drive on the right. Then we typically assert a moral proposition of kind (1a), which is made true only by a law—it wouldn't have been true if there had been no such law. On many views, the same holds of the directives that are made true by possession of property rights, since property rights are themselves generated only by law. (Legal and political theorists have focused on the question what makes moral propositions of this kind true.)

Two further points about moral propositions of kind (1a) should be mentioned. First, government is not the only source of formal social arrangements that make moral propositions true. For example, all private clubs have explicit rules governing their members, such as that members must pay their dues on time. Also, people very often explicitly contract or promise to do things, thereby making it the case that they ought to.

Second, while a formal social arrangement may clearly make some moral propositions true, it may need interpretation if it is to become clear whether it makes others true, and interpreting it may require knowledge of the informal social conventions in force in the relevant community. Suppose, for example, that Alfred contracted to deliver a cow to Alice. Then he clearly breaks their contract if he doesn't deliver a cow. The informal social conventions in force in their community may make it also true that he breaks their contract if he delivers a dead cow, even though he delivers a cow and the contract doesn't explicitly say "*live* cow."

Suppose, finally, that there was a line at the bus-stand, and that for no good reason, newcomer Alfred went to the head of the line. If Bert therefore asserts that Alfred ought not have done so, then we can suppose that he asserts a moral proposition of kind (1b), made true only by the existence of an informal social convention to the effect that newcomers go to the end of the line at bus-stands. (Social theorists have been particularly interested in the question what generates informal social

conventions, and why people act in accord with them when they do.)

4. The normative is not limited to the moral and the aesthetic, however. Suppose Alfred volunteered to set the table for dinner, and Alice therefore asserts a normative proposition to the effect that he ought to put the forks on the left of the plates and the knives on the right. We can suppose that in doing so, she asserts a non-moral-non-aesthetic normative proposition of kind (1b), which is made true only by the informal social convention governing table-setting.

Some games are governed by informal social conventions: hide-and-seek, for example. When the child who is *IT* starts counting, Alice might assert to a newcomer-child that he ought to hide. If she does, then she is likely to be asserting a non-moral-non-esthetic proposition that is of kind (1b).

Other games are governed by formal social arrangements—tennis, golf, and chess, for example. So when a chess teacher asserts to a student that the student ought not move his or her rook on a diagonal, the teacher is typically asserting a non-moral-non-aesthetic proposition of kind (1a).

What of non-moral-non-esthetic propositions of kind (2)? Suppose Alfred tells Alice that he wants to buy a computer, and she asserts that he ought to go to Staples and does so because she thinks he would best satisfy his want by going there. Then the proposition she asserts is arguably non-moral and non-aesthetic, and is not made true by any formal social arrangement or informal social convention. The proposition she asserts is arguably made true (if it is true) by the fact that Alfred would best satisfy his wants by going to Staples.

Again, suppose it has been raining, and Alfred gazes up at the sky, which is now clearing, and says the words "The sun ought to come out soon." He might, of course, be asserting a moral proposition to the effect that the sun is under a duty to come out soon; however he is far more likely to be asserting an epistemic proposition to the effect that it is likely that the sun will come out soon. (If he is, is the proposition he asserts normative? On some views, it is analyzable into the proposition that people in possession of the evidence he has in hand ought to believe that the sun will come out soon, and if so, then it *is* normative.)

Another kind of epistemic proposition is plainly normative, for example, the proposition (asserted by Alfred) that Bert ought not jump to conclusions, and the proposition (asserted by Carol) that Dora ought to be rational. (But are those propositions non-moral and non-aesthetic? There is room for argument that they are both epistemic and moral.)

Still other propositions asserted by people who say words of the form "A ought to φ" are about things that (like the sun) aren't human beings, yet they aren't (anyway aren't merely) epistemic propositions. The manufacturers of a brand of toaster may advertise that their toasters ought to provide many years of safe, even toasting. If they assert this, then they aren't (anyway aren't merely) asserting that their toasters are likely to provide many years of safe, even toasting; they are asserting that their toasters are required to do so. (That is why they invite you to return the toaster you buy if it turns out to be defective.) So the proposition they assert is normative, but it is neither moral nor aesthetic.

5. The existence of many kinds of non-moral-non-aesthetic normative propositions that are asserted by use of the word *ought* has tempted some philosophers to think it is multiply ambiguous: that it has a moral meaning and an aesthetic meaning, and also an etiquette meaning, a game meaning, a practical-reason meaning, one or more epistemic meanings, and a function meaning. A growing literature by philosophers and linguists argues that there are better ways to accommodate this multiplicity of uses of *ought* than by appeal to its ambiguity.

6. It should also be noticed, moreover, that *ought* is not the only word that can be used to assert moral, aesthetic, and non-moral-non-aesthetic normative propositions: the same holds of *should, must,* and *may. Good* is also used to assert moral, aesthetic, and non-moral-non-aesthetic normative propositions, for while Alfred may say the words "Bert is good" because he thinks Bert is a good person, Alice may say them because she thinks Bert dances beautifully, and Arthur may say them because he thinks Bert is good at playing chess. The same holds of *right, wrong, correct,* and *incorrect*. Charles may say the words "That was right" because he thinks that what he refers to by *That* (perhaps David's killing of Dora) was morally right, Carol because she thinks that what she refers to by *That* (perhaps the color

green) was the right color to use on David's walls, and Carl because he thinks that what he refers to by *That* (perhaps the word *Yes*) was the right answer to the question "Is David older than Donald?" If so, then they all assert evaluatives, Charles's moral, Carol's aesthetic, and Carl's non-moral and non-aesthetic.

It should be noticed too that if Carl says those words for that reason, then on any plausible view of the matter, he asserts a proposition that has a truth-value. (It is on any view true or false that *Yes* is the right answer to the question "Is David older than Donald?") If we were right to say that the proposition Carl asserts—like those asserted by Charles and Carol—is normative, then we are entitled to conclude that the expressivist is mistaken in thinking that there are no normative propositions.

Still other words—such as *able, careful, intelligent, sensible, suitable, satisfactory, defective,* and *comfortable*—are typically used to assert evaluatives that are non-moral and non-aesthetic; and many (arguably all) of those evaluatives can very plausibly be thought to have truth-values.

Our communication with each other is rich in normativity. Focusing on the moral and aesthetic alone was short-sighted: no theory of normativity is adequate unless it explains what normative propositions generally have in common.

OBJECTIVITY

This entry discusses the nature and place of objectivity in science, and especially the social sciences, and introduces the various issues making up the topic of objectivity as well as various critical approaches to it.

Being objective is an attribute that can be related to truth, knowledge claims, and persons. Aiming at objectivity is traditionally considered as a necessary condition of all science, but this is challenged by relativists and social constructivists. The formulation of the ideal of objectivity by scientific realists usually relies on assumptions that are typical to natural science, but it can be defended also in the case of the social sciences.

Let us briefly see what objectivity involves for the three items mentioned above: (1) truth, (2) knowledge, and (3) persons.

According to the realist theory of truth, a belief or statement is true if its content corresponds to facts obtaining in reality. A modern explication of this correspondence theory, or reality theory, of truth is given by Alfred Tarski's semantic definition: Truths have to be expressed in some interpreted language or conceptual system, but in the objective or absolute sense, truth is not relative to person, gender, social class, culture, belief, theory, or paradigm.

Knowledge, classically defined as justified true belief, is objective if it is true in the absolute sense. Most scientific realists are fallibilists, who acknowledge that all knowledge claims about matters of fact are corrigible by further inquiry. Even though complete certainty cannot be reached, the most reliable way of finding well-grounded knowledge is justification by publicly accessible scientific evidence.

According to the traditional ideal, a scientist should be an objective person: just, impartial, unbiased, not misled by emotions, personal prejudices, or wishful thinking. Thus, science is objective in so far as its results correspond to the real properties and lawlike relations of the research object, and in contrast, science is subjective insofar as its results are influenced and biased by personal motives, values, wishes, beliefs, and interests.

Objectivity and Science

Science is the systematic and institutionalized pursuit of new knowledge by using critical methods of inquiry. The object of research is a domain of reality consisting of some natural, mental, or social phenomena. Researchers propose hypotheses about this domain and test them against evidence obtained through interaction between the researchers and the studied objects. Such interactions include observations, measurements, experiments, and interviews. To guarantee that reality itself is the standard of scientific knowledge, the results of such interactions should be intersubjectively recognizable: Research data should be openly accessible; observations, public; and experiments, repeatable. The results of research constitute scientific knowledge only when they have passed the internal quality control and critical discussion within the scientific community. In this sense, the real subjects of scientific knowledge are communities of investigators rather than individual scientists.

The ideal of objectivity relies on the conceptual distinction between subject and object, but its actual realization depends on subject–object interactions. This distinction may be problematic in some natural sciences: In microphysical experiments, the measuring apparatus disturbs the measured objects by changing their properties in an unpredictable manner. This kind of disturbing effect is quite common in the human and social sciences, since people may behave in a nontypical manner in interviews or controlled experimental situations.

Scientific realism accepts the ontological assumption that nature is independent of human mind, language, and culture: Natural reality does not change when we conceptualize and describe it by means of scientific theories. In contrast, relativists contend that each theory defines its own ontology, and social constructivists have claimed that theoretical entities described by scientific theories do not exist independently of the scientists but are outcomes of "negotiations" in research laboratories.

On the other hand, ever since the time of Francis Bacon in the early 17th century, scientists have known that knowledge about causal laws allows us to manipulate and control nature. Knowledge about such causal laws is sought in applied natural sciences such as engineering sciences and environmental sciences, and the results of these sciences are applied to transform nature by various kinds of science-based technologies.

Objectivity and the Social Sciences

The ontological situation in the social sciences is more complex. Social reality is constituted by meaningful intentional actions of social agents who have beliefs, wants, and wishes. Social reality also includes institutions established and sustained by collective beliefs and interactions between individuals, and such institutions and organizations may act as social agents with their collective intentions. So the social reality is not mind independent in the same way as nature. Still, Émile Durkheim argued that social facts ought to be treated as "things" by the social sciences, as they are "endowed with a power of coercion" to control individuals. Karl Popper called the human-made reality studied by the social sciences World 3, in contrast to the physical World 1 and the subjective mental World 2.

In spite of this ontological difference, the methodological goal of objectivity can be defended in the social sciences as well. Even though social facts are complex entities involving collectives of people with their beliefs and intentions, statements about them can have objective truth values (true or false) in the correspondence-theoretical sense. For example, a statement such as "Snow is white" has relatively simple truth conditions referring to the color of snow, but the truth of a statement about the value of the euro in relation to the U.S. dollar depends in a complex way on the attitudes and behavior of the economic market. Similarly, a statement about the legal norms valid in a society refers to the practices and consensus within the relevant legal community. Furthermore, there are social laws that are usually based on temporal statistical regularities in human behavior. Even though they are not unchanging "iron laws" like the law of universal gravitation in physics, one can make true or false statements about them.

It is, furthermore, important to distinguish between value neutrality and interest neutrality of science. Scientific inquiry is not interest neutral, as the selection of the topics to be studied is influenced by the interests of the researchers and the funding organizations. Scientific knowledge, when properly warranted by evidence, can then be applied to serve various kinds of practical interests, such as emancipation from oppressive social conditions (as Jürgen Habermas has argued), but these interests cannot function as criteria in the assessment of the evidential support of the best theories. Indeed, science is valuable just because its hypotheses are accepted in a value-free way by appealing to its own "epistemic utilities" (e.g., truth, information, truthlikeness, and explanatory and predictive power, as Ilkka Niiniluoto has argued). Of course, this demand of objectivity may sometimes fail. Sociologists of science have given historical case studies to show that political interests have in fact influenced the conclusions of scientists. In its guide of medical research funding, the National Institute of Health wishes to eliminate "conflicts of financial interest." But if a bias is detected, it should be corrected by the self-criticism of the scientific community.

A famous defense of objective social science was given by Max Weber in 1904. Weber accepted the fact/value distinction and the demand of value-free social science. Ultimate values cannot be proved scientifically, so that they do not belong to the goals

or results of scientific inquiry. On the other hand, statements about instrumental value, or the relations between given ends and the rational means of establishing them, can be defended by scientific investigations. Such means–ends relations are studied in applied social sciences, like social policy studies, social work, business economics, military studies, peace research, and urban studies. Their typical results can be formulated as conditional recommendations with a value antecedent: "If you want *A* and believe that you are in situation *B,* you should do *X*." Even scientists, who do not endorse the value *A,* can defend the truth of this kind of conditional.

Society may change with the development of social science. Phenomena known as "self-fulfilling prophecies" and "self-refuting predictions" show that the publication of the results of social sciences can as a by-product change the attitudes and behavior of social agents. Applied social sciences, or "sciences of the artificial" in Herbert Simon's sense, develop systematically the opportunity of intentionally transforming society so that desired goals are effectively reached and some social problems are thereby solved.

Unlike purely natural phenomena, intentional social actions are laden with meanings. To describe and understand such actions, one has to reconstruct their meaning by referring to the concepts, beliefs, and intentions of the agents. It is sometimes argued that such ascription of meaning is always an evaluative task. So the hermeneutics of Hans-Georg Gadamer argues that the understanding of a cultural object (e.g., a work of art, historical text, or event) always involves the uncovering of its significance for our own lives. However, a distinction should be made between the actor's and the researcher's meaning. When we ask why Germany attacked the Soviet Union in 1941, we should consider the relevant political situation, including the intentions and beliefs of the leaders of the Third Reich, and hypotheses about this historical situation have a truth value independently of us and can be tested by appropriate evidence.

Special problems for the social sciences arise from the possibility that the researchers may themselves be part of the research domain under study. In many cases, there is a temporal or cultural distance between the subject and the object of research, such as when a political historian studies the French Revolution or a Protestant social anthropologist studies religions in Africa. Sometimes it is claimed to be an advantage if the researcher knows the studied phenomenon from inside, so that Buddhism should be studied by Buddhists and ethnic or sexual minorities by representatives of the same group. But such an involvement or "positioning" has also been seen to impair the impartiality of the researcher. Sandra Harding's feminist "standpoint theory" suggests that oppressed and marginalized groups at the bottom of social hierarchies have an epistemologically privileged position in grounding reliable knowledge claims, so that "we all—men as well as women—should prefer women's experiences to men's" (Harding, 1987, p. 10). This is a modification of the Marxist view that the proletariat in a capitalist society has a more adequate perspective on social problems and the progress of history than the bourgeois. The alternative view to such standpoint theories is to try to maximize objectivity by ensuring that the community of investigators has persons from a different background, so that academic education is open to all irrespective of their socioeconomic position.

Observation and Theory-Ladenness

In the philosophy of science, observations are said to be "theory-laden" when they are affected by the theoretical presuppositions held by the investigator. The thesis of theory-ladenness is most strongly associated with the late 1950s and early 1960s work of N. R. Hanson, Thomas S. Kuhn, and Paul Feyerabend, and it was probably first put forth (at least implicitly) by the French physicist, historian, and philosopher Pierre Duhem about 50 years earlier. The issue of theory-ladenness has played a key role in the philosophy of science. Lineages of the early treatment of theory-ladenness go back to Ludwig Wittgenstein and Willard van Orme Quine's holist view of language. In the philosophy of the social sciences, theory-ladenness has been associated with epistemic relativism.

The thesis of theory-ladenness, if true, has troublesome consequences for theory testing. If there are no theory-neutral observations, then this raises doubts about whether empirical tests can truly decide between competing theories. So if theories partially determine the meaning of observation terms, two investigators holding incompatible theories will mean different things when they use the same observational vocabulary, and if theories partially determine "what we see," two investigators holding incompatible theories will see the objects relevant for discriminating between their theories differently.

Fundamentals

Although often run together, at least two forms of theory-ladenness should be kept separate: (1) the *meaning* of observational terms is partially determined by theoretical presuppositions and (2) the theories held by the investigator, at a very basic cognitive level, impinge on the perceptions of the investigator. The former may be referred to as *semantic* and the latter as *perceptual* theory-ladenness.

A thesis that also goes under the heading of theory-ladenness may be (more appropriately) referred to as *theory dependence of instruments,* on which much discussion has focused: The investigator's confidence in the truthfulness of the results obtained with certain instruments depends on his or her having sound theories of how these instruments work. Such theories are also referred to as "background" theories. The theory dependence of instruments is particularly problematic when the background theories are the very theories that the investigator seeks to test, for in those scenarios the testing procedure is rendered circular.

Theory-ladenness should not be confused with certain other ideas. Theory-ladenness does not imply that our perceptions are *fully* determined by our theories; it does not imply that we see "*whatever* we want to see." No philosopher of science of some standing has defended such an extreme position. We cannot see flying pigs even if we had theories that told us that there were such things. On the other hand, theory-ladenness does not simply amount to perceptions being *interpreted* differently by different people. Nor is theory-ladenness the mere theoretical *guidance* of empirical inquiries—that is, the decision to perform certain experiments rather than others or to investigate a certain aspect of the world. Both of these ideas are platitudes and philosophically not particularly interesting.

A gray area is the phenomenon of negative theoretical bias—in other words, the idea that empirical results not amenable to certain theoretical presuppositions are (wilfully or subconsciously) ignored by the investigator. Clearly, also in cases of theoretical bias, theoretical presuppositions impinge on the

data in ways that are comparable with the thesis of theory-ladenness. Yet negative theoretical bias is normally taken to be easily revealed through various control mechanisms in scientific practice (e.g., peer review). Since theoretical bias as a form of theory-ladenness has received rather little attention by philosophers of science, it will not be discussed here.

Semantic Theory-Ladenness

One of the best-known examples for semantic theory-ladenness concerns the (observational) term *mass,* which has a different meaning in Newtonian physics from what it does in Einstein's theory of relativity. Whereas in the former theory, mass is a constant, in the latter it depends on the velocity of the object in question. Or take the term *planet*. In the Ptolemaic system, the (observational) term *planet* referred to a class of astronomical objects that included the sun and the moon but not the earth. In contrast, in the Copernican system, the term *planet* included the earth but neither the sun nor the moon. Kuhn used examples like these to argue for his (perhaps most) controversial idea of the incommensurability of paradigms. Kuhn's view has been rejected by many philosophers on the grounds that he employs a particular theory of reference (descriptivism/holism) that most philosophers take to be inadequate. Still, largely due to Kuhn, Hanson, and Feyerabend, the vast majority of philosophers have accepted that there are hardly any observational terms relevant to scientific practice that are not theory-laden. Indeed, this was one of the major reasons that led to the demise of logical positivism/empiricism, which had postulated a strict distinction between observational and theoretical vocabulary, whereby any theoretical terms had to be relatable to observational terms for the former to be deemed meaningful. Modern-day empiricists such as Bas van Fraassen, however, do accept semantic theory-ladenness, the vagueness of the observation/theoretical distinction, and that theoretical terms are meaningful without being relatable to observational terms, but they do insist on skepticism about the unobservable referents of theoretical terms (e.g., "electron").

Perceptual Theory-Ladenness

An instructive example for perceptual theory-ladenness is a psychological experiment famously used by Kuhn (1996) in his *Structure of Scientific Revolutions*. In this experiment, the subjects were presented with a set of playing cards (one by one) that contained "anomalous" cards, such as the black four of hearts. Interestingly, with a sufficiently short amount of exposure, the subjects perceptually assimilated the anomalous playing cards to the normal ones; that is, they would report a black four of spades when being presented with a black four of hearts. Apparently, their belief that playing cards fall into certain categories "primed" their perceptual system accordingly. Other examples illustrating the second form of theory-ladenness include "Gestalt figures" like the duck/rabbit or the Necker cube, which are drawings that can be perceived in two different ways without the object of perception changing. These examples are, of course, merely illustrative. An example from scientific practice allegedly exhibiting Gestalt-like features, given by Hanson and Kuhn, is the difference between a Copernican (a believer in a sun-centered universe) and a Ptolemaian (a believer in an earth-centered universe) seeing different things when looking at a sunset. Whereas the Ptolemaian sees the sun falling behind the horizon (because in his or her view, the sun is moving, not the earth), the Copernican sees a fixed sun and a rising horizon. Likewise, an Aristotelian, who believes that all objects have the natural tendency to fall to the earth, sees the "constrained" fall of an object when watching a pendulum, whereas a Galilean, having developed an early form of the concept of inertia, sees damped inertial motion.

A straightforward criticism that can be leveled against those latter examples in particular is that they are based on a confusion between "seeing" and "seeing *that,*" the latter being a propositional attitude that requires judgment. Bas van Fraassen, in his influential *The Scientific Image,* illustrates this point with the example of an aboriginal tribe seeing a tennis ball for the first time: Although they do, as we would, see the tennis ball (i.e., a yellow fluffy thing that bounces), they don't see *that* this is a tennis ball, for this would require some basic familiarity with the game of tennis, immersion in Western culture, and so on. Likewise, Antoine Lavoisier and Joseph Priestley, as much as Aristotle and Galileo (both persons in each pair), would see the same objects, but each of them would make different (theoretically informed) judgments about them. However, there are examples where this interpretation seems less

plausible. A native speaker of Chinese, for instance, just *hears* (without needing to interpret or consciously judge) meaningful utterances when hearing Chinese rather than hearing a mere succession of vocal sounds, as a speaker without any knowledge of the Chinese language would. In examples like these, theory-laden observation has a character of immediacy and inevitability that is not reflected by the "seeing" versus "seeing that" distinction.

Another related critique of perceptual theory-ladenness was given by Jerry Fodor in the 1980s. Based on examples such as the Müller-Lyer illusion, in which two lines of equal length appear to be of different length, Fodor argued that perceptions are *cognitively impenetrable*. That is, even if we are made aware of the two lines being of equal length, we still perceive them as being of unequal length. Fodor's attack on perceptual theory-ladenness has been taken up by others in more recent works. Two things should be noted about Fodor's defense. First, appeal to examples such as the Müller-Lyer illusion can only show that *some* perceptions are cognitively impenetrable. Second, as indicated above, defenders of perceptual theory-ladenness do not claim that all of our perceptual experience is subject to cognitive penetration. If that were so, it would indeed be possible that we see what we wish to see. Again, no philosopher of science has defended such a view. On the contrary, the Kuhnian account of science, for instance, presupposes that there are observations that *resist* theoretical assimilation ("anomalies").

Still another influential way of countering perceptual theory-ladenness was made by Bogen and Woodward (also in the 1980s). They advance the view that scientific theories explain and predict unobservable phenomena rather than observable data. Phenomena are inferred from data (usually by statistical methods). But if this is so, neither phenomena nor data can be theory-laden: Phenomena are not perceptually theory-laden because they are unobservable, and data are not theory-laden because they do not form the basis against which we test theories. Bogen and Woodward's simplest example for an unobservable phenomenon is the melting point of lead, at 327.5 °C, which is inferred from individual data points, none of which might exhibit this exact value. A more advanced example for a phenomenon is the weak neutral current, which was inferred from bubble chamber pictures (the data). The Glashow-Salam-Weinberg model explains and predicts the neutral current but not the bubble chamber pictures.

Theory Dependence of Instruments

Paul Feyerabend, in his *Against Method,* pointed out that Galileo, when gathering telescopic observations in support of the sun-centered universe in the early 17th century, had no knowledge of the working of the telescope. Among other things, Feyerabend reasons that Galileo would have needed such a theory to provide good grounds to convince his skeptical contemporaries of the truth of heliocentrism. Pointing the telescope to terrestrial objects to demonstrate its magnifying effect would not have sufficed since his contemporaries thought that the physics on earth was completely different form the physics of the heavens. In fact, Feyerabend accuses Galileo of circular reasoning: For Galileo's telescopic observations to be acceptable evidence for his contemporaries, Galileo had to show the inadequacy of the Aristotelian "two-physics" world picture. But to show this, he relied on his telescopic observations, which, again, presupposed that the physics on earth and the physics of the heavens were the same.

Several strategies have been proposed to counter the alleged theory dependence of instruments leading to the circularity of testing procedures. Some philosophers, such as Peter Kosso, have accepted the theory dependence of instruments and have demanded that the tested theory be *independent* from the theories that are presupposed when instruments are used. Others have simply denied that one needs knowledge of how an instrument works to *use* that instrument in such a way that it produces reliable data. Ian Hacking's *Representing and Intervening* has been influential in this respect. He points out that observations made with microscopes in the 19th century were trusted despite no accurate theory of the microscope being available. Hacking also argues that the observations made by biologists when using microscopes are not undermined by the fact that biologists regularly know rather little of the physics that underlies these microscopes. And yet *someone* knows about it. But even if the reliability of experimental results depended on background theories, Hacking argues, scientists have a powerful strategy for addressing this problem. This

is Hacking's famous "argument from coincidence," which is also known as the "robustness" argument. It says that it would be a preposterous coincidence if the observations made with *several* instruments, each presupposing *different* background theories, were to converge and the observations were not reliable. Hacking's example is the presence of red blood platelets in the same locations (of a grid) when viewed with the optical and the electron microscopes. The robustness argument has been complemented with various other "epistemological strategies" in the work of Allan Franklin.

Still other philosophers have not been convinced that theory dependence of instruments of the circular variety should be taken seriously. Hasok Chang in his *Inventing Temperature* considers the example of establishing that mercury expands uniformly with a rise in temperature for the production of reliable thermometers in the 19th century. To do this, one had to plot the volume of mercury versus temperature. But for that one, of course, needs a reliable thermometer, which was what scientists had set out to discover in the first place. But Chang argues that this kind of circularity is innocuous: Even if the theory assumed when using a particular instrument is the same as the one at stake, the actual experimental result is still contingent. In other words, the reliance on assumptions that we wish to establish when using a certain instrument does not imply that the results gained with those instruments are guaranteed to be of a particular form.

Oppression

The concept of oppression has been controversial but powerful in the history of political philosophy and is characterized differently by Marxists, liberals, feminists, and race theorists. As it is used today, "oppression" refers to a harm in which groups of persons are systematically and unfairly or unjustly constrained, burdened, or reduced by social forces. The concept is thus fundamentally normative but makes important descriptive claims that engage social-scientific explanations. The main controversies about oppression include how oppressive institutions arise, which

groups are oppressed and why those groups, the main causes and harms of oppression, and the prospects for ending oppression.

The philosophy of oppression begins in the modern period with liberalism, which recognized the rights of individuals to freedom and justice. To modern liberal political theorists, "domination," "tyranny," and "oppression" were synonyms, connoting rule by an arbitrary or opposing will, resulting in violation of liberal political rights, economic deprivations, and physical brutality. They conceived oppression in individualistic terms, and its harms included being ruled by illegitimate governments and religious intolerance by the state. In the 19th century, the scope of liberal political rights broadened in the work of G. W. F. Hegel and Karl Marx and by works on women's rights and abolitionism. These theories posed a more social conception of oppression, where oppressor and oppressed may be related in a less politically formalized way. For Hegel, oppression was a failure to recognize the equal moral worth and dignity of another. Marxist, abolitionist, and feminist writers described oppressions of one social group by another (nongovernmental) social group.

Marx's historical materialism is the first attempt to scientifically explain the origin and maintenance of oppression. Marx understands oppression as causally based in the economic system of the epoch. Exploitation, a form of oppression, begins with division of labor and thus with the ability of one group to coercively appropriate the product of another's labor. In capitalism, the working class is systematically and materially disadvantaged through the organization of production, in which the capitalist class appropriates the surplus value of workers.

Contemporary discussions of oppression extend this analysis and provide different causal accounts of its origin and endurance in different oppressed groups. Three fairly standard conditions characterizing oppression can be summarized as follows:

1. *The harm condition:* A wrongful harm that comes out of an institutional practice
2. *The coercion condition:* Unjustified coercion or force that brings about the harm
3. *The social group condition:* Harm that is perpetrated on a social group

Condition 3 may seem to posit social collectives that exist over and above the individuals that make them up, which would raise ontological worries. Philosophers have shown how social groups can be constructed from individuals and the causes and effects of their actions.

Many accounts of oppression point out that when one social group is oppressed, another is typically raised up—materially, culturally, or psychologically. This extra boost to the nonoppressed has come to be known as "privilege" and can be stated as a fourth defining condition:

4. *The privilege condition:* Another social group that benefits from the institutional practice in Condition (1)

Recent theories have explored the significant psychological causes and effects of oppression. Some theorists of oppression use psychoanalysis to explain how individuals in certain social groups are motivated to be dominant or submissive, particularly gender groups and colonized national groups. Some contemporary thinkers theorize oppression as a problem arising from misrecognition, dehumanization, or failure of cultural respect. These theories share the core idea with Hegel that to be oppressed is fundamentally to be denied dignity or equal moral worth, either as individuals belonging to a social group or as a group as a whole.

Other theories are more concerned about the economic inequalities of oppression. Women's oppression on these theories is both an economic constraint and a psychologically degrading and distorting force. Theories of racial oppression have focused on dehumanization and invisibility as harms. Finally, Marxist and liberal political theorists, insofar as the latter treat aspects of oppression at all, tend to give primacy to the problems of economic distribution.

Another important development in recent theories of oppression is the recognition that persons belong to intersecting social groups, some of which may be oppressed while others may be relatively privileged. For example, Black men are both oppressed as Blacks and privileged as men, although intersecting group status does not always combine in the same way, and some privilege can turn to disadvantage under certain circumstances. Black feminist theorists originated this so-called intersectional analysis of oppression, which has now become standard, especially in feminist discussions of oppression and in discussions of the nature of race and ethnicity.

A controversy about oppression concerns its inevitability in human society. According to one prominent evolutionary psychological account of social dominance, there will always be a dominant and a dominated social group as a result of the basic structure of human psychology. Human males have evolved to form in-groups in order to have exclusive sexual access to the females in their in-group, the boundaries of which they will then violently enforce. The theory explains all forms of social group domination as a matter of evolved tendencies of males to police in-group/out-group boundaries. Since females have fewer tendencies toward domination, the theory predicts that they are easily dominated by males and that females are less likely to dominate others of any group. The evolutionary approach to explaining oppression equates oppression with dominance, making it impossible to distinguish justified from unjustified forms.

Finally, there are libertarian concerns about the claim that there are oppressed social groups, as opposed to simply individuals who are unjustly treated. However, recent work on stereotype threat and implicit bias, and a well-developed literature on stereotyping by psychologists show that individuals are perceived by others as belonging to social groups and are treated in stereotypical and biased ways as a result. There can be little doubt that individuals' social group status affects their opportunities in ways that are completely out of their control. Thus, social group status must be seen as an important locus of oppression.

Paradigms of Social Science

Thomas Kuhn's *The Structure of Scientific Revolutions*, published in 1962, introduced the word *paradigm* to discussions of the nature of science. The term rapidly passed into wide circulation, accompanied by complaints that Kuhn in fact used it promiscuously and confusingly. Kuhn accepted some of that criticism and responded that he had primarily intended to identify two main features of mature natural sciences, which could be differentiated into (1) a disciplinary matrix and (2) an exemplar. Both were meant to identify a way in which mature natural sciences, *unlike social studies such as sociology*, possessed a large measure of agreement on their fundamentals, which could be taken for granted in developing and conducting investigations into phenomena. *Disciplinary matrix* was meant to index a substantial measure of agreement on the aims and purposes of their field among the scientists working in it—agreements on central concepts and methods of investigation. *Exemplar* emphasized the extent to which a developed branch of natural science is unified around a quite specific idea of how research is to be done, which was defined by a distinguished and potent achievement—hence "exemplar"—that was accepted as a model for how research was to be done.

Kuhn's work was always controversial and led, quickly, to questions about whether the social sciences were as different from the natural sciences as Kuhn had made them seem. If one understood the question "Does sociology have paradigms?" in the sense of "Does it have a disciplinary matrix?" then the ready answer would seem to be yes. There are shared positions within sociology, ones that are often called "schools" or "approaches," many of which could as well be called disciplinary matrices. Then, one could talk about sociology as a multiparadigm science, having in mind a wide assortment of positions including Marxism, functionalism, rational action theory, interactionism, structuralism, and postmodernism, among others. These are marked by some internal agreement on broad and significant matters. However, it should not be assumed that the agreement within these "disciplinary matrices" is especially deep and strong, and in any case, there is reciprocal mutual skepticism between these positions. In relation to Kuhn's revised terminology, it would seem that a social science such as sociology can, like a natural science, have paradigms.

Kuhn's initial intent was to contrast natural with social science, and calling sociology a multiparadigm discipline does not mitigate the contrast. Kuhn's point about *mature* branches of natural science was that they were internally unified and would typically have only one paradigm—division into disputing paradigms was only an occasional and transient feature in times of "Scientific Revolution." The usual and defining condition was that of "normal science."

The weight of Kuhn's contrast, in terms of both the disciplinary matrix and the exemplar, was to emphasize how close the agreement was among researching scientists, so close that scientists did not have to spend large parts of their time arguing

about and trying to justify what they took to be the fundamentals of their discipline. Nor did they have to work out for themselves how to implement their general ideas and methods, for the exemplars embodied quite concrete and precise displays of the forms of investigation currently acceptable in the field and thereby solved such problems. The exemplar thus plays the key part in enabling normal science, a period in which researchers can take close agreement with their colleagues for granted and can apply accepted standard methods in the investigation and solution of empirical problems, confident that success in applying those procedures will ensure that their results are recognized as additions to their area's knowledge.

A multiparadigm discipline like sociology is not like that, as sociologists very well know. The sociological paradigms nominated above do not embody exemplars, and many sociologists complain bitterly over sociology's inability to develop an accumulating body of empirical knowledge (rather than just a heterogeneous assortment of largely unrelated studies), to enter, in Kuhnian terms, a period of normal science.

Is there anything in sociology that at least approximates Kuhn's formal criteria for exemplars? Some good candidates tend to be rather marginal to sociology's mainstream, as for example, conversation analysis (CA, the study of talk-in-interaction), which is perhaps more influential outside sociology, in fields like linguistics and psychology, than it is in sociology, and expectation states theory (EST, the study of formal properties of hierarchical relations), which is largely disregarded outside its own boundaries. In CA's case, the article "A Simplest Systematics for the Organization of Turn Taking in Conversation" by Harvey Sacks, Emanuel Schegloff, and Gail Jefferson (1974; first published in a linguistics journal) and Sacks's collected *Lectures on Conversation* (1986) provide a model for analyzing the way the distribution of turns at talk in conversation and other "speech exchange systems" (such as courtroom questioning or therapeutic dialogues) is organized as well as how turn distribution shapes innumerable aspects of what is done in those turns. This model has been closely followed in a large and increasing number of studies by other researchers.

EST, originating in experimental studies of status relations in small groups by Joseph Berger in the 1950s, has tried to develop a systematic and formal theory together with an integrated set of studies to show how individuals' expectations based on assessments of others' status affects group formation and structure. Much of that project's work is recorded in volumes of *Sociological Theories in Progress*. There undoubtedly are other areas of sociology, such as the more prominent *social network theory*, that could also qualify. How such cases compare with the natural science instances Kuhn had in mind and whether they do involve genuine accumulations of knowledge are questions that cannot be explored here; but even if they do, these cases are not typical representatives of sociology's multiparadigm situation.

Pareto Optimality

This entry explains the notion of Pareto optimality (after Vilfredo Pareto [1848–1923], the Italian economist, sociologist, and engineer), the normativity of Pareto-optimal outcomes, the function of economic actors' revealed preferences, and the role of Pareto optimality in welfare economics. The entry ends by looking at two main criticisms.

Pareto optimality (Pareto efficiency, allocative efficiency) is an important concept in economics and related social sciences, where it figures in both normative and descriptive claims. To understand Pareto optimality, it helps to understand *Pareto improvement* (PI). A situation *A* is a PI over a situation *B* if and only if at least one person (strictly) prefers *A* to *B* and no one (strictly) prefers *B* to *A*. A situation is Pareto optimal just in case no other situation is a PI over it—that is, no one can get more preference satisfaction without someone else getting less. Note that multiple situations can be Pareto optimal.

Desirability of Pareto Optima

Economists generally see Pareto optimality as desirable. This view is expressed in a number of ways—Pareto-optimal outcomes are *socially rational*; non–Pareto-optimal outcomes ought not to be chosen—but such claims are best seen as corollaries of a basic assertion about the value of PIs: If *A* is a PI over *B*, then *A* is *better* than *B*. A PI seems to make at least one person better off and no one worse off, and so to result in an uncontroversial gain in overall well-being. Human welfare has moral significance; such a gain is good, at least other things being equal. The *other-things-equal* (ceteris paribus) clause is required because well-being is not the only moral consideration: Fairness, justice, equality, and so on, also matter. If PIs are good (in this limited sense), then so are Pareto optima: Each is the end point of a series of PIs such that all of the uncontroversial preference gains have been achieved.

Preferences and Market Competition

Along with many other social scientists, economists hold that a person's preferences are revealed by her behavior. This allows them to determine the distribution of preference satisfaction, and so identify Pareto optima, by merely observing what people do. PIs are defined in terms of preferences precisely because the preference-to-behavior connection makes the existence of PIs empirically testable. Furthermore, economists think that they can identify social arrangements that lead to Pareto optima. They focus, in particular, on *perfectly competitive markets*. The basic idea behind the claim that perfect competition leads to Pareto optimality is simple: Voluntary trades are PIs; when no one is willing to trade further, the situation will be Pareto optimal. Perfect competition is defined to ensure that all voluntary trades are PI (e.g., no "entangled" preferences, so mutual agreement among traders suffices for a PI) and that no PI trades are blocked (i.e., no barriers to entry, so everyone can seek trading partners). Perfect competition is not required for Pareto optimality; central planning might suffice—for example, parental allocation of resources to children. Perfect competition stands out, however, because it has an internal dynamic that tends toward Pareto optimality: People trade for their own satisfaction, without any external incentives.

Welfare Economics

Both the normative and the descriptive aspects of Pareto optimality play a crucial role in standard welfare economics. The *fundamental theorems of welfare economics* spell out the usual approach. The first holds that the outcomes of perfect competition are Pareto optimal. The second holds that any attainable Pareto optimum can be achieved through perfect competition from an appropriate initial distribution of resources. The welfare theorems are usually taken to establish that a division of labor is appropriate in the realm of interpersonal morality: Efficient markets should handle welfare issues; lump-sum resource transfers should handle other moral considerations (e.g., fairness), without interfering with market mechanisms.

Critical Points

There are many criticisms of economic approaches where Pareto optimality plays a significant role, but this entry will discuss only two, which are perhaps the most common.

The first is that PIs are (practically) *unattainable*. To identify market transactions as PIs, economists typically assume that people care only about the trades in which they participate. But, in fact, people

are concerned with the transactions of others. Envy comes to mind, but there are also moral attitudes—many would prefer to see less self-degradation, unfairness, and so on, even when they aren't personally involved. Such entangled preferences undermine the connection between market transactions (even if unconstrained) and uncontroversial welfare gains since many voluntary trades will no longer be PIs. If most situations qualify, then being Pareto optimal is not much of an achievement.

A second criticism of Pareto-optimality claims in social science holds that there is no regular connection between preference satisfaction and welfare. The clearest illustrations involve people with implausible views about what benefits them, such as Scrooge from Dickens's *A Christmas Carol*. The distinction between satisfying preferences and actually being better off doesn't, however, depend on a particular view of the good. For any view, even someone who holds it will prefer some things that are inconsistent with that conception. In the most prosaic cases, false beliefs lead a person to prefer one thing when it would make sense (given their more basic values) for her to prefer another. Furthermore, psychology tells us that people have trouble bridging the gap between ultimate goals and situation-specific preferences; for example, they have a hard time resisting nearer but lesser goods. Reasoning goes awry in many ways, so it is practically certain that people will prefer things that are not beneficial on their own view of the good. Furthermore, there is no way to bridge the gap between the preferred and the beneficial without making the distribution of preference satisfaction irrelevant. In order to separate value-congruent from value-incongruent preferences, one must be explicit about the value standards at issue and use them to evaluate preferences. Once such standards are at hand, however, there is no point in consulting preferences—one looks directly at whether behavior advances the relevant values.

Path Dependence

The outcome of a *path-dependent* process depends on the course taken to reach that outcome and, in particular, on contingencies that have influenced the process prior to its reaching its outcome. The concept has attracted much interest among social scientists, partly because of the possible suboptimality of the outcome of a path-dependent process, a possibility that conflicts with the claims often made by economists of social processes and the "equilibria" on which they converge.

This entry examines what path dependence is, looks at a well-known case of path dependence, and considers the relationship between the concept and that of *market failure*.

Put negatively, path-dependent processes do not converge on a unique terminus irrespective of the "historical accidents" that occur on the way. This may be expressed by describing path-dependent processes as *nonergodic*. Path-dependent processes are consequently unpredictable (although not ontologically indeterminate), for without knowledge of the contingencies that occur along the path prior to their occurrence, an observer can predict neither the course of the path nor its resting place. Studying cases of path dependence therefore involves historical analysis, whereby such contingencies and their influence on the course of the process are traced ex post facto. This explains why studies of path dependence are associated with the motto "History matters": Only if a process converges uniquely to a given point (i.e., if the process is path *in*dependent) may one ignore the history of the process and the apparently "random" events that characterize its course.

The concept of path dependence has become common to studies of economic and technological

development since the 1980s, although Thorstein Veblen is usually acknowledged as recognizing the phenomenon of path dependence (though not by name) in 1915. The concept may be said to have "come of age" with the works of Brian Arthur and Paul David. The latter's account of the evolution of the QWERTY typewriter keyboard is the most famous study in which claims of path dependence are made. The QWERTY configuration was initially designed in the latter half of the 19th century to overcome a technical problem whereby the typebars became jammed during typing. The QWERTY configuration overcame this problem, yet it is technically inferior to other keyboard settings, as evinced by speed-typing world records, which have usually been claimed by typists using not QWERTY but the Dvorak keyboard, patented in the 1930s. One is thus led to ask why QWERTY is still the dominant keyboard design. One "historical accident" that provided a decisive fillip to QWERTY was the development in the 1880s of touch typing, originally done on the QWERTY keyboard. The association between QWERTY and the inception of touch typing meant that the early touch typists were QWERTY trained, and so those buying typewriters—primarily businesses rather than private households—had an incentive to install QWERTY equipment so that they could employ the most efficient (QWERTY) typists. This was obviously of advantage to QWERTY-trained typists; it also meant that those who sought a career as a typist were more likely to favor QWERTY given the increasing stock of typewriters used in business that were compatible with the skills of a QWERTY-trained typist. Every touch typist who opted for QWERTY increased the probability that others would follow suit and opt for QWERTY when making a choice between keyboard formats on which touch-typing skills were to be acquired, a selection process that has been likened to a Pólya urn process in mathematics. There was therefore positive feedback between businesses that installed QWERTY and typists who learned to touch type on QWERTY keyboards. Keyboard design thereby became "locked in" to QWERTY at the end of the 19th century, a terminus to this developmental path that has never been reversed. It is not clear how or whether convergence on the QWERTY keyboard could be reversed through a decentralized (market) process of the sort that led to QWERTY's dominance.

Further studies of path dependence have been undertaken for nuclear reactors, video recorders, and petroleum-driven cars. The concept of path dependence has also been applied to the development of social institutions, government policy, and scientific knowledge. In such studies, path dependence is often associated with inefficiency or "market failure" because decentralized market processes can fail to lead to the adoption of the optimal technology (as is claimed of QWERTY). Some economists, such as Stan Liebowitz and Stephen Margolis, have challenged such claims. One must note, though, that theorists of path dependence do not claim that a path-dependent process always or necessarily leads to an inefficient outcome, for path dependence is neither a necessary nor a sufficient condition for suboptimality. Nevertheless, paths that appear to lead to inefficient outcomes have captured the attention of social scientists, particularly of those who cast doubt on the "optimal" nature of decentralized coordination in the market and on the claims made on behalf of the market by neoclassical economic orthodoxy.

In a short space of time, *path dependence* has earned itself a place among key concepts in economics and technology studies and also, though to a lesser extent, in other social-scientific disciplines.

Performative Theory of Institutions

This entry presents Barry Barnes's theory of social institutions, known as the *self-referential model* or sometimes as the *performative model*, and explains how it differs in important ways from similar accounts of self-reflexivity involved in constructing the social world.

In everyday language, the word *institution* refers to things such as hospitals, prisons, banks, and universities. Sociologists and anthropologists use the word in a more extended sense and include, for example, the institution of gift giving, the institution of promising, and the institution of slavery. They also include forms of knowledge and culture, such as the institution of witchcraft. The philosopher Ludwig Wittgenstein even spoke of rules as institutions.

A list of examples does not tell us what sorts of things social institutions are. If air and water are made of atoms and molecules, what are institutions made of? Are they just numbers of people who behave in regular and predictable ways, or is more involved than mere regularity and predictability? It can be strangely difficult to marshal our intuitions on these questions. Institutions involve things such as status, authority, role, and obligation, and all of these are oddly intangible. The force of an obligation, for example, the obligation to respond to a gift, is not like the force of gravity. We may say that obligations have a moral rather than a physical character, but that merely reopens the original question: What analysis is to be given to such realities?

Barry Barnes's Account

The account of social institutions and social ontology to be given here derives from the work of the contemporary sociologist Barry Barnes, though pointers toward his approach can be found in David Hume, Émile Durkheim, Ludwig Wittgenstein, and Wittgenstein's pupil and editor Elizabeth Anscombe.

Linguistic Predicates and Collective Agreement

Barnes begins by analyzing the employment of the verbal labels by which reality in any form can be identified and described. He notes that there are two different sources of information that are used when responding to an object in the environment, for example, when one wishes to label or classify it. One source is the experience of the object itself and its empirically discernible properties. The other source is the response made to the object by other people. The first method involves looking at the object; the second method involves looking at the people surrounding the object.

These two resources give rise to two different sorts of highly idealized predicate. (Barnes acknowledges that the simplifications involved here are extreme but argues that they serve to focus attention on important dimensions of concept application.) Let a word applied on the basis of the empirical properties of an object be called an N-predicate and a word applied on the basis of other people's applications of the word be called an S-predicate. Thus, I may apply the label *cat* to objects that look similar to other cats I have encountered, and I may apply the word *slave* to objects that other people call "slaves." Thus far, we can say that "cat" is an N-predicate and "slave" is an S-predicate.

In reality, the word *cat* must have been introduced by a process of ostensive definition in which a finite number of authoritatively identified cats are presented to act as models for future applications of the word. The subsequent application of "cat" must also be subject to standards of correct and incorrect use. Objective limits must be placed on the subjective intuitions of similarity guiding the application of the word and an account given of the nature of the objectivity.

To meet these requirements, some authority must (a) select certain exemplary instances of cats to provide the stereotype against which putative instances are judged and (b) other concept users must monitor the boundaries of accepted cat-hood. Both of these activities involve *collective agreement*; that is, they depend on noting and conforming to how other people respond to certain objects in the world. *Cat* is the right word to use because other people use it like this. Thus, real natural-kind terms depend on the very mechanisms that were identified as lying at the basis of S-predicates. They involve not only a response to the material environment but a response to the *social* environment. Real predicates that are meant to capture empirical features of the material world can be thought of as *combining* the machinery of pure N-predicates and that of the so-called S-predicates.

Reference

More needs to be said about the mechanics of S-predicates. What is the specific reality to which S-predicates refer? What reality corresponds to the collective decision that some objects are properly called "cats"? In what does the propriety consist? More generally, what reality corresponds to the assignments of status, such as "slave"? To call these S-predicates indicates that they are not responses to the empirical properties of things but to other people's use of the predicate. In this case, these other uses of the predicate by other predicate users must have precisely the same character; that is, they too are responses to other people's use of the predicate. There is therefore only one consistent answer to the question about the reality of the reference and the object of the response. The use of an S-predicate by one person must be a reference to the use of that predicate by everyone else. Everyone else's use has the same character, so that, taken collectively, the system of usage as a whole is a self-referential system. *The only reality to which the predicate can refer must be the reality of the system of usage itself.*

Social Reality

Here then is Barnes's general model of social reality. Social reality is created by the references to that reality, where *reference* is used broadly to cover all orientations to, and all acts invoking, that reality. An institution is a pattern of *self-referential activity*. A status is created by its being accorded, acknowledged, invoked, and acted upon. A person is an "authority" because he or she is deemed to be an authority and deferred to as an authority. A rule exists in and through its being appealed to, cited, applied, and challenged. The process of "creation" involved here, for example, the creation of institutions and statuses, is not some magical power of conjuring up a reality that is independent of the discourse involved. The central point is that there is no independent object of discourse. The discourse and the object of the discourse are one and the same.

The Model

The model is sometimes called the *self-referential model* and sometimes the *performative model*. The latter label goes back to J. L. Austin's account of what he called *performative utterances*—that is, utterances such as "I greet you" or "I curse you" or, when said by an appropriate authority, "I declare you husband and wife." In each case, the act of utterance makes true the thing that is uttered, so its truth does not reside in a correspondence of the utterance with an external reality. It should perhaps be emphasized that in Barnes's case, as in Austin's, this form of analysis in no way *challenges* the commonsense assumption that these self-referential processes all take place within a material setting, that is, a discourse-independent reality whose empirical features can be the object of enquiry, reference, and physical engagement. Both Barnes's and Austin's versions of performative analysis presuppose that it is the environment outside the circle of self-reference that enables the circle to be established in the first place. Barnes calls this the process of *priming* the self-referential system.

Avoiding Misconceptions

The performative or self-referential model captures the obvious truth that social reality is a reality that humans *create* for themselves by virtue of their interacting with one another. But the model does more than confirm a truism: It also *explains* the mysterious character of social ontology. We hear a word that refers to an aspect of social reality, but when we look to see what it refers to, we cannot find anything. The strangeness derives from the false expectation that the word corresponds to some object that is independent of it, when there is no such object apart from other uses of the word. Failure to understand the mechanics of self-referential discourse may tempt the unwary to postulate mythical pseudo-objects to play the role that the empirical object plays in the case of N-predicates. Durkheim argued that the error of assimilating self-referential and other-referential discourse lies at the bottom of all religious and metaphysical speculation. Gods and spirits, as well as the mysterious powers attributed to the human soul and mind, are, in reality, misunderstandings of social processes. They are the transfigured experience of the social group acting upon itself.

Reflexive Awareness: The Mark of the Social Sciences

There is a venerable philosophical tradition in which the human sciences are differentiated from the natural sciences on the grounds that human beings possess special mental characteristics such

as self-awareness. To engage in any social action involves the actors thinking of themselves as being engaged in these actions. Thus, to give a gift involves thinking that you are giving a gift. Where does Barnes's model stand in relation to this tradition? The performative model permits a sharper formulation of these cloudy insights and avoids some of the logical pitfalls to which traditional formulations are subject. Indeed, one of the surprising consequences of Barnes's work is to expose a hidden individualistic premise in the traditional standpoint.

To see this, note that if gift giving really involved thinking that you are giving a gift, it would be impossible to define giving a gift. As Anscombe pointed out, to define "gift giving," it would be necessary to mention thinking that one is giving a gift, but then it would be necessary to define "thinking that one was giving a gift," and that would involve mentioning gift giving—which takes us back to the point from which we started. The definition would run in a circle. Barnes's account avoids this trap. The trap arises because in the traditional picture, self-awareness and self-reference are conflated. The process of collective self-reference, which is central to Barnes's model, has been misconstrued. A social process has been treated as an individual mental process and attributed to the inner structure of a mysterious "intentional state." Barnes takes the process of self-reference out of the head and puts it back where it belongs, that is, in the realm of collective behavior. The only form of self-awareness necessary on Barnes's model is one that enables individual actors to be susceptible to the causal influences exerted by others in the course of interaction. Thus, the only "thinking" needed to make an act an act of gift giving is that of being a responsive participant in the social institution of gift giving.

Critical Points

On first encounter, Barnes's model of social institutions may seem open to the objection that it makes society a mere matter of words. Slaves are slaves because they are called "slaves"—isn't that the theory? Barnes seems to have ignored the harsh, objective reality of exploitation and abuse. Being of low or marginal status can be a matter of life and death. If this objection were right, it would be devastating, but Barnes's model is not just about words, although the use of words has played a central role in its exposition. To be *called* a slave stands duly for all modes of treating someone as a slave and behaving toward them as a slave. Properly understood, the model does *not* minimize the way real-world consequences flow from, and motivate, the processes of social classification and the operation of social institutions. The model is simply designed to capture the essential character of social entities, such as institutions, and to say what they are, regardless of whether their consequences are benign or malign. Indeed, the model can help us understand the processes by which people sustain institutions that systematically deny others access to the resources they need. One can be sure that those who benefit from institutions that embody social injustice will be only too happy to encourage false and mystifying theories about the nature of social reality. The performative model can help dispel the mystification.

Personal Identity and Trauma

Many survivors of traumatic events have reported that their selves were shattered by the trauma. Survivors of Nazi death camps have said that they died in the camps, war veterans have remarked

that they lost themselves in battle, and rape victims have written of missing their lost selves. This entry attempts to make sense of these cryptic claims by discussing the effects of trauma on the self and exploring the connections between the philosophical literature on personal identity and the psychological literature on recovering from trauma. To the extent that social science deals with social persons, and hence with notions of selfhood, the study of traumatic experiences that shatters unified conceptions of selfhood is as crucial to social science as it has been to philosophers discussing personal identity over time.

Philosophical Accounts of Personal Identity

The question of personal identity, as addressed by philosophers for centuries, has traditionally been framed as "What are the conditions that make it possible (or impossible) for the same person to persist over time?" The various answers philosophers gave to this question were taken to be revealed by our intuitive responses to thought experiments, such as the one proposed by the 17th-century British philosopher John Locke, in which the consciousness of a prince is transferred from the prince to the body of a cobbler while the consciousness of the cobbler comes to inhabit the body of the prince. "Who is (now) the prince?" Locke asked. Locke, who defended a psychological criterion of personal identity, according to which what makes someone the same person over time is that person's consciousness, answered, "The one with the cobbler's body." Other personal identity theorists who have defended a bodily or biological criterion of personal identity have answered, "The one with the prince's body."

Philosophers since Locke have continued to puzzle over whether persons can survive transformations of various kinds. In recent decades, personal identity theorists have come up with increasingly imaginative and high-tech thought experiments involving freezing and thawing, dissolution and reconstitution, fission, and teletransportation, designed to test our intuitions about what makes someone the same person over time. They have not, until very recently, however, paid attention to the actual experiences of real people who claim to have been utterly transformed by trauma. This may be explained by the fact that what philosophers have traditionally sought in a theory of personal identity is an account of what makes it possible to reidentify a person at one time as the same person that existed at another time. Philosophers have sought a criterion of numerical identity for persons over time, a criterion different from, but with the same function as, a criterion of numerical identity for things, such as trees and ships and bicycles. If, in contrast, we want a theory of personal identity to be an account of a person's self-conception over time, then the study of trauma, including the examination of first-person narratives of trauma survivors, becomes not only relevant but also necessary to the search for a theory with adequate explanatory power.

Psychological Accounts of Trauma

Following the psychiatrist Judith Herman, this entry defines trauma as an experience of being completely helpless in the face of an overwhelming, life-threatening force. Whether it results from human-inflicted violence or a natural disaster, trauma overwhelms a survivor's agency and cognitive capacities and can lead to posttraumatic stress disorder, with symptoms that include hypervigilance, heightened startle response, sensory flashbacks, dissociation, and numbing. The intermingling of mind and body in these symptoms highlights the embodied nature of the self and suggests the inadequacy of both strictly psychological and strictly biological criteria of personal identity.

Psychologists and psychiatrists have observed that trauma survivors suffer the severing of bonds of trust with others and the shattering of fundamental assumptions about their safety in the world. The loss of sustaining attachments to others—family, friends, and community—is experienced as a loss of self by many trauma survivors. This phenomenon, along with the essential role reconnection to others plays in healing from trauma, is taken by some philosophers to support the view that the self exists only in *relation* to other people.

Trauma survivors who lose the ability to identify with their past selves and to project themselves into the future can become paralyzed in a present that no longer makes any sense. In order to carry on, they need to find meaning in the world again; talking about their traumatic experiences in the company of empathetic others has been found to facilitate this. This can be taken to motivate the view that the self is not only relational but also *narrative* in structure, unable to continue without the ability to tell a story about itself. The philosopher Hilde Lindemann

Nelson stresses the importance for survivors of being able to come up with empowering counter-narratives to repair narrative identities damaged by trauma.

As illuminating as the study of trauma can be for understanding the nature of personal identity, it remains unclear just what we ought to make of survivors' claims to have outlived their former selves. Unlike casually made everyday claims such as "I'm not myself today," trauma survivors' claims of lost or destroyed selves appear to be more than mere façons de parler. But if they are literally true, then who is the "I" who is able to say "I am no longer the self I was before the trauma"? What connects the "I" referring to the speaker with the "I" referring to the pre-trauma self? Whether or not these questions can be answered, the conversation between psychologists and philosophers about personal identity and trauma is a lively and engaging one that has only just begun.

Pessimistic Induction

A pessimistic induction is an argument that makes use of empirical claims about the history of science—especially accounts of past theories that are false by our lights—to argue that we have little reason to believe that our own theories are even approximately true, or refer to real objects, in the parts of their claims that go beyond matters observable by the human senses. These are claims such as that electrons have spin, since electrons are too small to observe directly with the human eye. The view that we do have reason to believe these things is called *scientific realism*.

What is usually counted as the first argument of this type, given by Larry Laudan, is not strictly an induction. That is, it does not enumerate examples of past failures of science in order to make a positive inference that we have reason to believe that our theories are also false. Rather, since the particular realist views Laudan argued against had put forth strong general claims, such as that the predictive success of our mature theories was a reason to think that they are approximately true, examples of past scientific theories with properties that did not fit those claims could be used to falsify them. Laudan argued that counterexamples to the connection between success and truth are very common in the history of science. We no longer believe the humoral theory of medicine or the physics hypothesis of the existence of an ether-permeating space, but these were assumptions that were successful in prediction.

Objections can be made to the relevance of some examples, though. The humoral theory of medicine enjoyed a reign of many hundreds of years from ancient to medieval times, but its success in diagnosing and curing disease does not seem comparable with that of our germ theory, for example. The only response to the plague that it had available were things like herbs and bloodletting. As for the ether, although physicists believed that there was such a thing, it has been argued that the assumption played no crucial role in their calculations leading to successful predictions. On the other side, it has been argued that the scientists did not know that the ether assumption was unnecessary to the success their physical theory as a whole enjoyed. We similarly may be unaware that some parts of our successful theories are inessential to their success. Thus, even if success were an indicator of truth, we may not know which truths our theories' success indicates.

Pessimistic arguments that have taken the form of a simple induction—roughly, since most successful theories in the past were false, our successful theories now probably are too—have fallen on hard times with the realization that these judgments depend on base rates. For the probability that a theory is true given that it is successful depends not only on the probability that a theory will be successful given that it is true but also on the probability that a theory chosen randomly without regard for its success will

be true and that a theory chosen randomly without regard for its truth will be successful. Making inferences without all of these probabilities is fallacious, and making an accurate judgment of what they are seems impossible.

The potent challenge that the history of scientific failures presents to us is better formulated by John Worrall, who focuses on the observation that for a given currently accepted theory, there is usually a theory that was accepted in the past and that contradicts our theory. The past scientists had evidence just as we do, so what reason can we give for thinking that we will not suffer the same fate of having our theories replaced with future theories that contradict them? A pessimistic argument of a similar form is given by P. K. Stanford and points to the fact that there were alternatives to our predecessors' theories, alternatives that were not conceived by them. We know this because we have since conceived of some of them, and they are written into our accepted theories. What is the reason to think that we are not also subject to conceivable but as yet unconceived alternative theories that will replace ours someday?

One kind of successful response to challenges of this form would be to explain how our justification for believing our theories is different in some principled way from the justification our predecessors had for believing theirs. Sherylin Roush has argued that the principled difference is our continual creation of new methods of investigation and evaluation. In a way that is highly relevant to reliability, we are not simply doing the same thing as our predecessors were, and doing more of it. She argues that this makes the failures of our predecessors to formulate true theories largely irrelevant to judging the expected truth or falsity of our own.

Another strategy, that of Worrall, is to accept that there is no reason to think that our theories will not be replaced but to point out that there is reason to think that significant aspects of our theories will be retained in the replacement. The reason is that significant aspects of successful past (fundamental) theories have been retained in ours. Despite the inconsistency of the older theories with ours, the retention of parts of the older in the newer theories means that we can continue to regard the earlier theories as approximately true. Similarly, we have reason to expect that though our theories will be replaced, we will be able to continue to regard them as approximately true. Worrall argues that in fundamental physics, mathematical structure has been retained over several centuries, a thesis that undergirds a view called *structural realism*.

Phenomenological Schools of Psychology

Phenomenology is a transnational, transdisciplinary approach to the study of conscious experience. Phenomenological research methods were originally articulated and developed by the philosopher Edmund Husserl in epistemology and ontology at the beginning of the 20th century. This approach has been extended into other areas of philosophy such as ethics and has generated knowledge in the full range of social, scientific, and humanities disciplines, from sociology and economics to theology and literary studies. This broad, dynamic movement continues to be vital and productive today.

Phenomenological psychology has been particularly significant for the philosophy of the social sciences in raising epistemological issues about human understanding.

This entry focuses on the phenomenological approach in psychology and related disciplines by delineating, with historical perspective, its

methodological orientation, fundamental concepts, major proponents, and recent advances.

Phenomenology: History and Basic Tenets

Above all, phenomenological research is based on a fresh and direct contact with the subject matter, apart from received knowledge, as it presents itself in living experience. Following from Edmund Husserl's inspiring and often cited call to return *Zu den Sachen selbst* (to the things, or matters, themselves), phenomenologists employ procedures developed by Husserl (technically called *epochés* [plural of *epoché*], from the Greek ἐποχή, pronounced as "ĕ-pō-ché," meaning "abstention/withdrawal") to set aside prior presuppositions drawn from theories, research findings, hypotheses, and material reality. Because it begins instead with concrete examples of mental life, phenomenology has been characterized by Husserl and later by Herbert Spiegelberg as proceeding "from below" and "from the grassroots." This kind of investigation aims to clarify the essential structure of its subject matter (i.e., to discover its essence, *eidos* in Greek) by using a procedure of meticulous reflections on specific examples, called "eidetic analysis." Crucial to this procedure, as explicated by Husserl, is the free imaginative variation of examples of the phenomenon and the discernment of the invariant core configuration of constituents and experiential processes that qualify all imaginable examples as instances of the phenomenon under study.

One of Husserl's fundamental insights regarding consciousness is its essential quality of "intentionality," the universal act–object correlation. Conscious acts such as perceiving, remembering, thinking, and feeling always "intend" ("are about") objects, such as a food on a plate, a former home, an equation, and a loved one. Moreover, experience apprehends the meanings of objects, including their usefulness and value, within their larger contexts. This most overarching context of living experience is called the *lifeworld* or *existence*, which includes embodied presence, practical engagement, relations with others, surrounding spatiality, temporality, and collective historicity. This concrete, lived world is also the ground of scientific knowledge. Each discipline, by employing its special attitude, thematizes and conceptualizes its own distinctive province of the lifeworld. Psychology, the discipline that focuses on individual persons and finds them to be centers of experience and situated action in the lifeworld, has been of central concern to phenomenological philosophers and psychologists for more than 100 years.

Phenomenological approaches were implicitly present in the psychological research of philosophers such as Wilhelm Dilthey, Franz Brentano, Søren Kierkegaard, and Friedrich Nietzsche. Husserl, who began to make the implications of the phenomenological approach to psychology explicit, was followed by a host of other philosophers who addressed the general philosophical problems of psychology and carried out specific psychological investigations, including Martin Heidegger, Jean-Paul Sartre, Simone de Beauvoir, Maurice Merleau-Ponty, Edith Stein, Max Scheler, Emmanuel Levinas, Gabriel Marcel, Alfred Schütz, Gaston Bachelard, and Paul Ricoeur. Topical areas included perception, behavior, the emotions, imagination, memory, language, personality, social relations, human development, and psychopathology. Phenomenological approaches were also implicitly present in the work of psychologists and psychiatrists such as William James, Carl Stumpf, Sigmund Freud (and other psychoanalysts), Carl Jung, Max Wertheimer (and the Gestalt psychologists), Gordon Allport, Carl Rogers, Abraham Maslow, and Kurt Goldstein. Psychologists who explicitly drew on the phenomenological tradition include Karl Jaspers, Ludwig Binswanger, R. D. Laing, Frantz Fanon, Eugene Minkowski, Erwin Straus, Frederick Buytendijk, Eugene Minkowski, Medard Boss, J. H. van den Berg, and Viktor Frankl, to name only a few.

Phenomenological Psychology

Herbert Spiegelberg has provided the most comprehensive account of the early history of phenomenology's influence on psychology and psychiatry. He showed how phenomenological psychology has brought to light new psychological phenomena, provided original insights and understandings, developed new hypotheses founded on concrete analyses of experience, and offered unique tools for scientific investigation. Although early attempts to institutionalize phenomenological psychology were made in the Netherlands and elsewhere, the most deliberate and systematic development of phenomenological psychology began in the 1960s at Duquesne University in the United States. Drawing on the work of phenomenological philosophers, the "Duquesne circle" produced original phenomenological investigations

and educated a generation of researchers who employed the phenomenological approach across the full spectrum of psychological subject matter, including perception and learning (Amedeo Giorgi), personality and psychopathology (William Fischer), social psychology (Rolf Von Eckartsberg), psychotherapy (Anthony Barton), psychological assessment (Constance Fischer), the imagination (Edward Murray), and group psychology (Frank Buckley). Of most lasting significance has been the development of phenomenological research methods for psychology by Amedeo Giorgi, who has specified procedures of collecting and analyzing lifeworld descriptions of psychological phenomena that have been employed internationally by psychologists with a wide spectrum of subject matter. The *Journal of Phenomenological Psychology*, founded by Giorgi in 1970, has been the leading venue for the phenomenological movement and in introducing qualitative research methods in psychology.

Amedeo Giorgi developed a research method for psychology that employs the traditional tenets of phenomenology drawn from Husserl, such as the *epoché* of the natural sciences, a partial *epoché* of the natural world, the focus on the meanings and experiential processes through which the situation presents itself, and the eidetic analysis of psychological structures using imaginative variation. This method distinctively enables researchers to investigate the full range of other people's psychological life as it occurs in the lifeworld. Data are constituted by descriptions of specific situations through which the research phenomenon was lived. Research participants describe their own or other people's experiences, either in written form or in an interview. For instance, the researcher may ask participants to describe a situation in which they learned something, were jealous of someone, or encountered someone who showed "courage."

Giorgi specified procedures that ensure rigorous analysis of all data in the achievement of general psychological conceptualizations of subject matter. First, the description is read over openly. Second, expressed changes in meaning are used to differentiate analyzable "meaning units" in the data. Third, each meaning unit is reflected on and imaginatively varied in order to articulate what it reveals about the matter under investigation and its relevance to the research question. Finally, reflective analyses of numerous descriptions, supplemented by free imaginative variation, are employed in explicating the essential psychological structure, or typical structures, of the phenomenon under investigation.

One important procedure demanded by the last step is the determination of whether the data reveal a single general structure or numerous typical structures. In *Phenomenology and Psychological Research*, using five examples/descriptions to demonstrate this method with the phenomenon of "learning," Giorgi (1985) found two different structures of learning, one never before reported in the literature, and thereby demonstrated how phenomenological research can reveal overlooked psychological processes in an important mainstream area of research. One typical structure of learning had already been identified by traditional psychologists and called "skill acquisition." This kind of learning involves no cognitive ambiguity and changing assumptions but rather a movement from awkward bodily activity to smooth functioning within a single expectational set. However, a second typical structure of learning that Giorgi called "Discovery of Discrepancy Between Assumptions and Situation" was found in a person's encounter with hard facts that are discordant with his or her assumptions. Learning of this kind occurs when the person pauses and thinks about these discordant facts according to a new perspective that illuminates the situation in unexpected ways. A newly clarified ambiguity transforms not only the meanings of the current situation but also, by implication, those of future situations of the same type. Giorgi recognizes both as types of learning in that the person makes "a discovery about himself or his way of relating to the world in such a way that all future situations of that type will be handled in a more adequate way" (p. 66).

In the 2009 demonstration investigating "jealousy" in *The Descriptive Phenomenological Method in Psychology*, Amedeo Giorgi and Barbro Giorgi independently and reliably discerned a single structure in the collected examples and their imaginative variations. They delved into the personal experience of not receiving sufficient attention and appreciation from a desired other person, whose appreciation is actively robbed by a third person. They elaborate the intense feelings of resentment and hostility when this third takes advantage of her or his unfairly privileged position in order to undermine the jealous person's position and possibility of gaining the appreciative attention sought. They also bring out the significance of shame and how, within this general structure,

the jealous person hides her or his experience from others. This demonstration shows the reliable way this kind of analysis leads to convergent results, in this case in the single-structure solution, on the parts of different researchers.

Phenomenology has recently been utilized and the methods articulated by a number of other psychological researchers. Max Van Manen in Canada, Clark Moustakas in the United States, and Jonathan Smith in Great Britain have also developed variant phenomenological research methods for psychology that have been and continue to be used in training and guiding researchers. Consistent with the principles of science, phenomenological psychology offers an evidentiary basis to criticize prior knowledge and to establish new rational claims that are themselves corrigible through methodical extensions of its procedures.

Phenomenological psychologists have generated original knowledge in and clarified relations among nearly every subdiscipline of psychology, including cognitive, social, developmental, experimental, psychometric, personality, behavioral, psychoanalytic, and humanistic. The phenomenological approach continues to be central in psychology's qualitative methodological revolution in the early 21st century.

Noteworthy among the current, continuing contributions to clinical psychology is the phenomenological participatory action research on recovery in schizophrenia by Larry Davidson. With individuals long considered by traditional investigators to be beyond the scope of empathic understanding, Davidson has consistently demonstrated that the lived world of the person with schizophrenia is not only intelligible but highlights the person's own active role in the recovery process. Davidson's phenomenological psychology has articulated key dimensions of this psychopathology beyond the usual focus on deficits, dysfunctions, and etiological theories, including individuals' hopes, assets, agency, and efforts at building a meaningful life in the community. Specifically, he details not only their "symptoms" judged "abnormal" by others but also their suffering of rejection from loved ones and friends, as well as their struggles to establish gainful employment, meaningful family involvements, confidence in navigating the world, contributions to others and society, and a hopeful future. Guided by transcendental phenomenology, Davidson's research on recovery in psychopathology integrates interdisciplinary work in demonstrating that what psychosis is cannot be understood apart from the lived world of stigma, poverty, unemployment, political oppression, and social marginalization. These analyses, based on in-depth interviews, have led to the development of community programs that employ the resources of peers and natural supports to empower recovering persons as social agents in their communities.

Concluding Remarks

Phenomenological psychology has entered the 21st century as a continuing movement, self-aware and self-critical. Phenomenological psychologists eschew dogmatism and exclusivity as they emphasize evidence and reflection, diversity and ambiguity, vision and revision. They aim to be continual beginners, gaining new knowledge by setting aside prior knowledge and returning to freshly reflect on concrete examples of living experience.

Philosophes, The

Although the French term *les philosophes* means philosophers in the strict sense, it also has a broader meaning for which there is no exact equivalent in English, hence its widespread use in other languages to refer to the group of public intellectuals and writers in 18th-century Europe and the United States associated with the movement now known as the Enlightenment, very few of whom were philosophers in the more restricted sense in which that word tends to be used in English today. They included natural scientists, philosophers, clerics, politicians, public officials, novelists, and journalists with a shared commitment to reason, science, and religious toleration.

While the best-known philosophes were French—men such as Voltaire, Denis Diderot, Jean le Rond d'Alembert, the Comte de Buffon, Étienne Bonnot de Condillac, the Baron de Montesquieu, and Jean-Jacques Rousseau, who was a French-speaking citizen of Geneva—they had counterparts across Europe and the United States, most notably Adam Smith and David Hume in Scotland, Immanuel Kant and Gotthold Ephraim Lessing in Germany, Thomas Jefferson and Benjamin Franklin in the United States, and Cesare Beccaria in Italy. These thinkers commonly referred to themselves as a society of men of letters ('*société des gens de lettres*') who owed allegiance to an international "Republic of Letters" devoted to the popular dissemination of enlightenment and the promotion of reform that began around the middle of the 18th century and continued until the French Revolution in 1789.

Most of the philosophes were empiricists who rejected the belief in original sin and the concept of innate ideas, both of which were closely associated with orthodox Christianity. They typically viewed the human mind as a blank slate that acquired knowledge via sensory experience. The *locus classicus* of this view is John Locke's 1690 *Essay Concerning Human Understanding*, which was widely read and admired throughout the 18th century by the philosophes. They attacked mysticism and obscurity in favor of clarity and openness, and they were champions of the scientific method of experimentation and direct empirical observation of nature pioneered in the 17th century by men such as Francis Bacon. Most of the philosophes were confident that by this approach we could understand the natural and human worlds, which was the surest means to progress and happiness.

The epitome of the philosophes' ambition to spread enlightenment as broadly as possible was the epic and ambitious *Encyclopédie*, edited by Diderot and d'Alembert. Published between 1751 and 1765 in 17 large volumes, it consisted of tens of thousands of entries and illustrations (with several later supplements and editions) written by virtually all of the leading philosophes of the day in France on a huge range of topics, from music and natural science to politics and religion. This controversial project was officially banned in France in 1759, although it enjoyed the support of some very high-placed officials, including the director of censorship and publication, Guillaume-Chrétien de Lamoignon de Malesherbes, who worked surreptitiously to ensure that the *Encyclopédie* continued to be published unofficially.

Among the most common myths about the philosophes is that they were naive optimists who believed in the inevitability of progress, even though Voltaire, the quintessential Enlightenment figure, openly mocked this view in his popular novel *Candide* (1759). At the other extreme was the Marquis de Condorcet's wildly optimistic *Sketch for a Historical Picture of the Progress of the Human Mind*, published in 1795 shortly after his death in prison during the French Revolution. The mainstream view of the philosophes on progress lay somewhere between these two extremes, tending toward a very cautious optimism about the prospects for improvement, with a keen sense of how slow and uncertain it could be. Even so, most believed that things had gradually improved and would likely continue to do so as reason, toleration, and science displaced religious fanaticism, intolerance, and superstition.

Another common misconception of the philosophes is that they regarded society as unnatural. In fact, most of them criticized social contract theory and affirmed natural human sociability, which they practiced in salons, cafés, and academies, where they met to debate and exchange ideas.

Although often caricatured by their opponents as atheists, very few philosophes denied the existence of God. Most were deists who rejected Christianity, attacked religious persecution, mocked traditional religious institutions and beliefs, and endorsed a minimalistic natural religion. With few exceptions, they were anticlerical, were highly critical of religious fanaticism, and advocated religious toleration. While some philosophes, such as Claude Adrien Helvétius and the Baron d'Holbach, rejected belief in God, they were rare exceptions, and many were as critical of atheism as they were of religious fanaticism.

In most European countries in the 18th century, the *philosophes* saw themselves as a self-appointed, unofficial opposition to the dominant political establishment. In some rare cases, they actually held political power, as in the United States (where Thomas Jefferson became president) and Prussia under Frederick II. There was surprisingly little agreement among them on the best means to the ends of social reform and the promotion of human well-being, which all agreed should be the purpose of government. Some, like Voltaire and d'Alembert, favored enlightened despotism, while others (a minority), like Rousseau, were democrats who put their faith in the virtue and good sense of ordinary people.

Philosophical Psychology, History of

Philosophical psychology is the philosophical analysis of theoretical psychological constructs such as rationality, emotion, motivation, consciousness, and intelligence. This entry briefly describes its first recognition as a discipline distinct from scientific or empirical psychology and its brief flourishing as a distinctive philosophical program in the 20th century.

As Hermann Ebbinghaus said of psychology, philosophical psychology has a long history but a short past. While philosophers have critically reflected on the theoretical constructs employed to explain human psychology and behavior for millennia, philosophical psychology was only recognized as a discipline distinct from scientific or empirical psychology in the 18th century, and it only came to fruition as a distinctive philosophical program for a relatively short period in the latter half of the early 18th century.

Since at least the time of the ancient Greeks, philosophers have engaged in critical conceptual analysis of the theoretical constructs employed in the explanation of human psychology and behavior, while advancing tentative theories of human psychology and behavior based (however tentatively) upon observation (including introspective observation) and experiment. Thus, for example, in his discussion of anger in *De Anima*, Aristotle not only describes the physiological basis of anger as the boiling of the blood around the heart (on doubtful empirical grounds) but also explicates the conceptual content of anger as an appetite for returning pain for pain.

Although many ancient, medieval, Renaissance, and Enlightenment thinkers provided quite sophisticated conceptual analyses of theoretical psychological constructs, these were always mixed with theoretical speculation and appeal to empirical facts; and the notion of a form of philosophical psychology distinct from empirical psychology did not develop until the 18th century, when the German philosopher Christian Wolff distinguished between rational and empirical psychology. According to Wolff, rational psychology is concerned with the rationally demonstrable principles of psychology (relating to the human soul), while empirical psychology is concerned with the empirical description and measurement of psychological faculties such as sensation, memory, and intellect.

Immanuel Kant demonstrated that there are no rationally demonstrable principles of psychology analogous to those of logic and mathematics (attacking the hyperbolic claims of reason), on the one hand, and that empirical psychology cannot attain the status of a genuine quantified science, on the other—a claim supposedly refuted by the development of psychophysics in the late 19th century (although Kant did not deny the quantitative measurement of the intensity of sensation but only the possibility of a quantified dynamical psychology analogous to Newtonian physics).

Nevertheless, most post-Kantian theorists ignored the distinction and continued to advance mixed philosophical, theoretical, and empirical claims about human psychology and behavior even after analytic philosophers and phenomenologists distinguished themselves from empirical psychologists in the early 20th century as a consequence of their rejection of psychologism, the view that the laws of thought are a part of empirical psychology. While they distinguished themselves from empirical psychologists, both analytic philosophers and phenomenologists conceived of psychology as a scientific inquiry, concerned with the causal explanation of human psychology and behavior.

This conception of psychology was challenged by a number of philosophical psychologists in the 1950s and 1960s, who denied that explanations of meaningful human action in terms of reasons or motives could be treated as analogous to causal explanations in the natural sciences. These philosophers, many of whom were students or followers of Ludwig Wittgenstein, maintained that reason or motive explanations violate David Hume's dictum that causes and effects are contingently related, because there is a "conceptual connection" (or internal relation) between reasons or motives and the actions they explain—for example, between motives of revenge and acts of revenge. Their distinctive position on this question reprised earlier 19th- and 20th-century views in the philosophy of social science, which maintained that there is a fundamental distinction between the modes of (causal) explanation and understanding characteristic of the natural and the human sciences. More generally, these philosophers endorsed Wittgenstein's famous claim that "in psychology there are experimental methods and conceptual confusion" (*Philosophical Investigations,* Pt. II, p. xiv) and developed detailed conceptual analyses of psychological constructs such as perception, emotion, motivation, intention, the unconscious, voluntary action, rationality, and self-deception. Seminal works in this tradition included G. E. M. Anscombe's *Intention* (1958), R. S. Peters's

The Concept of Motivation (1958), Anthony Kenny's *Action, Emotion and Will* (1963), Alasdair MacIntyre's *The Unconscious: A Conceptual Analysis* (1958), A. I. Melden's *Free Action* (1961), Norman Malcolm's *Dreaming* (1959), and Peter Winch's *The Idea of a Social Science* (1958). With the exception of Anscombe's *Intention*, all these works were published in the Routledge and Kegan Paul series *Studies in Philosophical Psychology*, later known as the "little red books" because of their distinctive color and size. This, predominantly British movement was relatively short-lived, and its death knell was sounded by Donald Davidson's 1963 article "Actions, Reasons and Causes," which maintained that reason explanations are a species of ordinary causal explanations and repudiated the "conceptual connection" argument advanced by the "Red Book Philosophers."

Although most philosophers have abandoned arguments against the causal explanation of meaningful human action in terms of reasons and motives, they have continued to develop conceptual analysis of the theoretical constructs of psychology, even as the status of conceptual intuitions has been questioned as philosophy itself has become more empirical and experimental and conceptual analysis has come to be treated as continuous with theoretical and empirical psychology. In recent years, the conceptual analysis of theoretical psychological constructs has been subsumed within the philosophy of psychology, which is nowadays frequently equated with philosophical psychology, as, for example, in the journal *Philosophical Psychology*, one of the premier journals in contemporary philosophy of psychology.

Philosophy of Economics, History of

The philosophy of economics, broadly understood as the philosophical reflection on economic matters, is almost as old as Western philosophy itself and dates back to the works of the ancient Greek thinkers Xenophon and Aristotle. More useful is a narrower understanding of the term as the systematic investigation of the nature and methods of the science of economics, which is contingent on the birth of economics (or political economy, as it was known then) as a discipline in the 18th century. The English philosopher and polymath John Stuart Mill was arguably the first philosopher of economics in this narrower sense. This entry surveys the development of ideas concerning the nature and methods of economics from its Millian origins until the present day.

The Methodological Tradition: John Stuart Mill and Neville Keynes

John Stuart Mill (1806–1873) is widely known for his writings on logic and the philosophy of science, utilitarianism and liberty, feminism, and classical economic thought. As a philosopher of economics, his major contributions are three interrelated ideas: the characterization (1) of economics as an *abstract science*, (2) of its method as *a priori*, and (3) of causal laws as *tendencies*.

Mill (1830/1948) defined economics as

> the science which traces the laws of such of the phenomena of society as arise from the combined operations of mankind for the production of wealth, in so far as those phenomena are not modified by the pursuit of any other object. (p. 140)

The most notable features of this definition are (a) that economics is defined in terms of the causes responsible for certain phenomena and (b) that these phenomena are conceived of as hypothetical: whatever *would* follow from the human pursuit of wealth if no other motive *were* present. This is what Mill meant by economics being an "abstract science": For the most part it does not describe concrete states of affairs we can see, touch, and feel because these are normally the result of a concomitance of causes. Instead, it describes what happens "in the abstract" when noneconomic factors are absent.

Concerning method, Mill distinguishes two main approaches: the *a posteriori* and the *a priori* methods. The former proceeds from specific experiences to a general conclusion, and thus inductively, while the latter, by reasoning from an assumed highly general hypothesis (which is supported by a wide range of experiences) to a specific conclusion, therefore mixing inductive and deductive argument. Mill thought that the nature of social phenomena undermines attempts to employ the a posteriori method fruitfully. Economists cannot perform experiments, nor do economic phenomena resemble natural situations that can be sufficiently captured by experiments, since such phenomena are too varied. Therefore, the economist must resort to the a priori method. She is, however, helped by the fact that the desires of human beings and what triggers them are observable and thus that the relevant laws are known. The main difficulty for the economist is therefore to calculate what will happen when the laws of human nature operate in a specific situation, but this is, according to Mill, not part of the business of science but of its application.

Causal laws, whether concerning humans or natural phenomena, are to be understood, according to Mill, as tendencies. That is, causal laws describe not what actually happens but rather what tends to happen in the absence of disturbing causes. In economics, these disturbances are the noneconomic causes—everything apart from the pursuit of wealth. Mill thought that in economics, different causes combine "mechanically" rather than "chemically." That is, when the operation of one cause is disturbed by another, both causes continue to affect the result in the same direction as they would operate if the other cause were absent. In chemistry, by contrast, when two substances combine, their product has completely different properties from those of its components. The success of the a priori method depends on the truth of this principle of composition: Understanding what economic factors do "in the abstract" would be of no use unless they contributed to results in predictable ways when other factors are present.

John Neville Keynes (1852–1949) was an economist and the father of John Maynard Keynes. In his methodological writings, he tried to adjudicate in the *Methodenstreit*, between the German historical school and the Austrian school of economics, by combining inductive and deductive elements more rigorously than Mill had. His attempts were met with little success, however, as subsequent generations of economists, especially after World War II, paid little attention to evidence in the choice and formulation of premises from which conclusions about concrete economic phenomena were to be derived. A lasting contribution to methodology is Keynes's three-part distinction of *positive*, *normative*, and *applied* economics. His notion of positive economics as a "body of systematized knowledge concerning what is" and of normative economics as "a body of systematized knowledge relating to criteria of what ought to be, and concerned therefore with the ideal as distinguished from the actual" (Keynes, 1890/1999, *The Scope and Method of Political Economy*, p. 22) are still in use today. By contrast, *applied economics* to Keynes was synonymous with the "art of economics" and meant more than just the use of economic principles in concrete contexts. It was rather a branch of economics, separate from both positive and normative inquiry, dealing with rules for attaining given practical purposes. It is only in recent years that methodologists have started to pay attention again to this aspect of economic thought.

A Century of Isms: Positivism, Instrumentalism, Falsificationism, and Postmodernism

The main methodological ideas that surfaced during the greater part of the 20th century were influenced by either logical positivism or critical rationalism, or both, or they developed as a reaction to these schools of thought. One uniting feature was their understanding of economics as a body of theoretical

statements such as *assumptions*, *hypotheses*, *postulates*, or *conjectures*.

Two methodological treatises received much attention during the 1930s: Lionel Robbins's *Essay* of 1935 (a first edition had appeared in 1932) and Terence Hutchison's work of 1938. Robbins defined economics as a science that studies behavior as a relationship between ends and scarce means, and he rejected, with Mill and Keynes, the idea that economic principles could be based on specific experiences or controlled experiments. But unlike Mill and Keynes, who aimed to develop sophisticated combinations of inductive and deductive styles of reasoning, Robbins (1935) downplayed the inductive part of the endeavor as the basic postulates of economics "are so much the stuff of our everyday experience that they have only to be stated to be recognized as obvious" (p. 79). Hutchison's book can be understood as a detailed critique of Robbins's ideas from a positivistic standpoint. In particular, he sought to secure economics' status as a genuine science by showing that it is based on substantive principles capable of empirical test rather than mere tautologies, and he emphasized the need for confrontation of these principles with evidence.

Milton Friedman's 1953 essay was and continues to be the most widely discussed contribution to economic methodology. The essay should be read as providing an answer to the question "What kind of evidence is relevant to assessing economic hypotheses?" In the 1940s, doubts were raised about the empirical adequacy of some of the basic postulates of economics on the basis of survey results about how firms make production and pricing decisions. Friedman denied that such evidence should worry economists because economic theories or hypotheses ought to be evaluated on the basis of their predictive success and fruitfulness, not their literal truth or falsehood. This position has later come to be known as instrumentalism, but it also clearly bears positivist, pragmatist, and Popperian influences.

The preponderance of Popperian ideas grew after World War II, and helped define the methodology and philosophy of economics as an independent field of inquiry, especially with the appearance of Mark Blaug's book in 1980. The book emphasized the importance of falsificationism à la Karl Popper and Imre Lakatos and argued that economists often preach falsification, though they rarely practice it.

By the time the book came out, falsificationism (and also positivism) had already largely been given up in philosophy circles because of complications that proved quite recalcitrant, such as the Duhem problem and the difficulty of drawing a meaningful distinction between observational and theoretical statements. In a provocative article and a later book, Donald McCloskey built on these philosophical advances, rejected the 20th-century methodologies as "modernist," and developed an anti-methodological stance named the *rhetoric of economics* to replace them. Instead of using maxims such as "test your hypotheses," "build predictive models," and so on, to evaluate the content of economics, we were invited to attend to the arguments given in support of a position and to assess them using the tools of rhetorical analysis.

The Millian Tradition Revived: Causality, Models, and Evidence

The last decade of the 20th century was marked by two developments in the philosophy of economics. On the one hand, there was a revival of Millian themes, most prominently perhaps in Daniel Hausman's 1992 book, which in many ways built on and developed Mill's methodological ideas. On the other hand, philosophers of economics followed a trend initiated by a group of general philosophers of science to turn away from issues surrounding scientific theory and its assessment and instead to attend more closely to scientific practice. Thus, more applied work in economics moved into the center of methodological attention: econometrics, modeling, experiments, and measurement. In much of this recent work, philosophical analyses of economic practices often also take their cue from Mill. Thus, Nancy Cartwright develops an account of "causal capacities," which is modeled on Mill's notion of a tendency, and she uses it to analyze econometrics as well as models; Uskali Mäki similarly understands economic models as "isolations," which is also closely related to Mill's ideas about abstract science and tendencies; Francesco Guala analyzes economic experiments on the basis of Mill's "canon of inductive methods," and Julian Reiss takes Mill's skepticism about the applicability of inductive methods to economic problems as a foil to develop a more thoroughly evidence-based methodology of economics. We can expect this trend of focusing on more applied matters to continue in the future and also to extend to normative issues such as economic well-being and policy (see,

e.g., the 2009 anthology edited by Harold Kincaid and Don Ross).

Philosophy of Expertise

Experts are everywhere. People rely on doctors, lawyers, and accountants for many matters of personal well-being. Politicians and managers regularly turn to scientists, professors, and professional consultants for policy advice. Judges and journalists put experts on the spot to weigh in on numerous issues. It is impossible to imagine life without experts. Yet what is an expert?

One answer is that we need to understand what distinguishes expert knowledge from other types of knowledge. Expert knowledge is often understood as *tacit* knowledge of domains like chemistry, the U.S. tax code, or football. Tacit knowledge refers to fluency gained only through long-term immersion in a domain's practices and credentialing processes. That is, tax professionals should not have to constantly reference guides and manuals to do someone's taxes. They should know just how to do it implicitly; the right things should stand out for them. Tax professionals' tacit knowledge can be contrasted with mere memorization of the tax code, which does not produce the fluency needed to make expert judgments.

Though we may accept that expert knowledge is tacit knowledge, we may disagree on who has tacit knowledge suitable for advising others. For example, is an expert in football only someone who has played football at all relevant levels and continued on to a coaching career? Or is a sports journalist who has covered football for many years, but never played competitively, also an expert? The former has had long-term immersion in the practices and credentialing processes of the domain; the latter only has mediated experiences, such as linguistic immersion with players and coaches as well as ample time spent as a spectator. Should both be considered experts?

This question is hard to disentangle from questions about expertise and power relations. Expert status carries authority; authoritative advice influences people's lives. Consider regulatory decisions about risky technologies. Citizens sometimes focus on aspects of risk that experts largely ignore, such as qualitative features that may be independent of probabilistic assessments of harm; they may also have different beliefs about the meaning of safety. In cost–benefit analysis, experts may offer good advice on the costs of permitting and regulating technologies, but they are less helpful in identifying and measuring the benefits. For example, experts' studies of citizens' willingness to pay are often unclear because it is not given that citizens express their values that way or that they know enough about the technologies to determine what they would pay. Should experts even measure people's preferences? Or should they seek to help people to have more informed preferences?

Expert advice can be bent against consumers' interests; expert opinions and decision processes can be used as excuses to sidestep informed consent procedures, transparency, and public or stakeholder engagement. The credentials used to identify experts may be biased in numerous ways. Consider the case of indigenous peoples whose members have traditional ecological knowledge of their lands but no formal scientific credentials. Failure to confer expert status on traditional ecological knowledge disenfranchises Indigenous people from environmental decision making.

The philosophy of expertise also addresses the role of experts in problems such as water availability, sustainable agriculture, and climate change, which are so complex that no one domain of expertise can support the efforts to address them. Climate change, for example, is relevant to domains ranging from meteorology to forestry to animal science to civil engineering to artificial intelligence (for modeling), and many others. Yet insofar as climate change concerns human beliefs, behaviors, norms, visions, and capacities to act, it is also the subject of sociology, cognitive science, literature, anthropology, philosophy, psychology, and art.

There are philosophical issues involved in understanding how experts in different domains ought to work to collaborate on problems like climate change. Experts use different methods (e.g., experimental, fieldwork, philosophical analysis) that are initially incompatible with one another because they reflect different assumptions about the nature of inquiry. Data sets may be difficult to integrate, compare, or even interpret faithfully in relation to one another. Different domains may have ingrained languages, norms, and professional standards that have not been adopted or are looked at critically by experts in other domains. It is also unclear how interdisciplinary collaboration should be assessed. Interdisciplinary collaboration might make problems like climate change even harder to deal with and may be more susceptible to political manipulation.

Efforts to address climate change will also only be effective if research is actionable by citizens in the localities where the findings must be applied. Making research actionable and relevant requires experts to consult nonexperts early on in the planning phases and that nonexperts serve among the external peers who judge the quality of the research. But exactly how far into expert domains should nonexperts go? Should nonexperts shape what research gets funded? Should they be involved in deciding standards of evaluation of evidence and modeling assumptions? Will citizen peer review reduce the autonomy of experts in their own domains?

Interdisciplinarity and nonexpert involvement in research challenge the traditional boundaries of expertise and expert domains such as disciplines and fields. Some philosophers address these challenges directly. They have supplemented typical philosophical work with empirical activities, which include putting together case studies, running experiments, and collaborating with engineers and scientists to set appropriate technical standards for innovations. They work directly with these experts in interdisciplinary research.

Philosophers often bring their expertise into interdisciplinary collaboration. They engage with practitioners of different fields, from biotechnology to organic farming, or with members of different communities, from urban farmers to state policymakers. Philosophers become members of these communities, with their own unique perspectives and contributions. They consider themselves *as* members with special contributions but not as privileged experts. They use this knowledge and status to publish in fora with a wider audience, engaging stakeholders and even the broad public on issues of research ethics and technological risk. The philosophy of expertise properly includes this work because of what it reveals about the value of philosophical expertise in relation to experts in other domains and the public.

Philosophy of History

What is history? What is involved in historical research and knowledge creation? What is the role for the philosophy of history? We might say that there are basically three relevant activities in the realm of historical thinking. First, there is first-order research into facts about the past based on currently available evidence. Second, there is analysis and explanation of those facts, including methods ranging from ethnography to process tracing to structured comparisons to application of findings from the social sciences. These two parts of historical research are guided by ensembles of historical methods and practices (historiography). And, third, there is philosophical reflection on the logic and limitations of these processes of inquiry and inference. This aspect of the discussion includes the conceptual work that philosophers are well qualified for—posing and answering questions like "What is history?" "What is a cause?" or "What is involved in expressing a meaningful action?"

History and Historical Inquiry

Let us begin by attempting to specify the meaning of the word *history*. Here is a schematic definition: History is the sum total of human actions, thoughts, creations, and institutions, arranged in temporal order. Call this "substantive history." History is social action in time, performed by a specific population at a time. Individuals act, contribute to social institutions, and contribute to change. People had beliefs and modes of behavior in the past. They did various things. Their activities were embedded within, and in turn constituted, social institutions at a variety of levels. Social institutions, structures, and ideologies supervene upon the historical individuals of a time. Institutions may have great depth, breadth, and complexity. Institutions, structures, and ideologies display dynamics of change that derive ultimately from the mentalities and actions of the individuals who inhabit them during a period of time. And both behavior and institutions change over time. "History" is the temporally ordered sum of all these facts.

We are interested in understanding history for a number of reasons.

a. We are interested in knowing how people lived and thought in times and settings very distant from our own. What was it like to be a medieval baker or a beadle or a wife? Understanding this kind of thing has a lot in common with ethnography or interpretive research; historians uncover what they can of the circumstances, actions, and symbols of a group of people, and they try to reconstruct

their mentality and their reasons for acting as they did. Robert Darnton's *The Great Cat Massacre* is a good example.

b. We are interested in the concrete social arrangements and institutions that existed at various points in time. We would like to know how marriage or tax collecting worked in rural Ming China. Understanding this kind of thing requires careful study of existing records that permit inferences about how basic institutions worked. Examples include bodies of law, charters, manorial records, and the like. Marc Bloch illustrates this kind of research in *Feudal Society*.

c. We are interested in the dynamics of change—the reasons for the rise and fall of the Roman Empire, the reasons for a rash of peasant rebellions in Qing dynasty China, or the reasons for the occurrence and characteristics of the Industrial Revolution. Understanding this kind of thing has to do with identifying dynamic causal processes of the sort that the social sciences study—why legislatures tend toward certain kinds of institutions and behaviors, why bureaucracies tend toward rigidity, why people are susceptible to extremism. This kind of question pays attention to both internal reasons for change and external reasons—an internal dynamic toward dynastic instability and an external shock imposed by sudden climate change, for example. Charles Tilly has contributed a great deal on this approach, especially in *The Contentious French*.

d. We are interested in quantitative assembly of historical data—population, economic activity, and other kinds of social data. Understanding this kind of thing requires discovering data sources in the historical records and archives that permit estimation of things like marriage rates, grain prices, or church membership totals and then analyzing and presenting these data in convincing ways using established methods in social science quantitative methodologies. A very good illustration of this kind of research is provided by Bozhong Li in *Agrarian Development in Jiangnan, 1620–1850*.

This suggests a fairly simple logic of historical inquiry and representation:

- Historians discover factual circumstances about conditions of life, action, and thought (mentality) during specific periods.
- Historians identify changes in these conditions from one period to another.
- Historians identify the features of social relationships, institutions, structures, and ideologies during specific periods.
- Historians use "path-tracing" and comparison methodologies to discern how circumstances and actions in one period led to specific outcomes in a later period.
- Historians make use of the findings of the social sciences to identify the social dynamics associated with specific kinds of social institutions, structures, and ways of thinking.

This description leaves out a great deal of what historians spend a lot of time on: formulating narratives that make sense, discovering unexpected causes or outcomes of historical circumstances, finding new perspectives on old historical questions, or just deciphering what is going on in an archival source, for example. The goal here is to strip away those elements of the historian's work in order to highlight the logic of the varieties of factual and explanatory claims that historians make. This description is abstract, of course, but it seems to capture the main elements of historical cognition. An important recent turn in the philosophy of history addresses precisely these features of historical inquiry and writing.

History and Philosophy

So far we have analyzed *history*. What about the *philosophy of history*? What is the work that we can hope to do with a philosophy of history? What is it about history that supports philosophical inquiry? Why is the enterprise of investigating, documenting, and explaining facts about the past amenable to philosophical study? What makes the effort to arrive at knowledge of facts about the past an area of philosophical concern?

There are a couple of matters that are relatively clear. First, the domain of historical knowledge is a familiar subject for philosophical inquiry. Epistemology is the philosophy of knowledge generally. Philosophy of science is the careful analysis of the methods and justification of scientific knowledge. And philosophy of historical knowledge is likewise an epistemic and methodological domain: How do we know about the past? Are there limits to our possible knowledge about the past? What is involved in explaining a historical fact? Answers to these questions and others

in the same vein may be difficult and controversial, but it is clear how they fit into existing conceptions of philosophical inquiry. Analytical philosophers like Patrick Gardiner, Carl Hempel, and William Dray have focused on this set of issues.

Second, there is a serious debate about the relative importance of hermeneutic and causal methods for historical inquiry and explanation. Some historians and philosophers have argued that history concerns human action, which is inherently meaningful; so it is necessary for historians to use methods of interpretation of actors and their products that derive from the hermeneutic tradition of Wilhelm Dilthey and Friedrich Schleiermacher if they are to succeed in their tasks. This set of topics intersects profoundly with the philosophy of action—the philosophical study of the facets of intentional individual thinking, choice, and behavior. Recent analytical philosophy (in the work of Harry Frankfurt, Elisabeth Anscombe, or Michael Bratman) has contributed significantly to these issues in the past few decades. This field is one where there has been productive work in both the Continental and the analytic traditions. Contemporary Continental voices contributing to this set of issues include Paul Ricoeur and Hans-Georg Gadamer.

Third is an area of philosophical investigation that arises in connection with the idea of historical and social causation. Some historians and philosophers acknowledge the role of intentional actors in history but argue that the tools of causal analysis are most valuable for historians: For example, this war occurred because conditions X, Y, and Z existed and instigating event E occurred. This debate raises questions across several philosophical fields, in that it requires that we have a more clearly specified theory of causation that is relevant to the social world.

If the philosophy of history were limited to these sorts of questions, then it would be an amalgam of the philosophy of science, the philosophy of action, and the philosophy of causation. However, some philosophers have felt that substantive history itself raises questions that do not reduce to questions about knowledge of these familiar domains.

In particular, some philosophers and historians have argued that we need a metaphysics of history—an account of the kinds of things, forces, structures, and direction that exist in the realm of history. Early exponents of this view of history include Giambattista Vico and Johann Gottfried von Herder. Perhaps the metaphysics of history can shed light on what kinds of structures and entities travel through history and what kinds of processes and systems propel change in the structures and entities.

For example, Karl Marx wrote that "history is the history of class conflict." This implies that classes are historical objects—they exist in the flow of historical events. Other historians have said things like this: Classical slavery gave way to feudalism, which was followed by capitalism. This formulation presupposes that large social-economic systems—for example, social property systems—exist in history and conform to some set of dynamics. And yet others have tried to carve up world history into a set of more or less distinct civilizations—bodies of values, ideas, identities, and institutions that differ significantly from one another.

We might better say, however, that none of these questions pertains to a metaphysics of history, but rather they pertain to a metaphysics of the social world. History is about change and transformation, but the subject of change is the social structures, cultures, and agents that exist within the social world at a period of time. So classes, social property systems, ideologies, and religions are all social arrangements that change over time. If there is such a thing as a "civilization," this is a fact about society at a certain time and not a fact about the structure of history. History has to do with events and dynamic properties; the social world encompasses everything that is happening at a moment in time. We might consider an analogy with the ocean—"history" is the waves, society is the water.

We might be more inclined to recognize a metaphysics of history if we thought there were enduring temporal structures that could be discovered in substantive history—perhaps the business cycle, the Kondratiev long-wave economic cycle, or the rise and fall of civilizations. In other words, if we thought that events and changes conformed to a higher-level pattern of temporal change, we might want to say that the metatemporal pattern is a metaphysical characteristic of history. This was the inspiration of 18th- and 19th-century Continental discussions of history. Enlightenment philosophers discerned a steady movement toward a more rational world, as the Marquis de Condorcet did, and G. W. F. Hegel located an underlying rationality within the events of history themselves. But it is more persuasive to argue that these patterns of change too represent nothing more than empirical characteristics of social phenomena over time. They need to be explained using the tools of the social sciences and are not properly the subject of a priori investigation.

This discussion suggests a few conclusions about the possible scope of research in the philosophy of history:

- Philosophical work directed toward elucidating the epistemology and methodology of historical knowledge is straightforward but limited.
- Philosophical reflections on the nature of action and causation are valuable contributions to the philosophy of history.
- It is true that some historical investigation requires "hermeneutic" interpretation of meanings; but these efforts always fall at the level of interpreting the meaning of individual actions and their meaningful creations, not the large expanse of history.
- The dynamics of historical change are properly the subject matter of the social sciences rather than the philosopher of history.
- Philosophical work directed toward elucidating the metaphysical underpinnings of "history" will be disappointing; those foundations exist within the domain of the philosophy of the social sciences rather than the philosophy of history.

Conclusion

This analysis suggests that the primary tasks for the philosophy of history lie within the philosophy of action, the philosophy of causation, and a specialized portion of the philosophy of science. How do we know about the past? How do we understand the actions of historically situated actors? What is involved in making assertions of causality within the play of history? When these sorts of questions are addressed in the writings of talented historians, the results of work in the philosophy of history can be very illuminating.

Philosophy of Politics, History of

The entry introduces the foundational questions raised by a philosophical reflection on the nature of politics as a social science and traces their provenance in the history of political philosophy.

Questions

The history of the philosophy of politics may be defined along a spectrum: At one end are theories treating politics as largely derivative of other domains of philosophy or science, and at the other are those stressing its significantly autonomous nature.

Both of these opposing tendencies address fundamental questions about the *nature* of politics. Is there a distinct domain of the political, distinct, for example, from the moral or ethical, from the economic, from the religious? Is politics a universal feature of human society or a mode of interaction that arises only in certain contexts, and is it historically mutable? Should one think about politics in terms of scientific approaches, such as the implications of neuroscience; or in terms of mathematical approaches to instrumental reasoning, such as rational choice theory; or in terms of the underlying economic forces, as Marxism would contend? Or should one approach politics by means of an interpretative understanding of the meanings of a social and political world, as Max Weber would insist?

A related set of questions is what the philosophy of politics is *for*: Is it designed to counsel political agents as such, or can and should it be the detached knowledge of a political scientist? Should it be addressed to the outlining of a utopian ideal or to political life as it is currently practiced? How a philosopher or political theorist answers such questions, whether implicitly or explicitly, sketches out the philosophy of politics that she or he adopts.

History

The polar ends of the spectrum of the philosophy of politics were influentially modeled among the ancient Greeks. Indeed, it has been argued that the ancient Greeks themselves invented the domain of the political and the idea of politics in their practice of a more or less widely shared civic role of deliberation and execution of policies for the security and flourishing of the community. One line of philosophical interpretation of this domain is exemplified by Aristotle's integral connection of ethics and politics, both aiming at the flourishing of the individual, understood as possible only as a full participant in a political community. Aristotle held ethics and political science to be forms of practical wisdom dealing distinctively with choices about matters that could be otherwise, as opposed to philosophical contemplation, which deals with truths that are independent of human decision. He articulated this view in criticism of the prior expression of roughly the polar opposite view on our spectrum in Plato's *Republic*, which treated political expertise as depending crucially (though not exclusively) on philosophical knowledge of the nature of reality. Thereafter, from the Roman and medieval periods through the 20th century, Aristotelian approaches to the philosophy of politics (and also Epicurean ones) have stressed the relative autonomy and distinctiveness of politics, while Platonic approaches (and also Stoic ones) have stressed its dependence on a wider and higher philosophical framework.

Of course, the ensuing centuries have brought innovation as well as recurrent recourse to the Platonic and Aristotelian extremes. On the one hand, both of these approaches came under fire for being excessively idealistic about politics and its ties to ethics and the moral virtues, with Niccolò Machiavelli in the early 16th century taking princely politics to be neither a philosophical deduction nor an optimistic domain of flourishing but rather a bold and morally risky venture or art (though in republics it remained a form of action for shared liberty). On the other hand, the aspiration to ground politics in knowledge shifted from the domain of philosophy to the domain of science, with Thomas Hobbes in the 17th century deriving laws of reason as basic theorems from a scientific account of the human

condition (though Hobbes was also aware of the role of rhetoric in persuading people to adopt such a rational outlook). Thus, Machiavelli and Hobbes came to stand for two further types of approach to the philosophy of politics, the former treating politics as an art of executive action, the latter as a would-be science of justification.

The history of philosophy of politics in the 20th century can be broadly schematized along the lines of these forebears, notwithstanding elements of novelty. Some thinkers questioned the autonomy of politics, elevating economics (as did Marxists), psychology (as did Freudians), or even metaphysics (as did the followers of Martin Heidegger) to a higher explanatory plane. Others, including Martin Heidegger's sometime student and lover Hannah Arendt, reasserted that autonomy, defending the political as a threatened space of disclosure of individual distinction in terms influenced by Aristotle and ancient Greek practice. Still others, such as Carl Schmitt, a self-described (but arguably inauthentic) follower of Hobbes, insisted that politics was not the space of deliberation but rather the space of a unique, nonderivative domain of existential opposition between friend and enemy. These philosophers agreed at least that politics was not a domain of instrumental reason and that it could not be studied by descriptive social science. Yet a descriptive and even predictive study of instrumental political reasoning was strongly defended by partisans of the new approaches of behavioral and, later, rational choice political science.

Today, the philosophy of politics remains a contested subject, with political science departments divided among interpretative and historical approaches, rational choice modeling, and scholars of the historical development of the philosophy of politics itself. An alternative line of thought is the revival of republicanism in contemporary political theory.

Philosophy of Sociology, History of

Philosophy and sociology have a complex and intertwined historical relationship. Early figures in sociology, such as Auguste Comte (1798–1857), the inventor of the term, also figure in the history of philosophy of science as the inventors of "positivism." In this case, the philosophy served as a methodological warrant for the claim that the "sociological" theories of Comte were "scientific," and the problem of justifying particular forms of sociology as "science" was a persistent theme in both philosophical writing on social science and the field of sociology itself. Nevertheless, other philosophical sources, notably Immanuel Kant, played and continue to play an important role both in the problematic relations between the fields and as a philosophical source for sociology.

The basic problem posed by sociology for the philosophy of science is this: There seems to be no reason in principle why the social world should not be understandable scientifically. But finding the right analogs to existing science proved difficult. Comte had to rethink the notion of scientific law and scientific development itself in order to construct such an account, and his result combined both: Law was no more than prediction, and the scientific character

of sociology was confirmed by the possession of a law, the three-stage law of the development of the sciences through the stages of theological, metaphysical, and positive, which itself predicted the development of sociology as a science.

This clever solution had many consequences, not the least for the anti-metaphysical program of logical positivism itself. But it also spurred John Stuart Mill (1806–1873), in Book Six of *A System of Logic*, to construct a different account of the place of sociology in relation to other sciences, as well as a reconsideration of the notion of scientific law as it might apply to the various social sciences. Mill recognized that problems of casual complexity, the probabilistic character of laws, the problems of combining laws, and the problems of relating different kinds of social-scientific reasoning, including his associational psychology and deductive economic theory, meant that at best social science could produce approximations to laws.

Even finding approximations to laws proved difficult, so core Millian ideas were replaced and revised in various directions. Émile Durkheim (1858–1917) tried to construct laws governing the probabilities of suicide for different categories. Max Weber (1864–1920) drew on an alternative account of probability, which he used to warrant causal attribution in ordinary-language terms in the absence of laws. The mathematician Karl Pearson's correlational methods were used by American sociologists, notably F. H. Giddings and his students, following Pearson and the physicist Ernst Mach's slogans: Mach's that laws were no more than descriptions and Pearson's that supposed laws even in physics were idealized correlations. Other forms of sociology relied on analogies with organisms or with organic evolution, appealing to teleological or functional explanation.

These ideas of sociology as a science produced an "idealist" response that drew on various sources and took various forms. One was the idea of understanding, or *Verstehen*, and the idea that the human realm required this kind of knowledge rather than law. Another was an application of the Neo-Kantian idea of science, which took a science to be a hierarchically ordered realm of concepts that constituted a domain of fact. Scientific understanding, on this account, was primarily conceptual understanding of a world, in this case the social world, that is already conceptualized.

The Neo-Kantian approach was applied in early German sociology from the early work of Georg Simmel (1858–1918), who asked the self-consciously Kantian question "How is society possible?" and constructed a system based on the concept of the social. The autonomy of sociology in this approach depended on the existence of such a distinct ordering concept. German sociology became a series of constructions of this kind, based on different concepts of the social. In the 1930s, the American sociologist Talcott Parsons (1902–1979) produced a famous version that proved influential in the American context, and later the world, but he gave a meta-theoretical justification of it that linked it to approximations in physical science.

The relationship between sociology and philosophy becomes confused at this point, the point at which logical positivism begins to dominate American philosophy. Attempts to make sense of Parsons's ideas of "theory" in terms of logical positivism, or indeed any notion of theory that was explanatory, were unavailing. Philosophers like Carl Hempel and Thomas Nagel made an extended effort to explicate sociological thinking in the 1950s, primarily in terms of the functionalist aspects of Parsons's and also Robert Merton's (1910–2003) writings. But Parsons eventually denied that he was a functionalist. The English philosopher Max Black analyzed Parsons's writings at length and concluded that they were essentially devoid of meaning or expressed tautologies or truisms.

Sociologists ransacked logical positivism for hints at how to make their theories scientific. But the various borrowings from logical positivism never meshed very well with the actual forms of statistical analysis normally practiced in sociology. Instead, a practical convergence occurred with variants on the casual modeling methods of Herbert Simon, which were taken up eagerly by sociologists in the 1960s and 1970s, initially in the form of path analysis. Later, these became important topics in philosophy, in the work of Clark Glymour, James Woodward, and Judea Pearl.

Peter Winch's *The Idea of a Social Science*, which appeared in 1958, provided a "Wittgensteinian" critique of sociology and suggested that it was better understood as a form of conceptual analysis, like philosophy, but with the aim of understanding the concepts of a particular society or understanding that social action was to be placed within language-games and understood in terms of rule following. Karl Popper, in *The Poverty of Historicism*, suggested that explanations of action in terms of what

he called the logic of the situation were the appropriate form of social explanation and required only considerations of instrumental rationality. The latter prefigured rational choice explanation and restated Weber; the former reinforced the idea that the only proper explanations of human action were in terms of the concepts of the agent. Little of this survived the criticisms of Donald Davidson in articles like "The Very Idea of a Conceptual Scheme."

Plural Subjects

This entry reviews Margaret Gilbert's theory of *plural subjects*, draws parallels to and differences from other sociological traditions, and goes on to provide a critical examination of its various aspects.

The notion of "plural subject" was coined by Margaret Gilbert in *On Social Fact*. It has played an increasing role in the contemporary philosophy of social science and in the social sciences themselves. The notion of the plural subject is at the core of Gilbert's philosophy, along with a closely related notion, that of *joint commitment*. This conceptual link became clear in Gilbert's (2006) more recent definition: "A and B (. . .) constitute a plural subject (. . .) if and only if they are jointly committed to doing something as a body" (p. 144).

The main interest of the notion of plural subject is that it consists of an attempt to give a more analytical and simpler form to "holistic" intuitions that have been formulated either by sociologists such as Émile Durkheim or by idealist philosophers such as G. W. F. Hegel. Gilbert's challenge is to try to reconstruct these intuitions within the limits of methodological individualism (in a version much closer to Georg Simmel's than to Marx Weber's) and on contractarian bases, which, at first sight, seems paradoxical.

Like Simmel and more clearly than Weber, Gilbert assumes that groups are not "reducible" to individuals but are nevertheless "constructed" by interactions or relations between human individuals. In this way, the notion of plural subject is clearly framed in a constructivist view of social life. However, unlike interactionist sociologists (e.g., Erving Goffman) or relationist social scientists (e.g., James Coleman), Gilbert does not think that common interactions or relations (e.g., trust) are sufficient as bases of social life. Moreover, unlike David Hume and Adam Smith or, more recently, Michael Bacharach, she does not think that identification as a very specific relation would fill the gap. On the contrary, contracts—in the sense of *actual* contracts (and not in the sense of hypothetical contracts, as in Thomas Hobbes, Jean-Jacques Rousseau, or John Rawls)—are required.

Most of these "contracts," Gilbert argues, are *tacit* or implicit, unlike formal contracts but like informal agreements. They are not necessarily based on a cost–benefit calculation from the viewpoint of participants' self-interest, and it is not even necessary that the association forged by these agreements be primarily self-interested either. What is necessary, in any case, is that there be a reciprocal *commitment* of each participant to the common goal (whatever it is) but, furthermore, that this reciprocal commitment be a *joint* commitment. This means that the realization of the common goal (e.g., to play a symphony, to make a revolution, to increase the income of a company) has to be the priority, and each participant in the collective action has to act as a mere member of the social body ("as a body": Gilbert's own phrase, used frequently by her). This is a crucial point that is not expressed by the simpler notion of reciprocal commitment. It should be mentioned that the above definition of plural subjects is redundant (i.e., "as a body" means nothing more than "jointly") yet not circular as several scholars have argued.

Gilbert avoids using both the notion of collective intentionality, much debated since John Searle,

and Raimo Tuomela's more idiosyncratic notion of "we-mode." It seems obvious, however, that the concept of joint commitment requires notions similar to these. Speaking, for example, of a "plural subject collective intentionality" would be relevant. Unfortunately, neither Searle nor Tuomela have used the idea of commitment, an element inherent in the proper understanding of collective intentionality according to Gilbert. Michael Bratman tackled this issue carefully, arguing that, although Gilbert might be right generally speaking, there is however a more basic notion of collective intentionality (or, as he says, "shared intentionality")—or of plural subjecthood—that does not require the idea of commitment. Bratman urges that we should consider Hume's well-known example of two people in a boat rowing together without ever having given promises to each other: It would be natural to take these rowers as having a shared intention to row the boat together. In these cases, mere mutual adjustment is required. One could argue, however, that promise or, at least, joint commitment is implicit (Gilbert argues that joint commitment is not based on promises but that, in fact, the opposite is true) and that if one rower did not attempt to adapt his rhythm to that of the other rowers, they would feel entitled to reproach him.

The notion of plural subject is *normative* in the sense that it involves the normative notion of joint commitment. However, joint commitments are neutral ethically speaking, and one might have to violate joint commitments to fulfill moral commitments (Nazi leaders were probably jointly committed and constituted a plural subject). In this respect, Gilbert's notion of joint commitment and Amartya Sen's notion of commitment differ since, according to Sen, commitment means moral duty. On the other hand, if one views political obligations as ethically neutral, the notion of joint commitment can be thought of as the basis of political obligations.

Other reservations might come from the phenomenological method favored by Gilbert. As she regularly refers to subjective experiences (e.g., the feeling of being committed, the feeling of acting as a body), it may be argued that these mental states might not be universal. Psychological experiments should be conducted. However, until now, psychologists have been especially interested in searching for the anticipation of plural subjectivity (involving joint commitments) in children. Primatologists also are interested in similar possible anticipations in apes, although current investigations are not refined enough to provide any satisfying response here. Indeed, the idea of normativity inherent in joint commitment is often forgotten, and the notion of joint commitment is often implicitly replaced by the less demanding notion of shared intentionality.

Policy Applications of the Social Sciences

The application of social science knowledge to improve public policies is of great interest to philosophers, social scientists, and laypersons. Although "science" as a specialized form of reliable knowledge did not develop until the 19th century, the production and use of diverse forms of policy-relevant knowledge is as old as civilization itself.

Emergence of Policy-Relevant Knowledge

Policy-relevant knowledge emerged at a point in the evolution of human societies where practical knowledge was consciously cultivated, thereby prompting a self-reflective examination of links between knowledge and action. What we now know as the "policy sciences"—namely, policy-oriented social

sciences including political science, sociology, and economics—are a modern attempt to promote practical knowledge, that is, knowledge about what works.

Specialized procedures for analyzing policies arose with the emergence of urban civilization out of scattered tribal and folk societies. The policy sciences followed the changes in social and, above all, political organization that accompanied new production technologies and stable patterns of human settlement. For example, early Mesopotamian legal codes were a response to the growing complexity of fixed urban settlements, where policies were needed to regulate the distribution of commodities and services, organize record keeping, and maintain internal security and external defense. A growing consciousness of relations between knowledge and action fostered the growth of educated strata that specialized in the production of policy-relevant information. These "symbol specialists," as Harold Lasswell called them, were responsible for early forms of policy forecasting. Symbol specialists were expected to foresee crop yields at the onset of the planting season or predict the outcomes of war. Because these early producers of policy-relevant knowledge used mysticism, ritual, and the occult to forecast the future, their methods were unscientific by present-day standards.

Then as now, however, policy-relevant knowledge was ultimately judged according to its success (or failure) in shaping better policies, not simply because particular methods were used to produce it. Even the ancients seemed to know what some contemporary analysts forget—when methods are used for ritualistic purification, political persuasion, or symbolic legitimation, analysts and their clients eventually must face the decisive test of performance, namely, the pragmatic test of whether the use of specialized procedures produces better policies.

Over the centuries, there have been preeminent individual producers of specialized knowledge, for example, Aristotle in his role as tutor to Alexander the Great. However, entire classes of educated persons would later influence policy making in Europe and Asia. In the Middle Ages, the gradual expansion of urban civilization brought with it an occupational structure that facilitated the development of specialized knowledge. Princes and kings recruited policy specialists to provide advice and technical assistance in areas where rulers were least able to make effective decisions: finance, war, and law.

The age of the Industrial Revolution was also that of the Enlightenment, a period in which a belief in human *progress* through science and technology became an ever more dominant theme among policymakers and their advisers. The development and testing of scientific theories of nature and society gradually came to be seen as the only objective means for understanding and solving social problems. For the first time, policy-relevant knowledge was produced according to the canons of empiricism and the scientific method.

The 19th-Century Transformation

In 19th-century Europe, producers of policy-relevant knowledge began to base their work on the systematic recording of *empirical data*. Earlier, for several thousand years, there was an essential continuity in methods for investigating and solving social, economic, and political human problems. If evidence for a particular point of view was provided, it was typically based on appeals to religious authority, ritual, or philosophical doctrine. What was new in the 19th century was a basic change in the procedures used to understand society and its problems, a change reflected in the growth of empirical, quantitative, and policy-oriented research.

The first censuses were conducted in the United States (1790) and England (1801). It was at this time that statistics ("state arithmetic") and demography began to develop as specialized fields. The Manchester and London Statistical Societies, established in the 1830s, helped shape a new orientation toward policy-relevant knowledge. Organized by bankers, industrialists, and scholars, the societies sought to replace traditional ways of thinking about social problems with empirical analyses of the effects of urbanization and unemployment on the lives of workers and their families. In the Manchester Society, an enthusiasm for quantification was coupled with a commitment to social reform or "progress of social improvement in the manufacturing population." The London Society, under the influence of Thomas Malthus (1766–1834) and other academics, took a more disinterested approach:

> The Statistical Society will consider it to be the first and most essential rule of its conduct to exclude carefully all opinions from its transactions and publications—to confine its attention rigorously to facts—and, as far as it may be found possible, to

> facts which can be stated numerically and arranged in tables. (Statistical Society of London, 1838, p. 70)

The London and Manchester societies used questionnaires to carry out studies, and paid "agents" were the counterpart of today's professional interviewer. There were similar developments in France, Germany, and the Netherlands.

A preeminent contributor to the methodology of social statistics and survey research was Adolphe Quetelet (1796–1874), a Belgian mathematician and astronomer, who was the major scientific adviser to the Dutch and Belgian governments. In contemporary texts on designing social and economic surveys, there are many topics that were addressed by Quetelet: questionnaire design; data collection, analysis, and interpretation; data organization and storage; and identification of the conditions under which data are collected. In the same period, Frederic Le Play (1806–1882) wrote *Les Ouvriers Europeans* (The European workers), a detailed empirical investigation of the family income and expenditures of European workers in several countries. In Germany, Ernst Engel (1821–1896) sought to derive laws of "social economics" from empirical data expressed in statistical form.

In England, the work of Henry Mayhew and Charles Booth, who studied the life and employment conditions of the urban poor in natural (what we now call "field") settings, is representative of the new empirical approach to the study of social problems. Mayhew's *London Labour and the London Poor* (1851) described the lives of the laborers, peddlers, performers, and prostitutes who constituted London's urban underclass. In writing *Life and Labour of the People in London* (1891–1903), Booth employed school inspectors as key informants. Using what we now call participant observation, Booth lived among the urban poor, gaining firsthand experience of actual living conditions. A member of the Royal Commission on the Poor Law, he was an important influence on the revision of policies on old-age pensions. Booth's work also served as something of a model for policy-oriented research in the United States, including the *Hull House Maps and Papers* (1895) and W. E. B. Dubois's *The Philadelphia Negro* (1899), both of which sought to document the scope and severity of poverty in urban areas.

Dominant social groups valued policy-oriented research as a means to achieve political and administrative control. In the sphere of factory production, for example, the political organization of work preceded scientific and technological developments that later culminated in efficiency-enhancing machinery and the specialization of tasks. Methods of empirical, quantitative, and policy-oriented analysis were a product of the recognition by bankers, industrialists, politicians, and the Victorian middle class that older methods for understanding the natural and social world were no longer adequate. The key questions of the day were practical and political: How much did members of the urban proletariat need to earn to maintain themselves and their families? How much did they have to earn before there was a taxable surplus? How much did they have to save from their earnings to pay for medical treatment and education? How much should capitalist owners and the state invest in day care facilities so that mothers might put in an effective day's work? How much investment in public-works projects—sanitation, sewage, housing, and roads—was required to maintain adequate public health standards, not only to maintain a productive workforce but also to protect the middle and upper classes from infectious diseases cultivated in urban slums?

The 20th Century

An important feature of the 20th century, as compared with the 19th, is the *institutionalization* of the social sciences and social professions. Policy-oriented social scientists played an active role in the administration of Woodrow Wilson, particularly during World War I. Later, under President Herbert Hoover, social scientists carried out major social surveys, *Recent Economic Trends* and *Recent Social Trends*. The largest influx of social scientists into government came, however, with Franklin Roosevelt's New Deal. Social scientists staffed the numerous new agencies established during the Roosevelt administration. During World War II, military and civilian agencies used social scientists to investigate problems of national security, social welfare, war production, pricing, and rationing. The activities of agencies such as the Office of Strategic Services were continued after the war in the form of the Research and Development Board (subsequently RAND) and numerous other policy think tanks.

The landmark work in the development of the policy-oriented social sciences was published in

1951 by the political scientists Daniel Lerner and Harold D. Lasswell. *The Policy Sciences: Recent Developments in Scope and Method* was the first systematic effort to develop an explicit policy orientation within the social sciences. The "policy sciences" were not confined to testing theories; they also had a fundamentally practical orientation. Their purpose was not only to provide a basis for making efficient decisions but also to provide knowledge relevant to the practice of democracy and the realization of democratic values.

Specific methods and techniques of policy analysis grew out of engineering, operations research, and applied mathematics. The idea of "analysis" came to be associated with the decomposition of problems into smaller components; for example, problems of national defense were decomposed into discrete policy alternatives (e.g., nuclear warheads, manned bombers, and conventional ground troops), the benefits and costs of which could be estimated.

This turn toward a more technical perspective was accompanied by the growing influence of nonprofit research organizations ("think tanks") such as the RAND Corporation, which fostered the spread of cost-effectiveness analysis and related techniques to academics as well as policymakers. The idea was to "purchase" national security in the most efficient manner. It is noteworthy that as much as 90% of all research funded by governments, nonprofit organizations, and the private sector is applied research on practical problems.

By the 1970s, many social science disciplines had established institutions expressly committed to policy-oriented research. These include the Policy Studies Organization (Political Science), the Society for the Study of Social Problems (Sociology), and the Society for the Psychological Study of Social Issues (Psychology). In the 1980s, the process of institutionalizing policy-oriented social science was carried a step further by the creation of multidisciplinary professional associations, such as the Association for Public Policy and Management, which holds annual research conferences and publishes a journal of record, the *Journal of Policy Analysis and Management*. The new journal brought a more technical focus than mainstream policy journals, including *Policy Sciences*, the *Policy Studies Journal*, and *Policy Studies Review*. In addition to the mainstream journals were hundreds of others that focused on specific issues involving health, welfare, education, criminal justice, education, science and technology, and other areas.

The 21st Century

In the first decade of the 21st century, there was an increasing recognition that the complexity of problems faced by governments requires the systematic use of the social sciences to develop policies and assess their consequences. The call for *evidence-based policy making* in the United Kingdom, the United States, and the European Union is a response to this complexity; it is also a recognition that ideological, religious, and political influences—usually hidden and lacking in transparency—have exerted a harmful effect on policy making in areas ranging from health, education, and welfare to national security and the environment. Evidence-based policy making in the United Kingdom and the European Union takes several forms, including *regulatory impact assessment*, which refers to the use of social science analyses to examine the benefits, costs, risks, and consequences of policies before they are adopted. In the United States, evidence-based policy has been promoted by leading program evaluators and policy analysts, who founded the Coalition for Evidence-Based Policy of the Council for Excellence in Government. More than 40 countries participate in the Campbell Collaboration, a professional and scientific organization that promotes evidence-based policy. The evidence-based policy movement testifies to the continuing commitment to policy applications of the social sciences.

Political Psychology

Political psychology is an interdisciplinary field concerned with research questions that lie at the intersection of psychology and political science. Lacking one widely accepted definition, political psychology might be conceptualized as the study of "how people think about politics and how this cognitive process affects their political behavior" (Monroe et al., 2009, p. 878). We can define political psychology broadly as the study of how patterns of political thinking, feeling, and identity interact to influence political choice and political behavior.

Historical Overview

Political psychology has a long, if informal, tradition. Thinkers from the Greek philosophers to Confucius were fascinated by problems of politics in relation to human nature. Greek mythology and fables captured concepts such as sour grapes. Later political theorists such as Niccoló Machiavelli emphasized the importance of appearance for a political leader. Historians such as Alexis De Tocqueville drew attention to the political importance of psychological phenomena such as the revolution of rising expectations or the feeling of relative deprivation.

The origins of political psychology as a modern scientific field, however, tracks to early- to mid-20th-century scholars such as the German philosopher Theodor Adorno (one of the founders of the Frankfurt school), the American psychologist Gordon Allport, and the American political scientist Harold Lasswell, whose work blended psychology with political behavior to understand the outbreak of wars, political movements, and mass violence. Political psychology became a separate field only in the mid 20th century, in response to dissatisfactions with the behavioral movement. As this new field developed, it contained research that clusters into many related topics: the nature and acquisition of political belief systems, the psychology of leadership and decision making, the cognitive processes involved in warfare, group violence and terrorism, the individual as political actor, political movements, political alignments and structures, intergroup relations, political processes, foreign policy and group think, government and self-esteem, and identity and group conflict.

The first handbook of political psychology, edited by Jeanne Knutson, suggested that when constructing work in political psychology, scholars need to focus attention on the interaction of political and psychological phenomena, to ask how responsive and relevant political psychology is to societal problems and whether context makes a difference for the problems being analyzed. Furthermore, we need to emphasize the process as well as the outcome and to be tolerant of multiple methods for gathering and analyzing data. As a contemporary definition, then, political psychology might be appropriately considered both an approach and a perspective on politics and political life, a way to understand politics that emphasizes the workings of the human mind as it influences human political behavior.

Political psychology itself exists at the nexus of political science and psychology, with scholars of political psychology drawn chiefly from these two disciplines but with important contributions from sociologists, psychiatrists, and scholars of communication, education, and other disciplines that enrich the field. As a field, political psychology utilizes multiple methodological techniques, from surveys and experiments to narratives, interviews, and content analyses. Recent work from neuroscience and biology has enriched and broadened the methodological field.

The Discipline

In contrast to its deep historical roots, solidifying political psychology as an independent discipline began comparatively recently. The field's international organization, the International Society of Political Psychology, was founded in 1978, and the first issue of its journal, *Political Psychology*, appeared in 1979. Less than a dozen graduate programs currently offer degrees or formal certificates in political psychology, though considerably more offer graduate-level courses. The field differs in emphasis, with American schools reflecting a more behavioral approach than European and Australian schools.

Empirical investigation into the nature of political psychology as a discipline uncovered a number of broad topics on which political psychologists initially

focused; chief among these are political beliefs and ideology, personality, cognition, and international relations/intergroup conflict. Scholars such as Lasswell located political psychology's roots in pioneering work on psychopathology and politics; Adorno and his colleagues highlighted the authoritarian personality; and Robert Lane emphasized the origins of political belief systems, especially research on values/ideology and on personality, including work on the psychological correlates of political belief systems. James Sidanius and Felicia Pratto employed work on politically relevant personality traits to develop social dominance theory, and scholars such as Rose McDermott (also a contributor to this encyclopedia) drew on recent work in neuroscience to suggest possible biological bases for political attitudes and the effects of gender differences on decision making. Research by George Lakoff on cognition encompassed work on perception, memory, decision making, and other mental processes as they relate to political activity; it was expanded by Milton Lodge and Kathleen McGraw to explain vote choice and candidate evaluation. Robert Jervis's research in international relations and intergroup conflict encompasses studies of foreign policy decision making. Ervin Staub, Janusz Reykowski, and Kristen Monroe described the psychology of war and genocide, and Gerald Post used psychoanalytic models to explain terrorism. Henri Tajfel and John Turner developed social identity theory and self-categorization theory, which revolutionized our understanding of the psychological roots of the prejudice and discrimination that drive group conflict. Research on the psychology of leaders is a perennial favored topic of political psychologists, from Alexander and Juliette George's classic psychobiography of Woodrow Wilson to more contemporary analyses of the personalities, cognitive traits, and leadership styles of leaders from Wilson and Bill Clinton to Saddam Hussein done by scholars such as David Winter, Rose McDermott, and Gerald Post.

A recent focus of study has been the role of emotion in political decision making and behavior, as found in work by George Marcus. The field itself continues to evolve, with new and exciting work being done on a wide range of topics, such as how migration and multiculturalism influence politics, including consideration of enmity among groups, and how this relates to prejudice, civic and political participation, nationalism, and right-wing extremism. The increasing influence of religion—especially fundamentalism—has spurred exciting work on group identity and political violence and how this relates to religion and civic inclusion/participation. The use of narrative as a tool and how it can yield insight into the workings of the human mind is an especially rich area, as qualitative interpretive analysis is being wedded with sophisticated computer programs from computer science and linguistics to provide insight into the cognitive processes underlying political life.

Popper's Philosophy of Science

Traditional philosophies of science going back to Francis Bacon in the 17th century presented science as natural and infallible. It was believed that careful attention to the inerrant methods of science would result in proven truth. This promise clashed with

well-known facts: Science emerged late in human history, against a background of diverse superstition and ignorance; hence, how could it be natural? Its teachings changed over time, and scientists were far from united on all issues. So, far from being infallible, it was neither unified nor stable. Bacon's response was that pride and sloppy mental habits explained our late achievement of science, and their persistence explained the lack of consensus. The Austro-British philosopher Karl Popper (1902–1994) rethought the whole issue by paying close attention to the greatest scientific revolutionary of the 20th century: Albert Einstein. Einstein said that science was the work of the imagination in the service of explaining both the facts and the success and failure of previous scientific explanations of the facts. Popper's key move was to treat the diversity and disputatiousness of science not as a vice but as a virtue: It was that which enabled scientific objectivity and the pursuit of truth. Science required the social discipline of institutions because its critical method did not come naturally, and dispute and argument were needed to test its claims.

Popper's General View of Scientific Method

Popper offered a social rather than a natural account of science as driven by imagination and checked by intersubjective criticism (especially experimental). Science emerges from certain sorts of disciplined and institutionalized social interactions in which participants sometimes hit on good ideas, most of which are sooner or later shown to be false. Science was far from infallible; Popper viewed its fallibility as part and parcel of human fallibility.

Popper's philosophy of science described the logical situation in science as follows. The traditional philosophical view of science as proven truth totally depended upon solving the problem of induction. The problem of induction in Popper's formulation reads thus: How is (theoretical) learning from (particular) experience possible? The 18th-century Scottish philosopher David Hume had shown that solving the problem of induction was logically impossible—hence his ensuing skepticism about the possibility of inductive logic. Hume mistrusted his own results and suggested that we carry on as though nothing were amiss. Einstein said that he had learned from Hume that we can both admire our predecessors and try to improve upon them. Popper elaborated on this significantly and argued that deductive logic, which was not subject to Hume's strictures on induction, was sufficient to account for science, provided we give up all claims to its being infallibly proven and, instead, rest content with the progress that the elimination of error provides. Popper's alternative approach pictured scientists conjecturing theoretical solutions to problems (in well-defined problem-situations) formulated so that testable consequences can be deduced from them. Testing these consequences by observation and utilizing deductive logic, we may be led to contradiction between theory and observation report. In such a case, guessing that our deductions have been sound, and given that the observable consequences contradict our theories or conjectures (premises), we can infer, by deductive logic, that the premises (as a body) are false. The next challenge is to see if the source of error can be narrowed down and isolated. Each stage is conjectural, including all the deductive inferences we make.

The deductive logic of scientific explanation consisted, then, of a set of premises that included theories—that is, general theoretical conjectures—plus particular conjectures about the entities or processes under discussion (initial conditions). From these premises, statements were deduced that describe what is to be expected (predictions). If these latter are simple and precise enough to undergo empirical testing, then that should be undertaken. If the test result is that what is observed conforms to what was predicted, then we learn only that this test did not refute the package of premises. If what is observed contradicts what was predicted, then we can conjecture various possible sources of error, including human error, as well as the possibility that some statements of theory or of initial conditions, or of both, are mistaken. Errors bring our theories into contact with the world. By discovering that they are mistaken, we learn that the world is not as we were conjecturing it to be but otherwise. This does not tell us how the world is but, rather, how it is not. Our theories have bumped into reality.

Criticism and Rebuttals

Some of Popper's critics accuse him of being a thoroughgoing skeptic, a Bad Thing for many philosophers. Others said that deductions rested on induction and so succumb to Hume's criticism. On the contrary, Popper replied, theoretical premises are conjectured, not inferred. He reaffirmed

Bacon's assertion that there is a logical asymmetry between falsification and verification: No amount of evidence allows an inductive inference to a generalization; but a single conflicting instance calls a generalization into question. Nonetheless, such moves remain conjectural, not unerring. Popper thus offered no escape from the reality of human fallibility but offered, instead, comfort in the capacity error offers us to widen our horizons. Scientific success was a matter of imagination, guesses, and tests and not of accumulated evidence toward proof. Pressed to say why science deserved credence, he responded that it did not and that all we knew about severely tested theories was that we had done our best to test them. He did once try to devise a quantitative theory of approximation toward the truth, but his effort was quickly shot down, and he reverted to the qualitative one.

Applications to Social Science

Before World War II, few philosophers and scientists were familiar with Popper's breakthrough. The exceptions included two economists, Terence Hutchison and Friedrich Hayek. Events in Europe in the 1930s sent Popper into permanent exile from his native Austria. He turned his attention to problems of society and politics and discovered there important connections with scientific method. Politics has always been understood as matters for debate and compromise, but there was no coherent methodology for their pursuit. Methodology was infallibilistic; and political thinking was utopian. Popper argued that if science was fallible, then so of course was thinking about society and politics. Utopianism offers solutions to all problems. It thus assumes that we know (or could know) even the unintended outcomes of all actions and find ways to avoid the undesirable ones. It is not hard to show this assumption to be mistaken. Instead of trying to establish politics on a utopian vision, Popper developed a minimal account of democratic and rational politics that closely followed his fallibilist account of science.

Paralleling his emphasis on testability that he connects to falsifiability and falsification, he characterized a free society as one where the ruled could replace the rulers without violence. He insisted that bad government was a much more urgent and serious problem than good government. Bad government played havoc with people's lives; good government attempted to enhance lives. The reduction of suffering, he taught, is more morally urgent than the betterment of life's chances. He found ranged against this simple and intuitive view the majority of philosophers and other intellectuals, who, he claimed, have a tendency to worship power and hence rationalize it. High on his indictment sheet of enemies of freedom were Plato, Aristotle, Hegel, Marx, and many lesser figures.

Popper passionately advocated the open society. He characterized it as one that enabled political participation of all adults; minimized restrictions on individuals, including allowing free exit; encouraged criticism and debate about public policy; and engaged in a good deal of state intervention in order to protect weaker and disadvantaged citizens from avoidable suffering. Such a social order needed social science in order to document social conditions and the effects of government policies. Such social science needed to be grounded in moral concern and responsibility for the alleviation of avoidable suffering. It needed to be conducted with a sense of urgency, since avoidable suffering was intolerable. Otherwise, sciences of society, though similar to natural science in comprising conjectures and refutations in a framework that encourages criticism, differ from it in having to take account not just of morality but also of rationality, that is, people's capacity to suit means to ends. It also must take into account the "Oedipus effect," that is, self-fulfilling prophecies, or looping effects, namely, altered courses of action, and hence outcomes, due to actors' changing knowledge and ideas.

Friedman and Kuhn's Alternatives

When Popper translated and published his *magnum opus* on philosophy of science in 1959, it was well received by philosophers of science and caused ripples in economics. Hayek had long said that he followed Popper; so had Hutchison and Robbins. Initial enthusiasm was followed by worried retreat. The enthusiasm was because Popper offered a clear criterion of scientific character, testability, so economists could legitimate their work as science by developing testable theories and testing them. Immediately, mathematical economists and others challenged this criterion on the grounds that their abstract models were a priori intellectual structures, not testable generalizations. Milton Friedman in 1953 had already offered a way out: Treat economic models instrumentally and judge them by their fruitfulness and

predictions. He ascribed to the neoclassical model of practical success. His was a philosophy of science variously called pragmatism and instrumentalism, which sacrificed truth as an aim and replaced it with *usefulness*. It fails as soon as we raise the question "Are claims of success true?" Popper, however, allowed that instrumentalism could be held without inconsistency, but he argued that the aim of science was to seek true explanations, not just useful knowledge. The latter was too narrow to capture the enterprise of scientists such as Galileo, Newton, and Einstein.

Not long after Popper's translation appeared, the American historian and philosopher of science Thomas S. Kuhn published his *The Structure of Scientific Revolutions*, in which he argued from historical materials that science differed significantly from the picture presented by Popper's philosophy. Kuhn took his inspiration from "Big Science," that is, science in large organized research units, often publicly funded and more or less modeled on the Manhattan Project for building the atomic bomb. Instead of valuing disputatiousness, such science valued consensus. In fact, if there was no consensus, there was no science, at least not efficient science as we know it. The process of achieving consensus was described by Kuhn in political terms. He described disputatiousness in politico-psychological terms as power-seeking persuasion. Adherents of a theoretical paradigm defended it as any political establishment will. But there comes a time when its anomalies create social instability and scientists cast around for an alternative. When consensus fails, research is at best pre- or proto-science. The next candidate for consensus emerges from the ranks of the leadership, or else Young Turks overthrow the old guard and establish the new paradigm themselves. Once consensus develops again, science resumes as researchers smooth out minor anomalies, try better to formulate the tenets of the new paradigm (especially by writing textbooks), and generate research programs that employ it.

Social scientists found Kuhn's model much more appealing than Popper's, since it had no normative dimension, or the normative dimension was submission to authority, as you will; it is naturalistic: Science is what scientists do. If social scientists differed from natural scientists in their lack of consensus, that was a difference, not a deficiency. (Indeed, Kuhn did not claim that his view applies to social science.) Popper and Kuhn (and their followers) had a number of sharp exchanges. Kuhn was equivocal about whether science pursued truth and made progress. Popper allowed that much of Kuhn's description of science was ethnographically accurate; this was because Big Science had become an uncritical, dogmatic, and rent-seeking enterprise that endangered the very existence of science as a self-critical quest for truth. Popper's model was Einstein and his theories of special and general relativity. Popper was a theorist of the best science being always spoiling for a new and earth-shaking revolution. Kuhn was a theorist of the bureaucratization of science, of its settling down into routine, what he famously dubbed "Normal Science." Kuhn thought puzzle-solving within an unquestioned paradigm was the state in which science performed best. Popper wondered where the big, world-shaking, exciting ideas would come from. Kuhn sought consensus; Popper relished dissensus. Kuhn's model was of conformity and productivity; Popper's was of rebellion and challenge. Yet the choice between them is not a matter of mere preference: Science is a central aspect of modern society, and its description is true or false. Kuhn did not deny Popper's characterization of some science as revolutionary but claimed that it was limited to periods of crisis, when it gets inefficiently mixed up with less respectable intellectual activities. He then admitted that there are big revolutions and small. This amounts to capitulation to Popper.

Positivism, History of

Generally speaking, positivism is a label given to any philosophical position that embraces scientism, which is the view that all genuine knowledge is obtained by combining empirical observation and logical reasoning in a manner best exemplified by the natural sciences.

The idea of a "positive philosophy" was first formulated in the early 19th century by Auguste Comte, but its best-known version is Vienna Circle logical positivism, developed in Germany and Austria in the mid 20th century. The story of positivism is usually told backward, starting with the rise and fall of logical positivism, contrasting it with classical positivism, and concluding that our century is largely post-positivist. However, positivism is not entirely a phenomenon of the past; hence, one learns more by starting with what all positivists share.

All positivists agree that the most important fact about the modern world is the *success of science*. Only science obtains truly objective knowledge, independent of ideology and sociohistorical contingency. The reason for this success is the use, in every science, of some variant of a single method; hence, positivist philosophers must be epistemologists of science, articulating and defending this method. All positivists assume that the fundamental aim in acquiring objective knowledge is improvement of the human condition. Logical positivists deny that they espouse any philosophical doctrines and define their task entirely in epistemological terms, but this obscures the fact that their view, as much as their predecessors', is the intellectual expression of a broadly secular, antispeculative, science-promoting, politically reformist position. All positivists agree with Comte's slogan (emblazoned on Brazil's flag): Order and Progress: From knowledge of the natural and social order of things comes progress in successfully dealing with them.

Positivists also hold that this slogan remains true even when the "knowledge" embraced is prescientific. Thus, a world superstitiously understood leads to lives superstitiously lived. Comte offers an elaborate "Law of Three Stages" to explain this point. Under the right conditions, human intelligence goes through three developmental periods: (1) the theological (superstitious), (2) the metaphysical (ideological), and (3) the positive (scientific). This law characterizes human development from several angles: individual intellectual growth, world history, the rise of each science, and the emergence in human societies of religious, military, industrial, and legal activities suited to each stage.

Overall, Comte's law tells the story of our failure to explain reality in terms of the supernatural or natural powers hidden behind what we experience. Yet from these very failures, we learn to limit our search for knowledge to what we can actually observe. Every positivism is thus some species of *empiricism*. Reason should not be a slave to feelings or faith (as in theology); it cannot be its own authority (as in metaphysics). Mature minds abandon all efforts to solve life's ultimate mysteries (Why are we here? What happens after death?), confine their quest for knowledge to the study of observable phenomena, and develop a hierarchy of sciences—the last and most complex being *sociology* (a term Comte invented), which has special importance. It is certainly good to have power over material nature, but knowledge of ourselves as social beings facilitates an even higher purpose: establishing truly peaceful, flourishing societies.

Later positivists rejected Comte's law, in its details and as an empirical theory, but much of his "positivist spirit" passed through to them, even as they denied it. Émile Durkheim's early writings and John Stuart Mill's *Auguste Comte and Positivism* foreshadow the rigorous but still implicitly Comtean revisionism of logical positivism. They praise Comte for conceiving science methodologically, for promoting the idea of a distinctively "social" science and for extending the method of the natural sciences to it, and for appealing to the authoritative character of scientific knowledge to press for material and social reform. But they deem Comte's account of the rise of the scientific era irrelevant now that it has arrived and condemn his epistemology of science for its imprecision. Against the background of this critical appropriation, Comte's 20th-century progeny often rebranded themselves. Logical they surely are; but since they see history as philosophically irrelevant and base their knowledge

claims on science-minded observation strictly, not loosely, they are really logical "empiricists," not just positivists.

In its heyday, logical empiricism's hostility toward history (and the humanities and, of course, metaphysics), its formal-logical "rational reconstruction" of scientific reasoning, its narrow conception of "meaningful" utterances, and its picture of science as essentially cognitive and neutral constituted the gold standard for English-language philosophy—what was to become "analytic philosophy."

But by the 1970s, all its main features were being rejected by both scientists and philosophers. Yet if rejection of its explicit program is today virtually complete, the views that have replaced it are not entirely post-positivist. The legacy of classical positivism survives (a) in the widespread privileging of science and its technologies, (b) in the idea that human practices are at their best when they are known scientifically and follow sciencelike advice, (c) in the secular-progressivist construal of political economies, and (d) in the assumption that the whole drift of world history is necessarily toward the completion of what "we" call the "developed" world.

Postcolonial Studies

The entry introduces the blossoming, transdisciplinary, recent field of postcolonial studies, critically reviews its main elements and theoretical presuppositions, and shows its relevance to a renewed type of social science.

Postcolonial (often "post-colonial") studies deal with the effects of colonization on cultures and societies. Unlike *colonialism*, the term *postcolonialism* is of recent provenance, emerging in the late 1970s to describe a range of literary and cultural analyses of colonized and formerly colonized societies. As originally used by historians after World War II in terms such as the *postcolonial state*, "postcolonial" had a chronological meaning, designating the postindependence period. However, from the late 1970s, "postcolonial studies" has referred to the analysis by cultural critics of the various social, political, and cultural effects of colonization. The term *postcolonial* now describes neither a historical period nor a fixed range of societies but is best understood as a discourse generating a specific reading practice.

Origins

The study of the controlling power of representation in colonized societies had begun in the 1950s with the work of Frantz Fanon, and it reached a climax in the late 1970s with Edward Said's *Orientalism*. This study led to the development of colonialist discourse theory in the work of critics such as Gayatri Chakravorty Spivak and Homi Bhabha, although the actual term *postcolonial* was not employed in these early studies of the power of colonialist discourse to shape and form opinion and policy in the colonies and metropolises. While the analysis of the effects of colonial representation were central to

the work of these critics, the term *postcolonial* itself was first used to refer to cultural interactions within colonial societies in literary circles (see, e.g., the 1977 special issue of *New Literature Review*—the work of Ashcroft, Cotter, Docker, & Nandan). This was part of an attempt to politicize and focus on the concerns of fields such as Commonwealth literature and the study of the so-called New Literatures in English, which had been initiated in the late 1960s. *The Empire Writes Back* by Ashcroft, Griffiths, and Tiffin offered the first systematic account of the theoretical issues generated by postcolonial literatures and initiated the field that became known as *postcolonial literary studies*. The term has subsequently been widened to the field of *postcolonial studies*, which analyzes the political, linguistic, social, and cultural experience of societies that were former European colonies.

Postcolonialism and Globalization

The remarkable rise of postcolonial studies in the 1990s was partly due to the fact that by the late 1980s the world was hungry for a language to describe the diversity of cultures and the intersecting global range of cultural production. Postcolonial theory provided that language, a way of talking about the engagement of the global by the local, particularly local cultures, and, most importantly, provided a greatly nuanced view of globalization, developed from its understanding of the complexities of imperial relationships. According to critics such as Simon Gikandi, a substantial overlap existed between postcolonialism and globalization studies in that they shared at least two important elements: Both kinds of studies seek to explain forms of social and cultural organization that aim at transcending the boundaries of the nation-state, and they are also both concerned with offering new standpoints for understanding cultural flows that a homogeneous Eurocentric narrative of development and social change cannot explain.

It can be argued that the language of postcolonial studies drove a cultural turn in globalization studies in the 1990s, and it did this for three reasons. First, the systematization of postcolonial theory occurred at about the same time as the rise to prominence of globalization studies in the late 1980s. Second, it was around this time that literary and cultural theorists realized that debates on globalization had become bogged down in the classical narrative of modernity. Third, it became clear that there were many globalizations and that, far from the homogenizing downward pressure of economic globalization and the Washington consensus, a circulation of local alternatives could be seen to affect the nature of the global. It was through *cultural* practices that difference and hybridity, diffusion and the imaginary, concepts that undermined the Eurocentric narrative of modernity, were most evident.

Disciplinary Contests

The term *postcolonialism*, however, was a potential site of disciplinary and interpretative contestation almost from the beginning, especially the implications involved in the signifying hyphen or its absence. The heavily poststructuralist influence of the major exponents of colonial discourse theory—such as Edward Said (and Michel Foucault), Bhabha (and Louis Althusser and Jacques Lacan), and Spivak (and Jacques Derrida)—led many critics, concerned to focus on the material effects of the historical condition of colonialism, as well as on its discursive power, to insist on the hyphen to distinguish postcolonial studies *as a field* from colonial discourse theory per se, which formed only one aspect of the many approaches and interests that the term *postcolonial* sought to embrace and discuss. The hyphen has also been used as a reminder that postcolonialism is not a master discourse but a plethora of overlapping discourses concerned with the cultural effects of imperialism.

While this distinction has been largely superseded, the term *postcolonial studies* has come to refer to the wide and diverse analysis of European territorial conquests, the various institutions of European colonialisms, the discursive operations of empire, the subtleties of the construction of the subject in colonial discourse as well as the resistance of those subjects, and, most importantly perhaps, the differing responses to such incursions and their contemporary colonial legacies in both pre- and postindependence nations and communities. While postcolonial studies have tended to focus on the cultural production of such communities, they have expanded to include historical, political, sociological, and economic analyses, as these disciplines continue to engage with the impact of European imperialism upon world societies.

Historical Boundaries

The prefix *post* in the term also continues to be a source of vigorous debate among critics. The simpler

sense of *post* as meaning "after" colonialism has been contested by a more elaborate understanding of the working of postcolonial cultures that stresses the articulations between and across the politically defined historical periods of precolonial, colonial, and postindependence cultures. *The Empire Writes Back* used the term to refer to all the literature written after colonization. Thus, the term *postcolonial* is best understood as a reading practice that analyzes the continuing resistances, appropriations, and transformations of dominant ("imperial") discourses, institutions, and methodologies by colonized and formerly colonized societies. As a result, further questions have been asked about what limits, if any, should be set round the term. Aijaz Ahmad complains, for instance, that when the term *colonialism* can be pushed back to the Incas and forward to the Indonesian occupation of East Timor, then it becomes "a transhistorical thing," something that is always present but also always in a process of dissolution in some parts of the world. It is clear, however, that *postcolonial studies*, as the term has been employed in most recent accounts, have been primarily concerned to examine the processes and effects of, and reactions to, European colonialism from the 16th century up to and including the neocolonialism of the present day.

Locality and Materiality

An equally fundamental constraint is attention to precise location. Colonialism itself is much more complex and problematic than it seems at first: It is by definition transhistorical and unspecific, and it is used in relation to very different kinds of historical oppression and economic control. Every colonial encounter or "contact zone" is different, and each "postcolonial" occasion needs, against these general background principles, to be precisely located and analyzed for its specific interplay. A vigorous debate revolved around the potentially homogenizing effect of the term in the early 1990s. The effect of describing the colonial experience of a great range of cultures by this term, it was argued, is to elide the differences between them. However, there is no inherent or inevitable reason for this to occur. The materiality and locality of various kinds of postcolonial experience provide the richest potential for postcolonial studies, and they enable the specific analysis of the various effects of colonial discourse.

The theoretical issues latent in these two fundamentals—materiality and location—lie at the basis of much of the dispute over what the term *postcolonial* refers to and what it should or should not include. Yet, despite these disputes and differences, signs of a fruitful and complementary relationship between various postcolonial approaches have emerged in recent work in the field. Whether beginning from a basis in discourse theory or from a more materialist and historical reading, most recent discussions have stressed the need to retain and strengthen these fundamental parameters in defining the idea of the postcolonial. As critics like Robert Young have indicated, the crucial task has been to avoid assuming that the reality of the historical conditions of colonialism can be safely discarded in favor of 'the "fantasmatics of colonial discourse." On the other hand, as Young also warns, although the totalizing aspects of discourses of the postcolonial are of real concern, it is necessary to avoid a return to a simplified form of localized materialism that refuses entirely to recognize the existence of general discourses of colonialism and their effect on individual instances of colonial practice.

The challenge for many postcolonial critics and theorists lay in the need to strike a proper balance between the specific cultural and social conditions of colonized and formerly colonized peoples and the larger theoretical frameworks in which the cultural practices of those societies are analyzed. Not every colony will share every aspect of colonialism, nor will it necessarily share some essential feature since, like any category, it is—to use Ludwig Wittgenstein's metaphor—a rope with many overlapping strands. Despite the material differences of particular postcolonial peoples, each must deal with a common discursive, social, or political media provided or imposed by colonialism itself. Postcolonialism in general is an engagement, in all its many varieties, with these media. For instance, the ways in which postcolonial peoples have appropriated and transformed metropolitan languages may differ in particular instances, but the general political processes by which this appropriation occurs show the continuing value of broader postcolonial frameworks.

Diversity of Themes

A major feature of postcolonial studies has been their ability to analyze a vast array of cultural developments: race and racism, expressions of anticolonial nationalism, the paradoxical dissolution of the idea of nation along with the continuous persistence of national concerns, the question of language and

appropriation, the question of the transformation of literary genres, the question of ethnicity and its relation to the state, the increasing mobility of formerly colonized populations, and the impact of diasporas upon the social complexion of metropolitan centers. Since their emergence in the late 1980s, postcolonial studies have widened their reach to include issues such as the place of translation; the space of the sacred; the field of biopolitics, ecological theory, and animal rights; the role of the city; and, most importantly, the relation between local communities and global influences. This relationship is one for which postcolonial studies have long been prepared, both from their involvement in the cultural turn in globalization studies and from their long interest in the relation between local differences and the broader global impact of imperialism. An aspect of this outward movement is the rapidly growing interest in the mobility of formerly colonized populations, the movement of refugees and asylum seekers, and the characteristics of diasporas of various ethnic groups.

Thus, the future of the field seems set to move further out of the realm of classical imperialism and its cultural and political effects and into a growing investment in globalization studies, diaspora, transnationalism, and cosmopolitanism. The historical experience of imperial and colonial relations appears to provide valuable insights into the agency of local communities and the cultural production of subaltern, marginalized, and exiled peoples in a global era.

Postindustrial Society

There are perhaps as many definitions of postindustrial society as there are of industrial society. Yet at the heart of all definitions has been the idea that the evolution of industrialism was in the process of undermining its traditional classic forms. In this sense, speculations on postindustrial society share many similarities with subsequent discussions and debates over *post-Fordism* and *postmodernism.* The concept and theory of postindustrial society inherited the classical language of sociology, forged in the cultural trauma surrounding the birth of modern industrial capitalism. It invoked the language of a Great Divide and portrayed sociology as the witness, harbinger, and prophet of a new, unborn age.

The continuing relevance of discussions of postindustrial society does not rest so much in its somewhat dated 1970s and 1980s analysis of the rise of a knowledge-based service society, the characteristics

of which are outlined in the first part of this entry. As outlined in the second section, it lies, rather, in its expression and embodiment of a particular grand narrative, portraying a particular view of present society as on the brink of a radically new era. The weaknesses of this discourse are addressed in the conclusion.

The Earlier Analysis

The idea of postindustrial society was popularized in academic circles by Daniel Bell in his book *The Coming of Post-Industrial Society*. Bell gave particular significance to the transition from a goods-producing economy to a service economy; the increasing predominance of white-collar and professional occupations; the development of electronics and the growth of automatic, computer, and communication technologies; the increasing role of theoretical or scientific knowledge; and widespread affluence. Bell argued that these developments were leading to the increasing economic centrality of *knowledge*, the university and white-collar professional occupations and ethics, the transformation of the corporation into a social institution, and a culture that assigned increasing priority to self-expression, equality, participation, and the general quality of life.

In contrast to Bell's thesis, radical critics of postindustrial society regarded such trends within a knowledge-based service society as an extension rather than a transcendence of key principles of industrialization such as centralization, bureaucratization, specialization, the pursuit of economic growth, and the continued development of science in the pursuit of more extensive control of nature and society. True postindustrialism, they argued, should be defined in opposite terms, through the emerging potential for decentralization, the demythologization of science, the recognition of limits to growth, growing public participation, and the challenge to traditional, scientific, and professional authority.

Despite their differences, such theories of postindustrialism came under fire for exaggerating the extent and significance of the trends they described. A particular area of contention was the significance of the role and power attributed to theoretical knowledge and those who possessed it, the homogeneous characteristics that were attributed to white-collar and professional work, and the effect this had on class consciousness, social values, and the political system.

Criticizing the Debate

The details of the debate are, however, less significant than the general terms in which it was carried out. Similar to previous debates over the rise of postcapitalist societies, a central weakness was the explicit or implicit technological and economic determinism embodied in such theories and their one-directional evolutionary approach to social change. The speculations over postcapitalist and then postindustrial society shared the same one-dimensional, apocalyptic, and universalistic approach to social transformation and the "issues of the age" that characterized the work of much of the writings of the 19th-century founding fathers of sociology.

From the 18th-century Enlightenment onward, intellectuals in Western society have grappled with the nature and implications of the development of reason and the establishment of progress in human affairs. Traditional speculations on the rise of industrial society, and subsequently postindustrial society, have tended to restrict the sociological imagination to a particular limited perspective on such issues. This has occurred in three main ways. First, industrial and postindustrial society theories have focused attention on the nature and implications of *scientific* reason and *technical and economic* progress. This contrasts and clashes with alternative critical and radical traditions that emphasize the development and significance of alternative forms of reason to that of science, the presence or removal of social domination, and the establishment of more democratic societies within alternative paths of development. Second, industrial and postindustrial society theorists tended to view the main transition in history as either having already occurred or being the result of ongoing evolution of existing trends. Little or no recognition was given to the possibility of, or requirements for, reason and progress taking the form of radical political transformation, of the kind advocated by revolutionary theorists. Third, social transformation was seen in universal and deterministic terms as the inevitable working out of a logic of reason or social development, possessing similar requirements and creating similar impacts throughout the world, with relatively less significance given to the possibility or value of alternative trajectories in different cultures, eras, or locations throughout the world.

Concluding Remarks

It is possible to observe the continuing influence of such restricted views of the sociological imagination in many contemporary grand narratives of late-modern societies, viewing such societies as undergoing a process of transition to post-Fordism or postmodernism. While current debates over postmodernity are more complex, sophisticated, and multifaceted than previous discussions of postindustrial society, the fate of speculation on postindustrial societies should warn us of the temptation and dangers of adopting a too one-dimensional, evolutionary, and deterministic view of social transformation and the central issues of the age.

Postmodernism

Postmodernism may be defined in the broadest sense as a crisis of representation. The concept seems to have originated in literature and the arts in the late 19th century, when it was used to describe various aesthetic movements and techniques that were seen by their advocates as somehow superseding the modernist orthodoxy.

Philosophy

In philosophy, postmodernism takes the form of a radically antifoundationalist approach that rejects all attempts to provide a universal grounding for knowledge and truth. Associated most closely with the French philosophers Gilles Deleuze, Michel Foucault, Jean-François Lyotard, and Jacques Derrida, postmodern antifoundationalism is based largely on two sources: (1) a controversial interpretation of the work of the 19th-century German philosopher Friedrich Nietzsche and (2) the poststructuralist critique of structural linguistics. For French postmodern philosophy, Nietzsche's radical, anti-Enlightenment critique of reason negates the possibility of universal scientific knowledge in any form, leading to a radical perspectivism where there are no such things as facts but only interpretations. Structural linguistics was arguably the dominant paradigm in French intellectual thought during the 1960s. Based on the original analysis by the Swiss linguist Ferdinand de Saussure, the goal of structural linguistics, which Saussure termed *semiology*, was to identify a universal set of linguistic rules that underlay all particular forms of speech. The poststructuralist critique, however, rejects the notion of an underlying structure in favor of an emphasis on the arbitrary nature of linguistic signs, also a concept taken from the work of Saussure.

Social Science

While the impact of postmodernism in American philosophy has been minimal, it has been far greater among the social sciences, especially sociology and anthropology, beginning in the 1980s with the translation into English of the works of the major postmodern French philosophers.

Four distinct usages of the concept of postmodernism may be identified: (1) as a substantive-historical category, (2) as a theoretical term, (3) as a methodological approach, and (4) as an ethico-political concept.

1. As a substantive category, postmodernism denotes a series of structural transformations in advanced industrial societies of sufficiently far-reaching nature and scope to suggest the rise, or at least transition toward, a new historical era: "postmodernity." Dated by some as beginning after World War I, by others after World War II, and by yet others since the 1960s, postmodernity is characterized by fundamental changes in virtually every sphere of contemporary life, including major institutions such as the economy, the polity, the family,

religion, science, architecture, and the arts, as well as those shaping core aspects of the self, including the nature of gender, racial, and sexual identities. Primary emphasis is placed on the role of new transportation and communication technologies, especially the airplane, the mass media, and the computer.

Most social scientists whose work is focused on postmodernism as a category describing contemporary social and cultural changes do not consider themselves postmodernists, however. Many of those who study the institutional changes that define postmodernity are critical theorists or Neo-Marxists who situate the development of new technologies within the broader context of a more advanced political-economic system, variously termed *global*, *digital*, or *multinational capitalism*. Similarly, many of those who characterize contemporary changes in the nature of self and identity by employing terms such as *the mutable*, *the saturated*, the *mass-mediated*, or *the fragmented self* base their analyses on conventional sociological and social-psychological approaches.

2. Others, however, embrace the notion, first suggested by the maverick sociologist C. Wright Mills, that new times call for different tools. Thus, as a theoretical term, *postmodernism* implies a renunciation of universal theories in favor of more particularistic approaches. In so doing, postmodern theories in the social sciences adopt the position of the French philosophers, especially that of Lyotard, who calls for a rejection of the grand "metanarratives" of universal science and political emancipation that characterized modern thought, in favor of more limited, local narratives. Postmodern theorists also employ the deconstructionist approach of Jacques Derrida to expose the constructed, arbitrary character of social categories such as gender, race, and sexual identity.

3. Postmodern research methods in the social sciences fall generally into two categories. The first apply poststructural strategies for the reading of literary texts, heavily influenced by the work of Foucault and Derrida, to a variety of social settings and, more controversially, to films and other mass media. These studies focus variously on revealing unintended, ideological, and/or multiple meanings in social settings and mass media texts. The second version of postmodern research methods employs the poststructuralist critique of texts and authorship to challenge the status of conventional ethnographic accounts in anthropology and sociology. Instead, postmodern ethnographers turn to models from literature and the arts in developing new or experimental ethnographic styles that, in their view, more authentically represent the groups they study. These include autoethnographies, dialogic or polyphonic ethnographies, ethnographic poetry, and ethnographic performances.

4. Finally, as a normative or ethico-political concept, postmodernism implies a renunciation of all claims to universal ethical and political principles in favor of an emphasis on pluralism and diversity. Criticizing the failure to recognize the rights of marginalized groups historically in the name of modern Enlightenment concepts of science and reason, postmodernists call for a new respect for difference without the need for transcendental grounding. To avoid falling into the opposite error of moral or political particularism, postmodernists advocate a strategy of coalition politics based on common interests with regard to specific issues.

Critical Remarks

Despite the incorporation of several aspects of postmodernism into some sectors of the contemporary social sciences, it remains a controversial and highly contested term. Criticisms of postmodernism in philosophy and the social sciences are largely organized along paradigmatic lines. For positivists, the postmodern rejection of the universally scientific project of the Enlightenment is intellectual heresy and is further seen as a dangerous form of irrationality. For interpretive social scientists, postmodernism is regarded as frivolous and narcissistic, especially in its advocacy of the new, experimental versions of ethnography. Finally, for critically oriented researchers, the postmodern deconstruction of social categories such as gender, race, and sexual orientation goes too far, undermining the basis for solidarity among marginalized groups that is seen as necessary for progressive social change.

Power

Power in its most generic sense simply means the capacity to bring about significant effects: to effect changes or prevent them. The effects of social and political power will be those that are of significance to people's lives. When these effects of power are such as to affect people's interests adversely, we speak of power being held or exercised *over* them—and the social scientist's quest is to try to reveal what this involves. There are other ways of identifying social and political power: for instance, as *collective* power to achieve shared goals (as when people cooperate to promote a cause or pursue a campaign) or as *positive* or beneficent power, where power serves others' interests (as, ideally, parents, teachers, philanthropists, and social workers are supposed to do).

This entry focuses on power exerted over others—while noting that power over others will often involve collective power and be combined with beneficent power. Power, thus understood, is arguably the more effective the less perceptible its workings are to agents and observers alike, thereby posing a problem for its social-scientific study. Four conceptions of power are outlined, each claimed by its proponents to reveal more of the phenomenon than its predecessor.

The One-Dimensional View

Power is most visibly at work when in a conflict of interests between agents (individual or collective) one prevails over another or others. By *exercising* power, the powerful agent demonstrably *has* that power, but since power is a capacity, that agent can also have the power without exercising it. The conflict, on this view, is between agents' overt preferences as revealed by their chosen behavior and can be interpersonal, within or between organizations, or between countries. It can be legitimate or illegitimate, or legitimacy may be what is at issue. And the winning agent may prevail through the rules of the game (as in political decision making or economic markets) or by threats or the offer of rewards.

Thus, the political scientist Robert Dahl and his colleagues sought to test the thesis of a ruling-power elite by investigating whether in New Haven, Connecticut, the preferences of the hypothetical ruling elite regularly prevail. They concluded that there was no power elite, since power, in this first sense, was distributed *pluralistically*, with different groups prevailing over different key issues.

The Two-Dimensional View

Critics—such as Peter Bachrach and Morton Baratz—objected that this conclusion resulted from seeing power as only manifested in behavior that concerns key issues over which there is observable, overt conflict, where that conflict is between the interests of the parties and where their interests consist in their conflicting observable preferences. Power, they claimed, is also at work when the powerful can, with more or less deliberate intent, suppress or thwart challenges to their interests by agenda control—that is, by deciding what gets decided, for example, by denying the *grievances* of marginal or excluded groups a hearing, through a variety of means, from censorship to the manipulation of procedures, thereby preventing potential demands from becoming actual ones.

This view of power relaxes the requirement that the conflict between parties' interests be manifested in overt behavior: Power must still involve conflict, but the conflict can be covert, involving that between dominant interests and the grievances of

the excluded or marginalized that have thus failed to be publicly heard. In the face of acquiescence, with no observable conflict between parties, there will, on this view, be no way to determine empirically whether their interests are opposed and thus whether consensus is genuine or has been attained through power.

The Three-Dimensional View

This issue has led to a further view, which, it has been claimed by Steven Lukes, incorporates the previous two but enables one to see further and deeper into the phenomenon. According to this view, power can indeed be at work in ways that are hidden from the view of those subject to it and even of its possessors. The powerful may work to avert conflict by contributing (intentionally or unintentionally) to getting others to want what they want them to want, shaping their perceptions, cognitions, and thus preferences. Of course, those subject to such power are typically themselves active participants or subjects, not just its objects or victims. Here, power is not just the ability to prevail over others in conflicts of interests and set the agenda of what such conflicts are about, it also encompasses being able to secure their dependence, deference, allegiance, or compliance, even without needing to act and in the absence of conflict.

This view rejects three assumptions implicit in the foregoing views. The first is that power must involve positive, intended actions by the powerful. Those subject to their power may anticipate their reactions and so engage, for instance, in self-censorship. They may defer or be attracted to the powerful and regard their subordinate place in the social order as self-evident, natural, unchangeable, and even beneficial. Pierre Bourdieu calls such power "symbolic power" and unreflective dispositions, and so to regard it as "habitus." A second assumption is that since power shows up where there is conflict, conflict is essential to power relations. But sometimes the most effective form of power is the capacity to prevent conflict from arising in the first place. The third (most problematic and contested) assumption is that this form of power can deflect people from understanding and thus pursuing their own interests. It can induce them to accept mythical and simplistic beliefs, playing on their fears, prejudices, and limited information and their disposition to engage in faulty reasoning. So the power to frame issues and thus help shape beliefs can be the power to mislead, misleading people to support leaders and follow policies that work against their interests.

Difficulties and Alternatives

But how are we to know, in the absence of observable conflict, whether or not the apparent acceptance and compliance that we observe has been secured by informational and cognitive power—the power to frame issues and thus help shape people's beliefs? More particularly, how would we ascertain whether the consensus results from what we have called *the power to mislead*, namely, misleading people to support leaders and favor policies that work against their interests?

There are various approaches within the social sciences to these questions. One is to avoid them. This is the approach of mainstream neoclassical economics and of those areas of political science influenced by it and by rational choice theory. This approach takes individuals' preferences as given, ignoring altogether the question of how they are formed. Within sociology, a roughly similar approach is adopted by those who take "value consensus," when they find it, as given, without raising the question of the extent to which it may in turn be shaped by power. That question is most directly raised within the Marxist tradition, in the form of what has been called the *dominant-ideology thesis*. According to this, as Karl Marx wrote in 1845, the ideas in every epoch are the ideas of the ruling class: The thesis was developed most explicitly by the 20th-century Italian Marxist Antonio Gramsci, who employed the notion of *hegemony* to refer to the inculcation of such ideas across civil society in subordinate classes that affirm, believe, and follow them in "normal times," when their conduct is not independent and autonomous but submissive and subordinate.

That thesis has been challenged, for example, by James Scott, who, focusing on studies of slavery, serfdom, untouchability, racial domination, including colonialism and highly stratified peasant societies, and also of total institutions, such as jails and prisoner-of-war camps, maintains that the victims of domination are in a state of constant rebellion. They are tactical and strategic actors who dissemble in order to survive. The appearance of consent and unanimity is for the public stage. Behind the scenes,

they voice their dissent in religious and ritual life. The subordinate group is constantly devising strategies to thwart and reverse the attempts of the powerful to maintain and exert their material control and symbolic reach.

An alternative account of quiescence, expounded by Jon Elster, is in terms of *adapative preferences*, where agents themselves display a disposition to accommodate their desires to what they view as feasible. This psychological mechanism can, of course, be adduced and encouraged by power, as when the underdog learns throughout a lifetime of socialization to endure the burdens of life by conformism and cheerful endurance, as in the case of traditional Indian women, as described by Martha Nussbaum. Profoundly dependent on males, often subject to domestic violence and denied opportunities for promotion and the learning of skills available to men, they can lack any sense of being wronged and regard their situation as natural and normal.

A Fourth View: Michel Foucault

The three previous views all agree in seeing power of some over others as power relations, and they assume that such power relations link *subjects*, or agents—that is, individuals or collective agents, such as groups or institutions—that are capable of choice, reflection, and the pursuit of strategies to achieve their goals. But not all students of power share this assumption. One such was Michel Foucault, whose view of power—often expressed in a rhetorical and exaggerated way—has been hugely influential across many disciplines.

Foucault agreed that power is at its most effective when least observable, but his focus shifted away from individuals and groups that dominate and are dominated. He saw power as operating "through" individuals rather than against them, as "constituting" the individual, who is at the same time its vehicle. He wrote of power as producing "subjects," forging their character and "normalizing" them, rendering them capable of and willing to adhere to norms of sanity, health, sexuality, and other forms of prevailing propriety. He claimed that these norms are maintained by policing the boundaries between the normal and the abnormal and by continuous surveillance and self-surveillance. This was the central theme of his earlier work on discipline and punishment and its suggestion that we live in a "carceral" or "disciplinary" society. That work is famous for deploying the image of Jeremy Bentham's late-18th-century conception of an ideal prison, the Panopticon, where continuous surveillance (or even just the belief that it is occurring) suffices to induce in the inmates a state of permanent and conscious visibility that ensures the automatic functioning of power. His later work concerned what he termed *governmentality*, referring to the ways in which in modern societies various authorities administer populations, in which individuals shape their own selves, and in which these processes get aligned. Now, Foucault wrote of *bio-power*, meaning a "life-administering power" concerned with social science and statistics to "normalize," control, and regulate the life and health of populations.

Pragmatism

Pragmatism as a philosophical doctrine traces back to the academic skeptics in classical antiquity. Denying the possibility of achieving authentic knowledge (*epistêmê*) regarding the real truth, they taught that we must make do with *plausible information* (*to pithanon*) adequate to the needs of practice. This entry gives an overview of philosophical pragmatism, its development and reception, as well as its significance as a philosophical school with repercussions for scientific method.

Charles Sanders Peirce

Pragmatism as a developed philosophical position stems from the work of Charles Sanders Peirce. For him, pragmatism was primarily a theory of meaning, with the meaning of any concept that has application in the real world inhering in the relations that link experiential conditions of application with observable results. But by the "practical consequences" of the acceptance of an idea or a contention, Peirce meant the consequences for *experimental* practice—"experimental effects" or "observational results"—so that for him the meaning of a proposition is determined by the essentially positivist criterion of its experiential consequences in strictly *observational* terms. And, moving beyond this, Peirce also taught that pragmatic effectiveness constitutes a quality control monitor of human cognition—though here again the practice issue is that of *scientific* praxis and the standard of efficacy pivoting on the issue of specifically *predictive* success. Peirce developed his pragmatism in opposition to idealism, seeing that the test of applicative success can lead mere theorizing to stub its toe on the hard rock of reality. But his successors softened up the doctrine, to the extent that with some present-day "pragmatists" the efficacy of ideas consists in their mere *adoption* by the community rather than—as with Peirce—in the success that the community may (or may not!) actually encounter as it puts those ideas into practice.

William James

Although Peirce developed pragmatism into a substantial philosophical theory, it was William James who put it on the intellectual map in his enormously influential *Pragmatism: A New Name for Some Old Ways of Thinking*, published in 1907. However, James changed (and—as Peirce himself saw it—ruined) Peircean pragmatism. For where Peirce saw in pragmatism a road to impersonal and objective standards, James gave it a personalized and subjectivized twist. With James, it was the personal (and potentially idiosyncratic) idea of efficacy and success held by particular people that provided the pragmatic crux, not an abstracted community of ideally rational agents. For him, pragmatic efficacy and applicative success did not relate to an impersonalized community of scientists but to a diversified plurality of flesh-and-blood individuals. For James, truth is accordingly what reality impels and compels human individuals to believe; it is a matter of "what pays by way of belief" in the course of human activity within the circumbient environment, and its acquisition is an invention rather than a revelation. With James, the tenability of a thesis is determined in terms of its experiential consequences in a far wider than merely *observational* sense—a sense that embraces the affective sector as well.

Variations

One overarching and ironic fact pervades the divergent development of pragmatism, namely, that the doctrine can be seen either as a validation of objectively cogent standards or as a subverter of them. There is a harder, *objectivistic* pragmatism of the right, a Peircean pragmatism of "what works *impersonally*"—though proving efficient and effective for the realization of some appropriate purpose in an altogether person-indifferent way ("successful prediction," "control over nature," "efficacy in need fulfillment"). And there is a softer, *subjectivistic* pragmatism, a Jamesean pragmatism of "what

works for *X*"—in proving efficient and effective for the realization of a particular person's (or group's) wishes and desires. The objective pragmatists stand in the tradition of Peirce and include the philosophers F. P. Ramsey, C. I. Lewis, and Rudolf Carnap; the subjective pragmatists stand in the tradition of William James and include F. C. S. Schiller and, more recently, Richard Rorty. (John Dewey straddles the fence by going to a social interpersonalism that stops short of impersonalism.) Looking at James, Peirce saw subjective pragmatism as a corruption and degradation of the pragmatic enterprise since its approach is not a venture in validating objective standards but in *deconstructing* them to dissolve standards as such into the variegated vagaries of idiosyncratic positions and individual inclinations. And this is how objectivistic pragmatists view the matter down to the present day.

Meaning and Truth

In the hands of this founding father, pragmatism had two principal components: one as regards *meaning* and the other as regards *truth*. Peirce's *meaning pragmatism* encompasses a pragmatic view of the meaning of concepts and ideas. The crux, so Peirce (1931–1958) maintained, lay in the "pragmatic maxim": "To ascertain the meaning of an intellectual conception one should consider what practical consequences might conceivably result from the truth of that conception; and the sum of these consequences will constitute the entire meaning of the conception" (p. 9). Meaning, in sum, is as meaning does. As Peirce put it in his classic 1878 essay "How to Make Our Ideas Clear," "There is no distinction of meaning so fine as to consist in anything but a possible difference of practice" (p. 257). Peirce insisted that the prime function of our beliefs regarding the world is to commit us to rules for action—to furnish guidance for our behavior in point of what to think, say, and do—and, above all, to canalize our expectations in matters of observation and experiment in scientific contexts.

And much the same sort of story here told with respect to meaning holds also with respect to *truth*. Those theses are true whose implementation in *practice* "work out" by way of yielding success in matters of prediction and application. For Peirce, the best route to this distinction is the scientific method, whose rivals—evidence-ignoring tenacity, pious adherence to authority, a priori speculation, and the like—simply cannot compare with it in point of producing trustworthy results. True factual beliefs, ipso facto, are those that achieve *efficacy* by guiding our expectations, beliefs, and actions in satisfying ways—where specifically cognitive satisfactions are at issue. And they must achieve this on a systemic basis.

As Peirce (1931–1958) saw it, truth in *scientific* matters consists in those contentions that are "fated to be ultimately agreed to by all who investigate [scientifically]" (p. 407). It is what the community of rational inquirers is destined to arrive at in the end—the ultimate consensus of informed opinion among investigators committed to the principles of science. To his mind, it is not mere inquiring as such but *properly conducted* inquiring that must eventually get at the truth of things. As Pierce saw it, it is the scientific method—not the scientific doctrine of the day—that is crucial for rational inquiry. And he rejected an ideology of the "look to science for all the answers" sort for the same reason that he rejected dogmatism of any sort, because it is itself ultimately unscientific.

Themes and Developments

In a community of rational agents, there is bound to be a parallelism between applicative efficacy and substantiative justification. This circumstance has far-reaching ramifications, since pragmatism here becomes conjoined to *evolutionism*. And control is a pivotal factor here. To be sure, if a bounteous nature satisfied our every whim spontaneously, without effort and striving on our part, the situation would be very different. For then, the beliefs that guide and canalize our activities would generally not come into play—they would remain inoperative on the sidelines, never being "put to the test." There would then be no need for active (and thought guided) intervention in "the natural course of things" within an uncooperative (at best indifferent, at worst hostile) environment. But *as things stand*, we are constantly called upon to establish varying degrees of "control over nature" to satisfy even our most basic needs (to say nothing of our virtually limitless wants).

The *developmental* perspective and the pragmatic approach thus join together into a seamless whole. A continuous thread links together the entire tradition of realistic pragmatism in its conviction

that the ongoing work of an enduring community of rationally competent inquirers will be self-monitoring—that mistakes will be detected and reduced in the course of time. The guiding conviction is that the community will, over the course of time, learn how to improve its procedures of inquiry through the processes of inquiry itself so that rational inquiry is in this sense self-monitoring and self-corrective. And here, we cannot reasonably look on nature as a friendly collaborator in our human efforts, systematically shielding us against the consequences of our follies and crowning our cognitive endeavors with a wholly undeserved success that ensues for reasons wholly independent of any actual adequacy vis-à-vis the intended range of purpose. And this leads us back to Peirce's grounding insight. Our cognitive methods are able to earn credit as giving a trustworthy picture of the world precisely because they evolve under the casual pressure of that world. In sum, the methods of scientific inquiry stand superior in its claims to provide an appropriate inquiry method on grounds that are essentially pragmatic. And this pragmatic superiority of science as a cognitive venture in matters of effective description, explanation, prediction, and control both manifests and serves to explain its emergence in cognitive evolution by rational selection via considerations of pragmatic efficacy.

The development of modern pragmatism has seen a steady diffusion of John Stuart Mill's idea that practice is the crux of normativity, as, for example, his idea that desirability is simply a matter of being desired. This tendency was clearly manifested in the thought of William James, for whom the meaning of language is to be equated with its manner of application, and the truth of claims, with their successful implementability in personal practice. And it is in much this spirit that John Dewey launched his assault on distinctions, in particular those between fact and value, between factual usability and normative appropriateness. This tendency continued in spades in the work of contemporary American pragmatists, as manifested, for example, in Richard Rorty's insistence on abandoning the whole armamentaria of concepts in classical philosophy. And we find it reemphasized in Hilary Putnam's identification of truth as nothing but the result of "our best practice" in inquiry.

Against this tendency, a more authentically Peircean realistic pragmatism would insist on construing objective normativity as something distinct from practical efficacy. Instead of taking the relation here as one of *identification*, it would be seen as merely a matter of *evidentiation*. Accordingly, one would not join Mill in seeing the condition of being desired as *constituting* desirability but rather merely (and vastly more plausibly) as *betokening* it. And we need not see truth as *constituted* by our inquiries but as merely *evidentiated* by them. In sum, the nondeconstructive pragmatism espoused here is not revisionary and reconstructive but merely *evidential*. And now the successful supplementation of our beliefs in application is merely the best *evidence* we can secure for the its implicative appropriateness as true, but it is not "the real meaning" of truth. Such an evidentialistic pragmatism does not see those dualistic distinctions, anathematized by Dewey, as conceptual illusions but rather as real gaps that can be crossed by the standard resources of evidential substantiation.

Regrettably, this is not how this line developed. As the 20th century progressed, pragmatism increasingly became a pathway to subjectivism.

Epistemic pragmatists want to reduce truth to warranted accessibility. Semantical pragmatists want to reduce meaning to conventionalized usage. Philosophical pragmatists want to substitute subjective intentions for objective norms. Historist pragmatists want to replace objective fact with what people think at the time. Metaphysical pragmatism wants to replace philosophical deliberation with interesting conversation. Where originally in Peirce's hands pragmatism provided an impersonally objective standard of judgment—to wit, purposive efficacy in application—now it became a way of loosening up to a position of subjectivistic and personalistic orientation.

Reception

Pragmatism has had a mixed reception in Europe. In Italy, Giovanni Papini and Giovanni Vailati espoused the doctrine and turned it into a party platform for Italian philosophers of science. In Britain, F. C. S. Schiller was an enthusiastic follower of William James, while F. P. Ramsey and A. J. Ayer endorsed pivotal aspects of Peirce's thought. Among Continental participants who flourished in the United States, Rudolf Carnap also put pragmatic ideas to work on issues of logic and

philosophy of language, and Hans Reichenbach reinforced Peirce's statistical and probabilistic approach to the methodology and prolification of induction. However, the reception of pragmatism by other philosophers was by no means universally favorable. The British idealist F. H. Bradley objected to the subordination of cognition to practice because of what he saw as the inherent incompleteness of all merely practical interests. The British philosopher G. E. Moore (an opponent of Bradley) also criticized William James's identification of true beliefs with useful ones—among other reasons because utility is changeable over time. Bertrand Russell objected that beliefs can be useful but yet plainly false. And various Continental philosophers have disapprovingly seen in pragmatism's concern for practical efficacy—"for success" and "paying off"—the expression of characteristically American social attitudes: crass materialism and naive populism. Pragmatism was thus looked down upon as a quintessentially American philosophy—a philosophical expression of the American go-getter spirit with its materialistic ideology of worldly success.

Pragmatism and the Social Sciences

Originating in the United States in the 19th century, pragmatist philosophy has had a profound impact on the humanities and social sciences both within America and further afield. The first generation counted Charles Peirce, William James, and John Dewey among its ranks; more recent proponents have included Richard Rorty and Richard Bernstein. There are different forms of pragmatism, but most self-proclaimed pragmatists share an antifoundationalist stance in that they question the possibility of establishing temporal, universal criteria to judge ethical, aesthetic, or knowledge claims. Most pragmatists also oppose what Dewey called the "spectator theory of knowledge"—that is, the assumption that knowledge somehow passively represents the inner essence of the outer world. Instead, they see knowledge as an active intervention in the world. Finally, most pragmatists are reluctant to enter theoretical debates without a visible practical payoff.

Pragmatism initially developed at Harvard, but from the 1890s onward, the philosophy department at the newly founded University of Chicago became a vibrant center of pragmatist thought, eventually inspiring neighboring departments such as sociology. With key empirical works on various aspects of city life, the Chicago school of sociology became a hallmark for high-quality qualitative research on socially relevant topics. Among the earlier pragmatists, James and Dewey had a considerable influence on psychology and educational science, while George Herbert Mead had probably an even more significant impact on sociology. Educated at Harvard and in Germany, Mead taught in the

philosophy department at the University of Chicago, but he was not a prolific writer and only became influential in sociology posthumously through the interventions of former students Charles Morris and Herbert Blumer. Morris edited *Mind, Self, and Society* in 1934, a collection based on student notes of Mead's lectures on selfhood and social interaction, which has since become one of the canonical texts in sociology. Blumer was equally influential because he championed the sociological school of "symbolic interactionism," which was inspired by his former mentor's lectures on social psychology.

Mead's ideas became important for those sociologists who were interested in how people attribute meanings to their surroundings and act accordingly. Mead emphasized the distinctive nature of human interaction, which relied on symbols such as language. Because the meanings of symbols are shared, they enable participants in an interaction to adopt the perspective of the other participants. Thereby, the participants are able to predict what meaning these others would attribute to their possible "gestures" and to act accordingly. While Mead recognizes the power of the community (what he calls the "generalized other") over the individual, he insists that people's ability to adopt the attitude of others ties in with their capacity to transcend social, or indeed any, determination and thus to exercise genuine agency. In sociology, this account provided the theoretical building blocks for a research program that investigated the microfoundations of social life—that is, the interactions between individuals. Blumer's symbolic interactionism had particular affinities with Erving Goffman's dramaturgical approach and to a lesser extent with Harold Garfinkel's ethnomethodology. Albeit distinctive, all three approaches presented an alternative to the dominant structural-functionalist outlook at the time.

From the late 1940s and until the late 1970s, American philosophers increasingly focused on analytical philosophy at the expense of American pragmatism, but it is also during this period that Continental European philosophers, notably Jürgen Habermas, started to engage with pragmatism. While the first generation of the Frankfurt school was antagonistic toward pragmatism, Habermas turned toward Peirce to develop his critique of positivism. It is in this context that Habermas's 1971 work *Knowledge and Human Interests* emphasizes the interests that underscore distinct types of knowledge, with *empirical-analytical* knowledge directed toward control and prediction, *hermeneutics* tied in with understanding, and *critical theory* geared toward emancipation. Habermas's later *Theory of Communicative Action* (1984, 1987) also relied to a considerable extent on Mead's social theory. Mead's work, then, appeared as the theoretical basis for conceptualizing the potential of an open, unconstrained debate among equals.

With the publication in 1979 of *Philosophy and the Mirror of Nature*, the American philosopher Richard Rorty contributed to the revival of pragmatism in American philosophy, although it is particularly his later *Consequences of Pragmatism*, published in 1982, that elaborated on his indebtedness to Dewey. For Rorty, recent contributions to analytical philosophy have helped undermine the analytical enterprise as such, leading him to embrace the dialogical promise of hermeneutics instead of epistemology and its misguided promise of a neutral algorithm. Rorty only touches upon the social sciences, but some social theorists, such as Patrick Baert, have tried to demonstrate the relevance of this neopragmatist perspective for social research, arguing for self-referential research, whereby the encounter with difference potentially leads researchers to reevaluate the presuppositions that originally shaped their research. Several contemporary French social scientists share similar pragmatist concerns but draw inspiration from Dewey rather than Rorty. This is the case with Luc Boltanksi too, a former student of the French sociologist Pierre Bourdieu, who relies on Dewey to develop a sociology that maintains a notion of critique while recognizing the reflexivity and resourcefulness of people in everyday settings.

PREFERENCE

The notion of preference is central to many social science disciplines. It also raises a number of philosophical issues central to the philosophy of social sciences. However, there is considerable disagreement about how to interpret this concept, with various incompatible accounts in use. This entry starts by sketching the main formal properties of the preference notion and their justification. It then addresses the relation of preference to choice, and the various interpretations offered.

The preference concept is often characterized as a binary relation defined over a set X of alternatives. In particular, there are two basic relations, strict preference ($\succ$) and indifference ($\sim$), and one derived relation, "at least as good as" ($\succcurlyeq$), defined as follows:

For all $A,B \in \boldsymbol{X}$: $A \succcurlyeq B$ if and only if $A \succ B$ or $A \sim B$ (weak preference).

In most applications, preferences are assumed to be *complete*. That is,

For all $A,B \in \boldsymbol{X}$: $A \succcurlyeq B$ or $B \succcurlyeq A$.

Completeness is sometimes difficult to justify. Indeed, we often do not have, and do not need, complete preferences. Consider a person who has to choose between three alternatives A, B, and C. If she knows that she prefers A to the others, she does not have to make up her mind about the relative ranking between B and C.

Incompleteness may arise for different reasons. Agents may not have a preference between two alternatives because they have not sufficiently thought about the alternatives (or lack sufficient information to do so). Thinking more about the issue will thus resolve incompleteness. Yet not all cases of incompleteness are resolvable. Even after maximum information intake and reflection, an agent may not be able to rank two alternatives. Such unresolvable incompleteness problems often arise when people consider alternatives to be *incommensurable*.

The other main assumption concerns the transitivity of preferences, which says that

For all $A,B \in \boldsymbol{X}$: If $A \succcurlyeq B$ and $B \succcurlyeq C$, then $A \succcurlyeq C$.

People often violate transitivity. The controversial question is whether transitivity should be a normative-rationality requirement.

The money pump argument states that those who violate transitivity stand to be exploited. Take the case where an agent has the preferences $A \succ B$, $B \succ C$, and $C \succ A$, (i.e., transitivity is violated), and she currently possesses C. Then, a cunning trader could offer to exchange (for a small fee) C for B, which the agent will accept given her preference. The trader could then do the same by offering first A and then C. In the end, the agent is left with the same alternative, C, as before the trade but has paid three small fees to the trader. Violating transitivity thus is considered irrational because it makes the violator subject to exploitation.

Another argument for the normative appropriateness of preference transitivity suggests that transitivity is constitutive of the meaning of preference. For example, Donald Davidson has claimed that violating transitivity undermines the very meaning of preferring one alternative to others.

All the arguments for preference transitivity are philosophically controversial. The money pump argument applies straightforwardly only to transitivity violations of strict, but not weak, preferences. Even then, additional conditions must be satisfied for the cunning trader to be able to arrange the money pump. A critic of the meaning argument can point out possible connections between intransitive preferences and choice.

Regardless of their substantial legitimacy, transitivity and completeness are—among others—technical prerequisites for the numerical representation of preferences through a utility function. Various axiomatic systems exist in which such representation theorems are proven (as in Decision Theory). Crucially, these utility functions not only represent the preference ordering but also allow the

measurement of preference intervals—that is, how much more an alternative *A* is preferred to *B* than another alternative *C* is preferred to *D*.

In the social sciences, preferences are commonly related to choice. We can represent choice as a function ***C*** on the set of alternatives ***X***. ***C(X)*** then delivers a set of "chosen elements" from ***X***. Economists standardly define preference in terms of choice. According to the revealed preference approach, *A* is (weakly) preferred to *B* if and only if *A* is chosen from a set of alternatives when *B* was available. Formally,

$$A \succcurlyeq^R B \text{ if and only if for some } \mathbf{X}, \quad A \in \mathbf{C(X)} \text{ and } B \in \mathbf{X}.$$

If the choice function is defined over all subsets of ***X***, $\succcurlyeq^R$ is complete. However, $\succcurlyeq^R$ does not necessarily satisfy transitivity. To secure this, various constraints have to be imposed on the choice function ***C(X)***.

There is considerable disagreement over how to interpret this relationship between preferences and choice. In its strongest form, revealed preference theorists sometimes hold that preference is nothing but choice—just a convenient shorthand, really. Against such a strong behaviorist position, philosophers have argued that choices and preferences are in fact entities of quite different categories. Preferences are states of mind, whereas choices are actions. Some, like Daniel Hausman, further argue for a broadly folk-psychological notion of preferences, where preferences in combination with beliefs cause choice.

Many economists, however, reject this folk notion as the "causal utility fallacy," as explained by Ken Binmore (2009): In revealed preference theory, it is not true that an agent chooses *B* rather than *A* because she prefers *B* to *A*. "On the contrary, it is because [the agent] chooses *B* rather than *A* that we say [the agent] prefers *B* to *A*, and assign *B* a larger utility" (p. 19). This perspective does not imply that preferences are identical to choice, but it shows that economists measure something with the revealed preference approach that considerably differs from the folk-psychological concept. What exactly the nature of this measured concept is needs to be further explored.

Prejudice and Stereotyping

Prejudice and stereotyping, which represent two different facets of social bias, have profound impact for social justice and hierarchy. *Prejudice* is an individual-level attitude (whether subjectively positive or negative) toward groups and their members that creates or maintains hierarchical status relations between groups. *Stereotypes* are associations and beliefs about the characteristics and attributes of a group and its members that shape how people think about and respond to the group.

This entry explains each notion separately as well as how they operate jointly and shows the importance of both for understanding intergroup bias and its effects on how groups are structured hierarchically vis-à-vis each other. This pair of notions therefore is important in social-scientific inquiries about social cognition and group identity.

Prejudice

Psychologists have traditionally conceptualized prejudice as a negative attitude (i.e., a general evaluative appraisal) characterized by "antipathy." Recent definitions, however, have focused more on the functional aspects of prejudice than on the general negativity associated with it. Prejudice functions

psychologically by subjectively organizing people's environment and orienting them to objects and others within it. Prejudice also serves other purposes, such as enhancing self-esteem, maintaining group hierarchy (social stratification), and providing material advantage.

Recent definitions of prejudice bridge the individual-level emphasis of psychology and the group-level focus of sociology by concentrating on the dynamic nature of prejudice. Prejudice operates through individuals' reactions to maintain status and role differences between groups in ways that produce and reinforce structural disadvantage for another group. People who deviate from their group's traditional role arouse negative reactions; others who exhibit behaviors that reinforce the status quo elicit positive responses. Consistent with this view, prejudice toward women has both "hostile" and "benevolent" components. Hostile sexism punishes women who deviate from a traditional subordinate role, whereas benevolent sexism celebrates women's supportive, but still subordinate, position. Thus, current prejudices do not always include only an easily identifiable negative view about the target group but may also include more subtle, but patronizing and also pernicious, "positive" views.

In addition, people are not necessarily aware of their prejudices. Although prejudices may be explicit (controllable and deliberate), they may also be implicit (automatically activated and unconscious). Whereas explicit prejudice is assessed with conventional self-report measures, implicit prejudice is typically measured with response latency measures, such as the Implicit Associations Test.

Stereotyping

Early research conceived of stereotyping as a faulty thought process and focused on the content of the stereotypes of different groups. The current social-cognitive approach places more emphasis on the dynamics of stereotyping and, as with prejudice, its functions. Stereotypes guide the way information is attended to, processed, and recalled. Stereotypes not only reflect beliefs about the traits that characterize the typical member of a group and distinguish the group from others but also contain information about other qualities, such as social roles. They imply a substantial amount of other information about a person besides what is immediately apparent and generate expectations about individual group members beyond the current situation. Like prejudice, stereotyping frequently occurs automatically and implicitly.

In general, stereotypes produce a readiness to perceive behaviors or characteristics associated with the stereotype. At the earliest stages of perceptual processing, stereotype-consistent characteristics are attended to most quickly. People also recall stereotype-consistent information better than stereotype-inconsistent or stereotype-irrelevant information. Nevertheless, when there are cues in the immediate environment that prime these memories or when people are motivated to form accurate impressions of others, stereotype-inconsistent information is better recalled than stereotype-consistent information.

Stereotypes are particularly rigid and resistant to change because they distort perceptions and interpretations in ways that reinforce the stereotype. Stereotypes also justify discrimination. People infer the characteristics of groups based on the social roles that they appear to occupy. As a consequence, groups that have lower socioeconomic status (which may be caused by discrimination) are assumed to be less competent and/or less motivated than are members of groups of higher status. Minority group members may also be socialized to adopt these system-justifying ideologies.

Stereotyping *and* Prejudice

Although prejudices toward and stereotypes about different groups have unique characteristics related to specific intergroup histories or current circumstances, general principles also shape the content of stereotypes cross-culturally. The "Stereotype Content Model" proposes that the nature of stereotypes is determined by perceptions of where a group stands on two dimensions: warmth and competence. The resulting stereotypes arouse specific emotional reactions to a group, which in turn motivate actions toward the group.

Groups low on both warmth and competence (e.g., undocumented immigrants and poor people) are associated with feelings of disgust, anger, and resentment. These are particularly dehumanizing emotions; they lead to both passive harm (e.g., neglect) and active harm (e.g., attack). Groups high

in warmth but low in competence (e.g., housewives, the elderly) produce pity and sympathy. Pity elicits both passive neglect and social isolation, simultaneously with active help but often in paternalistic forms. Groups low in warmth but high in competence (e.g., Asians, Jews) elicit envy and jealousy. People are distrustful of these groups and react with pleasure to their misfortunes (*schadenfreude*). Finally, groups high in warmth and high in competence (e.g., the in-group, close allies) elicit pride and admiration, which in turn motivate positive actions, including both active and passive help.

Conclusion

Prejudice and stereotyping are two different forms of intergroup bias. Prejudice reflects *general* evaluative and affective orientations toward a group; stereotyping reflects *specific* characteristics ascribed to a group and its members. Both operate implicitly as well as explicitly. These biases originate from particular historical relations between groups and from current structural relations between groups (along the dimensions of warmth and competence). Stereotyping and prejudice both function, frequently in coordinated ways, to establish, reinforce, and justify hierarchical relations between groups.

Primatology and Social Science Applications

Why should students of the human mind and human society have any interest in nonhuman primates? This entry answers this question by putting forward three important applications of primate research to human sciences. First, understanding the behavior of our closest biological relatives can help us understand the evolutionary origins of human behavior. Second, research on related primate species can help us understand the mechanisms underlying human behavior. Finally, a comparison of various solutions that other primate species have found for coping with social life may inform us of alternative ways to think about and, possibly, alter our own behavior.

There are two major ways to search for evolutionary similarities. The term *homologies* refers to traits we have in common with our closest evolutionary ancestors, the great apes. Shared traits among related species indicate that these traits must have been shared by our common ancestors. The further back in phylogeny that one can find shared traits, the older the evolutionary history of such traits. For example, many species, including macaques, quail, and chinchillas, categorize human speech sounds in a similar way, suggesting that we have constructed our language on ancient perceptual structures. Homologies represent a shared evolutionary heritage, and departures from homologies indicate evolutionary divergence.

The term *homoplasies* refers to traits that are not shared with common ancestors but are shared instead with species that appear to have similar adaptive problems, with similar structures or behaviors to adjust to these problems. Thus, whereas we share many of our cognitive and physical traits with chimpanzees and bonobos, our closest relatives, our pair-bonded mating system with shared parental care is not seen in any great ape species but can be seen in pair-bonded primates that are phylogenetically removed from humans. These species also share with humans a relatively rich system of vocal communication compared with great apes, as well as greater sensitivity to others' needs. The convergence of these traits in pair-bonded monkeys and humans suggests an evolutionary convergence that is likely due to common solutions to common adaptive problems.

The origins of human behavior are therefore a mixture of homologies and homoplasies, and only by examining a divergent range of nonhuman primate species can we develop a full picture of human evolution. Some illustrative examples are as follows.

We can see in chimpanzees the origins of some of our cognitive skills in the creation and use of tools, the rapid learning and use of arbitrary symbols as words for communication, mirror recognition, the acquisition of numerosity skills, and the complexity of memory. However, chimpanzees appear relatively unable to share (especially in the context of food), to teach offspring, or to learn socially from others (except in competitive contexts). However, rapid social learning, sharing of food resources (even at a cost to the sharer), cooperation, and even rudimentary teaching behavior are seen in cooperatively breeding primates quite distant in evolution from humans. The primatologist Sarah Hrdy has argued that humans are cooperative breeders and that our cognitive skills are the result of an amalgam of cognitive skills shown by chimpanzees with the social sensitivity and other-regarding abilities of cooperative breeding primates.

Human social organization is fundamentally different from that seen in any single species of nonhuman primate, but the primatologist Bernard Chapais has argued that a synthesis of information from pair-bonded primates evolutionarily far removed from the great apes, where fathers play an active role in infant caretaking, coupled with the male philopatry seen in apes, has led to bilateral kinship relationships with the kin of both parents, leading to the emergence of tribes, which characterize early human social groups. Again, the combination of homology and homoplasy provides an accurate understanding of how humans evolved.

The emergence of morality is another area where an understanding of multiple primate species can inform the origins of human behavior. Many studies have looked at reconciliation following an aggressive act as a mechanism to restore social homeostasis within a group. Evidence from several species also suggests that primates evaluate equity, actively rejecting food (which would have been preferred otherwise) if another receives a greater amount. Primates also behave reciprocally with respect to cooperating to obtain resources. In some species, we see mechanisms to punish those who fail to follow rules. At the same time, one can find the emergence of empathy, grief, and other emotional reactions often attributed solely to humans—as is shown in studies by the primatologist Frans de Waal.

Specific types of sounds (harmony versus dissonance, staccato versus legato notes, and broad-band versus narrow-band sounds) appear to convey or induce emotions and are used by humans with both infants and pets. Constructing music in the frequency range and tempos of other species with these principles can induce either calming or aroused behavior depending on the structures used. These findings suggest that music may have emerged from emotional communication and that the emotional components of music have a long evolutionary history.

Developmental, behavioral, and neural mechanisms affecting behavior may be more clearly studied in nonhuman species. One can study in primates the development of social, cognitive, and communication skills under controlled environments. Communication skills, fear of predators, and parenting skills emerge through learning and social interactions. Mirror neurons that may form the basis for imitation were first discovered in monkeys and were inferred to exist in humans. The hormonal basis for pair bonding and male care of infants was documented first in pair-bonded primates and subsequently extended to humans.

Finally, understanding the diversity of behavioral solutions found in nonhuman primates might suggest novel solutions to human problems. There is no evidence of dominance or aggression between or within the sexes in muriqui monkeys in Brazil. Learning how they manage social life peacefully may have relevance to humans. Since pair bonding and biparental care are key components of human social cognition and social organization, knowledge of the social organization, behavior, and biology of nonhuman primates that also exhibit pair bonding and biparental care is of critical importance.

Probability

Probability plays several crucial roles in science: Analysis of statistical data, modeling of both physical and social systems (e.g., rational choice models in economics), and risk analysis would all be impossible without it. The subject has *mathematical*, *metaphysical*, and *epistemological* aspects. This entry reviews these three aspects in turn.

Mathematical Aspects of Probability

The mathematical foundations of probability are simple. When analyzing some scenario probabilistically, we select a space of *basic possibilities*, requiring that they be exhaustive (at least one must obtain) and exclusive (no more than one can obtain)—for example, in a toss of a pair of dice, the 36 possible ways the dice can land are usually taken to be the basic possibilities. Each possibility gets assigned a number in the range (0,1), which represents its *probability*—1/36 in our example, assuming that the dice are fair and independent. A *proposition* (what mathematicians call an "event") is something that turns out true according to some of the basic possibilities and false according to the rest (e.g., "at least one die lands 6"). The probability of any proposition is then simply the sum of the probabilities of those possibilities that make it true.

Standard axioms for probability theory fall out immediately: Given any propositions A and B,

i. $0 \leq \text{Prob}(A) \leq 1$;

ii. if A is a *contradiction* (true according to no possibilities), then $\text{Prob}(A) = 0$;

iii. if A is a *tautology* (true according to all possibilities), then $\text{Prob}(A) = 1$; and

iv. if A and B are *incompatible* (no possibility makes both true), then $\text{Prob}(A \text{ or } B) = \text{Prob}(A) + \text{Prob}(B)$. (Some presentations use an infinitary version of this axiom.)

It is then usual to define the *conditional probability* of A, given B, as

$\text{Prob}(A, \text{given } B) =_{df} \text{Prob}(A \text{ and B})/\text{Prob}(B)$, when $\text{Prob}(B) \neq 0$.

A and B are *independent* iff $\text{Prob}(A \text{ and } B) = \text{Prob}(A) \bullet \text{Prob}(B)$. If so, then $\text{Prob}(A, \text{given } B) = \text{Prob}(A)$ when the left-hand side is defined.

This presentation simplifies one detail, since we have assumed that the space of possible worlds is at most countably infinite; if it is uncountably infinite, then, typically, each basic possibility gets a probability of zero, and we apply techniques from calculus to integrate over sets of basic possibilities in order to arrive at nonzero probabilities for propositions. The axioms listed above still hold.

Beyond laying down the requirement that the basic possibilities be exclusive and exhaustive, the mathematical structure of probability does not dictate the choice of what they are, let alone what their probabilities are. In practice, some judgment is required in making this choice, so that subsequent analysis can proceed in the clearest and most illuminating fashion.

Metaphysical Aspects of Probability

Turn now to metaphysics: What is a statement of probability *about*? For example, if a meteorologist

asserts that the probability that it will rain tomorrow is 30%, what must our world be like for that assertion to be *true*? Approaches to this question display a striking disparity.

On the *classical* approach—now fallen into disfavor—the probability of a proposition is simply the ratio of those basic possibilities according to which it is true to the total number of basic possibilities. This approach assumes, implausibly, that in any given application, there is a uniquely best way to select the set of basic possibilities and that each possibility in the set should be treated as equally probable.

According to *subjectivist* approaches, statements of probability are facts about the *degrees of confidence* rational agents do or should have in the proposition in question. Rational opinion can come in degrees intermediate between full belief and full disbelief; the subjectivist takes the axioms of probability to articulate the structure these degrees of confidence ought to display. A subjectivist might say that our meteorologist is asserting that her own degree of confidence that it will rain tomorrow, in light of all the evidence available to her, is 0.3.

Relatedly, the *logical* approach to probability claims that an assertion of probability is an assertion about the *degree of logical support* certain premises (often tacitly specified) give to some conclusion. Thus, our meteorologist's claim is true just in case the total evidence available to her logically supports the conclusion that it will rain tomorrow to degree 0.3. Spelling out the details of this notion of logical support remains an elusive goal for fans of this approach.

Objectivist approaches treat probabilities as physical features of the world—that is, independently of how rational agents do or ought to think. Thus, frequentism claims, roughly, that statements about probability are statements about long-run frequencies; our meteorologist might be understood as asserting that in 30% of those situations that are, in relevant meteorological respects, like the present one, rain follows a day later. A persistent difficulty is to say in detail how facts about frequencies constitute facts about probabilities—particularly given that, in actual practice, we often take it for granted that frequencies can fail to match the underlying probabilities (e.g., it is surely possible for a fair coin to land heads every time it is tossed.). One way to preserve objectivism in the face of the difficulties that beset frequentism is to go primitivist and insist that there is no way to reduce facts about objective probabilities to any other sorts of facts (concerning frequencies or anything else).

One need not choose between subjectivism and objectivism: In fact, it has become common for authors to argue that there are different kinds of probability, for some of which a subjectivist approach works and for others, an objectivist approach. Important recent work takes pluralism for granted and seeks to articulate precise principles connecting different species of probability.

Epistemological Aspects of Probability

That there is no settled view about the metaphysics of probability is important to keep in mind when considering how to *establish* or *test* a claim concerning probabilities: The relevant kinds of evidence or argument may depend on whether the claim is interpreted in a subjectivist or objectivist manner. Regardless, probably the most important principle in the epistemology of probability is that one should expect probabilities to be reflected, with reasonable accuracy, in the long-run statistics of suitably designed experiments. In the ideal case, one runs an extremely large number of repetitions of the same experiment in such a way that one can be confident that the outcomes of distinct trials are *independent* of one another and that the probability of each kind of outcome remains *constant* from trial to trial. Then, one can prove that the long-run frequencies will, with high probability, accurately reflect these underlying probabilities (this is the *weak law of large numbers*).

But two caveats complicate the epistemology of probability considerably. First, it is only rarely, in actual scientific practice, that one can meet these conditions. Second, emphasizing statistics of repeated experiments can blind one to other sources of knowledge about probability. An illustrative example follows: Presented with a coin of unknown bias, you may have no way of determining this bias without tossing the coin repeatedly. For all that, you can know, on general physical grounds, that the probability that a pair of tosses will land heads, then tails, is exactly the same as the probability that it will land tails, then heads. That is a fact about the probabilistic behavior of the coin, ascertainable without the need of performing repeated pairs of tosses and observing their statistics.

Promises and Agreements

Of the many obligations that we acquire in our lives, those that arise from promises and agreements are among the most commonplace. Any general theory of moral obligation ought therefore to be able to explain what promises are and why they obligate. Modern moral philosophy, much concerned with ideas of duty and obligation, has thus been impatient to provide such an explanation. But the humble promise has been stubborn in refusing to give up its secrets. Our ability to give another the right to demand that we perform some act that was previously wholly optional, just by uttering a few inoffensive, prosaic words, has appeared opaque even under the lights of some of the most penetrating philosophical minds. "Since every new promise imposes a new obligation," David Hume was driven to remark in his *Treatise on Human Nature* (1739/2000), "'tis one of the most mysterious and incomprehensible operations that can possibly be imagin'd, and may even be compar'd to *transubstantiation* or *holy orders*" (p. 336). A theory of promise is a theory that explains what a promise is and how it creates obligations.

This entry surveys the prevailing theories of promise and concludes with some remarks on the relationship between promises and agreements. Recent philosophy of the social sciences has developed elaborate views on collective agency and collective intentionality, placing them at the center of philosophical theories of sociality. Such shared acts and collective intentions are based on notions such as joint commitment, promising, agreement, mutual beliefs or mutual obligations, and the like; it is therefore important for such a social ontology to be clear about what agreeing and promising amount to. In addition, these two ideas were important to historical social contract theories that have also been central to philosophical theories about the constitution or creation of social institutions based on joint commitment and social conventions. Promises and agreements are such vehicles of creating sociality.

A promise is a communicative act, and as such it can be analyzed in terms of the communicative intentions of a promisor. Promising is the act of uttering "I will φ" (or an equivalent future affirmation), with the intention of being understood to be promising to φ. Theories of promise can be distinguished according to the way they characterize this intention. Most fall into one of two camps.

Theories in the first camp conceive of promising as a creative act whereby a speaker communicates an intention to create, by that act of communication, an obligation to the hearer to do what he is saying that he will do. This "creative-act" conception of promising finds its origins in Hume and has been advanced in more recent times by philosophers and legal theorists like Elizabeth Anscombe, John Finnis, H. L. A. Hart, David Owens, John Rawls, Joseph Raz, Seana Shiffrin, and John Searle, among others.

The creative-act conception of promising presupposes a rule of promise keeping that renders this morally inert speech act normatively significant. Many creative-act theorists hold that this rule is embedded in a social practice the violation of which contravenes some moral principle, such as one forbidding people from departing from just social practices. Others insist that the obligation of a promise may be institutional or conventional without also being moral. Still others hold that the norm of promise keeping is a moral one that can be justified without resort to the idea of a social practice.

Theories in the second camp hold that what is essential to promising is not that the speaker communicates an intention to become obligated but that he communicates that he intends to φ, with the aim of assuring the hearer that he will φ. These theories begin from the observation that the ordinary pragmatic function of a promise is to assure the hearer that the speaker will adhere to some course of conduct and to count on that belief in her deliberations and planning. They conceive of promises as (or as involving) ordinary (albeit often emphatic)

statements of intention made with a view to inspiring assurance, reliance, trust, or the like in the hearer.

These "expectational" theories of promise seek to explain the obligation of promises without invoking a special rule of promise keeping. They hold that breaking a promise is wrong, when it is wrong, because it amounts to a kind of mistreatment of the sort that is proscribed by some moral principle of general application, such as that which requires that we not betray the trust we invite others to place in us or that which forbids the doing of avoidable harm to others. The idea is that once a speaker has invited the hearer to form and possibly act upon a belief that the speaker will follow some course of conduct φ that he knows the hearer wants to be assured of, his failure to φ is a failure to treat the hearer with due respect. Some early utilitarians, such as Adam Smith and John Stuart Mill, subscribed to an expectational view of promising. In more recent times, expectational theories have been advanced by Páll Árdal, Patrick Atiyah, Neil MacCormick, Thomas Pink, and Thomas Scanlon, among others.

These, then, are the contours of the two main schools of thought in the philosophy of promising. What of agreements? In contrast to promises, which are the focus of a prodigious literature, the equally pervasive social phenomenon of agreements has attracted relatively little philosophical attention. This neglect may be the result of the widely held assumption that agreements are just exchanges of promises. This assumption is implicit in everyday discourse, where "promise" and "agree" are often used interchangeably and people who dishonor agreements are censured for breaking their promises; and it is orthodoxy in the law that defines contracts as enforceable agreements and agreements as exchanges of promises.

In a 1993 article titled "Is an Agreement an Exchange of Promises?" Margaret Gilbert challenged this assumption. Gilbert argued that no two promises, when exchanged, will yield obligations for the promisors that are both interdependent and simultaneous. Since interdependence and simultaneity are essential features of the obligations that are acquired by the parties to an agreement, moreover, an agreement is not a promise exchange. Gilbert's article has spawned a small but growing literature on the kinship between promises and agreements, including work by Kent Bach, Oliver Black, and Hanoch Sheinman.

Prophecy, Self-Fulfilling/Self-Defeating

Robert Merton (1968) coined the phrase *self-fulfilling prophecy* to describe "a *false* definition of the situation evoking a new behavior which makes the originally false conception come *true*" (p. 477). It is not the truism that people's perceptions depend on their prior beliefs. Nor is it the truism that beliefs, even false ones, have real consequences. To count as self-fulfilling prophecy, a belief must have consequences of a peculiar kind: consequences that make reality conform to the initial belief. The converse is the *self-defeating prophecy*, where the initial belief leads to behavior that falsifies the belief.

The latter has attracted far less attention from social scientists, so this entry will focus on the self-fulfilling kind. The entry begins with a definition and then discusses some plausible instances.

A simple example will aid definition. First, a teacher believes that a particular student has exceptional academic ability. Second, this belief leads the teacher to encourage and stimulate the student. Third, the teacher's behavior causes the student to manifest exceptional academic ability. A self-fulfilling prophecy implies that any change in Step 1 would alter the outcome: If the teacher had believed the same student to be mediocre, then the teacher would have behaved very differently, and in consequence, the student would have performed poorly. This counterfactual assumption avoids the problem of specifying the prior reality. There is no need to decide whether the student was really exceptional or mediocre at the outset; what matters is that altering the teacher's belief would transform the outcome accordingly. A self-fulfilling prophecy implies that the actors (or at least some of them) misapprehend the causal process by overlooking the third step. The teacher assumes that the student's presumed ability—rather than the teacher's behavior—caused the subsequent high achievement. If the true causal sequence could be recognized, then the process would be transformed. For example, the teacher would behave like this with every student, thus elevating them all.

Instances of self-fulfilling prophecies have been discerned at a range of scales. The relation between teacher and student can be extended to relationships between two collectivities. Police believe that a crowd is violent and so launch a preemptive attack; the crowd then reacts by fighting back. At a purely individual level, the placebo response can be considered a self-fulfilling prophecy. A patient believes that an inert substance is a powerful painkiller, and therefore, she feels less pain. This phenomenon is sociological as well as biological, as the patient's belief derives from a relationship with someone assumed to possess medical expertise.

The most interesting self-fulfilling prophecies involve more complex social processes, such as financial markets. Merton introduced his concept with a fictional story of a bank run. Depositors believe that the bank is insolvent and therefore withdraw their money. This sudden loss of funds drives the bank out of business. The bank run is typically used to exemplify self-fulfilling prophecies, though there is more empirical evidence for the opposite phenomenon: investment bubbles. Investors wrongly believe that the investment generates high returns and therefore invest their funds. As more people invest, the investment becomes more valuable. Moreover, subsequent investment enables a Ponzi scheme to provide initial investors with the promised returns; visible payouts further enhance the scheme's credibility. All this leads to further investment. The process can last for some time but eventually proves unsustainable. The ultimate outcome is financial failure, as for the bank run. The crucial difference is that the investment bubble's outcome negates rather than fulfills the prophecy. Ponzi schemes provide a quasi-experimental demonstration of the self-fulfilling prophecy.

In the most intriguing case, social theory makes social reality in its own image. Marxism predicts that capitalism is fated to end in revolution and thus encourages its adherents to foment revolution. Neoclassical economics, which likewise conflates description and prescription, has been more

successful. Its assumption that firms maximize profits, or equivalently shareholder value, was falsified when empirically tested in the 1950s. Instead of revising the theory, neoclassical economists argued that managers should be given appropriate incentives to maximize profits, namely, stock options. Thanks in part to their argument, companies adopted this form of compensation, and maximizing shareholder value became a social norm. As a result, short-term profit maximization—as neoclassical theory predicts—is more true today.

A self-fulfilling prophecy is not easy to demonstrate empirically. Only experimental intervention can ensure that actors' beliefs are not influenced by prior reality. To return to the example used at the outset, the investigator can select a few students at random and convince their teacher that they have been diagnosed with exceptional ability. Their subsequent academic achievement should be greater than average, if a self-fulfilling prophecy is to be operative. Such experimentation is limited by the difficulty of manipulating beliefs in human beings, especially when investigation is bound by informed consent. Experimental results will inevitably underestimate the causal impact of belief.

Self-fulfilling prophecies have an abiding fascination because they show how we can be caught in a web of our own making. By reifying social reality, we can fail to understand that we have been responsible for creating it.

Pseudoscience

The term *pseudoscience* refers to a highly heterogeneous set of practices, beliefs, and claims sharing the property of appearing to be scientific when in fact they contradict either scientific findings or the methods by which science proceeds. Classic examples of pseudoscience include astrology, parapsychology, and ufology; more recent entries are the denial of a causal link between the HIV virus and AIDS or the claim that vaccines cause autism. To distinguish between science and pseudoscience is part of what the philosopher Karl Popper referred to as the *demarcation problem*, a project that has been dismissed by another philosopher, Larry Laudan, but that keeps gathering much interest in philosophers, scientists, educators, and policymakers.

This entry provides the basics of the debate about demarcation, as well as a brief discussion of why it is of vital importance not just intellectually but for society at large.

Popper and the Demarcation Problem

Popper began working on the problem of demarcation between science and pseudoscience (as well as more generally nonscience) as early as 1919. He was particularly concerned with David Hume's famous problem of induction, the idea that there does not seem to be a logically independent way to justify inductive reasoning, the basis for the scientific method. Popper thought he had arrived at a single idea that represented both a solution to Hume's problem as well as a clear-cut demarcation criterion: *falsificationism*. He proposed that science is in the business of advancing falsifiable (i.e., refutable in principle) theories about how the world works. This appeared to have bypassed Hume's issue about induction because falsificationism can be thought of as an application of *modus tollens*, therefore relying on deductive, not inductive, reasoning. At the same time, it seemed to Popper that pseudosciences (among which he counted various schools of psychoanalysis as well as Marxist theories of history) made statements that were not falsifiable, and were thereby unscientific.

While Popper's contribution to both issues remains a fundamental starting point for any discussion of demarcation and induction, there are good reasons to believe that he was a bit too quick in

declaring victory on both fronts. This entry directs the reader to two comprehensive articles concerning the problem of induction and focuses instead on falsification as a demarcation criterion.

It is easy to show that falsification leaves much good science out and allows a significant amount of pseudoscience in. For instance, the history of science is riddled with examples of scientific hypotheses that—when first proposed—were apparently falsified by the data and yet scientists kept them alive because they seemed promising enough. The initial version of the Copernican system, with its circular planetary orbits, was doing no better empirically than the Ptolemaic system it was supposed to replace, and it was not until Kepler realized that the planets move along elliptical orbits that the theory was vindicated. Copernicus's book was published in 1543, but it was not until 1609 that Kepler put out his fundamentally revised version of the theory.

On the other side of the divide, so-called scientific creationism does make perfectly falsifiable predictions, such as that the earth is only a few 1,000 years old. These predictions have indeed been amply falsified by modern geology, physics, chemistry, and biology, and yet there does seem to be a strong sense that we should not simply consider creationism a science, even a failed one (for one thing, because of its appeal to supernatural, by definition inscrutable, forces, which are themselves outside the purview of science).

What the inadequacy of falsification in establishing a demarcation criterion hinted at was something that became progressively clearer in the decades following Popper's pioneering work: Science and pseudoscience are simply not the sort of concepts that admit of being defined by a small set of individually necessary and jointly sufficient conditions, the way classical logicians would want the task to be accomplished. However, it is important to understand that this sort of situation is not limited to the case of the science/pseudoscience demarcation. Plenty of other complex and interesting concepts are too "fuzzy" (in the technical sense of fuzzy logic) to admit of sharp boundaries and clear-cut definitions. Examples include the idea of "game" (as famously pointed out by Ludwig Wittgenstein) as well as the concept of biological species.

Take games, for instance. Clearly, we seem to know what sort of activities reasonably fall into that category (chess, soccer) and which don't (war, philosophizing), and of course, we are aware of borderline cases (e.g., "games" actually used to solve practical problems, e.g., the 3-D folding of proteins). Yet it is easy to appreciate how difficult it is to come up with a small number of criteria that sharply define what a game is. For each candidate, say, "done competitively," there are both instantiations belonging to the set of interest that fail the criterion (e.g., solitaire) and others that meet it while clearly not belonging to the set (e.g., business transactions). So in some sense, it should not really be surprising that the terms *science* and *pseudoscience* are difficult to define exactly and yet still refer to reasonably coherent types of activities that are distinct in important ways from each other.

Laudan and the Alleged Demise of the Demarcation Problem

The philosopher Larry Laudan declared the demarcation problem dead, and the concept of pseudoscience useless and pernicious, in a famous article published in 1983. Laudan pointed to the "failure" of philosophers to agree on necessary and jointly sufficient criteria for demarcation as an indication of the futility of the project. Moreover, he asserted that since *pseudoscience* is an emotionally charged word (clearly always used in dismissive terms), it does not really belong to philosophical discourse. The real issue, Laudan maintained, is to assess the epistemic warrant behind each individual claim to knowledge, regardless of whether it is made from within fundamental physics or astrology.

While Laudan's critique has been important in the history of the debate about pseudoscience, there are several counterpoints to consider, which explain why philosophical discussions of demarcation have been on the rise again during the past decade, with no sign of abating any time soon. Let us start with Laudan's last point, that epistemic warrant should be attached to specific claims, not to broad endeavors. This is much too restrictive and impractical. When a field like astrology has repeatedly, and for a long time, demonstrated its inability to make progress—due to the incoherence of its theoretical constructs (e.g., "constellations" are actually optical illusions) and its failure on empirical grounds—it seems the time has arrived to archive the whole thing as not warranting any more serious investigative efforts. Within a successful and dynamic science, on the other hand, the advice to examine each claim on its own merits makes sense precisely because that

science has established methods and background knowledge against which the epistemic warrant of any new claim can be reasonably assessed. Labeling something as pseudoscience—if called for—serves the same practical shortcut function of throwing an obviously frivolous lawsuit out of court before one invests money and time in something that has no chance of succeeding.

As for Laudan's argument that philosophers have failed at the demarcation task, and that we should therefore move on, it seems to be based on a peculiar understanding of "failure" for a philosopher. It can be reasonably argued that it is precisely through the exploration and criticism of possibilities in logical space that philosophy makes progress. Popper was wrong about having solved the problem of induction, but his attempt based on replacing inductive with deductive reasoning was a potentially good move that had to be properly explored and criticized before we could consider more sophisticated proposals. The same can be said of other areas of philosophical inquiry: Utilitarianism in ethics, as originally conceived by Jeremy Bentham and then John Stuart Mill, has not survived unscathed in the modern philosophical literature; but modern utilitarians like Peter Singer have been able to develop a much more nuanced view of their approach to moral philosophy precisely because they have been confronted with several rounds of criticism. The abandonment of the quest of necessary and jointly sufficient criteria to define science and pseudoscience in favor of, for instance, Wittgenstein-type family resemblance ("fuzzy") concepts constitutes progress, not failure.

Finally, let us consider Laudan's point about the emotional ladenness of the term *pseudoscience*. There is no doubt that this is the case, but Laudan himself argues that philosophy should be able to tell us what is reasonable to believe and what is not, and it is hard to imagine how "unreasonable" is the kind of label that would be much more palatable and emotionally neutral than "pseudoscience." Indeed, here, Laudan actually hits the nail on the head in implying that a major role of philosophy of science is to be prescriptive, particularly when it comes to discussions of science in the public sphere, where the consequences of our views are not merely academic but involve policy and politics.

The Role of Philosophy in Combating Inferential Biases

The current philosophical literature on pseudoscience is exploring some of the alternatives to the classical demarcation approach briefly mentioned above, such as solutions based on fuzzy logic or on making more precise the notion of Wittgensteinian family resemblance concepts. A significant number of papers have come out recently vigorously debating whether supernatural claims (e.g., Intelligent Design [ID] creationism) belong to a separate category of pseudoscience by virtue of their very invocation of the supernatural or whether they are simply another type of unscientific claim along the lines of astrology, ufology, and so on.

This particular discussion has, again, very tangible social repercussions, as was clearly on display during the 2005 trial over the teaching of ID in public schools in Dover, Pennsylvania. During the court proceedings there, both Barbara Forrest and Robert Pennock had the increasingly less rare distinction of being called as witnesses by virtue of being philosophers of science, and hence capable of providing expert testimony on the scientific nature (or lack thereof) of ID theory. As a result, Judge John E. Jones III's decision in the Kitzmiller versus Dover Area School District is a nice summary of the philosophical issues surrounding the demarcation problem. The judge came down on the side of philosophers, who were arguing in a prescriptive fashion that ID is a pseudoscience, one of the reasons why it should not be taught as science in the district's public schools (another reason being, as Judge Jones also noted, that ID is no different in substance from classical creationism, which other courts have found to be a religious doctrine, the teaching of which would violate the establishment clause of the First Amendment to the Constitution of the United States).

Pseudoscientific notions will likely stay with us for a long time, as recent literature in psychology shows that human beings are naturally prone to a number of cognitive biases that favor the persistence of pseudoscience. Interestingly, many of these biases find their equivalent in the philosophical literature on logical fallacies (e.g., the post hoc, ergo propter hoc fallacy—by which one confuses correlation with causation—is a major mechanism that we use to

make preliminary inferences about causality). On the positive side, psychologists have shown that an awareness of cognitive biases diminishes one's proneness to perpetuate the mistake. This in turn would seem to suggest that the teaching of critical thinking skills in philosophy classes is a fundamental component of the education of an intelligent citizenry.

Psychoanalysis, Philosophical Issues in

Philosophical discussions of psychoanalysis have frequently focused on two topics: (1) how well psychoanalytic theories can be regarded as *evidentially supported* by the clinical data they are initially framed to explain and (2) how far particularly psychoanalytic conceptions of *unconscious mental states and processes* should be regarded as viable. The first of these will be the main topic of this entry, and the second will be briefly considered at the close.

Free Association and Freud's Claim About Evidence

The relevant clinical data arise in the practice of *free association*, as pursued by patients in analysis over the course of months and years. To free-associate is to describe the contents of what is sometimes called the *stream of consciousness*—passing experiences, thoughts, feelings, and so forth, as fully as possible as they occur and without omitting or censoring anything. This leads rapidly to thoughts and feelings that are unexpected even to those thinking them.

The data thus generated enabled Sigmund Freud and his successors to learn as much about what went on in the minds of their patients as the patients were able to put into words and, in addition, to base further conclusions on patterns that could be observed while they were doing so. Thus, there were the patterns relating associations to elements of the manifest contents of dreams, described by Freud in his own case in *The Interpretation of Dreams*. Again, there was the pattern Freud described as *transference*, in which emotions and conflicts felt early in life toward parents and siblings were revived in patients' current experience of the therapist. Since free association and the experiences that emerged in analysis were Freud's main sources of data, he maintained that persons who did not have firsthand experience of them were not in a position to criticize his theoretical conclusions.

Dispute About Freud's Claim: Advocates and a Comparison With Darwin

This claim has been at the core of disputes about evidence in psychoanalysis. Advocates characteristically maintain that the claim reflects the fact that psychoanalysis has a unique and remarkably rich source of data that are otherwise unfamiliar and unexpected. Such data cannot be ignored, but they also cannot readily be communicated, except in small and isolated vignettes. Freud's description of the publishable parts of his associations to elements

of his dream of Irma's Injection, for example, takes up many pages; and even such a detailed written description of mental processes leaves out much of the information available to the subject experiencing the processes at firsthand. When we reflect that such an accumulation of data is relevant for just a partial understanding of a single dream, we can see that there is no prospect of adequately summarizing or surveying the full range of data relevant to the main conclusions to be drawn from even a relatively short period of interpretive thinking of this kind.

In this perspective, we might compare psychoanalysis with Darwin's theory of natural selection. Darwin's theory also relates to a great range of data, drawn both from the observation of current forms of life and from countless traces of extinct and very different forms left in the incomplete and largely uncharted fossil record. Here again, we have a vast field of potential data, much of which remains unknown. These data, however, are relatively enduring and publicly available for classification, discussion, and survey. So investigators working with them have been able to use them to show a larger and often skeptical scientific public how they confirm the kind of theories Darwin and his successors devised. In the case of psychoanalysis, by contrast, the data are private and perishing and emerge in each analysis in ways unique to the individuals concerned. So for psychoanalysis, despite a comparable wealth of data drawn from countless hours of individual analyses, there can be no such disciplined public demonstration of confirmation, or any such assuaging of skepticism, as obtains for Darwin's theory.

Critics and the Questioning of Evidential Support

But where advocates of psychoanalysis see a problem about the *communication* of confirmatory data, critics see a problem about the *status as confirmatory* of the data themselves.

Explanation, Evidence, and Bayes's Theorem

We can review these disputes in terms of standard notions from the philosophy of science. Roughly, insofar as we make observations or establish other data, we accept them as they are (this is why we regard them as *data*). Nonetheless, we may want to know *why we might expect these data* to be as we find them. We cannot answer this merely by considering the data on their own; but we can link them with other things by framing *hypotheses* or *theories* that *explain* them, characteristically by representing them as effects of some more encompassing causal mechanisms. In this, we cease to regard the data as isolated phenomena but instead see them as having a particular place in a larger causal pattern, which includes mechanisms that explain why we should expect them to be as we find them.

This means that such explanatory hypotheses or theories are always also *predictive*, in the sense that they represent the data they cover *as to be expected in accord with the working of the mechanisms that explain them*. But for this to be so, the hypothesis (or hypothesized mechanisms) must perforce confer a *probability of the data given the hypothesis* that is higher than the *probability* of *the data given the negation of the hypothesis* (supposing that there is no such mechanism). This is simply what it is for the hypothesis to explain the data in the sense of showing why they should be expected to be as they are. From this, however, it follows that where we advance such a hypothesis in explanation of some open-field data, we should also be able to *confirm* or *disconfirm* that hypothesis—that is, to increase or decrease whatever credibility we initially assign to it. For we can do this simply by updating our assignment of credibility to the hypothesis in accord with Bayes's theorem, as it seems rational to do.

This is because the condition required for the hypothesis to explain the data—that *the probability of the data given the hypothesis* be greater than *the probability of the data given the negation of the hypothesis*—entails that for further data that are as the hypothesis predicts, *the probability of the hypothesis given the data* (the credibility to be assigned to the hypothesis after further data have been collected) will be greater than *the prior probability assigned to the hypothesis*, whatever that was. So even a weakly predictive hypothesis gains credibility—is confirmed—as we observe that things turn out as it predicts. (And the relation is reversed, and the credibility of the hypothesis diminished, where the data turn out not to be as even weakly predicted.) The increase or decrease in probability engendered by further observations, moreover, should be proportional to the probability the hypothesis confers upon them.

On such an account, Freud's hypotheses should be regarded as confirmed insofar as they provide the best available explanation of the data they cover and render expectable; and this is apparently what Freud

was attempting to illustrate by repeated example in publications such as *The Interpretation of Dreams*. His overall claim there was that if an individual seeks to interpret her dreams by pursuing free association in relation to the elements of the dreams, then data will emerge from the free association that allow the dream to be interpreted in the kinds of ways Freud describes. The instances he produced apparently encompass the data explained by his overall account. If so, then, as he claimed, critics ignorant of such data, or the way his hypotheses served to explain them, would not be in a position to evaluate them properly. Criticism of explanatory theories that does not take full account of the observational data upon which they are based is not empirically well-founded.

Critiques by Popper and Grünbaum

Understanding confirmation and disconfirmation in this way also bears on the celebrated critiques of Freud by Karl Popper and Adolph Grünbaum. According to Popper's criterion of *falsifiability*, the only general hypotheses that can be regarded as truly scientific are those that predict data so precisely that they would be conclusively falsified if particular instances of data were not forthcoming. Again, only such precise general hypotheses can be said to explain data, and to be confirmed by them, in a fully scientific way. Such falsifiability should not be confused with the kind of Bayesian confirmation and disconfirmation indicated above. Rather, Popper's account in effect requires that truly scientific hypotheses confer a probability very near to certainty on the data they explain, so that any predictive failure renders the probability of the hypothesis itself negligible. As Popper stressed, the hypotheses of Freud and Darwin mostly do not satisfy this criterion; and for this reason, he regarded them as metaphysical, as opposed to scientific.

This categorization by Popper has very often been used to discredit Darwin or Freud. This, however, misrepresents both Popper's argument and his intentions. Popper not only allowed but emphasized that the general theories he characterized as metaphysical might have true and confirmed instances. His account turned on the difference between singular instances and the unrestricted theoretical generalizations thought of as inductively supported by them. The establishing of singular instances of a general claim (e.g., finding that this or that dream was well understood as a Freudian *wish fulfillment*) could not conclusively verify the unrestricted generalization involved (that all dreams are wish fulfillments). By contrast, establishing a single negative instance (finding a dream—e.g., an anxiety dream or a nightmare—that was not best understood as a Freudian wish fulfillment) could conclusively falsify the generalization.

In light of this, Popper held that genuinely confirmed instances, even in the context of a general theory as scientifically fertile and invaluable as Darwin's, did not suffice to render the generalizations themselves truly scientific. Likewise, and despite criticisms, he stressed that Freud's explanations of instances in *The Interpretation of Dreams* were fundamentally correct and that Freud's description of the unconscious therefore constituted a great discovery. Popper regarded the generalizations of Darwin and Freud as unscientific, not because they lacked confirmed positive instances but rather because the terms in which they were cast were not so precise as to render them conclusively falsified by ostensibly negative ones.

Advocates of psychoanalysis agree with Popper that psychoanalytic hypotheses do not generally yield strict and readily falsifiable predictions like those attainable in the "hard" sciences. This holds, indeed, for the whole of the natural human psychology of desire, belief, perception, emotion, and experience in which we understand one another in everyday life. But in this psychology—and contrary to Popper's claims—our ability to understand one another with precision far outruns our ability to predict one another's actions. This is particularly clear in the case of language, in which we may be able to understand what a person says with as great an exactness as we understand anything in science but without thereby being able to predict what he will say next.

Advocates also stress that in this field examples that admit a degree of generalization may have great importance even if they are subject to restriction. The interpretations of dreams that Popper regards as basically correct already provide grounds for revisions in commonsense psychology that are deep and potentially cumulative and radical. It is highly important—as Popper conceded in speaking of a great discovery—that many, if not all, dreams can be understood in this way. So advocates maintain that if, as Popper agrees, Freud's hypotheses are sufficiently predictive to impose genuine relations of confirmation and disconfirmation on instances

of explanation, and if they provide the best explanations we can frame for the many instances that would be unexpected on other accounts, they should be regarded as constituting a significant and empirically cogent extension of our everyday psychology of motive, by means internal to it.

Comparing Darwin and Freud brings out another methodological point. Where a theory explains data by representing them as produced by an underlying causal mechanism, its predictions entail claims about the mechanism as well. Where the mechanism itself is as yet unexplored, finding out about it becomes part of the project of confirming or disconfirming the theory. Darwin's theory made claims about the mechanisms of heredity—that they produce resemblances between parents and offspring that also allow for modification by natural selection—as did Freud's theory about the neural mechanisms of motivation, dreaming, and mental disorder. The predictive scope of Darwinian theory, and with this the degree of confirmation it enjoyed, steadily increased as the mechanisms of heredity were anticipated and described. Once Darwin's theory could be exhibited as predicting the great fact that the vital and reproductive processes of all living things are regulated by the same basic family of molecular mechanisms, Darwinism attained a degree of confirmation comparable to other paradigms of science. This also illustrated the failure of Popper's criterion, for of course we remain unable precisely to predict the alterations that natural selection will produce (e.g., in the flu virus), even though we may attain detailed understanding of them afterward.

Advocates of psychoanalysis hold that progress in developmental psychology and neuroscience will likewise generate further and significant confirming or disconfirming data. But this will also depend on actively searching for evidence about the working of the mechanisms, as in the Darwinian case of combining physiological research with digging for fossilized instances of forms of life altered or eliminated by natural selection. In psychoanalysis, such digging is shown in looking for the deepest and most significant connections in free associations, memories, motives, and conflicts, as well as in relating these to findings in psychology and neuroscience. In both cases, the digging is mandated by the hypotheses under consideration, which predict the kind of thing (but not in detail) that digging should disclose. And in both cases, digging for evidence is liable to be mistakenly characterized by critics as a search for confirmation in violation of falsificationist strictures.

In contrast with Popper's falsificationism, Adolph Grünbaum provided a critique of Freud on inductivist grounds. Psychoanalytic claims about motives, he argued, were causal claims. Therefore, they required noninterpretive and extraclinical experimental or correlational support, such as the double-blind control group procedures used to test the causal powers of drugs. Again, advocates of psychoanalysis contest these criticisms as failing to take full account of the nature of Freud's hypotheses and data. Certainly, psychoanalytic claims about the role of motives are causal, just as are claims about the roles of perceptions, desires, beliefs, and emotions in everyday life. But then in the indispensible and fundamental psychology of meaning and motive that we naturally use in understanding one another, we already constantly establish such causal connections by intuitive interpretive means. In maintaining that Freud was extending this psychology by means internal to it, advocates of psychoanalysis were also perforce maintaining that other forms of correlational testing, although they might be desirable where possible, were not required.

"Suggestion" as an Alternative Explanatory Hypothesis

In addition, and like many before him, Grünbaum argued that the kind of confirmatory clinical observations to which Freud refers may well be contaminated by the influence of the analyst—for example, by unconscious suggestions with which the patient unwittingly complies. In this, his critique recycled the oldest but also the most influential grounds for rejecting psychoanalytic claims; and similar arguments have also been cited to explain the apparently confirmatory data that sustain competing psychoanalytic schools.

To this familiar charge, advocates reply yet again that it does not take full account of the methodological situation. This is simply that all hypotheses purporting to explain the data in question, including hypotheses that postulate processes such as suggestion, require to be evaluated by how well they actually explain and predict the data involved. In fact, psychoanalytic hypotheses seem to be the only ones that do so with any degree of adequacy. For critics who stress the role of suggestion have provided no account as to how it is supposed to explain psychoanalytic data; and these data, as recorded, show patterns inconsistent with the claim.

Thus, data recorded as explained by early Freudian hypotheses are very often better explained by quite different psychoanalytic hypotheses framed later in order to explain different data. For example, the associations to Freud's dream of Irma's Injection, and to others in *The Interpretation of Dreams*, are clearly better explained by the mechanism of *projection* that Freud was to emphasize in later work than by that of *wish fulfillment* he used in his initial book. (The hypothesis of wish fulfillment does not explain why the derelictions with which Freud is concerned should be assigned to Otto in the dream; that of projection has this as a direct consequence. In addition, projection is the mechanism most explicative of paranoia and so serves to explain the anxiety dreams and nightmares with which critics still tax Freud's first formulation.) Such retrospective but more cogent explanations can be given for a considerably large number of recorded instances of psychoanalytic data, and this pattern is inconsistent with the claim that the data are explained by psychoanalytic hypotheses because they emerge from suggestion in terms of them.

Again, critics often cite the fact that patients of therapists of different schools come to free-associate, and so they produce clinical data using the concepts of those schools. Advocates regard this as showing, as would be expected, that these patients are using the theoretical framework in terms of which they are attaining a deeper understanding of themselves for the purpose for which that framework was devised—that is, to enable them to understand themselves better than they would without such a framework. Likewise, advocates regard the persistence of differing schools of depth psychology as a natural and inevitable consequence of the richness of the data forthcoming in free association (and unconstrained play in the case of the analysis of children) and the motivational complexity of the human mind. As with the long, intricate development of life itself, we may never attain a single best perspective on these things; but that is no reason not to seek such better and deeper explanations as we can frame.

Recent Work in Developmental Psychology and Neuroscience

Advocates and critics of psychoanalysis thus remain in epistemic deadlock about the significance of clinical data. In this situation, it has seemed relevant to both advocates and critics to consider related fields such as developmental psychology and neuroscience, especially since Freud began work as a neuroscientist and framed many of his psychoanalytic concepts so as to be consistent with his own neuroscientific understanding.

Work in both fields has burgeoned in recent decades, and advocates urge that, as was to be expected, the results systematically favor psychoanalytic hypotheses. Thus, attachment theory, developed by the psychoanalyst John Bowlby as an empirical and evolutionary approach to the formation of emotional bonds and to the effects of parental care, has become a well-established field of developmental psychology. It has produced powerful empirical evidence of the influence of parenting on psychological development from as early as four months, and its main modes of testing, such as the "strange-situation" procedure, are in effect ways of determining the role of emotional conflicts that Freud took to be central to mental disorder. So it has arguably produced systematic evidence of the pervasive and lasting role of what Freud described as the earliest parental imagoes in engendering emotional conflict—and with this, evidence for a range of psychoanalytic claims about the importance of such conflict in development.

The observations of attachment theorists also coincide with current hypotheses in developmental neuroscience, which stress how representations of self and other in the infant's relatively unformed cortex are structured under the impact of emotion by interaction with parents and carers over the first year of life. Again, recent work has provided accounts of emotion and dreaming consistent with Freud's and confirmed clinical phenomena that seem to require explanation in psychoanalytic terms. Neuroscientific work seeking to determine the construct validity of psychoanalysis has shown a range of consistencies between key Freudian ideas and recent perspectives on global brain function that have emerged in neuroimaging and Bayesian neuroscience.

The neuroscientific framework of the Bayesian brain, moreover, seems also to provide a simple and direct account of repression and other Freudian concepts, thereby contradicting a range of traditional philosophical arguments against them. As regards the therapeutic effect of psychoanalysis, neuroimaging studies now seek to specify the changes effected by successful psychoanalytic theory in neural systems related to emotion and attachment. So while such empirical work is not directed to the particular clinical observations stressed by Freud, it seems to offer indirect but wide-ranging empirical support

for them, now in terms of the working of the causal mechanisms that underlie them. No doubt philosophical critics of psychoanalysis will respond to these new claims and data; at present, however, they are yet to do so.

Public Goods

Public goods are goods that the free market cannot provide efficiently. Two characteristics distinguish public goods from private goods: *non-rivalry* and *non-excludability*. This entry defines these two characteristics, explains why goods that have these characteristics cannot be efficiently provided by the market, considers the different ways in which the government can provide these goods efficiently, explores the contested and related concept of "merit goods," and considers the relationship between the provision of public goods and the principle of liberal neutrality.

Non-Rivalry

The first characteristic of public goods is non-rivalry. A good is non-rival if one person's consumption of the good does not diminish the benefit that any other person can obtain from consuming the good. An example of a good that is non-rival is a radio station signal. On the other hand, most goods (e.g., clothing) are rival goods. There are some goods that are non-rival up to a point and then become rival when use becomes sufficiently high (e.g., a public park). These are known as *congestible goods*.

The free market will not provide non-rival goods efficiently. When goods are non-rival, it is often the case that the economic benefit from allowing someone to consume another unit of the good is greater than the cost of providing that extra unit (e.g., providing an extra person with cable television access). Therefore, society could obtain greater total economic benefits by having greater production of the good than what the free market would provide.

Non-Excludability

The second characteristic of public goods is non-excludability. A good is non-excludable if it is very difficult or impossible to prevent individuals from using the good once it exists. So, for example, fish stocks in international waters are an example of a non-excludable good. On the other hand, an ice cream cone is excludable since it is easy to prevent someone who did not pay for it from enjoying it.

Different problems of efficiency arise depending on whether the non-excludable good already exists (e.g., natural resources) or whether it still needs to be produced. If the good does not already exist, the inefficiency is straightforward to see. Any private actor who produces the good will not be able to recoup his or her costs. And so, barring altruistic behavior, the private market will not produce this good.

If the non-excludable good already exists and it exhibits rivalry, different efficiency problems arise. First, each person who uses the good will diminish everyone else's benefit from using the good and will not have to pay the costs of doing so. When enough people act in a narrowly self-interested way, game theory predicts that this will lead to the *tragedy of the commons* (an overuse of the resource). Second, assuming that there are barriers to trading the good, it may end up being used by individuals who do not place the highest economic value on it. Finally, individuals may expend effort and resources to appropriate the good early simply in order to prevent others from taking the good.

Types of Economic Goods

We can use these two characteristics to place economic goods in four categories: (1) goods that are excludable and rival (*private goods*), (2) goods that are non-excludable but rival (*common goods*), (3) goods that are excludable but non-rival (*club goods*), and (4) goods that are both non-excludable and non-rival (*pure public goods*).

Note that non-rivalry and non-excludability can *each* provide an efficiency-based justification for the government to intervene in a particular market. This is why some economists classify both club goods and common goods as types of public goods. However, the justification for intervention is often strongest when both characteristics are present (e.g., in the case of pure public goods like national defense).

Table 1 Types of Economic Goods

	Excludable	Nonexcludable
Rival	Private goods Example: ice-cream cone	Common goods Example: limited fish stocks in ocean
Nonrival	Club goods Example: scrambled radio signal	Pure public goods Example: national defense

Efficient Government Provision

Faced with the private market's inability to provide public goods efficiently, it is not always the case that the government can do better. However, the government has three general techniques it can use to efficiently provide public goods. First, the government can conduct a cost–benefit analysis to measure the willingness to pay of citizens for different types and different quantities of the public good. Second, the government can rely on democratic processes to determine the right level of the public good. Third, different localities can produce different public goods and people can then sort themselves based on the taxes they are willing to pay for the public goods provided.

The success of each of these methods is subject to a wide variety of caveats. Moreover, given imperfect information, often some taxpayers will effectively subsidize others' public good consumption. Finally, the inefficiency of government provision is an important issue. Often economists advocate government *financing* rather than government provision of public goods.

Liberal Neutrality

However, even if the government can efficiently provide a public good, it is not always clear that it should do so. A key concern has to do with the principle of liberal neutrality, which states that the government should not favor one conception of the good life over another. So, for example, even though many religious institutions exhibit non-rivalry, liberal governments do not directly support them. There is also controversy about how a neutral government can justify

building a baseball field rather than a children's recreational area or, even more controversially, whether it can justify publicly funding art.

Merit Goods

Just as there are public goods that the government should arguably not provide, there are also private goods that the government arguably should provide. For example, elementary school education is both excludable and fairly rival. Yet most believe that government should provide this type of good. Some economists refer to private goods that the government should nevertheless provide as *merit goods*. Some even expand the definition of public goods to include merit goods. The justifications for classifying a good as a merit good are controversial and include equity concerns, paternalism, and community values.

Public Reason and Justification

This entry introduces the idea of public reason and justification that plays a central role in contemporary liberal theories of political legitimacy. The idea of public reason is important for the philosophy of the social sciences since it delineates an important element of public, or collectively constituted, life.

The liberal idea of public reason has its roots in Immanuel Kant's 1784 essay "What Is Enlightenment?" In Kant's usage, private reason is addressed to the members of a particular association, such as a state or church, and presupposes the existence of an authority that is recognized by the members of that association, such as a set of positive laws or scriptures. Public reason, in contrast, acknowledges no other authority than that of reason itself and is therefore addressed, at least in principle, to the entire community of reasoning creatures. Kant holds that the free and public use of reason is a necessary condition for the progress of enlightenment.

The liberal idea of public justification is associated with the revival of contractarian thought that followed the publication in 1971 of John Rawls's *A Theory of Justice*, in particular with the emphasis that Rawls places on the "fact of reasonable pluralism" in his *Political Liberalism* (1993). Rawls argues that disagreement about fundamental questions is a permanent feature of life in modern democratic societies and that we should therefore distinguish between public reasons, which are accessible to all citizens, and nonpublic reasons, which are only accessible to those who endorse a particular moral, religious, or metaphysical view. He holds that the exercise of political power is only legitimate if it can be justified through the use of public reasons—that is, in terms that transcend or abstract away from the more "comprehensive" matters on which they disagree. Such a liberalism would be "political, not metaphysical."

The idea of public justification is closely related to the traditional liberal idea of government by consent, and like all theories of consent, it contains a number of ambiguities. The areas of ambiguity are explained in what follows:

a. *Content:* It is not clear to what extent the content of public reason is defined by the beliefs that are *actually* shared by a given community and to what extent it is defined by the beliefs that they *would* share if they were fully rational, fully reasonable, and/or fully informed. Similarly, it is not clear whether the content of public reason varies over time and from place to place and to what extent the use of public reason should be expected to yield unique and

stable conclusions. To the extent that public reason is defined empirically and contextually, it will of course be subject to the various kinds of ignorance and bias that exist in all human communities. Moreover, because few if any substantive beliefs are universally shared, such an approach threatens to reduce the content of public reason to an empty set. Conversely, to the extent that public reason is defined normatively and counterfactually, its content is likely to be determined by exactly the kinds of controversial doctrines that it is supposed to transcend.

b. *Domain:* Rawls and many other political liberals argue that only the basic principles or "constitutional essentials" of a liberal regime—those rules that define the basic rights and duties of citizens—need to be publicly justified and that ordinary matters of legislation need not meet this standard. However, it is not clear why the domain of public reason should be limited in this way or that "ordinary" and "constitutional" questions can be easily distinguished from one another. Some political liberals therefore hold that all decisions in which the use of coercive force is authorized must be publicly justified.

c. *Jurisdiction:* Some political liberals hold that the norm of public justification only applies in official contexts—for example, among public officials or voters—and not in the "background culture" in which open discussion among citizens takes place. Others hold that public reasons only need to be invoked at the moment when a political decision is made and that no constraints should be placed on political debate up to that point. Many critics of the idea of public justification insist that despite these limitations it would have a chilling effect on discourse in the broader public sphere and would discriminate in particular against religious believers.

d. *Motivation:* Many political liberals hold that public justification requires that the reasons that are offered in support of a given set of policies be shared by those who are bound by them. Others argue that it is enough for public reasoning to converge on a set of policies even if different citizens endorse them for different reasons. Relatedly, some political liberals hold that citizens must sincerely endorse and be motivated by the public reasons that they offer, whereas others hold that public reasons only need to be acceptable to those to whom they are offered.

e. *Exceptions:* Rawls argues that it may be permissible to appeal to nonpublic reasons in political debate provided that sufficient public reasons are offered "in due course," a stipulation that he refers to as the *proviso*. The proviso is meant to lessen the motivational strain that some people—paradigmatically, religious believers—might otherwise feel in being asked to adhere to the norms of public justification. Other political liberals insist that the use of nonpublic reasons is never justified in public life and that the appeal to such reasons should therefore be confined to the background culture.

Race, Theories of

The modern view of humankind as naturally divided into different "races"—with population groups roughly linked with continentally demarcated origins (white, brown, black, red, yellow)—has had a huge influence not just on popular consciousness but also on academic theory and social structure. For hundreds of years, most Europeans took for granted not merely racial division but also racial hierarchy: Whites were seen as the race superior to all others. Since World War II, biological racism has officially been largely discredited, but controversy continues on how race should be regarded. This entry surveys some of the questions and problems raised for social theory by race as an issue.

Racist Theories Versus Antiracist Theories

Historically, most theories of race have been racist; it is only in recent decades that antiracist theories have become the norm. While all peoples are obviously capable of being racist, it is White racism that has historically had the greatest global impact, because of the shaping of the modern world by European expansionism.

Racist theories vary tremendously in their details, but in general, they make two key assumptions: (1) humankind can be divided into discrete subgroups—"races" and (2) these races are hierarchically positioned with respect to each other—that is, some races are superior to others. The metrics of this putative superiority have usually been cognitive (degrees of intelligence) and characterological (moral vices and virtues). However, aesthetic and physical criteria have also sometimes been employed, with the "superior" race being seen as more beautiful and physically more able than the "inferior" races. In White racism, Whites are placed at the apex of humanity, superior to the "colored" races. But intra-European racism has also demarcated (a) Aryans from Jews, Slavs, and Romani; (b) Nordics from Alpines and Mediterraneans; and (c) Anglo-Saxons from Celts and Latins.

The explanations given in racist theory for this hierarchy have included theological, biological, and cultural accounts, sometimes individually and sometimes in combination. Racist theories that posited separate origins for the different races (polygenesis) were always in tension with Christian orthodoxy, and they became even harder to defend after Charles Darwin's work. Thus, biological ("scientific") racism post-Darwin posited instead radical "racial" variation within a human race conceded to have a single origin (monogenesis). However, though no longer respectable in the academy, polygenetic theory can still be found in the ideas of some contemporary racist fringe groups—for example, the idea of non-Whites as "mud people" not descended from Adam and Eve. Many theorists argue that since World War II, the dominant variety of racism has become cultural racism, where the marker of inferiority is now a deficient and inassimilable culture rather than a deficient body.

Antiracist theories will always reject the second assumption (racial superiority and inferiority); however, they have diverged on the first assumption

(that humankind can be divided into races). Between World War I and World War II, most liberal antiracists would have affirmed the equality of all races while agreeing that humanity was naturally racially divided. But with the discrediting of biological racism by the Holocaust, many antiracists in the scientific community began to develop a more radical position—not only was there no racial hierarchy but there were no biological races to be hierarchically arranged in the first place. The human race was a continuum of varying traits and "clines," with no natural discrete divisions, and what had been thought to be "natural" demarcations were actually arbitrary social cuts, with more genetic variation to be found within groups categorized as "races" than between them. The phrase now standardly used is that race is "socially constructed"—an artifact of particular social systems and social divisions.

Periodization and Origins of Race and Racism

The discrediting of race as biology naturally raises the question of what explains the origins of racial thinking and the genesis of race as a social category. Unfortunately, there is no consensus on this issue. A wide range of theories have been put forward: (a) innate human ethnocentrism mutating into a more dangerous "racial" form, (b) European color symbolism (for White racism specifically), (c) sociobiology, (d) Marxist political economy, (e) psychosexual drives, (f) cognitive psychology, and (g) group conflict theory. Some theorists have been insistent that racism is distinctively modern or, at the earliest, late-medieval, with seemingly contrary evidence from the classical Greco-Roman world to be categorized as color prejudice or ethnocentrism rather than racism. Other scholars have disagreed, contending that racism, albeit not in our contemporary form, goes all the way back to antiquity. Within this latter group, racism has been seen as distinctively Western by some (a Greco-Roman product) and as generally diffused within ancient civilizations (China, India, Japan, the Arab world) by others.

"Race" Today

Contemporary antiracism is divided on whether the social construction of race should be taken to imply that race does not exist at all, and should be eliminated from our vocabulary (eliminativism), or whether races should be seen as nonbiological social entities that are brought into existence by this history of racism and so have a social reality that requires retention of the language of race (anti-eliminativist constructivism). So *race* as a term would now be functioning differently, referring to a socially created group rather than a natural one. Often this division on the metaphysics of race carries over into a corresponding division on public policy recommendations—the question of whether public policy should be color-blind or color conscious. Advocates of the former view would argue that the language of race helps keep racial thinking alive and only perpetuates social division. For the latter, however, racial division objectively exists because of the legacy of White domination, independently of whether it is acknowledged or not, and the language of race is indispensable both for tracking ongoing racial injustice and for devising measures and mobilizing political support to eliminate it.

Racial Critiques of Social Science Applications

We often classify each other by race and sometimes treat people of different races differently. Race is often used in the social and biomedical sciences to describe or explain differences between people in socioeconomic status or health. In order to use race as a variable in studies of social or biological

differences in a population, each member must be assigned to one or more of a fixed number of racial categories. This entry describes how these assignments are made and the issues of racial definition and assignment raised by the use of race in the social and biomedical sciences.

Racial Differences

Blacks are reported to have a lower median income and higher rates of morbidity and mortality than Whites in the United States and the United Kingdom. However, the direction and magnitude of the differences depend on how the racial categories are defined and how members of the population are assigned to each racial category. Different assignments to the Black or White category can result in larger or smaller racial differences in socioeconomic status or health. If more members with large incomes count as Black and fewer as White, the racial difference in median income decreases.

Assigning Race

The current official U.S. standard for collecting and reporting data on race lists five categories but is silent on how members of the population should be assigned a race and how to decide whether a member is one race, such as Black, rather than another, such as White. While the U.S. Bureau of Census assigns members a race based on the race they report themselves to be, the National Center for Health Statistics assigns them a race based on the race on their birth or death certificate. However, a member's self-reported race can be different from the race on his or her birth or death certificate. As a result, the member can be assigned one race at birth, a different race as a young adult, and a different one again when he dies.

When measuring racial disparities in income or health, social and biomedical scientists routinely assign members of the population the race they assign themselves. When measuring racial differences in mortality, however, they routinely treat a decedent's race on his death certificate as his apparent race and his self-reported race on an earlier population survey or birth certificate as his actual one if the two are different. They assume that a member's race can't change but can be misassigned or misreported and there can be errors in a count of the number of members of each race in a population.

Error Measurement

Bias or error in the measurement of a variable is only possible if the variable has an actual value from which the apparent value can diverge. If T is the actual value of a variable V, O the observed or apparent value, and e the error in the measurement of the variable, then e is equal to the difference between O and T, but e has no value unless V has an actual one. If beauty were simply in the eye of the beholder, then no measurement of the beauty of members of a population could be biased or in error and no report could over- or undercount the number of members who are beautiful, since there would be no difference between a member's observed and her actual or true beauty. For a measure of the race of a member of the population to be in error, he would have to have an actual race different from his observed or apparent one.

Race cannot be measured like height or body weight, but a member of the U.S. or U.K. population is not whatever race he takes himself to be. There is a difference between being and appearing to be Black or being White and passing as White, but the difference can vary, and a member's actual race is sometimes taken to be his self-reported race and, at other times, his other-reported or parent's race.

Actual Race

Which race is a member's actual race can vary from one socioeconomic or health risk to another. A member's self-reported race can be his actual race in relation to his risk of obesity and his other-reported race in relation to his risk of unemployment. However, since many social scientists rely entirely on self-reported race in their studies of racial differences, their studies of populations in which self-reported and other-reported race are frequently different can be unreliable.

Other-reported race measures differences in risk better than self-reported race if the risk varies with a member's exposure to discrimination, since it is not based on the category the member assigns to himself or herself but on the one he or she is most often assigned by others. As a result, whenever differences between groups in risk are primarily due to racial discrimination, a member's self-reported race should be taken to be his or her actual race only if his or her self- and other-reported race are the same. No one measure describes or explains every risk better than all the others.

We cannot capture something as complex as race with a single way of defining race or by assigning a person to a racial category. Race, like many of the categories social and biomedical scientists use in their studies, such as class and marital status, has a number of dimensions, and one definition of the category can be a better measure of one and a worse measure of another. Allowing the methods of assigning race to vary follows a recommendation of the National Research Council that reports on race should rely on multiple methods of measurement rather than one, since no one measure can capture all the different ways race can affect the health or well-being of members of a population.

Rational Choice and Political Science

Rational choice theory has been used extensively in political science. While it remains a controversial method in the eyes of many, it is a mainstream method that has influenced thinking in political science well beyond its use in formal or game-theoretic articles. This entry first defines rational choice in the context of political science and then examines its influence through Social Choice Theory, in legislative studies, through agency models, in pressure politics, and in constitutional arrangements and the state.

Rational Choice Theory

Rational choice theory is a method of analysis that assumes that agents (people, organizations, groups) behave in a consistent manner, which in turn assumes that they have complete and transitive preference orderings. The consistency requirement of rational choice is simply a predictive tool that enables researchers to examine agent behavior in one context and then, armed with preferences derived from those circumstances, predict behavior in another context. Although agents are not always consistent in this way, when they are, the method enables explanation, and when they are not, it gives political scientists a starting point for a new set of questions. In political science, these preference orderings are virtually always appended to agents in roles and not to biological human beings. Thus, they are applied to "democratic politicians," "presidents," "bureaucrats," and citizens, not to actual people.

Social Choice Mechanisms

The study of voting and elections begins with considering the role of electoral systems. Social Choice Theory is normative, asking how a collection of agents, each of which has well-defined preferences over a set of alternatives, should determine the collective preference. Kenneth Arrow tried to answer the problem by setting a minimally demanding set of normative criteria and then examining which rules satisfied them. His surprising answer is that no decision rule, producing a rational collective ordering from individually rational orderings, satisfies his criteria. This result launched Social Choice Theory. Following from Arrow, it has been found that certain restrictions on the allowable set of individual

preferences will yield rational collective preferences: importantly, the requirement that preferences are single peaked. In that case, majority rule yields a rational group ordering that then reflects the preferences of the median voter. This result assumes that politics can be represented in a single, say, left–right, dimension. The Median-Voter Theorem has subsequently been used in multiple contributions across the whole gamut of political science.

A second set of corollaries from Arrow's theorem shows that all systems of voting are manipulable: That is, voters might vote strategically, ordering their preferences differently than how they really feel, in order to help a preferred candidate (not necessarily their most preferred candidate) to win. A third set suggests that if politics is multidimensional, then with a moderately large set of issues and a moderately large set of voters, we cannot predict a winner. This occurs because any bundle of policies can be beaten by a new bundle. This led to the key question: Why is there so much stability in politics? The answer is given by political institutions.

Legislative Studies

Kenneth Shepsle introduced the idea of *structure-induced equilibrium,* arguing that the committee structure of Congress turned a multidimensional issue space into a single issue space (or at least a smaller number of issue spaces). This allowed the median voter to dominate in committees, ensuring greater stability. Later contributions examined more complex rules for committees and logrolling across committees (which can introduce instability). In other systems, parties and the domination of the executive (cabinet ministers) in different issue domains bring about stability. A large part of legislative studies is now dominated by considerations from this perspective of the structures that lead to government policy.

Agency Models

Agency models examine the relationship between principals and their agents and have been extensively applied to executive–legislative relations and the bureaucracy. Principals use agents to carry out their wishes, but agents might have their own political interests (they might shift policy) and might not always be competent (they might shirk). The basic agency problem is asymmetric information, where principals do not know precisely what agents are doing; a related problem is adverse selection, where those least qualified for positions work hardest to attain them. Agency models examine these problems. They are applied to (a) the selection of candidates for elected office, (b) how legislatures monitor the executive, (c) how elected politicians monitor the bureaucrats, (d) help explain another role for legislative committees, (e) the function of parties, (f) why prime ministers reshuffle their cabinets so often, (g) failures in government policy, and (h) many other features of political life.

Voter–politician models examine not only how voters punish bad politicians but also how bad politicians try to behave like good ones until it is too late to punish them. This has obvious application to term limits, where a state governor or a president can only serve two terms and hence cannot be punished for actions in their second term. It also applies to politicians coming to the end of their careers. More general models of electoral politics examine coalition formation, where constraints include the desire to maximize the amount of power each party in the government enjoys while finding partners with adjacent ideological positioning. Median-voter models are important in these accounts.

Pressure Politics

The behavioral revolution in political science in the 1960s led political scientists to look beyond formal institutional actors to other agents in the political process. Organized pressure groups affect policy formation through the pressure they place on both elected politicians and civil servants. Following from Mancur Olson's *Logic of Collective Action,* rational choice writers have shown that groups will differentially mobilize depending upon the collective action problems they face and the resources they have to overcome those problems. One consequence is that businesses face fewer problems due to their size and concentration, while citizens have diffuse interests. Later models have examined the role of information and the interplay of special interests and citizen demands on vote-maximizing politicians.

Constitutional Arrangements and the State

Rational choice has modeled the most efficient organization of the state in terms of fiscal federalism, where political responsibilities follow fiscal responsibilities. In recent years, agency models have examined the development of the state. The formation of economic organizations such as guilds, kings giving power to parliaments, and the rise of democracy

have been modeled as attempts to overcome commitment problems associated with long-term contracts.

Rational choice is now part of the heartland of modern political science, and its influence extends far beyond articles that can be seen as exclusively formal. The questions its methods have raised are central to the modern enterprise of political science.

Rational Expectations

This entry deals with rational decision making under risk or uncertainty; it is not about what is known as rational expectations theory or rational expectations hypothesis in economics, developed by John Muth and others, concerning people's expectations of how economic variables will turn out in the future.

The prevailing theory of rational expectations is expected utility theory. According to this theory, rational decision makers choose that option among those available to them that maximizes expected utility—that is, the sum of the probabilistically discounted utilities of its possible outcomes.

The idea was first introduced by the Swiss mathematician and physicist Daniel Bernoulli (1700–1782) to solve what is known as the St. Petersburgh Paradox. A fair coin is to be tossed until it shows heads for the first time. If the first head appears on the kth trial, a player wins $\$2^k$. How much should one pay to participate in this lottery? Its expected *monetary* return is infinite—that is, $(\frac{1}{2})\ \$2 + (\frac{1}{4})\ \$2^2 + (\frac{1}{8})\ \$2^3 + (\frac{1}{16})\ \$2^4 + \ldots + \ldots\ldots\ldots\ldots + \ldots$, —but surely no one would pay all the money they can lay their hands on to play this lottery. What Bernoulli suggested was that one should evaluate the lottery instead in terms of its expected *utility,* where the utility of any given amount of money increases with its amount but at a *diminishing* rate.

Independence Axiom

Such an account of expected utility gets fully axiomatized for the first time in John von Neumann and Oskar Morgenstern's (vNM) 1947 book. The key assumption on the vNM account is what is known as the independence axiom. Although the axiom is buried in a definition of an equivalence class of lotteries, E. Malivaud diagnosed where the axiom was to be found. As it turns out, there are many formulations of the axiom. A relatively transparent version is the following:

> Suppose that a gamble A is indifferent to a gamble B. Then a gamble (A with probability p and C with probability $1 - p$) is indifferent to a gamble (B with probability p and C with probability $1 - p$).

Critique

A deluge of questions were originally posed by researchers regarding the plausibility of the independence axiom, whether the axiom was *descriptive* of how people choose among gambles or normative—that is, how they ought to choose. At a famous conference in Oslo in 1982 (on the Foundations of Utility and Risk Theory), many of the most distinguished decision theorists met (e.g., Amartya Sen, Kenneth Arrow, and Maurice Allais), and they were basically skeptical about the descriptive validity of the axiom, but the French theorist Maurice Allais was also skeptical about the normative status of the axiom.

Mark Machina presented a paper titled "Utility Theory Without the Independence Axiom," which sought to develop an account that avoided the independence axiom. His paper was so impressive that he was asked to come on the final plenary session to defend his view, even though he was a fresh PhD student from MIT. Virtually all took the view that the axiom was suspect as a descriptive axiom but was clearly very well-grounded as a normative axiom. Similar views were implicit in the work of

Daniel Kahneman, Amos Tversky, and many others. The dean of all decision theorists, Leonard Savage, was exposed to the examples that Allais constructed, chose *against* the independence axiom, and then announced that he was grateful for his own theory for setting him right!

However, Daniel Ellsberg wrote a very important paper in which he insisted that the axiom was suspect as a normative requirement. The trouble with the axiom, according to Ellsberg, could be illustrated by the following example: Suppose one has to draw, from each of two urns, a ball, where there are 30 red and 60 black or yellow balls, and then one has to draw again, either from g_3 or from g_4.

	(30)	(60)		
	Red	Black	Yellow	Range of Expectation
g_1	\$100	\$0	\$0	$33^{1/3}$
g_2	\$0	\$100	\$0	$0–66^{2/3}$
g_3	\$100	\$0	\$100	$33^{1/3}–1$
g_4	\$0	\$100	\$100	$66^{2/3}$

That is, the agent is to choose between g_1 and g_2, and again between g_3 and g_4, in each case based on drawing a ball at random from an urn that contains red, black, and yellow balls in the proportion specified: 30 of the balls are red, and 60 are either black or yellow, but how many of each of these two colors is not specified. Many people prefer g_1 to g_2, but they also prefer g_4 to g_3. As suggested, it would seem that they preferred determinate odds to ambiguous odds (as expressed in the last column), or perhaps the explanation is that they rank them in terms of minimum expected return odds to ambiguous odds (as expressed in the last column), or perhaps the explanation is that they rank them in terms of minimum expected return. What is clear is that it can be shown that such a preference ordering violates a version of the independence axiom. Many found this a much more convincing example of a plausible normative violation of the independence axiom.

There were also a number of developments in non-Independence theories as early as the 1950s. Harry Markowitz developed a separate account of how to deal with risk. This work contributed to his receiving the Nobel Prize in Economics. Essentially, he proposed a mean/variance model of evaluation. There was also an important paper on the theory of risk by Alexander Pollatsek and Amos Tversky, which attracted considerably less attention than it should have. The idea was that options, conceived as probability distributions over monetary amounts, could be ordered in terms of risk, expressible as a linear combination of the mean and the variance of the distribution. As they make clear, this cannot easily be squared with expected utility theory. The utility function thereby defined "tips" over and goes into negative territory, which is not permissible.

The discouraging fact, however, is that the serious concerns raised by the Pollatsek and Tversky paper (and other non–expected utility models) have been largely ignored. Virtually all decision theorists simply take the expected utility theory and the independence axiom for granted.

Rationality and Social Explanation

This entry reviews the role of instrumental rationality in social explanation and the way such rationality expected of social agents fares with respect to different approaches to social sciences (naturalist vs. interpretivist).

Social science has its origin in commonsense views about human behavior (what philosophers call *folk psychology*). Common sense holds, among other things, that people act to get what they want. The notion of *instrumental rationality* is meant to capture this desire-directed pattern of behavior. *Rational* is a term of commendation: To call something rational is to say that it makes sense in some fashion. *Instrumental* rationality is concerned with the fit between desire and action: An instrumentally rational action inherits (some) value from an agent's goals because it (is expected to) advance those ends. Understood this way, instrumental rationality specifies a (family of) relation(s) between each person's ends (and situation) and her behavior. The relation has its roots in a normative claim—people *should* advance their ends—but once identified, it can serve descriptive purposes. Folk psychology suggests that people do act to satisfy their desires and so that actions will (tend to) be instrumentally rational. Rationality, then, is central to the commonsense explanation of human behavior.

Social science should, of course, advance beyond commonsense views. There are, however, different views about the nature of social-scientific explanation. Some see social science as continuous in its goals and methods with natural science (e.g., cognitive psychologists). These naturalists aim to uncover the causal mechanisms behind behavior. Others see social science as discontinuous with natural science (e.g., cultural anthropologists). Humans are distinctive, they note, in that they are self-guiding. Given this sort of agency, the point of social-scientific theories is not to get "beyond" actions to mechanisms but rather to interpret behavior in a way that makes it intelligible.

Most naturalists think that a rationality-based account of behavior can be integrated into the natural-scientific picture of the world. They suppose that the mechanisms that underwrite behavior are characterized (partially and abstractly) by folk psychology: Beliefs, desires, and so on, have real causal powers; such mental states cause behavior just as hitting a piece of glass causes it to break. Causal patterns are often expressed by decision-theoretic formalizations that go beyond common sense, but the basic idea still involves instrumental rationality: Agents do what they expect will satisfy their preferences.

Basing a naturalist account of social science on rationality claims leads to difficulties. Philosophical critics emphasize conceptual problems—for example, worries about the possibility of mental representation and worries that actions and mental states are too conceptually connected for the latter to be causes of the former. Social-scientific critics focus on empirical problems: People don't always fit the rational pattern. In complicated situations, people sometimes become confused and fail to see how actions relate to ends. Even in simple situations, people can fail to attend to some circumstance or end. Several people, for example, have fallen over the edge of the Grand Canyon when a photographer asked them to step back. Both the photographers and their subjects knew they were at the Grand Canyon—that was the point of the photographs—but they were all so focused on the process of taking a good picture that they failed to utilize their locational knowledge. The upshot is that actual human cognition imperfectly tracks the norms of even instrumental rationality.

Naturalists have resources for addressing the foregoing issues. Many philosophers defend the conceptual coherence of rationality-based causal accounts. The basic story is that mental states are realized by entities that can also be investigated at the neurological or physical levels. Fleshed out, this is supposed to ease worries about both mental representation and mental causation. Empirical difficulties do not seem to warrant the wholesale rejection of rationality-based views. People engage in desire-directed action even when they fail to fully live up to rational norms. The unfortunate Grand Canyon visitors were still acting toward one of their ends—getting a good picture. The puzzle is that they focused exclusively on that end (and the beliefs that it made salient). Common sense has rationality doing double duty as both a normative and a descriptive account,

but naturalist can't sustain that intuition: An empirically adequate account of behavior will diverge from its normative roots.

On the interpretive view of social science, instrumental rationality is more than a mere behavioral hypothesis: It is the fundamental standard for intelligibility. Social science begins, then, with a proprietary scheme for making sense of human action. Familiar behavior is already intelligible, so the real work is to assimilate unfamiliar actions (e.g., those in other cultures) to the rational pattern. Interpretation, on this view, is a kind of translation project: Action is a sort of "text" that others attempt to "read." The conceptual background of action is like the language in which an utterance is expressed: Both have conventions and norms. Fluency, in either case, is the capacity to follow (and exploit) those conventions and norms. A social scientist must immerse herself empathetically in the concerns and situations of others in order to understand their "languages" and so their "statements." While this is very different from the naturalist approach, it depends even more strongly on instrumental rationality.

Interpretive social science faces an issue connected with the empirical challenges to naturalist social science: Some actual (sets of) behaviors just don't seem consistent with instrumental rationality. To the extent that someone's range of actions can't be seen as advancing her system of ends, her behavior can't be explained. Consider, again, a person who falls in the Grand Canyon after following the suggestion to "scoot back." Her desire to take a good picture renders her behavior only partly intelligible. Given what she already knows, a backward step thwarts virtually all of her ends (even her photographic goal). If some actions fail to meet the standard of instrumental rationality, then interpretivists will be forced to conclude that some behavior is at least "inarticulate" and probably just unintelligible.

Realism and Anti-Realism in the Social Sciences

The problems of realism and anti-realism are diffuse, ontological, and epistemological; roughly, they are problems of determining what exists and what can be known to exist. We are, accordingly, forced into some philosophical minefields with some huge consequences regarding the methodology and the goals and limits of social science. After explaining what common sense understands by realism, this entry reviews the rise of scientific realism and anti-realism; discusses the main issues involved in the realism/anti-realism debate in social-scientific matters—that is, the issues of explanation, objectivity, and what it means to hold that reality is socially constructed; and ends by presenting a third kind of realism, called *critical realism.*

Commonsense Realism

We begin with the realism of the ordinary person, called by philosophers *commonsense realism, naive realism,* or *pre-critical realism.* It is a realism that takes for granted the existence of the world just as it is experienced. Physical "things," rocks, chairs, and gorillas, are "out there," "observable," and all *certainly* exist. This "world" becomes the paradigm for existence claims. But this "world" might also contain ghosts, souls, or God. And this is bound to stimulate further inquiry. All inquiry, from the mundane to the philosophical and scientific, begins with commonsense realism. But philosophical inquiry has had its effects on our understanding of science, perhaps, especially the social sciences.

Indeed, once René Descartes convinced people that they could doubt the existence of nearly everything—the external world, even God—modern

epistemology was born. Speaking broadly, two programs emerged. One followed Immanuel Kant, who held that *scientific* knowledge was restricted to the phenomenal world—the world of sensory experience. Moreover, this world was concept dependent: We experience rocks because we have the concept "rock." As a "critical" philosophy, the *noumenal world,* the world *not* perceivable by mortals (i.e., the world of "things-in-themselves") exists, but it is unknowable. It is the realm of faith, of God, freedom, and immortality. Commonsense realism was rescued for science without compromising either faith in a supreme being or the new deterministic science.

But another philosophy aimed at understanding modern science became historically dominant. Clearly articulated in 1830 by August Comte, it was developed by philosopher-physicists in the last quarter of the 19th century. As *the* philosophy of science, it became hegemonic in the 1930s with the *logical positivism* of the Vienna Circle.

The Rise of Scientific Realism/Anti-Realism

Science had to expunge all metaphysics. There were two main problems. First, naive realism had to be cleaned up. Second, what about "quarks" and the other nonobservables of science? The biggest cleanup was ridding science of commonsense causality. By the time of Comte, David Hume's analysis had succeeded in this. For Hume, causes would no longer be unwitnessable powers—not the powers of Gods, the telos of Aristotle, the "dormative powers" of opium, or, remarkably, the very commonsensible power of, say, a tidal wave or unobservable mechanism. For science, "*A* causes *B*" would not mean "*A* produces *B*." Rendered into the extentionalist logic of *Principia Mathematica,* it would simply mean "If *A,* then *B*." Ernst Mach and Pierre Duhem had already grasped the consequence: Since to explain was "to strip reality of the appearances covering it like a veil," *science did not explain.* Bertrand Russell took a different and retrospectively preferable route: The very *idea* of cause should be expunged from science. A phenomenalism would replace both naive realism and a critical realism that affirmed the knowability of the independently existing world.

In response to Mach and Duhem and with the tools of modern logic, the deductive-nomological (D-N) model of explanation became the normative standard of scientific explanation. Briefly, some event (or law) *E* is explained not by discovering *what brought it about* but by *deducing* it from a set of experimental laws and conditions. To ensure the absence of metaphysics, a distinction was drawn between theoretical terms (*T* terms) and terms in the observation language (*O* language). *T* terms could be part of a theory only if they were given clear empirical reference in the *O* language.

Scientific realism and anti-realism enter when we ask whether *T* terms refer to an existing entity. Realists affirm that they do: The *T* term represents an existing entity. Instrumentalists ("pragmatists") deny this. For realists who accept the D-N model, statements about the behavior of postulated nonobservables are either true or false. Presumably, then, the theory explains by deriving true consequences from true premises. For instrumentalists, a theory is neither true nor false but "adequate" in the sense that it gives "good predictions."

By the 1950s, positivists saw a serious problem with the instrumentalist account of theory. Carl Hempel framed it as a dilemma. If the *T* terms of a theory achieve their purpose—to establish definite connections between observables—they are not necessary. But if they do not achieve their purpose, they are surely unnecessary.

Most philosophers have opted for a realist interpretation of *T* terms. Milton Friedman, the economist, is a famous exception. In a very influential article, he insisted that it did not matter whether the premises of a theory were true or false. All that mattered were "good predictions." This opinion is widely held by social scientists and occurs in textbooks in the social sciences.

Objectivism

In the effort to model social science on natural science, many social scientists followed Émile Durkheim's dictum: Treat "social facts" as "things." Whatever Durkheim may have intended, the analogy to "natural facts" allowed sociology to be a genuine science. *Social facts had objective existence and could be known objectively through observation, reasoning, and logic.* This assumed the *O* language of naive realism and made irrelevant metaphysics, including post-Kantian critical realisms (see below). The judicious use of tests and "operational definitions" ensured empirical reference. If there were problems (and there were plenty of them), these could be left to the philosophers.

Quantitative work provides the best example. It identifies factors in ordinary experience as *variables* to be measured and correlated—"data." Thus, for example, the *dependent variable* might be "mental development," measured by four tests, and the *independent variable* "ethnicity." The regression yields an "explained variance" (R^2) of 11%. It is, however, not clear what this means.

Anti-Objectivism

There is, however, a body of work that takes a different stance toward the commonsense social world. Most critically, it rejects the assumption that this world is "given" and, following Alfred Schütz, holds that "objectivist" sociology ignores its primary requirement: It asks, "What does the social world mean for the social scientist" without first asking "What does the social *mean* for observed actors within this world?" and "What does the actor *mean* in acting within it?" With these questions, the social world is no longer naively accepted just as it appears but demands inquiry into the mechanisms of the activity by which actors understand one another and themselves. It demands asking not just what they believe but the genesis of meaning and the processes involved in reproducing and changing belief and meaning—including here the practices of social scientists. *Verstehen* ("understanding") and the assumption of intersubectivity is methodologically critical.

There are a large number of otherwise very different versions of this view. Symbolic interactionism, ethnomethodology, and the work of Erving Goffman stand out. But the main idea is affirmed also by so-called postmodernists, some Marxists, and the more recent efforts of Pierre Bourdieu, Anthony Giddens, and critical realism. Both groups of writers are vigorously antipositivist. But in challenging objectivism, questions regarding relativism and the reality of the social world were challenged.

The Social Construction of Reality

Commonsense realism left no doubt as to the existence of rocks or trees. Consider then, mortgages, money, husbands, criminals, and a host of other commonsense "kinds." Surely these also exist and are real. But there is a huge difference in the ontology of the "objects" in the two lists. The objects in the first list exist independently of us in the sense that were there no longer persons in the world, these objects would still exist. *This is not true of the other list.* They are "concept and activity dependent." Without us, the paper of the dollar bill would still exist. It would still burn, but it is only money if people accept it in exchange. Indeed, *all our interactions* take for granted a host of interconnected socially constructed institutions and practices that, taken together, constitute our social world and its history. All of these have histories, which as Karl Marx noted, we make, though only with materials at hand.

It was perhaps inevitable, however, that social construction was particularly aimed at practices that were not only taken for granted but were deemed inevitable, bad, and, accordingly, demanded change. This has ignored the fact that no element of the social world escapes social construction in the foregoing minimum sense. While the focus on objectionable constructions has been liberating, there are problems. One is the tendency to ignore the *reality* of the social world, to ignore the *material conditions* of action, and to suppose a subjectivism in which reality is entirely in the mind of actors. But while social construction rejects "objectivism," it requires "intersubjectivity," *not* "subjectivity." The tendency toward subjectivism has led some writers to suggest a radical relativism and to hold that social change is merely a matter of showing that if the object is a social construction it is instantly malleable.

A bigger problem, perhaps, is the collapse of the distinction between "social reality" and "reality"—the view that *everything* is a social construction. Ontologically, this is a form of *philosophical idealism* (as in Bishop Berkeley: "To be is to be perceived") and, more recently, a *linguistic idealism* (in which only what is discursive exists). Idealism in this sense is a contrasting term to realism, that there is a knowable independently existing external world.

It is easy to see what motivates relativism and idealism. The realist supposes that there are true representations of reality. But the realist acknowledges that representations (ideas, concepts, theories, etc.) are socially produced, that we can know an object only under some description, and that we cannot achieve a "God's eye view of the world." Hence, "correspondence" cannot be the *test* of truth. Hence, as there are competing incommensurable descriptions, there are competing socially constructed "worlds."

To be sure, science is fallible; but if, as the pragmatist Charles Sanders Peirce insisted, belief needs to be constrained by "the real" and if competing worlds

("paradigms") are not incommensurable, then they can be evaluated. Indeed, the "quest for certainty" would seem to be an unspoken assumption of views that deny all utility to evidence and argument. Second, we can distinguish between the social construction of a *representation* of reality and the construction of reality itself. Thus, constructing "kinds" (gorillas, criminals, or subatomic particles) may well be open to various alternative conceptual schemes ("theories"), and this is important but, as noted, not fatal. The reality of the putative extension of a kind, like the choice of conceptual scheme, can be determined by evidence and argument. Thus, we have the concept ("idea") of witches, corpuscles, or (appropriating Ian Hacking's example) "satanic ritual child sexual abusers." For the realist, there are no witches, corpuscles, or satanic ritual child sexual abusers. There are, however, gorillas, child abusers, and quarks. And all three existed before we had the pertinent concept.

Here, another contrasting pair is pertinent: the dichotomy between *realism* and *nominalism*. In one of its senses, the realist holds that "the world" (natural and/or social) is structured. "A good account" represents this structure. Nominalists deny this. For them, there is more than one way to provide a good account. The difference in the ontologies of the natural and social worlds suggests that one might be a realist—even a critical realist—as regards one, the natural, and a nominalist as regards the other, the social. That is, perhaps there are "natural kinds"—NaCl, mammals, or oranges—but only "ideal types" as regard social "kinds." Max Weber here comes to mind.

Critical Realism

In the 1970s, *critical realism* began to attract attention. To distinguish it from those realisms that accept the D-N model, we refer to what follows as "critical realism," although this term has both a wider and a narrower reference, including, for example, Roy Wood Sellars, Bernard Lonergan, Roy Bhaskar's wing of the new realist movement, and, indeed, several important writers, such as Giddens and Bourdieu, who seem to share in a consensus on key critical realist themes but have not identified themselves as realist, critical, or otherwise. (Critical realism is also a recent position in economics advocated by Tony Lawson—see the entry "Critical Realism in Economics.")

One obvious point of consensus is the effort to articulate a third way between the neopositivist ("empiricist") philosophy of social science and antinaturalisms, which reject the idea of a human "science." As part of this, it holds to a post-Kuhnian epistemology, which denies a theory-neutral "given" and a God's eye view of the world. Instead, an ontological realism is joined to the hermeneutic tradition in epistemology, providing what might be called a "situated objectivity" and a "modest relativism."

Second, and perhaps most important, is the rejection of the empiricist Humean's conception of cause, and the "event" ontology on which it rests. The main idea is this: Instead of asserting that causality reduces to a regularity between two "observed" events *A* and *B,* the critical realist, following Rom Harré, seeks the *causal mechanism or mechanisms—observed or unobserved*—that *explain* the regularity. The D-N model is firmly rejected. Thus, NaCl dissolves in H_2O *because* of their respective molecular structures. Indeed, for the critical realist, providing an understanding of the contingent regularities found in experience is precisely the goal of theory. Accordingly, critical realists reject the idea that the goal of science is prediction and control.

The foregoing has been meant to apply to social science as well as natural science. But this has been controversial. The socially constructed character of society contrasts sharply with the mind independence of the natural world. This difference has many consequences, ontological and methodological. Rocks and money are both real. But first, the difference between them requires an ethnographic moment for social science in which we investigate the beliefs of members. This is not true of inquiry in natural science. Second, because practices are concept and activity dependent, there is an emancipatory moment in social science: When we act differently, structures change. But third, if independently existing "nature" is the object of inquiry in natural sciences, what is it in the social sciences? "Persons?" "Their actions?" "Social structures?" "Society?" In particular, to what may causal powers be attributed?

Among realists, this question has been contentious. But because critical realism is very much agent oriented (in contrast to "objectivist" sociology), there is a general consensus on two absolutely critical points. First, persons have causal powers: They can make things happen. Second, and as important,

what they do is *not* "determined" in the sense that they could not have done otherwise. This conclusion follows from rejection of the determinist ontology of positivism. There are no "closed systems," and all "events"—including the acts of persons—are outcomes of complex causality understood in realist terms. In what they do, actors are enabled and constrained. But how are they enabled and constrained?

Unfortunately, on this issue, the water is muddy. Perhaps four positions may be discerned.

1. Social structure is real in that it is causally efficacious (e.g., as evinced by Bhaskar). This is essentially the Durkheimian position, *except that* structures (and society) do not exist independently of human activity, the error of reification—treating what is unreal as real. Unlike the "dialectical model" developed by Peter Berger and Thomas Luckmann, action does not *create* structure: For any individual, it is already made. Hence, as medium and product, action can only reproduce or transform it. Some critics have found this position incoherent.

2. At the other extreme (e.g., in Harré), social reality is exhausted by what people do. The roles, rules, and conventions that are implicated in action are not "powerful particulars" but are only "discursive"; hence, they are the "wrong kind of thing" to have causal powers. For Harré, Bhaskar and most critical realists are guilty of reification. According to most of them, Harré lapses into a sociologically impoverished methodological individualism that even disclaims the theoretical use of, for example, class. Critics argue that discursive acts have both concrete meaning and material conditions and consequences. Thus, even if discursive acts sustain, for example, class, assembly-line activities presuppose workers who need a job, and there are material consequences, for example, the autos that are sold for profit.

3. A compromise is suggested by Giddens: Social structure has but "virtual reality," incarnate in the practices and activities of persons. On this view, social structure lacks "substantive" reality and is an abstraction from concrete activity. Since rules and conventions define resources that enable and constrain action and these are only intersubjectively sustained—to avoid reification—this is read by critics as an idealism.

At issue here is the question of whether Harre's realist causal theory of "productive powers" offers a sufficient analogy between causation in the social and natural sciences. The idea of a social mechanism, reproduced by acts of agents, with consequences, generally unintended, is pertinent here.

4. Finally, is a causal theory of explanation the preferred model of explanation? Here, commonsense realism is on the side of the critical realists, not merely in affirming a productive power account of causality but also in making the agency of persons the paradigm of causality. We are not likely to get from social science better explanations of action than common sense gives us. Accordingly, the goal of social science is not the explanation of behavior. Rather, it is, as in natural science, an understanding of the patterns and regularities found in social reality.

Reduction and the Unity of Science

Reduction replaces more with less. In philosophy and science, this means one of three things. In *ontological* reduction, one entity has its place taken by the other (often its own constituents). The other types are *epistemological:* In a *methodological* reduction, one way of studying something is used in favor of another. In a *theoretical* reduction, the work of one scientific theory is done by another.

Each of these suggests a way of *unifying science*. If everything is constituted from a set of basic entities, then we have general ontological reductionism. If there is a single correct method for all science, then we have general methodological reductionism. If all scientific theories reduce to one, then we have general theoretical reductionism. These reductions can, but do not need to, coincide. Even if overall reduction is blocked, partial reductions may be possible.

The history of social science includes various programs animated by ideals of unity or reduction. Auguste Comte wrote of a "social physics" (later called *sociology*) methodologically inspired by natural science, but he saw sociology as being less abstract than physics or mathematics. Karl Marx envisaged a science of history that could achieve the predictive successes of some physical sciences.

This entry looks at early views about reduction and unity and describes the main types of reduction and the major sources of opposition to reduction.

Early Ideas

Notions of unity are very old. Pre-Socratic philosophers proposed that everything was a single substance (water for Thales), a single principle (change for Heraclitus), or something more abstract (ideal forms for Plato, numbers for Pythagoras). That the world was unified made unified knowledge possible. In between these ancient thinkers and the modern Scientific Revolution of the 17th century, various mystical visions of unity were developed, some inspired by the idea that all knowledge was expressible in a single language or code.

Since the beginning of the Scientific Revolution, more modern visions of unity have been articulated and views rejecting unity developed. For Descartes, Galileo, and other "mechanist" thinkers, mathematics provided an inspiration, and they held that systematic knowledge was essentially mathematical. They were motivated by the power mathematical approaches showed in overthrowing ancient views about the universe and in explaining various mechanical and optical phenomena.

Most mechanists thought that the important properties of the physical world were quantitative and geometric ones like position, shape, and velocity and that all material processes could be explained by reference to them. They hoped that *all* physical knowledge could be found by the same means as had worked in areas like astronomy, ballistics, and optics, and so could be unified. Their views combined elements of ontological and epistemological reduction, with the important qualification that most of them were dualists, who thought that immaterial souls (and God) also existed and could not be studied by the same methods as physical things.

Mechanism failed for various reasons, both within physical science and outside it. Isaac Newton's account of motion was a major scientific success but was not strictly mechanist, partly because it referred to forces. His work suggested a different kind of method and also the possibility of other kinds of force. Charles-Augustin Coulomb's later discovery of a law and force of electrostatic attraction, along with increasingly sophisticated biology and chemistry, suggested that the material world was more active, and more varied, than the early mechanists had imagined. This suggested new ways of conceiving unity and different forms of and challenges to reduction.

Ontological Reduction

The most common form of ontological reductionism in contemporary philosophy is *physicalism,* or the view that everything real is in some sense physical. Physicalism is not mechanism, because what is physical includes things not recognized by mechanists (e.g., fields and forces), and it is up to physics, not philosophy, to determine what is physical. Many physicalists support the autonomy of some nonphysical sciences because they think that theoretical reductions are blocked. The success of ontological physicalism is partly attributable to the demise—within science—of metaphysical dualist views, which held that that people were a combination of mental and physical substances. Growing understanding of the brain helped defeat dualism, as did the failure of

vitalism (the view that nonphysical forces operated in some biological processes). Inspired by Newton's example, biologists and chemists had posited additional forces to explain biological and chemical phenomena that resisted mechanical explanation. Later experiments, especially concerning the conservation of energy, largely ruled out vital forces, and advances in quantum mechanics indicated that the structure of the periodic table was a fully physical phenomenon.

Ontological physicalism is dominant, but among the majority who support it, there is debate about whether any epistemological reduction of nonphysical knowledge is possible.

Methodological Reduction

The most successful and widely supported methodological reduction is mathematics, where it is commonly held that all mathematical knowledge can, or at least should, be expressed in axiomatic set theory. Matters are more complicated where theories have empirical content, as in science.

A historically important methodological reduction in philosophy was logical empiricism, which held that claims about material objects could be reduced to claims about the content of sense perception by human observers. Despite some important achievements, this program was defeated and is no longer a serious philosophical option.

The most famous and controversial methodological reduction in the human sciences was behaviorism. Behaviorists held that introspection was scientifically useless, so psychological phenomena should be studied by reference to evidence about publicly observable evidence—primarily inputs (stimuli) and outputs (responses). Behaviorists made important discoveries about motivation and patterns of behavior. But behaviorism has been displaced from its central role by research programs that study states and processes intermediate between input and output. Part of the explanation for this is the rise of methodological approaches that worked out how to infer aspects of the computational properties of intermediate processes from patterns in input and output.

In social science, Comte, John Stuart Mill, and others held that social phenomena were no more than the sum of activity by individual people and should be studied as such. A related view in biology held that living things could be understood in terms of the combined activity of their individual specialized organs. Neither view remained dominant. In psychology, Lev Vygotsky and others challenged it, arguing that higher mental functions depended partly on social processes, including feedback. The notion of feedback was also important for the rejection of simple organ decomposition in biology by cyberneticists. It is now clear that some but not all social phenomena can be understood individualistically.

There is no committed defense of global methodological reductionism in empirical science today. Besides the specific failure of logical empiricism, the reasons for this include the fact that few now think that there is any interesting sense in which there is a distinctively scientific method. Instead, we see occasional and specific reductions between this or that science. Most contemporary debate over reductionism concerns theoretical reductions.

Theoretical Reduction

In the natural sciences, reducing one theory to another usually means showing that under some conditions the one is a special case of the other. For example, Galileo's view that the path of a projectile is a parabola is a special case of Newton's that it is (a section of) an ellipse, under false assumptions such as that gravity operates in parallel lines. Even though the required assumptions are false, the reduction helps clarify how the theories relate. This kind of reduction, where the theories are about the same things, is not usually controversial. Most debate and discussion about reduction in the social sciences has focused on the issue of reduction between theories about different things.

Theoretical reductionism differs from methodological reduction in that it is not a view about how enquiry should be conducted but about how what is discovered can be related. Two sciences may proceed by different methods, but the theory produced by the one might still be reduced to the theory produced by the other. The two main forms of reduction in this intertheoretic sense are "microreduction" and bridging reduction.

Microreduction

In 1958, Paul Oppenheim and Hilary Putnam argued that the history of science showed a trend toward the unification of science by microreduction. One branch of science microreduces to another if the

parts of things described by the first kind are studied by the second and the second can explain any observations that the first can explain. They divided the world into six levels, from "social groups" to "elementary particles," and argued that there was a trend toward unification by microreduction.

This approach to theoretical reduction was partly motivated by a form of ontological reductionism where complex things had parts and there was a most basic physical kind of part, from which everything was made. But it is primarily a view about the relationships between theories.

General microreductionism failed spectacularly. The evidence in favor of it, especially for the social and psychological levels, was never strong, and there is overwhelming evidence that relational and external properties between parts are often scientifically crucial. Various programs of "cybernetic" or "systemic" thinking about biological and social systems have emphasized this and accumulated much of the evidence. Microreduction is unsuitable for describing important "within-level" reductions such as the reduction of Galileo's account of projectile motion to Newton's account of motion, because such reductions do not involve part–whole relationships. Finally, the other main form of theoretical reduction has led to more intense and fruitful debate.

Bridging Reduction

Most philosophical discussion of reduction has been organized around a model of reduction articulated by Ernst Nagel, who held that reduction is the (deductive) *explanation* of a theory by another theory. Nagel distinguishes between *homogeneous* reductions (where the theories share "descriptive terms") and *heterogeneous* ones (where the vocabularies of the two theories differ). In these cases, Nagel proposed that reduction would require additional assumptions in order to connect the theories.

He described an example where subject to a number of assumptions temperature could be related to mean kinetic energy of molecules and the Boyle-Charles law for ideal gases could be reduced to statistical mechanics. Nagel was clear that this reduction did not do away with thermodynamics (the study of temperature) and that achieving the reduction depended on various pragmatic factors, including the state of development of the two theories and the independent plausibility of the additional assumptions. Nagelian reductions can also be *partial*—so different assumptions may be needed in order to deal with nonideal gases, or no reduction may (yet) be possible. Much later discussion of reduction, especially in the philosophy of mind, and about the "special sciences" has ignored these pragmatic and contextual factors in two ways. First, it has focused on idealized or "toy" theories rather than specific actual science, and second, it has treated Nagel's requirement of connectability in narrowly logical terms, as requiring either laws linking the two theories or identities between the kinds referred to. This logical version of the requirement is the main target of the most famous and widely discussed arguments against reductionism. Under this idealized reduction, the reduced theory would become redundant, since *all* of its content could be generated from the reducing science plus the "bridge laws."

What this means is that it is important to be clear whether a specific reduction between actual theories is being discussed or general reductionism possibly about idealized theories, and in both cases, it is necessary to be clear about what counts as a reduction.

Contemporary Opposition to Reductionism

The most important positions opposed to the unity of science, or to reductionism, are various forms of dualism, emergence, and functionalism. These categories are not, as we will see, strictly exhaustive, and so some positions may combine elements of both.

Dualism

Metaphysical, or ontological, dualists hold that there are two different fundamental kinds of substance or stuff. Most commonly these are something material, or physical stuff, and something mental, or immaterial stuff; hence, "mind–body dualism" described what was the case for entities that consisted of both kinds of stuff—such as humans. Instead of two kinds of "substance," some more recent dualists prefer to speak in terms of one and the same individual entity having both physical and mental "properties." Whether this way of putting things amounts to an ontological dualism depends on the applicable theory of properties. From outside of philosophy, the difference is rarely easy to discern. Whether they are ontological or not, property dualisms (or pluralisms) are relatively common. And to

the extent that they are correct, they may present challenges to methodological reduction and theoretical reduction. If minds are not the same kinds of entity as bodies or if mental properties aren't the same kinds of property as physical ones, then it is not obvious that they should be studied in the same way or that theories about them could be integrated.

There are almost no contemporary metaphysical dualists within science. But some other dualisms continue to command respect. One used to be called the distinction between "spirit" and "nature." In the late 19th century, Wilhelm Dilthey argued that the human sciences (*Geisteswissenschaften*) should be contrasted with the natural sciences (*Naturwissenschaften*) because the former are distinctively concerned with interpretation, context, and normativity and because the importance of history and interpretation places limits on how general explanations in the human sciences can be compared with those in the natural sciences. Many still share this vision of a deep and fundamental division between natural and human sciences. More contemporary members of this family of views hold that intentionality or values are not reducible and hence that beings that have either (especially humans) should be studied accordingly.

Recent science has complicated matters for these views. Some theoretical approaches are used on both sides of the imagined division. Evolutionary game theory, for example, unifies aspects of microeconomics, biology, psychology, and political science, among others. The current range of applications of this theory wreaks havoc upon attempts to demarcate the natural and social sciences by reference to theory or methods, because the very same theoretical tools have proved illuminating with respect to phenomena that are human and nonhuman, social and nonsocial, conscious and nonconscious.

Emergence

A property of some system is called *emergent* if it arises out of the interactions of the parts of the system but is not predictable from the properties of the parts. Talk of emergence was first popular in the 19th century and was partly inspired by attempts to make sense of chemistry and biology. Mechanistic explanations of chemical phenomena were unconvincing, and chemical processes appeared to be nonadditive in that some combinations of substances had properties (transparency, flammability) that the individual substances lacked. Various biological phenomena lacked satisfactory mechanical explanations. In both cases, emergent properties, structure, or causal powers (sometimes called "vital forces") seemed to some like attractive hypotheses.

Not all emergentist proposals fared well. A physical explanation for key chemical phenomena was provided by quantum mechanics. Experiments with conservation of energy in living things suggested that there was neither need nor room for vital forces. More generally, what is predictable is partly dependent on the resources and technology available for making predictions. Contemporary computer simulations and models have been used to investigate the results of many kinds of interaction, and the results sometimes are called "emergent." But the existence of the simulation shows that the result is predictable in at least one way. If *emergent* is taken to mean surprising to at least some people, then it is irrelevant to reductionism or unity of science. To count against theoretical reduction, what emerges has to be patterns or regularities on larger scales, perhaps with functional properties.

Functionalism

Functionalism is the view that some states (including mental states) should not be understood by reference to their internal constitution but rather in terms of how they relate to other states and parts of the system they occur in (i.e., in terms of their function). This view suggests that part–whole reduction is irrelevant. Given an additional argument, part–whole reduction is also incorrect. The additional argument is the "multiple-realization" argument, contending that quite different internal constitutions can implement the same function. So, for example, a "memory" might be constituted from neurons or transistors—what makes it a memory is whether it can return stored information appropriately in response to a request from elsewhere in the system. A major motivation for functionalism and the multiple-realization argument was the artificial intelligence (AI) research program, which would have been doomed from the start if psychological states could not possibly occur in systems other than brains.

Functionalism has a more complicated relationship with bridging reduction. The multiple-realization argument is often taken to defeat bridging

reduction but is typically aimed at the caricatured version (idealized toy theories and construing the additional assumptions as laws) described above. Given this picture, some have argued that functionalism produces explanations that are redundant (there is no causal work for the functional states to do because that is all done "at the physical level") or that gratuitously multiply causes (actions are caused both physically and mentally).

Conclusion

Reductions are often contentious. One reason is that they sometimes threaten the autonomy of the science, entity, or phenomenon being reduced. Another is that they can seem to require leaving out or denying the reality of things that some people find important. This partly explains why "reductionist" is often a term of abuse. There is a trade-off here. Genuine reductions are worthwhile intellectual advances. Premature or failed reductions, if taken seriously, might foreclose inquiry where it is needed. That said, debating whether whole categories of phenomena or theory could be reduced without paying attention to real scientific detail has rarely produced anything of scientific interest. Individual cases need to be taken on their specific merits.

Reductionism in the Social Sciences

There are several ways the issue of reductionism in the social sciences could be pursued. A traditional philosophical approach might provide broad philosophical argumentation about the ontology of the social world and our knowledge of it, relying on conceptual considerations. This entry does not pursue such an approach, which embodies ideas that have largely been rejected in philosophy of science and has little if any direct connections to reductionism as social scientists conceive it.

A second approach, adopted here, could be called *naturalist*. A naturalist approach takes social science and the philosophy of social science to be continuous. Philosophical issues are not first decided by a priori conceptual analysis and then applied to the social sciences. Issues in the philosophy of social science are in the end empirical issues, though of course being clear on concepts is important. Moreover, social scientists worry about concepts all the time and often do what could be called philosophy of social science. Reductionism in the social sciences on this view then is an issue, or a set of issues, within social science, albeit one to which philosophical

tools may be relevant. Interesting reductionist claims will have to be investigated in the context of specific social explanations, evidence, and theories.

Reductionism Viewed From the Philosophy of Science

One possible form of reductionism in science in general has been described with some precision by philosophers in terms of what might be called *intertheoretic reduction*. It is assumed that there are well-confirmed and clearly statable theories available. A reduction takes place when all the well-confirmed generalizations or explanations of one theory can be derived from another. Such derivations will require some way to relate the basic categories or terms of one theory to the other, since different theories will use different categories or vocabulary. Usually, this translation is thought to come about via what are called *bridge laws*—connecting statements that link each basic category to some category or categories in the reducing theory. So reductionism in biology might have occurred when the notion of a gene, after having been postulated but not understood in biochemical terms until the mid 20th century, was identified with stretches of DNA that code for a protein. Such translations may call for refinements in the theory being reduced: To continue the genetics example, we might find out when we look at the DNA behind heredity traits that what we thought was one gene was the interaction of two separate genes. Such translations are also not necessarily equivalencies of meaning—the ordinary term *gene* did not have DNA as part of its original meaning, since genes were identified long before DNA was understood. Classical cases of such reduction are thought to be the reduction of genetics to molecular biology, as mentioned above, and the reduction of the gas laws (e.g., temperature is proportional to pressure and volume) to the branch of physics called *statistical mechanics,* which applies Newton's laws to the behavior of particles in a gas. By using the bridging link that temperature is the mean kinetic energy of the atoms of the gas, it can be shown that the gas laws follow from Newton's laws. Putting the further details of this philosophical account aside, the basic idea behind it does seem to capture one important sense of reduction: One theory reduces another when it can explain everything the other theory does.

Advocates of Theory Reduction in the Social Sciences

Both philosophers and social scientists have seemingly advocated this kind of reductionism in the social sciences under the guise of what is called *methodological individualism*. It is common to find philosophers and social scientists saying that everything in the social world can be explained in terms of individuals, their beliefs, their actions, and their relations to each other. Much of modern economics advocates such a view, where the paradigm explanation of social phenomena is in terms of individuals maximizing their outcomes in a market given their resources and preferences (rational choice theory). Numerous social scientists have thought that some such picture applies across the social sciences, not just in economics. For example, rational choice social science tries to show how political institutions, norms, and other social phenomena result from the rational choices of individuals, given their situation and circumstances.

Methodological individualists often define or defend their position with the seeming truism that society does not act or exist independently of real human beings. If an institution or organization exists and behaves in various ways (e.g., corporations exist to pursue profits), it is because individual human beings act collectively to do various things. Social influences, such as "the spirit of the times," that act independently of individuals are mystical and unscientific.

Methodological individualists in the social sciences have defined their position in opposition to what they call *holism*. Holism is often put forth as the view that macrosociological entities such as social classes and governments are real, have "emergent properties"—ones that cannot be predicted from knowledge of individual behavior alone—and even have causal powers of their own in that they can influence individuals. Founders of modern sociology such as Émile Durkheim, who talked about "social facts" that he believed were the domain of the social sciences, advocated holist views. Many contemporary social scientists do so as well, often putting the issue as one about the irreducibility of a social structure that constrains individual behavior. In economics, macroeconomics seems to work in terms of supra-individual aggregate entities such as gross domestic product and aggregate demand.

Reductionists in economics would claim that macroeconomics is not legitimate until it has what

they call *microfoundations,* which is sometimes put explicitly as the reductionist idea that macroeconomic results can be derived from the behavior of individuals maximizing their preferences under budget constraints in markets. Social scientists sympathetic to rational choice models in their disciplines similarly ask for microfoundations and put their demand as one of fully explaining social phenomena in terms of individuals acting on their beliefs and desires.

Important work in agent-based modeling in the social sciences also seems to require such individualist understanding of social phenomena. Agent-based modeling uses simulations, mostly computer based, to show how agents following relatively simple rules—their preferences—produce recognizable social phenomena when they interact. As social scientists sometimes put it, the idea is that you have not explained a social phenomenon until you have grown it from individual behavior. A pathbreaking early instance of this stance is found in the work of Thomas Shelling, who showed how residential racial segregation could arise from individuals who had only a very weak preference for living in neighborhoods where they were not a racial minority.

It is important to note that all these versions of individualist reductionism in the social sciences allow and generally make it mandatory that the interactions and relations among individuals are an important part of the explanation of social phenomena. There are some social scientists, however, who advocate an even stronger or demanding form of reductionism that gives relations and interactions among individuals little or no place. This doctrine is sometimes known as *atomism.* For example, social scientists sympathetic to sociobiology—the explanation of social phenomena in terms of traits in humans evolved by natural selection—sometimes advocate atomist ideas. Wars, for example, might be explained as the result of evolved aggressive tendencies of humans—groups of humans commit aggression because they are composed of aggressive individuals.

Potential Obstacles to Reductionism as Theory Reduction

The philosophy of science literature on this version of reductionism has identified several potential obstacles to viewing reductionism as theory reduction. First, social entities such as social classes, organization, and corporations and social processes such as revolutions are potentially what philosophers call "multiply realizable." They are multiply realizable in that a corporation, for example, can be organized in many different ways in terms of the individuals composing them, and while corporations may try to maximize profit, many different kinds of individual behavior may make that happen.

Multiply realized social entities and processes create a problem for theory reduction. The problem is that there does not seem to be one set of individual behaviors, attitudes, and relations that can be used to translate social categories into the categories of explanations solely involving individuals. Explanations such as "corporations seeking to maximize profit in a competitive market results in wages equaling the marginal product of labor" seem to work fine in invoking social entities and processes, but it is not at all clear what set of individual behaviors we can use to define those entities and processes in individualist terms.

The second problem for reductionism in the social sciences as theory reduction is that when we do explain social phenomena in terms of individual behavior we do so by taken as given and unexplained important social processes and entities. To the extent that we take social entities and processes as given or essential to an explanation, the social has not been reduced to individual behavior. For example, an important type of individualist explanation in the social sciences comes from game theory. Game theory models social phenomena as resulting from individuals pursuing their preferences with given resources by adopting strategies concerning how to react to specific behaviors of others. Game theory takes those possible strategies and shows what set of strategies would be an equilibrium—the situation where each individuals response was his or her best given the responses of everyone else—for individuals "playing" against each other.

Such explanations are about individuals, but they are about individuals in a social context. The norms and socialization influencing their preferences are assumed already to exist, as is the division of resources among individuals; the types of individuals—such as owner and worker—are often assumed to be in place. So these are explanations in terms of individuals but in a preexisting institutional context.

What are the consequences of these potential obstacles? They show that a common argument for reductionism in the social sciences that we saw earlier—that social entities are composed of and do not act independently of individuals—may not be

compelling. While it may be true that social entities do not exist and act independently of individuals, this does not tell us anything about our powers to explain. It does not tell us that the categories we use to explain social phenomena have translations into the categories we use to describe individuals—social categories may be multiply realizable. It does not tell us what our explanations of individual behavior are like—they may invoke unexplained social context.

Another consequence of these obstacles is that reductionism in the social sciences is an empirical issue and we need not expect any uniform answer to the question of whether the social is reducible to individual behavior. Maybe in some cases the multiple-realization problem is not real and explanations in terms of individuals are possible without invoking unexplained social context. Maybe in other cases the problems are real and reductionism is an implausible view.

Yet a third consequence is that successful reductionism may be a matter of degree. Some accounts may be more individualist than others in that they presuppose less unexplained social context. For example, we mentioned earlier the simulation-type explanation of residential racial segregation, which shows that it could result simply from the preferences of individuals to live in proximity with others in their racial group. However, it is an empirical issue whether this is a full explanation in terms of individuals. First, preferences to live with one's racial group may in fact result from participation in institutions and social arrangements promoting racial discrimination in general, and so social factors are still needed to explain residential racial segregation. Second, it is an empirical question even whether preferences for one's own race are sufficient to explain residential segregation. There is evidence that banks may discriminate against qualified African American loan applicants, preventing them from buying in prosperous White neighborhoods. If true, this explanation would explain not just in terms of individuals but also in terms of the social organization of society and its institutions.

Reductionism in the Social Sciences and Mechanisms

Another trend in the social sciences and philosophy of science that is in the spirit of reductionism is one that emphasizes mechanisms, in particular mechanisms describing the behavior of individuals. A contemporary approach in sociology that calls itself "analytic sociology" advocates such views, though many other social scientists have at times expressed such views. The basic intuition is that explanations of social phenomena are incomplete until we see how they are brought about by the actions of individuals.

Social scientists and philosophers have put forth different versions of the idea that we need individualist mechanisms, not always keeping the difference entirely clear. If the idea that we need individualist mechanisms means we can explain everything in terms of individuals, then this version of reductionism in the social sciences is not really different from the theory reduction version described above. Some advocates of producing individual mechanisms in the social sciences, however, are clear that they do not imagine the social sciences explaining without appealing to the existence of institutions and social organization. Rather, they view mechanisms as showing how individuals acting within the social constraints provided by the preexisting social organization and structure produce social phenomena—that is, why individuals act the way they do in the social situations they find themselves in. This, more moderate reductionism has been around since the beginning of the study of society by broadly scientific methods. For example, Karl Marx thought that society had to be explained in terms of the economic classes that composed it. Yet he also believed that people make their own history, but not just as they please—they face social constraints.

This more limited kind of reductionism in social science can legitimately be seen as being behind much of current social science. We mentioned game theory and rational choice theory earlier. Both are extremely influential in the social sciences. Both can be seen as explaining the actions of individuals, given the institutional constraints they face. It seems undeniable that such approaches have led to progress in the social sciences, though some social scientists think that they overstate their success, in part because they often rest on unrealistic assumptions about individuals—for example, that they are fully rational.

There are several other approaches in the social sciences that advocate reduction to individual behavior in social context. The traditions in sociology known as *ethnomethodology* and *symbolic interactionism* are very much about giving accounts of individual action in social context, arguing that such

accounts have a central place. Unlike game theory and rational choice theory, they advocate accounts of individual agency that de-emphasize the role of rationality and maximizing in explaining individual behavior, in favor of what they see as a richer framework involving the processes whereby individuals create meaningful social worlds.

Conclusion

Reductionist ideas have had an important influence in the social sciences. They have taken two main forms: as advocating either that all social phenomena can be accounted for solely in terms of individuals or that the social constraints imposed by societal organization and institutions must be linked to the individual behavior they shape. These programs have been popular and productive to different degrees, depending on the social science in question and the type of phenomena being explained.

Reflective Equilibrium

Reflective equilibrium is a philosophical account of method, justification, and theory construction in ethics and political philosophy. John Rawls introduced the term *reflective equilibrium* to depict a way of bringing principles, judgments, and background theories into a state of equilibrium or harmony. The thesis is that justification in ethics and political philosophy occurs through a reflective testing of moral beliefs, moral principles, and theoretical postulates, with the goal of making them as *coherent* as possible. Reflective equilibrium, as a theory, is therefore often referred to as a form of *coherence theory,* or *coherentism*. Proponents of justification by coherence hold that a theory or set of moral beliefs is justified if it maximizes the coherence of the overall set of beliefs that are accepted upon reflective examination.

The goal of a coherence of norms assumes that there are norms to be shown or made coherent. One must start, in moral and political reflection, with a particular body of beliefs that are acceptable initially without argumentative support. According to Rawls's account, method must begin with what he calls *considered judgments*. These moral and political convictions are those in which we have the highest confidence and that we believe to contain the lowest level of bias or distortion of perspective. Considered judgments deserve this status because they are so deeply entrenched in moral thinking that

any morally decent person would accept and act on them. Examples are norms about the wrongness of racial and sexual discrimination, religious intolerance, and political repression. Considered judgments occur at all levels in moral thinking, from those made in notably particular situations (e.g., a compassionate and caring response when a person is ill) to basic moral principles and rights (e.g., human rights).

The process of achieving a state of equilibrium is a process of reflective testing in which one prunes and adjusts one's considered judgments and beliefs to render the whole set of convictions coherent. The resultant moral and political norms can then be tested in a wide variety of previously unexamined circumstances (e.g., in a broad array of circumstances of apparent conflicts of interest never previously examined) to see if incoherent results emerge. If incoherence arises, conflicting norms must be adjusted to the point of coherence.

Bare coherence never provides a sufficient basis for justification, because the body of substantive judgments and principles that cohere could themselves be merely a system of prejudices and ill-considered judgments. Normative views are often wrong not because they are incoherent but because there is no way, when starting from considered moral judgments in shared morality, that one could, through reflective equilibrium, wind up with anything approximating these beliefs. Accordingly, reflective equilibrium is not a pure coherence theory but a process of starting with considered judgments and then engaging in reflective adjustment of norms and beliefs.

The goal of achieving a state of reflective equilibrium is an ideal in which all beliefs fit together coherently, with no residual conflicts or incoherence. This ideal can only be approximated. A stable equilibrium in the full set of one's moral and political beliefs is an unrealistic goal. Moreover, the trimming and repair of beliefs will occur continuously as new situations of the conflict of norms are encountered. However, this ideal is not a utopian theory toward which no progress can be made. Particular moralities (of individuals and groups) are, from this perspective, works continuously in progress, never finished products.

To take an example from the ethics of the distribution of organs for transplantation, imagine that an institution has used and continues to be attracted to two policies, each of which rests on a considered judgment: (1) distribute organs by expected number of years of survival (to maximize the beneficial outcome of the procedure) and (2) distribute organs by using a waiting list (to give every candidate an equal opportunity). These two distributive principles are inconsistent and need to be brought into equilibrium in the institution's policies. Both can be retained in a system of fair distribution if coherent limits are placed on the norms. For example, organs could be distributed by expected years of survival to persons 65 years of age and older, and organs could be distributed by a waiting list for persons 64 years of age and younger. Proponents of such a policy would need to justify and render as specific as possible their reasons for these two different commitments. Such proposals need to be made internally coherent in the system of distribution and also need to be made coherent with all other principles and rules pertaining to distribution, such as norms regarding discrimination against the elderly and fair-payment schemes for expensive medical procedures.

The ideal of maximal coherence of the overall set of relevant beliefs includes not only moral and political norms but also related empirical beliefs and all initial considered judgments. This is a version of so-called wide reflective equilibrium, in which equilibrium occurs after assessment of the strengths and weaknesses of the full body of all relevant and impartially formulated judgments, principles, and theories. Moral and political views to be included are beliefs about particular cases, about rules and principles, about virtue and character, about consequentialist and nonconsequentialist forms of justification, and the like.

Reflective equilibrium may seem to contain a conservative bias, but the method clearly encourages constant improvement and advances through innovative reformulations and testing that will bring about improved coherence. The method insists that even the most basic considered judgments may need to be revised in the process of reaching for equilibrium. No norm is privileged beyond modification.

Reflexivity

This entry introduces the notion of reflexivity of thought and practice and its critical function, reviews the major roles it has played in the history of the social sciences, and presents recent developments of it.

Reflexivity may be understood as the ability of thought to reflect back upon itself. To that extent, it is a condition of intelligence and a defining characteristic of philosophy. When philosophical reflection is concerned with not taking things for granted, it moves into second-order questions through reflections upon what informs the basis of thinking itself. Intelligence is informed by the possibility that one is in error or has falsely identified or misrecognized an object, concept, or experience.

In both cases, reflexivity has a *critical* function via an examination of the apparently self-evident through invoking a simple distinction between the subject (knower) and object (known) as if one were a reflection of the other.

Reflexivity: A Very Brief History

Different philosophical traditions inform how we view the role of reflexivity in thought and practice. Reflexive acts have been understood in terms of their possibility of inducing a heightened state of self-consciousness in the service of self-transformation, while those writing in the pragmatist tradition have examined reflexivity within language acts as the means through which mind, self, and society are linked.

From a social-scientific viewpoint, a reflexive focus helps understand the relationship between social-scientific knowledge and social practice by acknowledging a mutual interdependence between the observer and the observed.

For Max Weber, the practices of social science must replicate the same qualities that the philosopher Immanuel Kant found within the human mind. The social sciences cannot just collect social facts but are reflexive practices in terms of being ideas about ideas, as reflected in Weber's notion of *ideal type,* which serves as an analytic instrument for the ordering of empirical reality.

Alfred Schütz was critical of Weber for failing to see the episodic nature of human conduct in which we find that meaning is the event, or an act is a meaningful process. From this point of view, *Verstehen* ("understanding") is not a method for doing social research but what social scientists should study because the *life-world* exhibits the basis for our primary experiences of the world itself.

The life-world enables orientation through taking its self-evidence, or prereflexive constitution, for granted. These basic "meaning structures" are analytically rearranged by the social sciences, with the consequence that they do not accurately reflect the basis of social relations. Schütz thus argued that social-scientific constructs must satisfy the *postulate of adequacy*—that is, be compatible with the constructs deployed in everyday life.

This study of "lay reflexivity" is not a subjective state of affairs unique to each individual but an intersubjective one obtained through publicly available forms of communication, including language. Harold Garfinkel, the founder of ethnomethodology, took the analysis of these "experience structures" to examine the *situated* and practical manner in which the processes of recognition and production take place in everyday life through its inherently reflexive character. Other social scientists have been critical of ethnomethodology for not challenging the influence of dominant social structures on everyday life.

Feminist-inspired social science, although a diverse body of thought, examines the dynamics between subject and object not from a position of disinterest or disengagement but from being *engaged* in the construction of this relationship. Scientific abstraction glosses over women's experiences in everyday life, the result of which is the production of a "third version" of events that is explicable neither in terms of the subjectivity of the analyst nor in that of the subject herself.

In *standpoint feminism,* women's exclusion from dominant ways of ruling is deployed productively because an analytic focus from this distance uncovers processes and structures that, from a male point of view, appear natural but actually require

explanation. The result is argued to be a more robust, reflexive social science.

Reflexive Practice: Role and Limits

As social science seeks to explain the dynamics and contexts of our lives, reflexivity can be the unbearable grit in the oil of understanding. While we may agree that there is no simple distinction between reality and its construction, it also has the potential to translate into sterility and paralysis through a relativist route.

Postmodernist writings tend to activate differences via a focus upon the textual construction of reality. This functions to expose, or guard against, aspirations to universal knowledge. The French sociologist Pierre Bourdieu sought to avoid a relativism/objectivism divide through a focus upon agency and structure in social life and the role of a reflexive social science in explanation.

We may recognize ambivalence, but that does not relieve practitioners of the need to consider whether that is a characteristic of the world itself, and hence reflected in their practices, or the result of a disciplinary uncertainty that comes from an inward-looking, nonengaged set of practices.

If the latter predominates, the balance tilts in favor of the mode of production and places social science in question; it also ignores the importance of the reception of knowledge and its potential to inform subsequent actions. If the former is in ascendancy, it confuses the domains of social-scientific and everyday practice. It then relieves practitioners and audiences of the effort needed to reach understanding about the world itself and our place within it.

To guard against such possibilities, the French sociologist of science Bruno Latour has introduced the idea of *metareflexivity* and *infrareflexivity* in order that we can talk about the world, not simply focus on our words about the world. Tim May and Beth Perry refer to *endogenous reflexivity,* in which the actions and understandings of researchers contribute to the production of accounts and referential reflexivity, where the production of accounts meet contexts of reception among audiences who are positioned differentially. The movement from endogenous to referential reflexivity may be characterized as one from reflexivity *within* actions to reflexivity *upon* actions, enabling connections to be made between individuals and the social conditions of which they are a part.

Reification

This entry delineates three central aspects of the concept of reification: first, the economic structures that enable reification at an objective level, namely, commodity production and circulation; second, the subjective aspects of reification that give rise to the depoliticization of capitalist social relations; and third, the cognitive dimensions of reification.

The concept of reification (from Latin *res* for "thing" or "object"—hence objectification) is central to the lexicon of the Western Marxist critique of the capitalist mode of production. Reification refers to the unengaged, depoliticized, subjective attitude that individuals are structurally compelled to take toward the socioeconomic structures that characterize capitalist societies. This term is a central term in the philosophy of the social sciences insofar as it establishes a link between economic structures and an experiential and practical stance that individuals take in relation to economic structures.

Reification as an Objective Process of Capitalist Economy

The foundation of the concept of reification is to be found in an analysis of the objective economic structures that characterize capitalist societies. Karl Marx argued that the *commodity* form is the central structural principle of capitalist societies. Although commodities appear to be merely useful objects that satisfy human needs, commodities in fact are more importantly a form of social relation that is unique to capitalist societies. Commodities are both objects of use as well as objects that are exchanged on the market. Marx showed that commodities are a form of social relation that is contained in the form of an object. The *dual* nature of the commodity, which is both a thing and a social relation, makes it extremely difficult to observe the relationship between commodity production and circulation and the class exploitation that it necessitates. The *structural obfuscation* of the social relations inherent in capitalist production is generally referred to as *commodity fetishism*.

Reification at the Subjective Level

The structural, objective obfuscation of the socioeconomic relations of capitalist society generates the problem of reification at a *subjective* level. The concept of reification has been used to refer to the effect that the structural obfuscation of the social relations inherent in the commodity form has on subjective experience in capitalist societies. In capitalist societies, individuals are structurally compelled to take a passive and disengaged stance in relation to commodity production and circulation. Individuals are generally unable to perceive the ways in which the production of commodities, which appear to be mere things that satisfy human needs, actually compels a form of social life based upon *class exploitation* and *depoliticization* of economic relationships.

The Hungarian Marxist philosopher Georg Lukács, perhaps the most influential theorist of reification, emphasized the subjective and political dimensions of the concept. On his reading, reification is the unengaged and spectatorial experiential and practical stance that individuals in capitalist society take toward the constitutive structures of capitalist society. In a society in which the economy exists as a separate, self-grounding and autonomous realm of social life, operating in a way that is seemingly independent of human will, individuals become unable to perceive the ways in which human agency constitutes these structures. The structures appear to be ahistorical and permanent rather than historically specific to capitalism and socially constituted through human agency. Insofar as reification is a subjective stance that is related to a socio-economic form, the concept articulates the ways in which capitalist domination exceeds what is typically understood by the "economic" sphere in the narrow sense. Reification is both an "economic" problem as well as a practical and experiential problem. Moreover, the concept of reification identifies the ways in which depoliticization itself is central to the capitalist mode of production. Without depoliticizing social relations, the reproduction of capitalist social relations could not take place.

Alternative Accounts of Reification

Finally, the concept of reification also has been used to *critique* a particular kind of rationality, namely, *instrumental rationality*. Instrumental rationality is purely focused on ends and means to the exclusion of other forms of cognition. Theorists who have interpreted reification as instrumental rationality have tended to diverge from the aforementioned aspects of the concept. This usage of reification emphasizes the purely *cognitive* dimensions of reification rather than the relationship between cognition and socioeconomic structures. Two influential theorists of the Frankfurt school of critical theory, Theodor Adorno and Max Horkheimer, emphasize reification as a form of cognition. Their work eschewed the historicist tendencies of the early Western Marxist approach to reification and argued that reification is primarily a form of instrumental rationality that is not specifically bound to the commodity form as a mode of socioeconomic structuring.

This alternative approach, emphasizing the detachment of reification from its basis in commodity production and circulation, has also tended to characterize much contemporary discussion of the concept of reification. In the contemporary discussion, many theorists have tended to favor a concept of reification that focuses on the intersubjective and cognitive dimensions of reification alone rather than on the relationship between the disengaged and passive subjective stance of individuals in capitalist society and economic structures.

Relativism and the Social Sciences: From the Sapir-Whorf Hypothesis to Peter Winch

Linguistic or conceptual relativity has been associated with certain theses in the philosophy of social sciences, playing a key role, in particular, in earlier philosophical and methodological discussions of social and cultural anthropology. This kind of linguistic or cognitive relativism and, in general, the relation between language and thought or between linguistic terms and conceptual categories, which was seen as indispensable to social inquiry by antipositivist or antiscientist circles in the philosophy of social sciences, has also been associated with specific readings of Ludwig Wittgenstein's language-games and forms of life.

This entry critically reviews two major instances of this alleged linguistic/conceptual relativism and dispels the resultant erroneous assumptions about relativism in the social sciences that were once dominant in the philosophy of social sciences.

Origins

It is widely assumed that the mid 20th century saw the emergence of two powerful relativist theories that posed a significant threat to the prospects of the social sciences. This assumption underpins the further widely held assumption that these challenges have been rebutted. These assumptions are only half true.

One of the two theories in question was advanced by the American linguist Benjamin Whorf (1897–1941), building on the work of his teacher, the anthropologist-linguist Edward Sapir, and this theory is usually referred to as the *Sapir-Whorf hypothesis*. The second figure often identified as having advanced a relativist theory is the British philosopher Peter Winch (1926–1997), in his book *The Idea of a Social Science and Its Relation to Philosophy* (hereafter, *ISS*), a book that is informed by the approach to philosophy pioneered by Wittgenstein. While Whorf avowedly advanced a theory of linguistic relativism, Winch sought to advance no theses, and, moreover, his writings neither propound nor endorse relativism.

In the following sections, we will first look at the Sapir-Whorf hypothesis and assess some criticisms of that theory. We will then progress to Winch's writings, clarifying his claims about the nature of social studies. We will see that far from endorsing or providing a variant of Whorf's thesis, Winch actually provides one with the resources for a critique of Whorf.

The Sapir-Whorf Hypothesis and Linguistic Relativism

Whorf's theory of linguistic relativism is founded on his claim that speakers of different natural languages, or more precisely natural languages belonging to different families, operate according to different grammatical rules and that these different grammars shape the thoughts of the native speakers of that language. What follows from such a claim is that the same physical evidence does not necessarily force upon a perceiver the same picture of the universe, for the picture is formed by the grammar of the language. Therefore, different languages are said to entail different pictures of the universe irrespective of those pictures' basis in the same physical data. Grammar, for Whorf, is the "shaper of ideas" and that which provides "thought materials." Therefore, Whorf hypothesizes that the nature of reality is relative to the grammar of a natural language.

While Whorf's theory has been subjected to a number of criticisms, some miss their target by misunderstanding the precise nature of the theory. For example, some took Whorf to be making a point about different vocabularies: for example, that language *A* contains numerous words for phenomenon

X, for which only one word exists in language *B*. This was not Whorf's claim and is of little interest to him. Others have criticized Whorf's foundational claim that different natural languages, particularly those belonging to different language families, such as Indo-European and non–Indo-European, have different grammars. This is challenged by those who subscribe to Noam Chomsky's linguistic theory, wherein Chomsky advances the theory of universal grammar. Such critics reject Whorf's relativism by contesting the grammatical pluralism on which his relativism is founded. If Chomsky's theory is true, then this does indeed seem to undermine Whorf's hypothesis. However, one does not have to subscribe to Chomsky's theory of generative grammar and its basis in a theory of an innate universal grammar to undermine Whorf's relativism. Indeed, one might even believe that one can defend Whorf's theory against a Chomskyan criticism by, for example, questioning the validity of Chomsky's theories. However, there is another, alternative, way to undermine Whorf's thesis without appealing to or subscribing to Chomsky's theories; here, Whorf's argument is identified as residing *not* in the claim that different grammars exist in different natural languages but rather in a set of unacknowledged philosophical assumptions that are operative in Whorf's hypothesis. This criticism of Whorf brings to the fore the philosophical assumptions underlying Whorf's claim that grammatical differences *entail* different metaphysics. In other words, rather than focusing on his grammatical pluralism, one might focus on Whorf's claim that one can *read off* a metaphysics from the grammar of a language. For one thing of note, all too often overlooked in discussions of Whorf's theory, is that his relativism is not *entailed* by his observations about the grammar of different languages; nor did Whorf claim it to be so. There is, rather, a philosophical argument operative in Whorf's thesis, which is assessable independently of his grammatical pluralism. A criticism addressed to this aspect of Whorf's thesis is one that seeks to show that Whorf's thesis lacks intelligibility. John W. Cook's critique is an exemplar of this approach.

On close examination, Whorf's claim that different metaphysics can be read off from different grammars can be shown to fall short of his aims, and this can be seen by examining his remarks about his own language: English. A little like the anthropologist who writes of the primitive superstitions of the tribe he is studying, while it remains literally unremarkable to him that he then prays before dinner and kisses a photograph of a loved one before going to sleep for the night, Whorf's writings about the metaphysics he claims to read off Hopi grammar are accompanied by a distinctly superficial depiction of the grammar of his own language. His arguments about grammatical categories determining the metaphysics of the speakers of the language are consequent on his being led astray by the surface grammar of his own language, because where Whorf took himself to be identifying a metaphysics that can be read off the grammar of English (and, when he turned to study that, Hopi), he was rather reading into English a metaphysics that owed much to his own preexisting, underlying metaphysical assumptions about English grammar. To paraphrase John W. Cook, Whorf was not reading off a metaphysics from the grammar of English but rather reading into English a metaphysics not there. For example, Whorf employs the example of the concept of "time" in support of his claim that metaphysics is read off grammar, but his assumptions about the metaphysics of time are simply read off his observation that in English "time" is a noun, and he seems to assume that nouns must correspond to something. Whorf is therefore being led astray by the *surface* (superficial) grammar of "time." When he then takes himself to have read off a metaphysics of time as being composed of "moments," "time slices," or "time flows," he is actually being led astray by his unacknowledged assumption that "time" as a noun in English must correspond to something.

To summarize, the real problem faced by someone who is persuaded by the Sapir-Whorf hypothesis is not that it is based on a now unfashionable theory of grammar, in light of the prominence attained by Chomsky's work. Rather, the real problem is that what had appeared to many (including Whorf) as a thesis founded upon, if not logically forced upon one by, the results of empirical studies of the grammar of natural languages is actually a set of claims emerging from the observer, such as Whorf, who is in the grip of an unacknowledged picture of grammar that leads him to first misrepresent his own language and then proceed to misrepresent those he is studying.

Peter Winch and Relativism as One Consequence of Scientism

It is widely assumed that Peter Winch, at least implicitly, endorsed some version of Whorf's theory in his *ISS*. It is also widely assumed that Winch

propounded a theory of cultural relativism, based on his observations about grammar and rules. Both these assumptions are incorrect.

Winch claimed that social studies should be seen *as* philosophy. As he put the matter early in his book, where science is concerned with the explanation of particular real things and processes, the philosopher is concerned with the nature of reality in general—what counts as "real" or what we mean by "real." On this view, social studies are better understood as philosophy because their questions have central to them discussions about the meaning of that which is under study (e.g., "happiness," which has been the subject of much recent putatively empirical study). Specific normative questions such as "Should the state promote happiness through policy?" or questions demanding answers in the form of social facts such as "Is Britain happier than Norway?" or "Does socialism produce greater happiness than neoliberalism?" are parasitic upon the general question about the nature of happiness. The social scientist must concern herself with the question of what we take happiness to be or, put another way, what counts for us as happiness: Is it a psychological state, and if so, of what sort? Is it related to flourishing as a member of a species with a particular set of needs? Is a happy life necessarily a good life? Can happiness that is gained through the suffering of others be genuine happiness? Do we accept the drug addict's claim to be blissfully happy, following a fix, as *genuine* happiness? Is there a difference between genuine and subjective/apparent/false/synthetic happiness? And if there is, what are our grounds for saying so, and what are our criteria for "genuine happiness"? Are there degrees of happiness, and if so, how might these be measured? These are unavoidable questions, and they are questions that cannot be answered by empirical study or causal explanation. The point is that any attempt at empirical enquiry into happiness cannot bypass the philosophical discussion as to the general nature of happiness.

Winch's critique of certain assumptions in the social sciences is rich and multilayered; it has deep ethical dimensions that became increasingly prominent in his later post-*ISS* writings. Actions are meaningful, and their meaning is inextricably linked to the context and occasion of action. Believing that meaning can be understood through identification of an action's cause is to misunderstand the nature of action and meaning. So if one's conception of science demands that explanations are stated in the form of lawlike generalizations with predictive power, then that demands a noncontextual identification of act tokens, whereby the role of context in the meaning of an action (a specific act token) can be foregone. However, the nature of action is such that the context—the social situation—is intrinsic to its identity. Moreover, an attempt to deny or bypass the meaningful nature of action leads us to a misrepresentation of not only the actions of those whom the social scientist claims to be explaining but of ourselves too, for first and foremost the social scientist is an ordinary social actor. The act of understanding others involves understanding ourselves, and this is a point Winch increasingly sought to emphasize and one that might easily have been directed at Whorf. Failure to understand others through a misunderstanding of the meaningful nature of action results in failure to understand oneself in a manner that one might depict as *bad faith*. Furthermore, the observation that actions are meaningful leads to the recognition of them as open textured. Should one concede that lawlike generalizations might be possible for some general categories of action, it would still not be possible to rely on those generalizations having nonplatitudinous predictive worth because of their open texture.

Conclusion

In conclusion, Whorf sought to advance a relativist hypothesis, and we have seen that this emerged from his own underlying philosophical assumptions, which ultimately meant that he failed to achieve his goal. Winch was making specific observations about the nature of the questions and problems that are dealt with in social studies and how being in thrall to particular pictures of what counts as a valid form of explanation can impair our understanding of those questions and problems. For Winch, arguments for theories of cultural or linguistic relativism ultimately lack intelligibility, and they can usually be shown to emerge from a failure of self-understanding: a sort of bad faith or intellectual hubris. For Winch, relativism is usually a consequence of a subterranean scientism, and it is the tendency to the latter from which he sought to liberate his reader.

Relativism in Scientific Theories

Relativism in the context of scientific theories refers to views that argue that since judgments about truth and falsity are (always) relative to/dependent upon the individual person or culture, the concept of objective truth is either incoherent or useless. Some versions of relativism are heuristically useful. But strong variants, such as claims that scientific theories can never be assessed by reference to universal norms, lead to self-defeating skepticism—what Susan Haack calls the *New Cynicism*.

This entry offers a survey of influential relativist positions.

Cultural Relativism

According to *cultural relativism,* a fundamental methodological precept in anthropology, the beliefs and behaviors that individuals find acceptable depend on the culture to which they belong. At first glance, this claim is hardly news to any seasoned traveler—we get over our initial surprise that some people in Scotland really like haggis and think there is a Loch Ness monster. Cultural relativism serves as a useful reminder of the diversity of social arrangements and as a prophylactic against ethnocentrism. If a certain group confers religious significance on a huge meteorite, we should not blithely cart it off to our museum. On the other hand, we need not and should not conclude that the origin story associated with that rock has equal validity with the scientific account of meteors. The distinction is this: Everyone has a right to form their own opinion, and we should respect that right. But not all opinions are epistemically equal.

Strong versions of cultural relativism also have dubious theoretical consequences for research in social science. If each culture can only be understood in its own terms, would it not follow that the careful ethnographer should refrain from assuming that humans in various cultures share *any* perceptual, cognitive, or psychological characteristics? Should the ethnographer eschew *any* scientific explanations of social behavior that invoke universal generalizations? Yet might not ethnocentrism itself be a universal tendency? Anthropologists systematically utilize concepts such as kinship, ritual, taboo, and alterity when comparing cultures and are well advised to do so. Social scientists should always *be aware* of the influence of cultural differences, but they need not conclude that their research results are necessarily only valid in their own culture.

The Cui Bono Principle

Another form of relativism notes that since individuals' beliefs and behavior reflect their values, we should apply the cui bono principle to knowledge claims. Just as the detective asks who would have a motive to commit a crime, so we should always ask who stands to benefit if a new research result were accepted as reliable. Professional organizations address such concerns through *conflict of interest* regulations. For example, judges must recuse themselves from cases in which they have a financial interest in the verdict. A recusal does not imply that the judge would in fact rule in a prejudiced fashion; as the saying goes, it is also important that justice be *seen* to be done.

Scientific institutions are aware of this problem. Medical journals often ask researchers to report their sources of funding, but the financial incentives

are still skewed. To gain approval from the Food and Drug Administration, pharmaceutical companies need scientific assessments of new drugs, so they pay scientists to do research. Obviously, the companies are hoping for positive results, but so are the scientists! Journals are sometimes reluctant to publish negative results, and this makes it more difficult to get funding for future research, especially from the same company. One partial solution is to have more government involvement. Recently, there has been action to set up a public archive and to require the results of all pharmaceutical research, including studies with negative results and even incomplete studies, to be posted.

The cui bono variant of relativism reinforces the old proverb that the wish is father to the thought. But like any heuristic, it provides no guarantee. Not all hypotheses that serve the interests of the powerful turn out to be false. And even members of cults awaiting the Rapture will accept unwanted evidence when it is dramatic or recurring. Scientific norms are structured to minimize the biases of individual scientists. Examples include the emphasis on double-blind experiments and the recognition awarded to novel results. Once again, a relativist maxim that at first sounds like a sophisticated epistemic principle turns out to have limited applicability.

Incommensurability

Philosophical critiques of logical positivism have also generated relativist stances. The doctrine of the theory-ladenness of observation says that the observation reports used as evidence in science are inevitably couched in language that reflects theories about the world. Even the commonsense claim that there were two cardinals eating suet from my bird feeder presupposes that the flashes of red are not caused by pressure on my eyeball or holographic projections, and it further presupposes that birds have digestive systems, that a human intended to provide food for birds, and so on. None of this seems remarkable because we all share basic concepts about birds.

But what if someone or even several people, perhaps from a different culture, say that two ghosts wearing red robes were eating wafers from a ceremonial altar on the porch? Well, we might say, this claim cannot count as a scientific observation report because it presupposes that there are such things as ghosts. There are many ways in which the dialogue might continue, but the relativist conclusion is simple: All observations are laden with theory. So any scientific conclusions that we may draw depend on, and are relative to, the theoretical conceptual scheme within which we operate. But does this mean that there is no objective/impartial perspective from which we can appraise and compare the truth-value of claims?

Thomas Kuhn's account of scientific revolutions argued that even in physics, competing paradigms were *incommensurable,* so that when Einstein's theory replaced Newtonian mechanics, what really happened was like a Gestalt switch. Since Einsteinian concepts of mass, distance, and time were quite different from Newton's, strictly speaking, one could not compare experimental predictions from the two systems to see which was more accurate. There was no neutral, shared observation language. The implications for social science seemed staggering. If even physicists with their precise mathematical theories ended up talking past each other, what hope was there for rational debate between competing approaches in economics, psychology, or history?

There have been many philosophical critiques of the holistic theory of meaning that underlies the claims about incommensurable paradigms. To give a very simple example, just because there is no simple English equivalent for the French concept of bête noire or the German idea of Schadenfreude does not keep us from figuring out whether they might apply to a given situation. We can develop a metalanguage in which to compare conceptual schemes. And even Kuhn objected to relativistic interpretations of his account of the history of science, while continuing to emphasize that the rational comparison of competing paradigms was a long, complicated process. We can illustrate the general point by refining the Gestalt switch analogy: It may well be the case that there is no objectively true answer to the question as to whether the famous Gestalt sketch represents a duck or a rabbit. But in science, as in ordinary life, we can collect more evidence. We can view the creature from other angles; we can probe it; we can take X rays. There is no reason to think that the duck/rabbit ambiguity will persist after further inquiry.

Political Implications of Relativism

In the past few decades, relativism has often been viewed as a politically progressive epistemological stance. Scholars in Gender and Cultural Studies have pointed out errors and omissions in both the

sciences and the humanities arising from the biases and parochial perspectives of the intellectual elites who constructed these supposedly authoritative accounts of how the world works. There is no question that inquiry benefits from debate among a plurality of viewpoints and that highlighting any distorting effects of culture and concepts, financial interests, ideology, and identity is all to the good. But in an era where many politicians nonchalantly ignore the basic findings of evolutionary biology, climatology, and macroeconomics, the extreme versions of relativism that are sometimes identified with postmodernism, postcolonialism, and feminist epistemology are far from politically progressive. If it really were true that scientific assessments of truth and falsity could never be objective and could never be more than warring opinions, then we would be left with nothing but a clash of civilizations. Relativism provides no warrant for such a conclusion.

Relativisms and Their Ontologies

This entry presents varieties of relativism, explains the distinction between the ontic and the epistemic points of view, and critically reviews certain modes in which relativism contrasts with certain varieties of its contrary position—absolutism.

Relativism claims that values such as truth, goodness, or beauty are relative to particular reference frames and that no *absolute* overarching standards to *adjudicate* between competing reference frames exist. Many varieties of relativism can be distinguished, depending on the variables that are concealed in this definition.

Varieties of Relativism

One might be relativist with respect to truth but not with respect to goodness or beauty. One might be relativist with respect to goodness but not with respect to beauty or truth. And one might be relativist with respect to beauty but not with respect to truth or goodness. Still other variables in the definition include the ideas of reference frames, domains of inquiry, and levels (epistemic or ontic). Furthermore, relativists deny one or more strands of absolutism, namely, realism, foundationalism, or universalism.

Merely observing a diversity of beliefs or practices does not entail relativism. One might note such differences, for example, without concluding that truth, goodness, or beauty is frame relative. Also, the distinction between relativism and absolutism is not exhaustive. Antirelativism does not entail absolutism, and anti-absolutism does not entail relativism.

Relativists sometimes argue that any would-be absolute standards would reflect the biases of the absolutist's home culture and that one culture should not impose its values on another. Instead, they hold that we should understand other cultures in terms of their beliefs and values. In turn, some

absolutists worry that denying absolute standards would result in arbitrariness, anarchism, nihilism, or something of the sort. With no absolute standards, inquiries would have no worthwhile goal. By ruling out absolute standards, we rule out the possibility of progress in knowledge. Without absolute standards, we could not distinguish between true and false, advanced and backward, moral and immoral, beautiful and ugly.

Reference frames come in many varieties. They include, for example, cultures, communities, tribes, traditions, religions, forms of life, paradigms, conceptual schemes, and other cognates of "contexts." A person may be relativist with respect to conceptual schemes, for example, but not with respect to tribes. A person may be relativist with respect to communities but not with respect to individuals. Some relativisms are *global,* applying their relativism to all reference frames. Others are *local,* applying their relativism only to some reference frames but not others.

One might be relativist with respect to all or only some domains of inquiry. Relativism with respect to the cognitive domain asserts that a statement is true or false (reasonable or unreasonable, justifiable or unjustifiable) relative to a particular reference frame. Relativism with respect to the moral domain asserts that an action is morally right or wrong (good or bad, virtuous or wicked, praiseworthy or blameworthy) relative to a particular reference frame. Similarly, relativism with respect to the aesthetic domain affirms that something is beautiful or ugly (sublime or mundane) relative to a particular reference frame. Domains may be thought to be made rather than found, or found rather than made.

Ontology and Epistemology

Relativism may be taken to apply at the ontic level (pertaining to existence), the epistemic level (pertaining to knowledge), or both. A relativist at the ontic level embraces the relativity of existents to reference frames, such as virtues or vices being relative to a religious tradition. A global relativist at the ontic level affirms that all existents are frame dependent. A local relativist at the ontic level affirms that only some existents are frame dependent. A relativist at the epistemic level embraces the relativity of our knowledge to reference frames. A global relativist at the epistemic level affirms that all our knowledge is frame dependent, and a local relativist at the epistemic level affirms that our knowledge is only sometimes frame dependent.

Yet the distinction between ontic and epistemic levels is contentious, thus complicating the permutations that assume its validity. One might argue, for example, that if we have no direct access to the world-as-it-is-in-itself, we cannot compare our descriptions with the world-as-it-is-in-itself. At best, we have access to the world-as-it-is-in-itself only through some description of it. We can know the world-as-it-is-in-itself only as conceptualized in one way or another. Therefore, even when we seek to compare a description with the world-as-it-is-in-itself, we are comparing a description with the world-as-it-is-in-itself as conceptualized—which is to say, as already described. We are comparing our description with another description. The most that can be established in this way is a relationship between two descriptions, not a relationship between a description and the world-as-it-is-in-itself.

Thus, one might conclude that the notion of the world-as-it-is-in-itself is of no use in inquiry. Correspondingly, one might argue that the distinction between ontic and epistemic levels is of no use in inquiry. If the distinction between the ontic and the epistemic is deemed a distinction without a difference, those varieties of relativism that depend upon it collapse.

Against Absolutism and Its Varieties

Relativism is partly defined by its rejection of absolutism. Thus, relativists oppose different strands of absolutism, which include realism, foundationalism, and universalism. A strong relativism will negate all varieties of absolutism. A weaker relativism will negate only some of them. A strong absolutism will affirm all of its strands. A weaker absolutism will affirm only some of them. The weaker versions of both relativism and absolutism incorporate both relativist and absolutist strands. Thus, certain varieties of absolutism and relativism are compatible. So relativism and absolutism need not be mutually exclusive.

Consider a strand of absolutism that a relativist might oppose: realism. Realism holds that existents hold independent of reference frames. These existents may be cognitive, moral, or aesthetic. Ontically speaking, realism affirms that sticks and stones, for example, exist as such irrespective of reference

frames. At its epistemic level, realism affirms that our knowledge is secured on grounds independent of any reference frame. "Sticks and stones exist" is true because sticks and stones exist irrespective of reference frames. By contrast, anti-realism in its ontic sense holds that existents are frame relative. Accordingly, whether we conceive particular existents as sticks (or stones) or as collections of electrons in space is relative to a reference frame. While sticks and stones as such exist in a reference frame of middle-sized objects, they do not exist as such in a subatomic reference frame. Thus, the nature and number of existents depend on which reference frame we invoke.

A second strand of absolutism that a relativist might oppose is foundationalism. At the ontic level, foundationalism holds that existents in designated domains are reducible to ultimate and irreducible constituents. For example, Democritus held that objects are reducible to atomic constituents, which he took to be ultimate and irreducible. In its global variant, ontic foundationalism holds that existents in all domains are reducible to ultimate and irreducible constituents. In its local variant, ontic foundationalism holds that existents in only some domains are ultimate and irreducible. In turn, at the epistemic level, foundationalism holds that knowledge can be captured by first principles that are incapable of further analysis, that there must be a terminus to any stage of justification, without which there would be an infinite regress. It posits an irreducible self-evident grounding. In its global variant, epistemic foundationalism holds that irreducible first principles of knowledge hold for all domains. In its local variant, epistemic foundationalism holds that ultimate and irreducible grounds of knowledge hold for some but not all domains.

Relativists might also oppose a third strand of absolutism, universalism. At the ontic level, universalists hold that cognitive, moral, or aesthetic existents obtain for all peoples. Such existents are either frame independent or frame dependent. They are either realist or anti-realist. In the moral domain, for example, universalists at the ontic level might hold that human rights exist for all peoples. Nonuniversalists at the ontic level hold that such rights exist only for some or no peoples. At its epistemic level, universalism holds that no barriers of translation exist between peoples. In contrast, nonuniversalists could argue that incommensurability between designated reference frames blocks universalism. Those of shame cultures cannot fully understand those of guilt cultures, and vice versa. At the epistemic level, nonuniversalists may affirm that the search for a universal language is futile. They may affirm that no universally accessible cognitive, moral, or aesthetic principles for all peoples exist.

At the epistemic level, a universalist might counter that even to know that two reference frames are incommensurable requires both of them to be intelligible to someone who can make the comparison—hence universalism. But this argument is invalid. The possibility that some persons can compare pairs of reference frames does not entail that all peoples are capable of making such comparisons. Furthermore, the possibility that such reference frames are comparable does not entail that they may be *adjudicated* according to some absolutist standard.

We may further qualify universalism in foundational terms. Foundational universalism holds that all peoples, for example, can share some common characteristics, such as basic rights by virtue of what—ultimately or irreducibly—it is to be human. Nonfoundational universalism holds that all peoples share common characteristics without presuming that they do so by virtue of what—ultimately or irreducibly—it is to be human. Foundational universalism is a claim of necessity, while nonfoundational universalism is a claim of contingency.

One might urge that foundational universalism explains the contingent fact of the universal instantiation of certain characteristics—for example, that all peoples have some sort of morality or that all peoples share a taboo against incest. Without foundational universalism, one might urge, the commonality of shared characteristics might appear miraculous. But it is an open question whether such commonality without foundational universalism is miraculous. Evolution theory appears to explain the universality of shared characteristics without recourse to foundational universalism. So universalism appears not to require foundationalism.

In sum, realism does not entail foundationalism; frame independence does not entail ultimate or irreducible constituents. Realism does not entail universalism; frame independence may apply locally, not globally. Foundationalism does not entail universalism; foundationalism may apply locally and not globally. Universalism does not entail realism; that which is shareable by all peoples need not be frame independent. Finally, universalism does not

entail foundationalism; that which is shareable by all peoples need not be ultimate or irreducible.

Concluding Remarks

Pertinent variables that qualify varieties of relativism are values (truth, goodness, beauty, etc), reference frames (cultures, traditions, conceptual schemes), domains (cognitive, moral, aesthetic), or levels (ontic, epistemic). Also, a relativist might selectively negate particular strands of absolutism (realism, foundationalism, universalism). The strongest relativist position will be global, asserting itself across the board. The strongest absolutist position will also be global, asserting itself across the board. Weaker varieties of each combine variables in moderating ways. Accordingly, not all varieties of relativism and absolutism need oppose one another. Relativism is not a single doctrine.

Reputation, in Social Science

Reputation, from the verb *puto* in Latin, meaning "counting"' or "considering," plus the prefix *re-*, which indicates repetition, is the consideration of the value of an agent by other agents based on his or her past actions and creating expectations on the future conduct of that agent. Reputation is a special kind of social information: It is social information about the value of people, systems, and processes that release information. Reputation is the informational trace of our past actions: It is the credibility that an agent or an item earns through repeated interactions. If interactions are repeated, reputation may conventionalize in "seals of approval" or disapproval or in social stigmas.

The notion of reputation in social sciences has been mainly treated in the field of economics. In Adam Smith's liberal social theory, reputation is seen as a way of coordinating activities in a decentralized social space of transactions. According to Smith, in a free society, markets coordinate diffused knowledge in an asymmetrical way: People have a partial view of what other people know and how they will act. Also, given that most transactions occur over a span of time, parties have to trust each other that they will satisfy their reciprocal interest. These informational and temporal asymmetries call for efficient means of storing and retrieving information about possible partners in interactions. Reputation is more than pure information: It is evaluated information—that is, a shortcut of the many judgments and interpretations that people have cumulated about an actor. That is why people are interested in keeping a "good" reputation by signaling their trustworthiness to potential business partners.

In the rational choice tradition, reputation is modeled as a repeated game. These games raise the question of how you can signal your reputation

before any interaction occurs—that is, how you can signal your credibility in the absence of information about your past behavior. This question is studied within a rich body of work that goes under the name of *signaling theory.* Signaling theory aims at solving a fundamental communication problem: Given an interaction in which interests diverge between the two parties, how can a party be certain of the qualities of the other party? Honest signalers will try to signal their good qualities (trustworthiness, accountability, strength), but dishonest signalers will try to do the same by mimicking high-quality signals. Signaling theory may be traced back to the work of the American sociologist Thorstein Veblen. In his *Theory of the Leisure Class,* published in 1899, Veblen explains the display of wealth of the leisure class (luxury, expensive clothes, time-consuming unproductive activities such as sports) as a way of signaling its social position. Important developments of signaling theory go from the study of behavioral ecology to the sociology and the economy of cultural tastes and lifestyles. An agent emits signals in order to make a threat or a promise credible. *Costly signals* and robust signals—that is, signals that are difficult to fake for those who do not possess the signaled quality—are those considered more credible.

The economist George A. Akerlof has shown that quality uncertainty is such a risky feature of markets that reputation is needed: "Seals of reputation" in a market are labels, certifications, guides—that is, all the devices that tend to reduce the informational asymmetry. A rational agent, according to Akerlof, has an interest in embodying these devices in order to compensate the cognitive deficit of the informational asymmetry.

Quality uncertainty and informational asymmetries have become crucial epistemological issues in contemporary, *information-dense* societies. The vast amount of information available on the Internet and on the media makes the problem of reliability and credibility of information a central issue in the management of knowledge. Informational items that do not come with some label or seal of approval from the appropriate communities are lost in the data deluge of the Information Age.

From the evaluator's perspective—that is, from the standpoint of the agent who has to filter information—reputation has an informational value. This has become a prominent issue in Web studies. Given that the structure of the Web is that of a reputational network, in which each link from a page to another can be read as a "vote" from one page to another, a number of algorithmic techniques have been developed to compute the reputation of different entities on the Web: *recommender systems, collaborative filtering,* and *reputation systems.*

Collaborative forms of sharing ratings are also relevant in the study of *collective intelligence.* People do not share information; they share evaluated and classified information that creates a "reputational stream" of shared judgments. The epistemological implications of the massive use of shared ratings in networked societies are huge; relying on other people's judgments and authority challenges our epistemic responsibility. The reasons why we trust collectively filtered ratings about an item or an agent are seldom explored. Choosing a doctor, an academic institution, or a wine is a way of endorsing a tradition of values—a way of filtering information that is not always transparent and legitimate. Notorious biases in social networks—such as the *Matthew effect,* investigated by the sociologist of knowledge Robert Merton, according to which the nodes of a network that are more prominent have more probabilities to earn more reputation—create noise in the way reputation is diffused.

Other biases need further epistemological and cognitive inquiry. For example, people tend to form beliefs in order to acknowledge previously established reputations, such as voting for a certain party because a very well-reputed friend votes for that party. Also, reputations are resilient and may last over time even when the facts of the matters they are supposed to signal are no longer there. For example, the prestige of institutions and corporations may last a long time after their decay.

Reputation is a social commodity that needs to be handled in a scientific way in order to avoid informational cascades, conformism, and the perpetuation of received views.

Retrodiction and the Epistemology of Future Studies

This entry introduces the field of Future Studies, shows its importance for the social sciences, and reviews the epistemological issues underpinning this new field and its key elements. These include the notions of retrodiction, predicting–explaining (a) symmetry, social reflexivity, and the emerging significance of the social context as essential to knowledge production and therefore the significance of an essentially social-epistemological viewpoint.

Future Studies emerged during the second half of the past century as an interdisciplinary field at the boundary between the social sciences and philosophy. The field deals with a large range of themes related to the cognitive, epistemic, and practical challenges posed to the human mind and human action by the future. As such, it represents one of the most interesting and dynamic areas of interaction between philosophy and social-scientific research. From the very beginning, *epistemological* problems were central to the field's agenda: If the future is not the realm of the true or false but the realm of the possible, what are the implications for the ways we understand, define, and assess our predictive efforts? How do we project knowledge from the past and the present to the future? What is the nature of that knowledge? How do we incorporate the problem of the future in our social theories, and what methods should we use in order to make our conjectural knowledge about the future useful for today's decision-making processes?

As one may expect, the very distinctiveness of the field is centered on the assumption of the asymmetry between our knowledge of the past and our knowledge of the future. The epistemology of Future Studies is built on two major themes, identified by two *asymmetries:* (1) between *prediction and retrodiction* and (2) between *explanation and prediction*. The two themes are related but distinct. The benchmark is considered to be the structural dissimilarity between prediction and retrodiction. Their asymmetry has been described and analyzed using, among other things, the notion that there are many more "signs" of past events than of future events, the idea that there is noninferential knowledge of the past but not of the future, or the argument that a predictive inference must be an inference from a sufficient condition, whereas a retrodictive inference is an inference to a necessary condition.

In a typical move for Future Studies, an actional element is introduced along standard lines of epistemological reasoning. If in articulating our criteria of making true (or falsifying) a statement, the accent shifts from discovering, confirming, or disconfirming (whether it is true or false) to the performance of an action that may bring about (or prevent) the event predicted or retrodicted in the statement, then one could identify two types of situations. The first defines the context of retrodiction, while the second, the context of prediction. One can act now in ways that make true some predictions (or falsify them). One can even make a prediction, and by simply publicly uttering it, one may make it true (self-fulfilling prediction/prophesy) or may falsify it (self-defeating prediction/prophesy). In other words, due to "social reflexivity," the truth-value of future tense statements may be influenced and changed. That is not the case with retrodictions (past tense statements). One therefore needs thoroughly different conceptual frameworks to deal with the two types of epistemic situations.

The relevance for Future Studies of this simple observation is hard to exaggerate. Not only does it help set up the boundary conditions and the epistemic limits of the field, but it also (a) draws attention to the essential role social context and processes have to play and (b) by evoking cases of self-fulfilling prophecies, reveals the contours of the key problem of *social reflexivity*. Social reflexivity

situations are extreme and crucial case studies to be used in investigating the specific epistemic nature of futures research. The very idea that context matters and that, by the simple fact of being made public, pieces of knowledge and information may make empirically true or, by contrast, falsify the very predictions that incorporate them is pivotal for the ways in which the field has defined its epistemological identity and agenda.

Irrespective of how one conceptualizes it, the epistemology of Future Studies is using *retrodiction* as a benchmark. Yet its real foundations lie in its opposition to the conventional "covering-law" model asserting the symmetry between prediction and explanation. The main argument is that the extensions of these two concepts only partially overlap. To explain doesn't necessarily mean to be able to predict. To predict doesn't necessarily mean to be able to explain. There is an overlapping area where the two coincide—that is, they function symmetrically, as prescribed by the "covering-law" model. However, the common area contains much more than the covering-law structures. Probabilistic laws, quasi-laws, and genetic causal models of explanation are located in the same overlapping region. Yet they do not share the formal features and the specific mix of predictive and explanatory power of "covering laws." At the same time, the domain outside the overlapping area is also vast. On the explanation side, there are explanatory structures with no or limited predictive power (e.g., historical or evolutionary explanations). On the predictive side, there are correlational, time-series, analogical, and other predictive structures with limited or no explanatory power. Some predictions could be framed on the covering-law or explanatory models. Most could not. A proper theory and epistemology of prediction should deal with the entire range of predictive approaches and models. To try to force the whole lot in one mold is both unrealistic and unfeasible. This conclusion is a keystone of Future Studies.

Despite the inherent diversity and cognitive heterogeneity of *predictions,* there are nevertheless some common and unifying epistemological themes emerging. Two of them are of special significance. The first is that predictive argumentation is not demonstrative but merely evidential. Hence, formal logic–based argumentative structures of the "covering-law" type are indeed inadequate in giving a complete and accurate account of predictive argumentation and practice. If the nature of predictive arguments is evidential, then the epistemology of prediction should be based not on mere formal logic but on a larger theory of argumentation. That means that the efforts to articulate an epistemology of prediction and forecasting should be based at a formal level on a theory of evidentiary argumentation or, even better, on a general theory of argumentation that incorporates both formal and nonformal argumentative models.

The second theme is that the epistemology of prediction should explicitly deal with the intrinsic *social* nature of knowledge and knowledge production and diffusion. This aspect is especially salient in any situation in which, in order to be forecasting relevant, formal and explicit knowledge needs to be bolstered by background knowledge, with its informal, tacit, personal, and social dimensions. The social dimension is critical in yet another way, already mentioned. When making social predictions, social actors and groups are not inert parameters; rather, they have an intrinsic ability to react and adjust to changes in rules, in the environment, or in their own endogenous dynamics. In a word, they display "reflexivity"—feedback, adjustment, and strategic adaptation. Predictions can be easily invalidated if they become public knowledge and if, based on them, social actors revise and change the patterns of their behavior. That means that understanding the social context and processes associated with forecasting practices becomes intrinsically connected to the efforts to understand the epistemic nature and fate of a forecast. The interplay between the prediction and the social process becomes thus epistemologically relevant at more than one single level.

Thus, the whole cluster of these issues makes the anchoring into the social sciences of the epistemology of prediction (and for that matter of Future Studies in general) an unavoidable part of the Future Studies project. A *social-epistemological* approach emerges not as an option but as a necessity.

Risk

Risk denotes potential dangers or otherwise unwanted outcomes. Risk can be used to describe dangers generally, but it also has more narrow meanings, first and foremost linked to probabilistic calculus of possible (negative) outcomes. The concept of risk has evolved over time. This entry gives an account of the changing meanings of risk and the prominent political and social role of risk in contemporary society.

The concept of risk is linked in several ways with Enlightenment and modernity. First, in the early Enlightenment period the concept of risk constituted a new way of calculating potential dangers, which among other things served to circumvent a 14th-century papal ban on primitive forms of maritime insurance. Second, risk is a product of novel forms of inductive reasoning that emerged in the Enlightenment and that consisted of inferences about the future based on the past or on knowledge of causation. Third, linking the two former points, probabilistic calculus (itself one of the absolute key discoveries of this epoch) was the concrete means for such calculation of potential, future, dangers.

Thanks to probability calculus, risk, during the 18th and 19th centuries, became a cornerstone not only in insurance but also in modern forms of government, based (besides new notions of nationhood) on bureaucratic procedures, statistical data on the population, and social insurance regimes.

Concepts of risk based on probability calculus have also become cornerstones in a range of other sectors such as technology assessment and finance, where prognostications are sought after. Early in the 20th century, the economist Frank Knight made a famous distinction between risk and uncertainty that hinges on calculability. Risk, according to Knight, is calculable (by means of probability), while uncertainty is not.

Probabilistic risk calculus has later been significantly refined with new actuarial techniques and advances in knowledge of stochastics and complexity in the latter half of the 20th century. However, beginning in the same period, the Knightean distinction has been challenged in various ways. Risk has increasingly become used to describe also Knightean uncertainty. Furthermore, research on human risk perception and attitudes has demonstrated that risks often are subjectively perceived no matter how objectively risk may be calculated.

Not coincidentally, this development has occurred in a period where public insecurity regarding the side effects, or potential catastrophic consequences, of technology has been strongly voiced and became the center of many political conflicts. Much of the analysis in sociology and political science, especially the theory of a *risk society,* has focused on this new politics of risk and uncertainty. Established institutions and authorities (above all science) are challenged and politicized, and existing (national) political institutions struggle both with the transnational nature of many ecological problems and the ambiguity of the by now, in some respects, deauthorized and politicized scientific or expert knowledge. In this context, risk loses its objective basis, and the distinction between risk and uncertainty is conflated. The risk society thesis sees these developments as constituting a new or second modernity.

Research on human risk perception has added further insights into the subjectivity of risk. For example, it has been shown that voluntary risk taking—engaging actively and willingly in risky practices—increases risk acceptance markedly compared with involuntary or passive risk taking. Humans use a variety of heuristic tools for risk assessment, trying to establish a basis for comparison with known risks. However, this is something that often biases risk perception. Specific types of technologies and practices, particularly those with dramatic impacts and therefore high "dread factor," such as nuclear accidents, tend to be assessed as high risk. Cultural values also influence risk perception. For example, individualistic and entrepreneurial people tend to accept higher levels of risk. In later years, several of these research results have been criticized for only explaining marginal levels of variance in risk perceptions. It has been suggested that specific fears and ephemeral emotional affects (in many cases created by organizational climate), rather than deeply rooted cultural values or cognitive heuristics, influence risk

perception. Research also shows that moral values, for instance, those regarding what is "natural," are a highly influential factor. Finally, risk perception is the result of complex social and communicative processes where news media and centrally placed news transmitters and interpreters influence the public perception of risk. Such processes have been described as the social amplification (or de-amplification) of risk.

While subjective perceptions of risk thus have come to feature prominently in research, techniques for quantifying risk have also become more sophisticated and, above all, have become more widespread in industries such as insurance and finance. However, also in relation to these industries (not the least since the 2008 financial crisis), there have been discussions about the merits of standard probabilistic risk calculus. In particular, in finance, there are discussions today of "fat tails" or "black swans"—that is, low-probability, high-impact events that traditional probability calculus tends to discard as highly improbable.

In summation, risk today is both a prominent political problem and a prominent feature in attempts to control and predict. What unites these two forms is arguably a semantic of the future that accentuates a plurality of potentialities (and individual responsibility for the outcome). Under these conditions, both prognostication and uncertainty come to the fore.

Rule Following

The topic of rule following is closely associated with the work of Ludwig Wittgenstein. It consists of several interrelated issues: What is a rule? In what ways, if any, can rules guide or compel us? What is involved in committing oneself to following a rule? How do we come to follow rules? What role do rules play in speaking a language? Are rules always and essentially social phenomena? What makes it possible to identify which rules other people are following? Does the investigation of a rule-following community call for a different form of social-scientific investigation than the study of entities that do not follow rules? These questions are obviously of great interest to both philosophers and social scientists.

This entry focuses on the ideas of the two highly influential interpreters of Wittgenstein's rule-following considerations: Peter Winch and Saul Kripke. Winch made the issue of rule following central to the philosophy of the social sciences; Kripke's reading of Wittgenstein dominates the contemporary debate.

Rule Following and the Philosophy of the Social Sciences

Winch uses (his interpretation of) Wittgenstein's rule-following considerations to establish a principled divide between the natural sciences, on the one hand, and the social sciences and philosophy, on the other.

A child uses a word correctly if she uses it in the same way in which she has been taught to use it by her teachers. To speak of actions as "correct" or "incorrect" is to invoke a standard, norm, or rule. Thus, when a child learns new words and linguistic structures, she acquires rules for using these linguistic entities. The child's linguistic behavior can be evaluated as correct or incorrect with reference to these rules, and eventually, she is able to do the same kinds of assessment regarding the linguistic behavior of others.

For Winch, the most important feature of Wittgenstein's analysis of rule following is this: In order to determine whether a given individual *I* follows a rule, we need to study not only *I*'s actions but also the reactions of other people in *I*'s community to *I*'s actions. In other words, we cannot claim that *I* follows a certain rule unless the members of

I's community are able to discover which rule is in question. The reason is that creatures that follow rules are creatures that make mistakes. That is, after all, why we evaluate their actions as correct or incorrect. But for talk of mistakes to have a point, it must be possible to establish that individuals have misapplied the rules they intend to follow. Put differently, it must be possible to overrule an individual's own judgment as to what following the rule demands in given circumstances. It must be possible to appeal to something that is external to the individual in question. And this external check is the responses and judgments of other people.

Rule following does not only concern linguistic behavior. For Winch, all meaningful behavior can be evaluated as correct or incorrect and thus is an instance of rule following.

To understand rule following, Winch claims further, is to accept that the methodologies of the natural and the social sciences must be fundamentally different. Both natural and social sciences involve judgments according to which superficially different phenomena are actually the same kind of entity: Ice cubes and steam are both instances of water; moving the king and castling are both instances of making a chess move. Such judgments of identity presuppose communities, since to say that *A* and *B* are the same is to invoke a rule: the rule that the words *ice* and *steam* stand for some of the phenomena that *water* stands for or the rule that the words *king* and *castling* stand for permissible moves in chess. However—and this is the central point—whereas in the case of the natural sciences we have only one set of rules, in the case of the social sciences we have two. In the case of the natural sciences, we only have the rules that the scientists follow. But in the case of the social sciences, we additionally have to reckon with the rules followed by the people ("actors") under investigation. Winch insists that the latter rules are key for the social sciences. In order to understand, say, a religious community, we must learn which phenomena its members count as the same and as different. This is not to deny that social analysts might develop vocabularies that differ from those of their actors. And yet, the latter have a methodological priority. Winch holds that a study of the concepts of other people must be closer to philosophy than to the natural sciences—after all, conceptual analysis is the heartland of philosophical methodology.

Responses

Unsurprisingly, Winch's book had its greatest impact among philosophers of the social sciences. Much of the response was critical. Many readers were unconvinced by Winch's argument for a sharp separation of the natural from the social sciences. They objected that Winch's methodology is conservative and unable to pose critical challenges to the societies under investigation. A critical social science must (be allowed to) transcend the concepts of the actors. Other critics felt that Winch's focus on concepts and meaningful behavior pushed him toward a form of idealism in which phenomena of violence and suppression have no role. In the same vein, Winch has been accused of reducing social relations to concepts.

Rule Following and Private Language

Although Saul Kripke's interpretation of Wittgenstein's rule-following considerations was not intended as a contribution to the philosophy of the social sciences, it has had a significant impact on the field nevertheless. Kripke offers the following reconstruction of Wittgenstein's argument.

Suppose you are now calculating an instance of the scheme $x + y = z$. Assume furthermore that the respective x and y are larger than in any of your previous calculations according to this scheme. To keep things simple, let us stipulate that x is 57 and y is 68 and that you are infallible in your arithmetical skills. Thus, you will calculate as follows: 68 + 57 = 125. This is the correct answer since presumably you mean *addition* by "+"; it is the correct answer since you intend to follow the rule for *addition;* it is the correct answer since you are committed to using "+" in accordance with the addition function. At this point, Kripke introduces a "rule skeptic." This skeptic asks you to justify your belief that you are committed to following the rule for addition. More precisely, the skeptic challenges you to justify your belief that by "+" you mean *addition* rather than some other function, say *quaddition.* (The quaddition function coincides with the addition function as long as x and y are smaller than 57. Otherwise, the quaddition function gives the result of 5. Hence, according to the quaddition function, 57 + 68 = 5.) The skeptic demands that your justification take the form of your identifying a fact about yourself, a fact by virtue of which you meant and mean *addition*

(rather than *quaddition*) by "+," a fact by virtue of which you were and are following the rule for *addition*. The skeptic suspects that there is no such fact and, thus, no fact as to whether you should reply "125" rather than "5" (or any other number).

This skeptical challenge, Kripke claims, lies at the heart of Wittgenstein's rule-following considerations. Furthermore, Kripke argues that Wittgenstein was right to think that the challenge cannot be met: There is no "straight solution" to the skeptical challenge. We cannot cite any fact that would establish that we are committed to using our words in one way rather than another. To establish this point, Kripke discusses a variety of possible responses to the skeptic. Suffice it here to mention just two.

The first response cites your past usage with the plus sign: You have used "+" for the addition function in the past, so surely you use "+" for the addition function now that you are confronted with "57 + 68." Unfortunately, by our initial assumption, you have never before calculated with two numbers as large as 57 and 68. Hence, your past practice is compatible with the hypothesis that in the past by "+" you meant "quaddition."

The second response invokes your dispositions. When faced with the "+" sign, you are disposed to calculate according to the addition function rather than according to the quaddition function. Hence, by "+" you mean addition. Kripke rejects this proposal, among other things, on the grounds that it fails to capture the so-called normativity of meaning. It is part of our ordinary understanding of meaning that to mean something by a word obliges us to use the word in some ways and not in others. If you mean addition by "+," then you ought to respond "125" to "57 + 68 = ___." This "ought" is not captured by talk of what you are disposed to do. And hence, dispositional facts cannot establish that you mean addition rather than quaddition.

But if all proposals regarding meaning-determining facts fail, do we not then have to conclude, with the skeptic, that—despite appearances to the contrary—we never mean anything by our words and never follow any rules? Kripke denies this. On his reading, Wittgenstein has a "skeptical solution" in answer to the skeptical challenge. This solution focuses on what we do when we attribute meaning to others. When we talk of Mary meaning something by a given word, we are not referring to facts about Mary's mind or behavior, facts that determine how Mary uses the given word. Instead, we signal to others in our community in what kinds of interactions Mary is a reliable person. If (in ordinary circumstances) I say of Mary that she means addition by "+," I tell others in my community that under normal circumstances Mary is reliable, for instance, when it comes to calculating restaurant or grocery bills with prices ranging up to 68 units of my currency. Put differently, when I say to you that "Mary means addition by '+,'" my aim is not to say something that is made true by a meaning-determining fact about Mary. My aim is to say something that is appropriate given your interest in, and curiosity about, using Mary as person with whom you might have an interaction that involves numbers up to 68.

If Kripke's Wittgenstein is right, then talk of meaning and rules makes sense only in the linguistic contexts in which one individual recommends another to the members of his community. To speak of rule following and rule meaning outside such social settings would make sense only if we could find a straight answer to the skeptic. And that, Kripke takes himself to have shown, is not possible.

Responses

Kripke's interpretation of Wittgenstein has been criticized from many different directions. Many critics have sought to defend a straight solution to the meaning-skeptical challenge. Often such defenses have involved the claim that meanings and rules are not intrinsically tied to social contexts. Other objectors have tried to show that the facts of meaning are social facts—that is, that the fact that determines you to answer "125" rather than "5" (in answer to "57 + 68 = ___") is your membership in the social institution of calculating according to the addition function. Another important line of attack has focused on Kripke's idea that meaning is inherently normative. Critics have either argued against this idea or tried to show that normativity itself can be understood in natural-scientific categories.

Scheler's Social Person

"Social person" or *Gesamtperson* (collective person) is the German philosopher Max Scheler's (1874–1928) term for the actual and ideal personhood of community. Elaborated from different perspectives and at various points within his writings—notably in *Formalism in Ethics and Non-Formal Ethics of Values* (1913, 1916), *The Nature of Sympathy* (1913), and *Die Wissensformen und die Gesellschaft* (1926)—Scheler contended that a community is also a person, possessed of all qualities of personhood including consciousness and moral responsibility. Social person is similar to conceptions of intersubjectivity associated with the phenomenological tradition and also similar to corporate understandings of community in the tradition of life philosophy.

In Scheler's *The Nature of Sympathy* (a critical analysis of sympathy as the basis for community, friendship, and love), he outlined the theoretical genesis of the person. His account loosely parallels G. W. F. Hegel's conception of the development of consciousness in the *Phenomenology of Spirit* and similar thinking by other German idealists but is couched in Scheler's phenomenological understanding of consciousness as intentionality. Explored in *The Nature of Sympathy* are the bases of our relation to others, such as in community, friendship, and love. Scheler perceived these bases as stages from lowest to highest, moving from emotional identification, to vicarious feeling, to fellow feeling, to sympathy, and finally to love. In this, Scheler maintained that personhood is the completion of a process that begins with a primitive condition of ecstatic experience wherein intentionality is unreflective and immanent (*Mitwelt*). At this point, the self cannot be discerned. Self emerges only subsequently as human beings experience their environment and even other human beings as resistances to intentions. Gradually, this engenders self-awareness and alienation, manifesting at first and immaturely as an egoistic celebration of individuality. Strident, immature individuality then generates ever sharper alienation that begs overcoming the distance between the self and others by love. The mature person, thus, recognizes herself as an aspect of her loving participation in community with others. A community of such loving participation is also a social person.

In *Formalism in Ethics and Non-Formal Ethics of Values,* Scheler's phenomenological study of value ethics, he offered his most detailed discussion of the social person. He argued there that the person is a center or constellation of acts that occur only in the context of a community. In every execution of an act, the person also reflects participation in the community that encompasses her. Community then is an essential feature of a person's acts. From this, Scheler concludes that every person has an individual person and a social person. This means, among other things, that the individual person and the social person are mutually coresponsible and separately self-responsible for whatever ethical implications acts have. As its own person, the social person of the community, like the individual person,

perceives morally weighted values by which its acts are accountable. And, owing to the mutuality of their participation in the other, both the individual person and the social person share in the moral responsibilities of the other. The individual shares in the moral consequences of the acts of the community, and vice versa.

In *Non-Formal Ethics,* Scheler also presented a theoretical account of the social person from the perspective of a typology of community. In form, his account follows the same pattern as seen in his description of the genesis of the person. *Mass* and *herd* are terms for the ecstatic community of contagion in which individuality is not truly present and the community itself lacks self-awareness and responsibility. "Life-community" is what he called the hierarchical, but corporate, community in which individuals can be distinguished by the functions they perform as limbs or members of the whole. "Society" refers to noncorporate associations in which individuals are alienated from others and the whole and cooperation depends upon overlapping self-interests validated by consent and formal rules. *Social person* is Scheler's name for the highest form of community. Social person completes and incorporates the lower community types.

The social person is not a collection of individuals and also not a construct. Rather, from the perspective of the person, it is essentially concomitant with the idea of personhood. The complete person is not possible apart from the social person. Moreover, from the perspective of the community, the social person is also the theoretical ideal of the personhood of community. Scheler called it a solidary realm of love and explained it as an active and ongoing unity of individual persons within an a priori community of persons. Scheler often contrasted his conception of the social person with Ferdinand Tönnies's 1887 analysis of community as *Gemeinschaft* or *Gesellschaft*. For Tönnies, *Gemeinschaft* referred to the thick and vital community of a tribe or village, which he contrasted with the thinner relationships of modern *Gesellschaft,* or "society." A sharper contrast to Scheler's thinking presents itself vis-à-vis Hegel's 1820 dialectic of family, civil society, and state in *Philosophy of Right*. Scheler rejected comparisons of the social person with the state. Conceding that the state is "personlike," he yet insisted that state corresponds best with the "life-community" level of community in his typology, because state lacks the spiritual and loving qualities of the highest form of community.

In Scheler's 1926 study, *Die Wissensformen und die Gesellschaft* (Forms of Knowledge and Society), he spoke at several points about the mind of the social person but did not explore the concept fully. The social person also was an important aspect of Scheler's theological reflections. The loving and spiritual qualities of the union that is the social person, understood both as a community and as a person, were perceived by Scheler to anticipate a totalizing completion in an encompassing loving and spiritual communion with the divine person that is God. In Scheler's late writings, such as *The Human Place in the Cosmos* (1928), he utilized a new analytical perspective based on philosophical anthropology, and a philosophy of history led him to emphasize what he termed the All-man (*Allmensch*) rather than the social person.

Schizophrenia: Psychoanalytic, Phenomenological, and Contemporary Philosophical Approaches

This entry presents the various ways schizophrenia has been approached by psychoanalysis and different schools of philosophy.

The relationship between schizophrenia and philosophy is a topic of great conceptual range and historical depth. The ideas of a number of 20th-century philosophers (Henri Bergson, Edmund Husserl, Martin Heidegger, Michel Foucault, and Ludwig Wittgenstein) have been applied to understanding this psychiatric illness since its recognition around 1900. Beyond this, there is the question of affinity or opposition between two domains. Schizophrenia is the quintessential form of madness; philosophy often stands as the epitome of reason. The relationship between the two has often served as a proxy for the ancient question of the relationship between rationality and its antithesis—the latter conceived variously as unreason, dementia, the passions, or sheer incomprehensibility.

Affinity or Opposition?

The most influential formulation of this relationship in the 20th century is in Michel Foucault's *History of Madness,* a work that associates the advent of the Enlightenment or Age of Reason with a moment in René Descartes's first meditation when he presents madness (persons whose brains are so disordered that they claim to have bodies made of glass) as a condition so devoid of sense as to place the afflicted person wholly outside the charmed circle of mutual comprehension, rendering him unworthy of the philosophical dialogue on which Descartes is embarked.

This vision of madness as a condition of unreason is perhaps the central one in Western thought and has been formulated variously. In Homer and Greek mythology, madness generally appears as the opposite par excellence of rationality, with self-control and clarity of thought usurped by the passions in all their blindness and fury. For Immanuel Kant, madness involved a decline of the higher cognitive faculties of understanding and judgment and failure to work toward true cognition of things. G. W. F. Hegel emphasized social dysfunction involving involution and idiosyncrasy—a regressive inability or refusal to accept the social and linguistic structures that define mind or rationality itself. But though dominant, these visions have not lacked dissenters. In *History of Madness,* Foucault gives pride of place to far more ambivalent visions of what madness might be. He quotes Michel de Montaigne and especially Blaise Pascal's famous statement to the effect that human beings are so necessarily mad that not to be mad would be another form of madness. This suggests that madness is intrinsic to human nature and may even foster insight or imply a paradoxical kind of sanity.

One variant of the dissenting view would assimilate the madman *to* the philosopher, in the sense of finding in him (or her) the truest sources of wisdom and insight, perhaps in association with release from the thrall of authority and convention. In Shakespeare, the apparent nonsense of the fool (or madman) turns out to contain superior insight; King Lear gains wisdom only once he becomes mad. The other facet of dissent likens not the madman to the philosopher but the reverse, thereby showing the errors of too much faith in reason or abstraction. The *ur*-text for our time is Friedrich Nietzsche's *Birth of Tragedy,* a crucial influence on *History of Madness,* which presents Socrates as a literal-minded, even fanatical intellect who ruins the subtle Dionysian/Apollonian mix that accounted for the vitality and wisdom of Greek tragedy.

Madness as unreason, madness as insight, and rationality as containing a kind of madness: These notions form part of our broad cultural heritage. But they also constitute key vectors underlying specific approaches to psychopathology in three traditions in which philosophy and schizophrenia have been brought into dialogue in the past century: psychoanalysis, phenomenology, and Wittgensteinian philosophy.

Psychoanalysis

Sigmund Freud was, for the most part, an advocate of the traditional view of psychosis or insanity, including schizophrenia, as a decline of the rational faculties. Whereas in neurosis the ego suppresses the id, in psychosis it supposedly lets itself be overcome by the id and is detached from reality. Typically, Freud and his followers presented these

developments as involving regression to more primitive levels of personality or stages of development. A different view, more reminiscent of Montaigne or Pascal, was offered by the French psychoanalyst Jacques Lacan.

Lacan views psychosis in general as, in essence, a rejection of what he calls the "symbolic" order or register. The symbolic includes language and all conventional or language-like (diacritical) structures. Hence, the psychotic person's failure/refusal to assimilate this dimension deprives her of the orienting signposts and the symbolic/conceptual capacities enjoyed by nonpsychotic persons. But like all poststructuralists, Lacan emphasizes the *merely* conventional, arbitrary, indeed fictional nature of these symbolic formations, which, though enabling, have no direct correlation with objective reality. Psychosis is therefore viewed as a condition that combines the possibility of true insight (seeing beyond conventional categories, gaining intuition into "the real") with an inability to function in normal society. This dual vision is captured in a famous line from Lacan's seminar of 1973/1974, "Les non-dupes errent": "Those who are *not* duped wander, lost and in error."

Phenomenology

The first phenomenological student of schizophrenia was Eugene Minkowski, a Polish French psychiatrist who studied with the psychiatrist Eugen Bleuler (coiner of the term *schizophrenia*) but was decisively influenced by Henri Bergson, the most influential French philosopher of the early 20th century. Minkowski saw the *trouble genérateur* of such patients as their lack of "vital contact" with the environment and their consequent reliance, instead, on forms of "morbid geometrism" and "morbid rationalism" that lack the vitality, flexibility, and contextual appropriateness of more engaged forms of existence. A congruent formulation was offered several decades later by the German psychiatrist Wolfgang Blankenburg (later elaborated by Giovanni Stanghellini). For Blankenburg, the defining feature of schizophrenia was the loss in such patients of the sense of "natural self-evidence"—the unquestioned obviousness, the unproblematic background quality that normally allows one to take for granted many aspects of the social and practical world. Blankenburg associates natural self-evidence with the "natural attitude" and "everydayness" described by Husserl and Heidegger. He views its loss as having certain affinities with the *epoché* or phenomenological reduction, the setting aside of belief in external reality that is the key method of Husserlian phenomenology. Both Minkowski and Blankenburg describe how loss of "vital contact" or "self-evidence" can eventuate in hyperreflection on experience and the world, a philosophical or pseudophilosophical scrutiny that attempts to compensate for the loss of intuitive grasp.

The most extensive discussion of these aspects of schizophrenia is offered by Louis Sass in a 1992 book. In *Madness and Modernism,* Sass disputes the dementia, regression, and Dionysian visions of schizophrenia to be found in mainstream psychiatry, psychoanalysis, and antipsychiatry. He argues that the mysteries of schizophrenic experience and expression can best be illuminated by comparison with the modernist and postmodernist art, literature, and thought of the 20th century, which is characterized by forms of hyper-self-consciousness ("hyperreflexivity") and alienation. Sass's use of philosophy is extensive. He argues, for example, that the study of delusion in mainstream psychiatry exemplifies the "forgetting of the ontological difference" that Heidegger identifies as the central error of Western philosophical thought. As a result, there has been a failure to recognize the nonliteral *manner* or *way* in which delusional "reality" may be experienced by many patients with schizophrenia—whose experience will often be less literal, less an example of straightforward "poor reality-testing," than is typically assumed. Foucault's analysis of the paradoxes of the modern forms of self-consciousness introduced by Kant (the "empirico-transcendental doublet") is shown to illuminate certain paradoxes central to schizophrenic self-consciousness, which may combine experiences of one's own mind as both the solipsistic center of the All and a mere mechanism subject to causal forces.

These phenomenological perspectives on schizophrenia blend the three organizing vectors mentioned above. They have influenced the psychiatrist Iain McGilchrist's work on brain hemispheres, forms of attention, and cultural–historical parallels, as well as the philosopher Matthew Ratcliffe's analysis of "existential feelings" or "feelings of being"—experiential phenomena that (Ratcliffe argues) demonstrate the impoverishment of the

conceptions of mental life common in analytic philosophy and cognitive science.

Many aspects of the aforementioned, phenomenological perspectives on schizophrenia are synthesized in more operational form in recent work by Louis Sass and Josef Parnas, who conceptualize schizophrenia as a disturbance of "ipseity" or the minimal self—that is, of the most basic sense of existing as a center or subject of experience. Drawing on the work of various philosophers, including Michel Henry and Michael Polanyi as well as Husserl and Maurice Merleau-Ponty, they describe a two-sided self-disturbance. This involves (1) a diminished, basic sense of existing as a subject of experience ("diminished self-affection") together with (2) a complementary tendency toward focal awareness of aspects of consciousness and the body that would normally be experienced in a tacit manner ("hyperreflexivity," basically an "operative," automatic, or nonvolitional process, but one that also occurs in compensatory, even quasi-volitional fashion). Sass and Parnas have argued that this theory is not merely descriptive but has a certain explanatory potential; it has been operationalized by Parnas and colleagues and applied in research on diagnosis and clinical prediction. The closely related, and crucial, issue of disturbed "prereflective" or implicit forms of temporal experience in schizophrenia has been analyzed by Thomas Fuchs.

Wittgenstein

Despite the growing interest in psychopathology (particularly delusions) in contemporary analytic philosophy and cognitive science, little attention has been paid to schizophrenia in particular. The exception is work inspired by Ludwig Wittgenstein.

The most sustained use of a single philosopher can be found in *The Paradoxes of Delusion,* in which Sass applies Wittgenstein to understanding the famous Schreber case. Wittgenstein was a sort of anti-philosopher: a critic of the illusions that philosophy can suffer from when it turns away from standard "forms of life" and "language-games" in favor of abstraction and involutional concerns. Sass uses Wittgenstein in the service of phenomenology, arguing that the delusions of this classic case of paranoid schizophrenia result from a similar disengagement and self-consciousness and demonstrate forms of self-contradiction that are analogous to what Wittgenstein discerns in the philosophical tradition. In this light, Schreber's madness represents a perverse self-apotheosis of the mind: the end point consciousness reaches when, separating from body, emotion, and the social world, it turns in upon itself.

A final philosophical issue involves a questioning of the very possibility of the phenomenological interpretations discussed above, on the grounds that they fail to appreciate the essential bizarreness that is the very essence of schizophrenia. As Angela Woods explains in a book on notions of schizophrenia in psychiatry, psychoanalysis, and cultural theory, schizophrenia is the "sublime object of psychiatry," in the sense of being recognized precisely for its difficult-to-describe, awesome, or incomprehensible status. But is this incomprehensibility absolute and impenetrable? In his classic work *General Psychopathology,* Karl Jaspers (a psychiatrist before he turned to philosophy) actually *defines* schizophrenia as a condition of incomprehensibility that utterly defies empathic comprehension by normal human beings. But many have disagreed; indeed, schizophrenia has been the prime object of phenomenological analysis in psychiatry. The possible recalcitrance of schizophrenia to interpretation and understanding has been explained variously—for example, by arguing that schizophrenic delusions may involve an alteration of what Wittgenstein termed *hinge* or *framework* propositions and thus undermine the very basis of shared understanding or verbal description.

The philosopher Rupert Read has offered a friendly critique of Sass's use of Wittgenstein, arguing that Sass fails to appreciate Wittgenstein's own insistence on the limits of linguistic description, which (in Read's view) runs up against an absolute limit when encountering the doctrine (or pseudodoctrine) of solipsism and the literal *non*-sense of schizophrenic experience and expression. This disagreement turns, in part, on interpretations of the "new Wittgenstein," which are controversial. In reply, Sass criticizes the Neo-Jaspersian polarization of comprehensibility and incomprehensibility in either/or terms, which risks returning to Descartes's rejection of all possibility of comprehending madness. It would be more in the spirit of Montaigne and Pascal to *complicate* our grasp of empathy, namely, to argue (as do both Sass and Mads Henriksen) that although schizophrenia can defy *standard* forms of empathy, it is not closed to more *radical* forms that

recognize the need to postulate a profound alteration of the organizing structures or ontological horizons of human experience, including time, space, and self-experience.

Science and Ideology

This entry explains the intricate nature of the ideological critique of science. It first charts different notions of ideology and goes on to show how what is commonly taken as the paradigmatic domain of objective truth—scientific knowledge—can be viewed from the standpoint of certain conceptions of ideology as a sociology of knowledge and, furthermore, how certain scientific theories have been criticized as being themselves ideological.

Ideology is one of a family of terms referring to a comprehensive system of thought that is characteristic of an entire society or of a particular socioeconomic class, religious group, political party, social movement, or profession. Other terms in the family are *worldview* (*Weltanschauung*), *belief system, mentality, discourse,* and *paradigm*. These terms are not equivalent to one another, but all describe an abstract foundation of thought and action that is characteristic of a particular social group. Like other terms in the family, the concept of ideology describes a coherent intellectual system that transcends the particular opinions, beliefs, or doctrines that it incorporates and frames. According to many theoretical conceptions, a person can hold (or be held by) an ideology without being fully aware of the way it shapes and inflects perception, thought, and action.

Unlike some of the other terms in the family, *ideology* has negative connotations that are difficult to put out of play when the term is used analytically. Often, when we speak of a doctrine or belief as an ideology, we are suggesting that it is false, highly partisan, or contestable because of its association with particular interests and agendas. Proponents of belief systems that present themselves as universal abhor the term, except when using it to dismiss

doctrines and "special interests" they oppose. Some social scientists use the term in a critical and even denunciatory way, but others try to use it analytically, as a more or less neutral term of art. However, with few exceptions, social scientists do not characterize their own analyses as being ideological.

Genealogy of the Concept of Ideology

Tensions between polemical and analytical treatments of ideology have run through the entire history of the concept. Karl Mannheim, in his landmark *Ideology and Utopia* (1936), traces the word to Napoleon Bonaparte, who used it to denigrate a group of "ideologues" for promoting politically ineffectual ideas during the contentious debates following the revolution. These ideologues were a liberal republican group who promoted a political version of Enlightenment philosophy. One of these so-called ideologues—Destutt de Tracy—actually coined the word *ideology* to refer to a "science of ideas." Already there was a tension between *ad hominem* arguments that dismiss or denounce ideologies by reference to narrow partisan interests and efforts to treat ideology as a variable social or cultural phenomenon. Mannheim took up Destutt de Tracy's initiative, though Mannheim treated ideology not as the name for a science of ideas but as a social phenomenon to be explained in relation to specific historical and existential conditions.

Mannheim employed a historicist analysis in which a particularistic conception of ideology in polemical disputes develops into a general sociology of knowledge. In vulgar (and, not infrequently, academic) usage, the word *ideology* is a polemical weapon—part of a strategy to "unmask" absolutist doctrines that hide the particular interests of those who stand to benefit from them. Especially in Marxist traditions, ideologies are analyzed by reference to class interests, and "false consciousness" is said to result when members of subordinate economic strata adopt, for example, the laissez-faire ideology of the ruling class. Such an ideology is "false" not only because it fails to fit the characteristics of the real world but also because it does not fit the (theoretically imputed) interests of a particular group that holds it. Ideology critique typically involves an effort to unmask objective, apparently disinterested doctrines and cultural practices by revealing the base interests behind them. Mannheim noted, however, that such efforts at unmasking typically imply their own versions of absolutism, thus furnishing grist for further unmasking in an ongoing dispute. When, as in Mannheim's own time during the Weimar Republic in Germany, it should be apparent that all sides in a dispute are playing the unmasking game, it becomes possible to acknowledge that one's own position as well as those of all others can be traced back to particular interests and social backgrounds. Such insight, Mannheim suggested (overoptimistically as it turned out), can then become the basis for an ascent to an analytical position that renounces unmasking in favor of investigating the social sources of all knowledge.

The Sociology of Scientific Knowledge

Detached from the give-and-take of political disputes and the absolutist postures that fuel them, Mannheim's general *nonevaluative conception of ideology* was the cornerstone of his program in the sociology of knowledge. That program involved a set of requirements, which David Bloor later summarized in *Knowledge and Social Imagery* with a scheme of methodological postulates for the sociology of scientific knowledge: *causality* (explaining belief as a function of existential conditions), *reflexivity* (the application of that form of explanation to one's own position), *impartiality* toward the truth or falsity of the beliefs being explained, and *symmetry* (the use of the same general forms of explanation for all beliefs regardless of their truth or falsity). There was a key difference, however, between what Bloor dubbed the "strong program" and Mannheim's sociology of knowledge, which is that the strong program would apply to all scientific and mathematical knowledge without exception.

For Mannheim, a methodological requirement for the sociology of knowledge was to show that a particular body of knowledge does not simply reflect the nature of things or pure logical possibilities. He supposed that the most robust physical laws and mathematical constructions would not meet that requirement, since physical laws, by definition, describe the nature of things and mathematical proofs are the epitome of logical deduction. Bloor, however, made no exceptions. Consistent with Bloor's program, Michael Mulkay reinterpreted Robert K. Merton's norms of science—communalism, universalism, disinterestedness, and

organized skepticism—as rhetorical themes in a professional ideology that promotes extramural governmental support for science, with minimal regulation or public oversight. Thomas Gieryn put forward a similar reinterpretation of the project of demarcating science from pseudoscience or nonscience. Where philosophers searched for demarcation criteria (most famously exemplified by Karl Popper's criterion of falsifiability), Gieryn treated variable historical efforts to demarcate science from nonscience as expressions of a highly successful professional ideology. Demarcation thus became a sociological phenomenon rather than a philosophical criterion. *Boundary work,* as Gieryn called it, is analogous to establishing geographical boundaries in a historical political process. It is rhetorical, pragmatic, interested, and at times ruthlessly indifferent to consistency.

In addition to treating broad characterizations of science as ideologies, social and cultural studies of science followed Thomas Kuhn in *The Structure of Scientific Revolutions* by treating stable complexes of theory and method in the natural sciences as historical *paradigms*. Kuhn likened paradigms to worldviews: holistic conceptions of nature and cosmos that motivate the search for evidence, guide interpretations of data, and infiltrate the analytical language of a science. He argued that revolutionary changes in the sciences do not result from an accumulation of evidence supporting a new paradigm at the expense of the old; instead, supporting evidence often follows a shift in worldview that marks a community's adoption of a new paradigm. Kuhn tried to hold the line against irrationalism and relativism and insisted that he was not suggesting that science was mere ideology. This did not deter others from enlisting Kuhnian ideas in efforts to unmask the objectivity of science to reveal its ideological underpinnings.

Science *as* Ideology

Ideology critiques of science proliferated in the 1980s and 1990s. Some critiques, such as Stephen Jay Gould's *The Mismeasure of Man,* targeted specific historical and contemporary cases, exposing dubious manipulations of data that produced "scientific" support for ideological assumptions about racial, class, and gender differences. Others, such as Richard Lewontin, associated entire developments such as sociobiology and genetic reductionism with social and political ideologies. For the most part, these criticisms adhered to distinctions between valid and biased methodologies and focused on dubious methods and statistical interpretations. Others, particularly proponents of feminist epistemology such as Evelyn Fox Keller, Sandra Harding, and Donna Haraway, went further to launch more general critiques of the social and cultural assumptions that pervade Western science. The critiques went well beyond historical and sociological research that convincingly documented that women were often excluded, explicitly or by more subtle means, from full participation in science and engineering and that those who did participate often received insufficient credit for their achievements. Feminist epistemologists argued that the very contents of science were pervaded by tacit assumptions and metaphors (e.g., DNA as a "master molecule" and nature "herself" as the passive subject of scientific manipulation and control) that privileged a White, Western European, male, executive mentality. Philosophical critiques of the objective/subjective dichotomy—and of "hard" and "soft" sciences—were mapped onto the gender binary and its discriminatory uses. Feminist critiques focused heavily on the life sciences, particularly in areas associated with reproduction and sexual difference, but they were by no means limited to them.

Though often denounced for being part of a broader anti-science movement, feminist and related "standpoint theories" have often claimed to favor a stronger form of objectivity than the one they hoped to dismantle. Instead of being produced within the sealed-off, purified, specialist domain of the laboratory, the hoped-for science would be open to critical voices, inclusive, and relational. Politics would not be treated as external but as a pervasive and explicit part of method. Objectivity would emerge from the conversation among human and nonhuman agents, rather than being treated as the attitudinal and procedural conveyance of "nature itself" into collective human understanding and control.

Critiques of Ideology Critique

The concept of ideology continues to feature in social studies of science, but it also has been subjected to sustained criticism and partial abandonment. The particularistic conception of ideology as an intrusive source of bias that deflects research away from objectivity and value neutrality remains an integral part of arguments both within the sciences and in popular

and academic discussions of the sciences. Far from being antithetical to the ideals of objective science, such arguments often reinforce those ideals by singling out sources of bias and (in the case of commercialized research such as in the pharmaceutical industry) corruption. However, when those ideals are themselves held to be part of a professional ideology—a rhetoric and a politics that secures its authority by denying that it is rhetorical and politically motivated—ideology critique appears to swallow its own foundations. As a regressive explanation that explains explicit expressions and actions by reference to abstract, nonobvious, tacit, and deniable sources of knowledge and action, ideology critique easily spins out of control and becomes indistinguishable from conspiracy theories. Efforts to resurrect social-epistemological grounds in the space vacated by the dismantlement of objectivity often seem convincing only to the converted. Moreover, to speak of "science" as itself an ideology flies in the face of arguments about the disunity of science that are widely accepted in social studies of science. To note this is not to forecast an end to ideology but to suggest that particularistic uses of the concept will remain interesting as a topic, while its generalized uses will remain dubious as an explanatory resource.

Scientific Method

Are there methods of science? And if so, methods for doing what? Most would agree that there are particular methods for observing in each of the sciences, from those employed by, say, an ethologist in observing chimpanzees in Gombe Park in Kenya to those employed by astronomers in observing the positions of celestial objects. There are methods for carrying out experiments, from properly conducting surveys to following the protocols of randomized controlled trials. There are also methods for applying mathematics to some science. And there are methods for reasoning (deductive, inductive, etc.), of the sort we employ in everyday life as well as in science, though science has methods of reasoning that are specific to it.

The history of science has commonly been accompanied by a philosophy of science, an important part of which is a theory of method—the starting point being Aristotle's works. In modern times, Francis Bacon provided in his *Novum Organum* (1620; its full title is *Novum Organum Scientiarum*) some principles of eliminative induction, René Descartes produced his *Rules for the Direction of the Mind* (written in Latin, probably between 1619 and 1628, and published posthumously), and Isaac Newton included in his *Principia* (1687) four "Rules of Reasoning in Philosophy."

Scientific method is commonly taken to pertain to hypotheses (or theories or, more generally, the claims of some body of belief), and this will be the main focus of this entry.

Are there methods for inventing hypotheses (the context of discovery)? Are there methods for

testing them (the context of justification)? If so, are these definitional of science? Some deny that there is such a thing as an autonomous methodology for science. The deniers include sociologists of scientific knowledge (see, e.g., the so-called Strong Program propounded by David Bloor, one of the contributors to this encyclopedia); those such as Michael Polanyi, who thought that scientific methods are tacit insights that do not have an explicit formulation; and, finally, Paul Feyerabend, who famously claimed in his book *Against Method* that "anything goes." This is a position that the later Feyerabend qualified considerably when he said that each move in the game of science may be accounted for by some rule of method, but there may be no overall theory of method of the sort espoused by "rationalists" such as Karl Popper—that is, a view of method that fits all the significant moves that have been made in all the sciences.

Methods of Discovery

Are there methods for discovering hypotheses given some data? Statistics provides many methods for finding a mathematical function to fit, say, a number of data points. Thus, the method of simple linear regression finds a straight line that will be a "best fit" to the data points, where "best fit" can be determined in a number of ways, such as the least sum of the squares of the deviations of the data points from the line. In their 1987 book, *Scientific Discovery,* Pat Langley and colleagues developed several computer programs that generate from data a number of well-known hypotheses in science. For example, their program BACON generates the following laws: From Johann Kepler's own data, it generates his third law of planetary motion (the cube of a planet's average distance from the sun is proportional to the square of the period); from Robert Boyle's data, his pressure/volume law; from Galileo's own data, his law of free fall; and so on. Yet other programs are theory driven and can take into account theoretical assumptions about the data under consideration. It was once a commonplace that there could be no "logic" of scientific discovery, but this quite general claim can no longer be sustained. However, it should be noted that the programs mentioned do not generate laws only out of data; they need to be supplemented with some heuristic principles to guide their search. But the heuristic principles of the programs are not like principles of method as traditionally understood.

The remainder of this entry concerns some of the methods for testing hypotheses, whether of the natural or human sciences. Some suppose that the methodologies of the two areas of science are quite different, especially the explanation of human action as opposed to natural occurrences. However, there are good grounds to suppose that there is a unity of method across all the sciences.

Randomized Controlled (or Clinical) Trials

The randomized controlled (or clinical) trial (RCT) is recognized as the gold standard of scientific method; it has a wide range of uses from medicine to agriculture, education, and psychology. In the simplest kind of RCT applied to humans, a sufficiently large group of people are randomly selected from the wider population and then randomly divided into two groups: (1) the experimental group E, in which some intervention I is to be performed, and (2) a control group C, in which no such intervention is to be performed (or perhaps some "placebo" is given). The intervention I can be some medical treatment or some mode of instruction (say in reading in the case of education), or whatever. Suppose O is some outcome in which an experimenter has an interest. Then one needs to discover the frequency of O in the case of E with I (suppose it is high) and the frequency of O in the case of C without I (suppose O does not occur or occurs with only low frequency). Then one can claim that intervention I is a significant difference maker in that for the E group I brings about the desired outcome O (with a high frequency) while in the C group without I, O does not occur (or with low frequency).

Randomization is important, along with matters such as the size of the sample, if RCTs are to work satisfactorily. An important presupposition is that the members of the two groups, E and C, are sufficiently similar to one another, the only salient difference being the presence of I in E and the absence of I in C. One cannot always be sure that this idealizing presupposition holds. There are some strategies, however, for making the presupposition highly probable. One of these is to ensure that there is no selection bias of those in group E so that, say, more in E have a casually relevant feature that brings about O while those in C do not; random selection

would reduce the chances of such a selection bias arising. Another is to reduce the possibility of the presence of unknown "confounding variables." In the above experiment, we wish to show that I is an "independent variable" that gives rise to the "dependent variable" O; however, one could establish a spurious dependence when there is really no dependence between I and O but some unknown factor X is the cause of them both. To illustrate, a simple experiment can be performed to show that bottle-fed children are less prone to getting diarrhea than those who are breast-fed (contrary to an initial expectation, since dirty bottles may be used). However, this simple experiment is prone to a confounding variable, such as the level of education of the mother. More educated mothers are more likely to bottle-feed and also to adopt more hygienic practices in using the bottle, thereby reducing the incidence of diarrhea. Thus, a confounding variable, the mother's level of education, is related to both bottle feeding and the incidence of diarrhea (which it suppresses). The role of confounding variables can be reduced through not only increasing sample size but also randomization.

Other important aspects of RCT (as applied to humans) concern whether they are single-, double-, or triple-blinded and what ethical protocols are to be followed when experimenting on human subjects. Also, RCTs fit well with a statistical analysis of the data that can be obtained. And refinements need to be made to avoid Type I and Type II errors and to take into account the investigation of events that occur rarely.

The Hypothetico-Deductive Method

The hypothetico-deductive (HD) method is best suited to the examination of hypotheses concerning items that either cannot be observed (e.g., moving tectonic plates) or are unobservable (electrons, the Higgs boson, etc.). The general idea is to examine some hypothesis (or hypotheses) H (the "hypothetico" part) and then draw out some conclusions from H that are open to direct testing (the "deductive" part, but nondeductive inferences can be admitted as well). However, no deduction can be made from H by itself—auxiliaries are needed. To consider this further, let H be the conjunction of Newton's three laws of motion and the law of universal gravitation. These need to be applied to some model M of a real system (e.g., the solar system or a swinging pendulum). Extra information may need to be supplied, such as the initial state of the system at a given time, IS. And finally, some background theory B not under test may be needed to facilitate the deductions (e.g., if the hypothesis under test is about the drag of the atmosphere on a swinging pendulum, then Newton's own theory of motion may need to be supposed, but it is not under test). Granted H, along with auxiliaries M, IS, and B, suppose a test consequence C is deduced. This is to be compared with some evidence E, which may be a single observation, but more likely E is a low-level regularity obtained from the statistical analysis of observational data or even data arising from clinical trials. Either C entails E (in which case all of [H & M & IS & B] pass the test) or E and C are inconsistent (and all of [H & M & IS & B] fail the test).

As can be seen from the above, the HD method does not come equipped with a significant theory of confirmation or disconfirmation. In the first case, if all of [H & M & IS & B] pass a test (since C passes), then this still does not show that H (nested as it is in the context of other hypotheses) is to collect all the confirmatory support due to the one pass; there are yet other tests to be made. It might appear that the problem of induction makes its appearance at this point but in a more indirect form. In the second case, if all of [H & M & IS & B] fail the test (since C fails), then this does *not* show that the failure is due to H itself; one or more of the auxiliaries, M, IS, and B, may be false instead. So direct falsification of H is not possible (unless the auxiliaries have independent high confirmation). This also shows that a version of the so-called Duhem-Quine problem can come to haunt the HD method. Finally, matters can be complicated by the fact that evidence E might be collected on the basis of the supposition of some further background theory K, such as a theory about the instruments being used to generate E. For example, radiocarbon dating is used to test rival theories in archaeology; but such dating presupposes several background hypotheses K about the presence of radioactive carbon that are themselves theoretical in nature.

There is also a problem with the HD method that bothers the logically minded; this is the problem of irrelevant tacking. Suppose that H (with whatever auxiliaries A) leads to conclusion C, which passes a test. Then any other irrelevant proposition X, when

tacked onto H, as in the conjunction H & X (along with the same auxiliaries), will also lead to the same conclusion C. So the irrelevant X piggybacks its way onto whatever confirmation accrues to H. This is regarded as an undesirable consequence that needs to be remedied, but it is not easy to see what the solution is. These issues aside, the HD method is widely used in some of the sciences, for example, volcanology and tectonic plate theory: Hypotheses about unseen activity under the surface of the Earth are applied so they have testable consequences.

Karl Popper's Critical Rationalism

Popper is a hypothetico-deductivist who exploited certain features of the HD method to set up his own account of science. Popper's notion of falsifiability, or better testability, arises straight from the HD model. For a hypothesis H to be scientific at a given time (i.e., open to test at a time) it is required that it have some testable consequences (at that time); if it lacks any, then it is not scientific (though it is still meaningful). This is the case for the ancient Greek speculative hypothesis that all matter is made of atoms. For most of the life of this hypothesis, it was not open to test since it lacked the necessary auxiliaries that, when conjoined to H, yielded testable consequences. Only since the beginning of the 20th century, as, for example, in Einstein's 1905 paper on Brownian motion, were the right auxiliaries available to provide a test consequence, in this case a lower-level law that could be tested against the zigzag motion of the Brownian particle. Again, if a theory has been falsified, then it must be falsifiable. This allows many claims from the past that intuitively we would now not regard as scientific at all, such as the spontaneous generation of life from matter. But this is open to test and has been shown to be false.

For Popper, the distinguishing feature of science is its ability to constantly revise itself. Popper's proposal that the claims of science be open to test is meant to capture this distinguishing feature. In fact Popperian falsifiability, and so susceptibility to revision, is an aim of science, an aim that the rules of the method of science are intended to realize. To this end, Popper proposed in his *Logic of Scientific Discovery* a number of rules of method the foremost among which is the supreme meta-rule: "The other rules of scientific procedure must be designed in such as way that that they do not protect any statement in science against falsification" (sec. 11). Following from this are his three anti–ad hoc rules, the first of which concerns theory revision through the introduction of new auxiliaries and states, "Only those [auxiliary hypotheses] are acceptable whose introduction does not diminish the degree of falsifiability or testability of the system in question but, on the contrary, increases it" (sec. 20). This anti–ad hoc rule is not without its critics, such as Paul Feyerabend and Adolf Grunbaum. Popper invites us to think of the rules of method as hypothetical conditionals ("if-then" sentences) that say that following rule r will realize value v (e.g., falsifiability) all the time (or with high frequency)—that is, if methodological rule r is followed, then scientific value v is realized. Such a conception of methodology as rule–value pairs is more fully developed (but in a different direction from Popper) by Larry Laudan in his *Normative Naturalism*.

Bayesianism and Probabilistic Methods

If there is a leading theory of scientific method today, it is the probabilistic theory of reasoning embodied in Bayesianism. This contains two fundamental ideas. First, in its simplest form, is Bayes's theorem: $p(H, E) = p(E, H) \times p(H)/p(E)$, where H is some hypothesis and E some evidence, and "$p(\ldots,—)$" is the two-place probability function (the theorem can come in many other interesting forms). The other principle is that of conditionalization and tells us how we ought to adjust our probabilities in light of the new evidence, E, we have learned. It says that $p_{final}(H) = p_{initial}(H, E)$. This captures the following simple inference. Suppose, for example, that the probability is high that the creek running past your house will overflow given two days of steady rain but in the absence of steady rain the probability of its overflowing is low. Then you learn that there have been two days of steady rain. So what ought your (absolute) probability that the creek is overflowing be? The intuition that it is high fits the principle of conditionalization.

Bayes's theorem is able to capture the better aspects of the HD method while avoiding the problem of irrelevant conjunction (tacking, as we saw above); and in addition it comes equipped with an account of confirmation that the HD method lacks. Interestingly, all the principles of method espoused by the later Thomas Kuhn (his model of theory

choice as a set of weighted values) have an account within Bayesian methodology. And obviously, Bayesianism fits within the probabilistic inferences of science. In fact, a full probabilistic account of method will begin with the axioms of probability from which Bayes's theorem follows.

One way to understand Bayesianism is to interpret the probability function p(H) to be something like a person's degree of rational belief in H. Here, the requirement of rationality is simply that the person distribute her degrees of belief in accordance with the probability calculus. This leads to the interesting, so-called Dutch Book Theorem, which shows that if one does not distribute one's beliefs in this way then one can lose in bets against nature. A similar independent proof of the rationality of conditionalization is also available. Also of interest are certain "convergence" results. Suppose two scientists propose quite different initial prior probabilities for the same hypothesis; then it can be shown that as evidence comes in, these differences get swamped and the scientists come to agree on what the conditional probability of the hypothesis is given the body of evidence.

Scottish Enlightenment: Influence on the Social Sciences

Eighteenth-century Scotland witnessed a period of tremendous intellectual achievement and discovery as well as economic growth. The Scottish Enlightenment—centered in Edinburgh, Glasgow, and Aberdeen—ushered forth developments in the fields we now regard as history, sociology, psychology, economics, and philosophy, as well as in geology, chemistry, medicine, and architecture. Such varied accomplishments ensured that the Scots, long situated on the geographic and intellectual margins of Europe, were now at the forefront of thought.

Many Scottish thinkers had a primary and fundamental interest in the development of society. Some of their concerns may have arisen from the peculiar history of their nation. The 1707 union between Scotland and England generated economic growth, even as Scotland remained divided between the more advanced Lowland and the Highland culture. A variety of Scottish thinkers sought not only to explain social development but to explore the emergence of particular phenomena—language, law, morals, and social conventions, along with trade and economic growth. Although the work of these thinkers did not bring forth, in any direct way, the disciplines of social science that we now enjoy, their endeavors generated lines of inquiry that were original and influential as well as systematic and empirical.

This entry summarizes some of the intellectual background to the Scottish Enlightenment, examines specific areas in which Scottish thinkers made salient contributions, and focuses on several thinkers of significance.

The Background to the 18th Century

Several thinkers were particularly influential to the Scottish study of society. In his *Leviathan* (1651), Thomas Hobbes (1588–1679) developed an account of social and political order by describing what he took to be the natural properties and tendencies of the human being. Hobbes drew inspiration from Galileo Galilei (1564–1642), whose method of resolution and composition Hobbes deployed to resolve society into its smallest components—the individual and his or her particular qualities. Having characterized the human being as manifesting a seemingly egoistic drive to quench desire after desire, Hobbes explained, via a series of purportedly deductive arguments, how individuals so described would bring about *either* conflict, suspicion, and war *or,* alternatively, peaceful cooperation via the institution of a governing authority. In utilizing naturalistic description to deduce regularities of behavior and interaction, Hobbes delineated the development from a state of nature to a law-governed society. His appeal to a scientific description had enormous weight, but other thinkers also proved influential to the Scots. In *On the Law of Nature and of Nations* (1672), Samuel Pufendorf (1632–1694) argued that the human being possesses social as well as egoistic proclivities. His outline of the progress of the human being from a primitive, savage state to a developed and complex society would resurface in the works of several Scots.

The notion that society might develop from a more primitive to a more advanced state was also articulated by Bernard Mandeville (1670–1733), who rejected the idea of social contract and articulated a thesis of unintended social outcomes, as well as a naturalistic account of the origin of morals and society (*The Fable of the Bees,* 1714, a two-volume work that included the essay "An Enquiry Into the Origin of Moral Virtue"). By the middle of the 18th century, however, a work appeared of signal importance to the Scots and to the development of social science: *Spirit of the Laws* (1748), by Baron de Montesquieu (1689–1755). In reflections on the interrelated nature of society and politics, Montesquieu observed how nations differ in circumstance (climate, geography, resources, etc.) as well as in manners and beliefs (religion, law, and cultural mores). He then sought to delineate principles that would account for the differential development of societies (each characterized by a "spirit"). In so doing, he examined how some political constitutions are appropriate for distinct societies and how law is determined less by the discerning eye of reason than by forces of circumstance and belief.

Themes

The Scottish Enlightenment included historians, political economists, ministers, and philosophers, many of whom were friends or acquaintances. However, these thinkers did not form a school; neither did their work represent a single unified outlook. Nonetheless, from their varied treatises emerge several coherent themes, many reflecting the influence of the thinkers just noted.

Human Nature. For the Enlightenment Scots, it is hard to underestimate the importance of a seemingly simple idea: The essential basis or starting point of inquiry must be human nature. An understanding of human nature could invoke self-reflection (as it did for Hobbes), but it should also include observation as well as comparison. The relevant observations could be drawn from classical literature or current society, but the reports and testimonies of those who had voyaged to distant lands proved essential as well. Although the Scots recognized, as did Montesquieu, the wide divergences among societies, most assumed that human nature was universally uniform. The appeal to uniformity had implications both practical and explanatory. If variations among and between humans do not reflect essential differences of kind, then neither should one's moral estimation of the humanity of distinct persons. Moreover, any differences demonstrated the necessity of explanation. Since humans shared a basic and knowable nature, the explanation of sometimes stark differences required attention to the varying circumstances of the natural and social environment. In this way, the Scots drew inspiration from Montesquieu, who had referred to how "physical" and "moral" causes might explain the divergences among societies. Against the views of Hobbes and Mandeville, the Scots typically portrayed the human being as a creature of plural motives, some benevolent, some oriented to self. The human being was a creature of reason *and* feeling. Standards of moral judgment, therefore, were not understood either as products of divine revelation or as a priori propositions comprehensible by reason. A person's moral capacity was

identified less with reason than with a moral sense or particular kind of sentiment, one that often reflected a significant social element, as witnessed in David Hume or Adam Smith's distinct appeals to the role of sympathy in generating moral judgments within society.

Naturalism. Their accounts of human nature led the Scots to develop *naturalistic* theories of society and social development. These theories were inspired by Newton's account of the natural world as systematic and law governed. The human being, understood as part of a unified natural system, possesses specific qualities and tendencies original to his nature. An explanation of social patterns and institutions should not partake of theological assumptions (even as the Scots were not as secular or as skeptical as some of their counterparts in Europe) or appeal to final causes, though some (e.g., Adam Ferguson and Adam Smith) did not wholly depart from a broad providentialism. Nor did these thinkers invoke any founding legislators or wise men to explain the progress of society. In fact, many of their accounts predicate that the institutions and conventions of society reflect unintended and cumulative processes of development over time.

Insofar as their theories relied on the assumption not only of a universal human nature but also of a unified system of nature extending from the natural world around us to the realm within, then so did their accounts of human action rely on an empirical and causal understanding of motives and mind. The Scots generally opposed the notion that a priori reason might provide substantive notions of the natural or moral world. The phenomena of the social and psychological world (even the religious, as witnessed by David Hume's *The Natural History of Religion,* 1757) are to be understood in terms of general principles and causal laws of the sort previously utilized for the external world of nature. In society, as in nature, the same types of causes will produce the same kinds of effects, said Hume. For example, the passions of a person work as causes that generate actions. An understanding of these passions would require further causal explanation of a psychological nature. In large groups, the regular sequencing of motives and actions allows, Hume suggested, for the formation of general explanations of human activity. Apart from the appeal to causal explanation, Scottish thinkers also sought to devise social laws that would inform our comprehension of, say, politics (David Hume) or economics (Adam Smith). Although these laws did not carry explicit formulations setting forth conditions of application, the regularities advanced by the Scots implied both explanatory and predictive functions, thereby anticipating the sorts of laws invoked by later social scientists.

Social Change. To understand society is to comprehend its development over time. Having recognized that societies differ across space and time, Scottish thinkers explored the sequential development of society writ large rather than the progress of any particular society. Most assumed that the idea of a founding social contract was without basis in fact or logic, so the Scots sought alternative conceptions. For the Scots, the human being is typically found in groups. Adam Ferguson, Adam Smith, and John Millar were among those who, following Pufendorf and Montesquieu, offered stadial (or stage) theories of the progress of society. The stages of society were typically three or four. For example, Smith delineated a savage society of hunters and fishermen, then a pastoral age of shepherds, followed by an agricultural age, and then a polished commercial age with division of labor, clear rules of law and justice, and a standard of living higher than ever before. Each age was defined in large part by specific modes of production that influenced manners, morals, and law. The transition from one stage to another was not inevitable—and the specifics of the transitions were often vague—but *if* development occurred, then it occurred in this way. An appeal to sequential development is an idea that still resonates in anthropological and sociological studies.

In their accounts of change, the Scots appealed to the actions of individuals, but they also relied on institutions and social rules, including habits and customs. Moreover, social development, either on the large scale of society or in terms of specific laws or institutions, did not rest on the designs and intentions of individuals or great men. Individuals act with regard to local circumstances and with an immediate rather than long-term intention; as individuals act, the aggregative result of their endeavors appears to be a product of design, even though it is not wrought by anyone's intention or through any sort of agreement.

In pointing out the cumulative processes of development, the Scottish thinkers offered accounts that anticipate social evolutionary theories.

Conjectural History. The interest in the progress of society suggests a historical bent to Scottish theorizing. Some who wrote histories—including William Robertson (1721–1793), *History of Scotland* (1759); David Hume, *The History of England* (1778); and Adam Ferguson, *History of the Progress and Termination of the Roman Republic* (1783)—chronicled the development of a specific nation or epoch. Alongside these empirical histories, the Scots also employed a form of history that Dugald Stewart (1753–1828) referred to as "conjectural." A conjectural history offers a hypothetical and naturalistic account of what might have happened over a period of time. In the absence of evidence, but with a knowledge of human nature and the general characteristics of the world, one might hypothesize about the development of language (Adam Smith, *Considerations Concerning the First Formation of Languages,* 1761), the origin of rules of justice (Hume, *A Treatise of Human Nature,* 1739–1740), or the general progress of society (Adam Ferguson, *An Essay on the History of Civil Society,* 1767). Such histories should avoid speculation while nonetheless narrating the causal links between a known later state of affairs and some earlier and relatively unknown age. Histories such as these tended to point out the degree to which human achievement was often the result of the cumulative effort of many persons acting with specific and local intentions.

Economy and Society. A variety of thinkers, including David Hume, Adam Smith, and John Millar, took a great interest in economic questions. Certainly, Bernard Mandeville had recognized both the advantages of the division of labor and the need to set in place a legal framework for growth and prosperity, but the 18th-century thinkers highlighted the importance of specialization for a burgeoning economy and pioneered a model of a self-maintaining system of trade and production. Some, such as Adam Ferguson and Adam Smith, recognized how a division of labor might have unintended consequences disadvantageous to individuals and to society. Economic activity existed alongside other forms of endeavor and was, in fact, embedded within a larger moral and cultural context. Nonetheless, manufacture and trade could be comprehended in a systematic way and shown to have a means of self-coordination not dependent on a wise legislator. David Hume argued that money was distinct from wealth and, in anticipation of contemporary monetarists, noted the significance of fluctuations in the quantity of money ("Of Money," 1752, *Essays, Moral, Political and Literary*). He also examined how commercial development worked in tandem with moral and intellectual progress ("Of Refinement in the Arts," 1752, *Essays*). Adam Smith delineated how a framework of law and justice could permit individuals, blessed with a desire for improvement, to generate a commercial order of generalized prosperity. Smith developed, thereby, a systematic approach to trade and production that yielded insights into the coordinating movement of prices.

Significant Thinkers

David Hume (1711–1776). In his monumental work, *A Treatise of Human Nature,* Hume aimed to construct a science of human nature: The very foundation and starting point of any inquiry lies in the human subject. Drawing inspiration from Newton, Hume hoped to introduce experiment into his study of human nature, as the subtitle of his work makes clear: *Being an Attempt to Introduce the Experimental Method of Reasoning Into Moral Subjects.* Some of the experiments require us to probe our understanding or conceptions; others rely on observation or comparison, or point to historical examples. Hume applied to the operations of our minds and to society the principle of causality invoked in explanations of natural phenomena. A principle of psychological association explained the various connections and relations that unite the ideas of mind. When he turned to politics and morals, Hume employed history as a source of experiment, along with observation and comparison. On any review of history, Hume contended, one will find general relations of motive and cause that provide a basis for understanding and prediction. The basic rules of justice, he suggested, arise over time as implicit social conventions. Moreover, moral judgment rests on a mode of social communication referred to as "sympathy": the means by which the feelings of one person are communicated via inference and identification to a spectator.

Adam Ferguson (1723–1816). In *An Essay on the History of Civil Society* (1767), Ferguson offered a conjectural history of society that is less a history of particular events—the founding of nations, the outbreak of wars, and so on—than an explanation of the movement of society from primitive to commercial stages. Ferguson employed a comparative method, drawing from travelers' reports and ancient texts, to delineate a theory of human beings as cleaving to society yet relishing conflict and steadily seeking improvement. According to Ferguson, the advances of the human being are slow, piecemeal accumulations that generate rules of property and law, as well as manners and technological achievements. Unlike Hume, who believed that commerce and moral improvement worked in tandem, Ferguson worried that individualism may weaken social bonds. Moreover, the rise of luxury within commercial societies may dissipate moral vigor, thereby encouraging corruption and weakness and an inclination to serve private pleasure over public good. Ferguson is sometimes regarded as one of the first sociological thinkers. His accounts of the role of conflict as well as his emphasis on the social and moral effects of modern commerce resonated into the 19th century (influencing, e.g., G. W. F. Hegel and Karl Marx) and beyond.

Adam Smith (1723–1790). For Smith, human inquiry, including a study of society, attempts to imaginatively construct the systematic links between disconnected phenomena. Smith had hoped to develop a systematic account of society, in terms of morals, economics, and jurisprudence. However, he completed but two of these projects: *The Theory of Moral Sentiments* (1759) and *An Inquiry Into the Nature and Causes of the Wealth of Nations* (1776). In his theory of morals, Smith sought to show how a human being with proclivities to self-interest might nonetheless cooperate benevolently with others. Via a social and psychological explanation, he based moral judgment on an agreement (sympathy) in sentiment between spectator and agent, an agreement that comes about by an imaginative act in which a person puts himself in the circumstances of the other. In the *Wealth of Nations*, Smith argued against mercantilism and constraints on trade, raised questions about the economic value of imperialism and colonialism, and delineated how a system of natural liberty will increase productivity and wealth, thereby benefitting the working population. Smith relied on a notion of self-interest (less a description than an analytical hypothesis) and the desire to better our condition to reveal how trade and markets could be self-coordinating and function without a guiding hand. Although his labor theory of value proved influential into the 19th century, it was fraught with complexities. On the more positive side of the ledger, Smith's enduring legacy rests on his illumination of how the endeavors of individuals, situated within an impartial legal framework ("natural liberty"), could increase productivity and wealth without a legislating hand to guide their efforts.

Along with these significant thinkers, numerous others contributed to the understanding of society, including Henry Home, Lord Kames (1696–1782) on law (*Historical Law Tracts,* 1758; *Sketches of the History of Man,* 1774); James Burnett, Lord Monboddo (1714–1799) on the origins of language (*Of the Origin and Progress of Language,* 1773–1792); and John Millar (1735–1801) on relations of authority (*The Origin of the Distinction of Ranks,* 1771) and the evolutionary development of law (*An Historical View of the English Government,* 1787).

Concluding Remarks

None of the thinkers described above worked within established disciplines such as we know them today. Nor need we understand these inquiries as first installments in some continuous development of specific social science disciplines. However, it remains true that the Scottish inquiries proved influential to the later disciplines of anthropology, sociology, psychology, and economics. What we find in these Enlightenment thinkers is the appeal to a uniformity of human nature, the idea of causal law as relevant to the social as well as natural realm, the importance of a self-coordinating model of economic production, the idea of unintended yet complex social outcomes, and the use of history as a subject in its own right and as the basic framework for understanding the present.

Searle and the Construction of Social Reality

In *The Construction of Social Reality,* published in 1995, John Searle proposed a theory as to how the social world fits naturally into a physical world. Searle's theory is grounded in one core idea that unifies all of his philosophical thought: There is one world constituted by physical matter, and whatever exists in this world must be physical. It follows that a proper explanation of any phenomenon of this world must not violate the physical laws of current scientific paradigms. In light of the underlying presupposition of the physical unity of the universe, a tension immediately arises when we look around at the world in which we actually live. What we see is a world of objects that are not easily explained in terms of scientific reductions. For example, our daily lives consist of social interactions that depend on this mysterious production of sounds we know as language—with objects whose very existence depends on this language we produce. Searle's favorite example is that of money. Money might be realized in the paper or metal that you have in your pocket, but the possibility of its use as money resides in something beyond the mere physical stuff of which it is made and its linguistic representation.

Searle therefore needed to build a theory that could establish a set of necessary features for phenomena to exist as social objects, and then explain what relation these features have to the physical world. In the same way that science can tell us how the physical world is constructed from elementary particles, Searle intended to tell us how the social world in all its manifestations is constructed by human beings, by virtue of physical, biological features. Ultimately, his theory of social construction, if successful, would show higher-level social life to be unified with our lower-level foundational world of physics.

Background: Shaping Searle's Thought on Society

The path to Searle's social construction theory is historical. Beginning with his first book, *Speech Acts,* published in 1969, and continuing throughout his publications, including his latest book, *Making the Social World: The Structure of Human Civilization*

(2010), most of the elements that would eventually go into making his fully developed social theory have been gradually elaborated and put together.

Speech Acts

In *Speech Acts,* the foundational elements for his theory of social reality are first laid. In this extended essay on the philosophy of language, Searle introduced three key notions that would serve as the building blocks of human institutional reality. These are (1) the particular form of speech act that is a *declaration;* (2) the distinction between different kinds of *rules* that shape human activity, regulative and constitutive; and (3) the logical *formula* "X counts as Y in context C," which describes all human institutional facts.

1. Declarations are a particular type of speech act that enable the distinctly human capacity to both represent and create facts at the same time. Thus, by means of sincerely and explicitly stating that such and such is now the case, a new state of affairs is brought into existence by the simple act of representing it as being the case. Adjourning meetings, marrying people, christening ships or children are all acts of declarations. Although declarations can be performed by a single individual—for example, a child could say alone in her room, "From now on, this doll will hereby be called 'Ida'"—most declarations require recognized authority, incorporating more than one person as speaker in order to be successful. The declaration would prove pivotal in Searle's theory of social reality.

2. The second crucial notion for Searle's social construction theory in *Speech Acts* is about the kind of rules used for social construction. Rules are of two different types depending on the function of the rule itself. According to Searle, the function of rules that guide or direct already established human behavior is *regulative,* whereas the function of rules that create new forms of human behavior is *constitutive.* For example, driving a car down the street does not require a rule in order to engage in the activity of driving. But driving the car on one side of the road or other in order to abide by an established convention or directive is an activity that is rule directed. On the other hand, playing a game such as chess is only made possible by virtue of a set of rules that creates the game in question. Our daily life is a web of these rules, from nonsocial acts such as driving down a country road to social acts of eating together, walking down a crowded sidewalk, or getting married. Even our very births and deaths are structured by rules that shape our first appearance in this life to our very last breath in it. For example, a baby born in most modern societies must have a name by law and a birth certificate. A dying person must have a death certificate. Humans have a unique form of behavior differing from other kinds of animals in that they not only can have habitual, conventional forms of behavior that become codified, they can create new forms of activities for themselves by virtue of the very act of codification. And the causal effects of this codification on our daily life are just a powerful as the causal effects of natural events such as a thunderstorm, a drought, or a forest fire on wild animals living in nature.

3. It is also in *Speech Acts* that Searle introduces the underlying logical formula for human institutions, "X counts as Y in context C." At this point in his writing, the formula is presented as the logical structure of language. It is used as an extension of his discussion on rule distinction to illustrate how the very tool that humans use—language—is itself rule constructed. As he states, language is constructed by constitutive rules, in the form of "X counts as Y in context C," whereby making a certain string of sounds X counts as a meaningful utterance Y in context C, a given language. Searle would later employ this formula in his social theory as the logical form underlying human institutions. He would also explain in *Making the Social World* the apparent circularity that his analysis of language creates: language, which itself requires rules, creates the very rules it requires. The logical formula of "X counts as Y in context C" is without a doubt the iconic characterization of Searle's theory of social construction. As he will show, the logical formula encodes the rich cognitive processes that are required to construct social and institutional life.

Intentionality: Mind, Language, and Actions

The bridge for Searle between the physical level of the natural world and the higher-level reality of human institutions is *language.* After *Speech Acts,* Searle turned his concerns to the fundamental cognitive features essential for language. To this

end, Searle published his philosophical theory of mind in *Intentionality: An Essay in the Philosophy of Mind* (1983). There are several points in this book that would play a role in Searle's theory of social reality. First, Searle presents a theory of mind in which consciousness is an ontologically irreducible feature of the world. Second, this ontologically irreducible consciousness has causal power. These two points are vital to Searle's social theory because the single most important factor in building human reality for Searle is human collective consciousness with representational content that has causal power. Searle calls this power "intentional causation." On Searle's account, human reality is not only ontologically subjective, it exists in a kind of subjectivity that can have ontologically objective effects.

Another feature of *Intentionality* instrumental to Searle's social theory is his theory of action. Searle's social construction analyzes human reality as a blend of two levels, action and language. Part and parcel of human social and institutional reality is the ability of humans to act collectively, along with another capacity to use language in order to create social objects. A theory of action provides Searle with the link to explain how the two, language and action, work together to construct social reality. Searle's theory of action analyzes intentional human behavior in terms of three logical components: a prior intention, an intention-in-action, and a bodily movement. Prior intentions and intentions-in-action both have contents that are causally self-reflexive. Causal self-reflexivity allows intentional contents to cause their own conditions of satisfaction. Thus, if a prior intention is successful, it will cause an intention-in-action by virtue of causally realizing its contents. Similarly, the intention-in-action enables the realization of its conditions of satisfaction by means of a bodily movement. An example of this that Searle often uses is the simple action of raising one's arm. A prior intention to raise one's arm has the content "I intend to raise my arm," whereby if successful, one's arm rises, fulfilling the contents of both the prior intention and the intention-in-action.

In his analysis of action, Searle explains how our actions can be categorized in two different ways. Actions can serve as means to ends, or they can be meaningful in and of themselves. Searle calls the former by-means-of actions and the latter, by-way-of actions. An example of a by-means-of action is that of shooting a target. In order to shoot a target, a gun must be fired. This action of firing the gun is a means by which the target gets shot. The by-means-of action can consist of many auxiliary actions depending on the skill of the agent. In the case of target shooting, if a shooter is a skilled marksman, his prior intention and intention-in-action have the simple content of "I want to shoot the target," which if successful is satisfied by the simple by-means-of action of shooting the target. On the other hand, if the agent is a novice shooter, the intention of shooting the target might be broken down into several by-means-of actions, such as first aiming the gun, pulling the trigger, and then firing the gun. Now let us imagine that the marksman is in a competition and those who wish to continue in the competition must intentionally shoot the target to indicate their willingness to continue. Shooting the target then becomes a by-way-of action in that the bodily movement takes on two levels of representation: It is indeed a goal-directed action of shooting, but this action fulfills an intention that is secondary to the primary intention of signifying the intentional content: "I wish to remain in the competition."

The distinction of kinds of action would become useful to Searle later in his social theory in order to explain how individuals can collectively perform single goal-directed actions by means of individual performances. Furthermore, it would also be useful in explaining how performances acquire a double level of collective intentionality, as in the case of declarations whereby individuals collectively authorize the imposition of status functions on physical objects. Searle's analysis of action is inextricably tied to his analysis of language and society.

Collective Intentionality

In "Collective Intentions and Actions" (1990), Searle began constructing his social theory by analyzing cooperative action as the basis of all social behavior. It was in this article that Searle introduced a particular kind of psychological state, *collective intentionality,* as required for any kind of cooperative behavior. Although the notion of a psychological state consisting of shared content was not new at the time this article was written, Searle's notion of it was different in several ways from traditional notions. Rather than attempting to give an ontological definition of content or shared content, Searle establishes the essential features for psychological states to be collectively held: First, the collective psychological state must have a plural first-person agent, a "we"

rather than an "I," and, second, the collective psychological state must be directed toward a common goal or target.

Furthermore, because first-person-plural agency, along with a common goal, defines a collective intentional state and distinguishes it from an individual intentional state, the state cannot logically be decomposed into a cluster of I-intentional states mutually held among a collective. That is to say, a we-thought is a primitive, irreducible psychological state. For example, the psychological states required for two people to take a walk together is different from the psychological states held by two people who just happen to find themselves in pace with one another on the sidewalk. In the first case, the two people have intentionally created not merely an action of coordinated behavior but a coordinated behavior directed toward a single goal—taking a walk. In the second case, two individuals have different goals that happen to coordinate their behavior. In the first case, the cooperative walkers might think to themselves, "We are taking a walk." In the second case, the happenstance walkers do not think to themselves, "We are taking a walk," unless in fact, they decide to do so, at which point the goal of their intentional movement becomes common and their intentionality has shifted from I-intend to we-intend.

Searle allows for the possibility of error in grasping the fact of another's intentions in a collective action. He provides an example of two people pushing a car, one of whom is committed to a collective endeavor while the other is only pretending to push. In this case, the individual committed to the collective endeavor thinks, "We are pushing the car," but he is mistaken as to the intentionality of the other person. At first glance, this example seems to weaken Searle's claim for the irreducibility of we-intentionality, although it is not clear exactly where that weakness lies. Searle never makes the claim that a cooperative endeavor necessitates we-intentional states in all the participants. Surely in group actions, the possibility exists for individuals to simply "go along for the ride," without commitment to any goal whatsoever. The question is, what effect does the possibility of mistaking the contents of other minds have on the claim that collective intentionality exists as a primitive psychological state?

The problem is epistemic and does not affect Searle's ontological claim. Searle's ontological claim of collective intentionality has deep implications: Cooperative social behavior requires an individual to be able to conceive of himself in terms of being a plural agent, a "we" rather than an "I." Without this capacity, individuals could not engage in any cooperative social behavior whatsoever. Indeed, they could not even pretend to cooperate. In the case of the pretend car pusher, he presents himself as a cooperator insincerely in the same way an individual engaged in lying presents himself as telling the truth. Knowing how to cooperate first involves understanding what a plural agent is, along with understanding that plural agents have common goals. And this notion of agency is logically distinct from that of actions involving multiple individual agents whose personal goals converge, intentionally or unintentionally. Having argued for the necessity of a psychological state for cooperation, that is, collective intentionality, Searle then had to explain how collective intentionality could exist in individual minds yet motivate individual bodies to act. In other words, Searle needed to defend methodological individualism, inherent in his theory of mind, in light of collective intentionality.

Searle's theory of action already contained the key notion for maintaining both methodological individualism and collective intentionality. Specifically, the notion of by-means-of actions could be employed to explain how individual actions contribute to the greater goal of a collective action. Within a cooperative endeavor, each individual action is directed toward a goal that serves a larger purpose of fulfilling the overarching goal of the collective act. If the collective goal is to achieve x, each individual does his or her part, y, z, as a by-means-of action toward achieving the ultimate goal, x. As an illustration, Searle uses the example of making a sauce béarnaise, in which one person stirs while the other pours. Their overarching goal is to make the sauce, x, by-means-of their individual actions, y, z. The individual actions can occur outside the collective endeavor—for example, a person can make a sauce by pouring and stirring on his or her own—but the conditions of satisfaction of those actions are quite different from those within the collective endeavor in that the actions performed are not directed to a collective goal held by a plural agent.

As in the case of individual actions, collective intentionality rises to the level of background skill of the cooperators. For example, if the Emerson String Quartet decides to play Mozart's String Quartet No. 1, the performers play their respective parts without requiring multiple representations of

by-means-of actions of the intricacies of the music. The accomplished performance of the cello is a by-means-of action as one action in the same way as the accomplished performances of the viola and the violins are. On the other hand, the beginning grammar school quartet playing the same piece must contribute to the collective goal in bits and pieces, fits and starts, by means of multiple by-means-of actions. In individual actions, by-means-of actions are construed as means to personal ends. Applied to collective actions, by-means-of actions are construed as means to a collective goal that belongs to a plural agent, a "we."

Searle's Theory Shaped

By 1992, Searle had all the pieces together to form his theory of social reality and did so in *The Construction of Social Reality*. In this book, Searle questions the metaphysics of our everyday human life. Why is money, money? What makes an institution essentially the thing that it is? In other words, Searle questioned the ontology of our social objects: What are these things that make up our human world? Where did they come from?

Searle had long before noted in *Minds, Brains and Science* (1984) that there is a disjunct between the social world, the world of social objects, and the physical world, the world of physical phenomena. The disjunction was particularly obvious in the social sciences and the physical sciences. The physical sciences had achieved great success as a field by virtue of physical laws that could predict and explain physical phenomena. Although not for lack of trying, the social sciences never got so far as establishing any strict deterministic laws. Searle claimed that the reason for this gulf lay in the metaphysics of the objects under investigation. Whereas physical objects are constituted by matter, mental objects are essentially constituted by people's attitudes. All social objects, from tables and chairs to families, banking institutions, and national borders are what they are because of people's beliefs. Searle concluded that intentionality is the essential feature of the social world and, furthermore, although it is an extension of the physical world, it cannot be ontologically reducible to it.

In light of this, Searle needed to explain how in fact intentionality could create social objects from physical phenomena. To that end, he had what he called "the building blocks" of social reality already in place. There are three main building blocks: (1) social objects exist by virtue of collective attitudes, collective intentionality; (2) their realization comes about because individuals collectively impose a new metaphysical status on them, thereby giving them a status function, endowing them with new social roles; and (3) this collective endeavor is codifiable in principle. That is, this collective imposition of status functions on objects is by its very nature a constitutive rule; thus, it is not a coincidence that this collective endeavor has the logical structure "X counts as Y in context C," the structure Searle introduced in *Speech Acts* to explain the nature of a rule. In the case of social construction, the X of the formula is an object that is collectively chosen to undergo status function imposition. It becomes a Y by virtue of receiving its new status function, endowing it with a new social role in context C—a cultural context surrounding it.

The logical formula is the defining structure underlying Searle's theory of social construction. The simple formula proved to be powerful in several ways. One way is that it could be used to define a set of social objects, namely, institutions that differed essentially from merely physical objects such as tables and chairs by virtue of the types of functions they could serve.

Searle claims that functions are not innate to objects but are imposed on them. He stratifies the kinds of functions that humans can create into two basic types. (1) Humans can use objects instrumentally by virtue of their physical properties. This function is called *agentive* and can be imposed on an object by one or many users. If two people decide that a big rock serves well as a nutcracker, this rock can be a social object by virtue of its instrumental use, its physical structure. (2) A second type of function is *nonagentive*. Nonagentive functions perform not by virtue of physical structure alone but by virtue of a collective imposition of a status on it. Objects that receive this new status gain a particular new force, a *deontic power*. Deontic power endows social enablements of rights, responsibilities, and obligations to an object in the context of a particular culture. Thus, institutional objects, ranging from people to brute physical objects, such as pieces of paper used as money, driver's licenses, and birth certificates, are a special kind of social object. They are institutional objects that have important

social functions in a society. Indeed, they stabilize social relations within society by virtue of collective acceptance. They also have the benefit of being accessible to the collective consciousness at any time because of their codifiability. Institutions that lose their power are those that lose collective acceptance or fade out of collective memory. For example, the 19th-century institution of calling cards for home visits is no longer alive in the 21st century. Most people could not recall why they were needed anyway. Their function has faded from collective memory by virtue of past collective neglect or rejection.

A success of the logical formula is that it forms a natural connection between the brute physical world and the world of intentionality. This natural connection forms a web of relations between objects in interesting ways. Searle claims that the formula can be iterated upward, such that the basic X that has a physical structure receives a status function Y, creating a new object, which then can serve as a an X, open to imposition of another status function, Y, and so on. For example, a female X can become a wife Y in some cultural context C. That very wife X can become a mother Y in the context of the family C, and so on. In this way, the logical formula can illustrate how one object can bear many social roles. But the number of social roles that an object can bear is not limitless and certainly not predictable. In any upward construction that is meaningful—that is, the variables of X, Y, and C have semantic value—the variables are constrained by their contexts. That is to say, not any X that satisfies the generic requirements for a social function can indeed be a Y term in given contexts. In the female–wife–mother example, the iteration of X into Y only works given the cultural expectations that females are the sole candidates to be wives and mothers. Beyond the trio of female–wife–mother, the iteration of social roles can continue for a given X, but it is completely dependent on cultural expectations rather than on the properties of the X term itself. In some societies the social statuses (the Y function) of mother–grandmother is the upper limit of iteration for a female. On the other hand, in some societies the social roles of motherhood and marriage have changed their institutions by expanding the domain of who can satisfy the function of wife or mother. Gay marriage is a good example in which the function of marriage and parenting has changed how the iteration remains logically the same yet the variables differ radically: An X that is a candidate for the function of marriage is not gender dependent in gay marriage, creating the possibility of two discrete Xs with the same status function of Y (wife or husband) in the same marriage.

Searle's Recent Elaboration of His Theory

In 2010, Searle published *Making the Social World: The Structure of Human Civilization*. In this book, he elaborates on aspects of the theory that he introduced in *The Construction of Social Reality*. There are two discussions that are pivotal to the construction of the social theory itself. These are (1) the reconsideration of the psychological attitude of the collective required for participation in and maintenance of social structures and (2) categorizing the logical formula as an implicit- or explicit-declaration speech act.

In the initial formulation of the logical formula, Searle claimed that for social statuses to be imposed, the collective had to have some form of collective acceptance toward the fact of status function imposition on some object. Logically, collective acceptance functioned as an operator over the entire formula, as in "We accept that X counts as Y in context C." An objection to the notion of collective acceptance was that it made social-institutional life sound agreeable to the collective at large. Institutions such as slavery or institutional facts such as war appeared to be a kind of happy collective cooperative activity. But this was not Searle's intended meaning of *collective acceptance*. Rather, he intended collective acceptance to reflect a notion more in line with collective recognition when he created his social theory. In *Making the Social World,* he reconsidered the notion of collective participation in social contexts in which not all participants are cooperators or are agreeable to the social statuses that they find they and others bear. In this later discussion, Searle maintained that cooperation required the psychologically primitive state of collective intentionality but that one could participate in a collective without active cooperation by means of another psychological state, that of *collective recognition*.

Collective recognition is not a psychologically primitive state. It is a state in which one recognizes that a state of affairs is the case and that others also recognize this fact, along with mutual belief about

each other's states of recognition. For example, Searle again uses the case of money. The medium used for money is only successful because of collective recognition. If individuals begin to realize that the medium they use for money is not collectively recognized, or that collective recognition is beginning to wane, the fact of this medium as money also begins to weaken. But the very act of using money is a cooperative behavior requiring both collective acceptance and collective recognition. Dutch guilders were accepted as money until 2002 in Europe. After 2002, a Dutch guilder could not buy a loaf of bread. The guilder lost its value because it lost its institutional status and therefore its collective acceptance, that is, its use, along with collective recognition, that is, its status as money.

Collective recognition and collective acceptance can come apart in a social setting. This is the case of individuals who find themselves in societies with which they are for one reason or another not in accord. Individuals can participate in these institutions without collectively accepting them by means of recognizing that things are the way they are and that others recognize the validity of the current state of affairs. This is a case of collective recognition without collective acceptance. There is no collective acceptance without first collective recognition. Searle thus amended his original account of social construction to allow for social participation without cooperation.

The second pivotal addition to the theory is the categorization of the logical formula as a *declaration* speech act. Although the logical formula itself, that is, "X counts as Y in C," is transparently a constitutive rule with the function of a declaration, Searle did not declare it an implicit or explicit speech act until *Making the Social World*. The motivation for this is twofold: (1) human institutions are created only by virtue of creatures who have language and (2) the deontic powers of the Y term are only realized in terms of actual human beings.

Searle's theory of social construction argues for a level of social fact that extends beyond mere cooperative behavior. Animals can act cooperatively in their various food-seeking behaviors. Searle allows for this as a kind of cooperation. But his interest is in a social reality that extends beyond mere behavior. This is an institutional reality grounded in relations of power between individuals, power relations that are not only collectively accepted and recognized but also collectively required in given contexts. This power resides in status functions that are not a matter of brute physical force but an invisible force, *deonticity*. Deonticity is a linguistic notion. There are no behavioral equivalents of the concepts of obligations, rights, and responsibilities. Because of this linguistic requirement for deonticity, only humans have social behavior that is institutional.

Thus, the logical formula "X counts as Y in C" is always a *declaration* made implicitly or explicitly by a linguistic collective with the authority to do so. In any institutional fact, there is always an implicit "We make it the case that p," whereby the collective statement both creates a fact and states a fact. The declaration not only states a new fact, this fact is one of granting powers. And all power ultimately is grounded in individuals with the capacity to exercise it.

An objection made by Barry Smith (2003) to Searle's theory of social construction in which all statuses bottom out in some physical X is the example of corporations. Corporations are what Barry Smith calls "freestanding Ys"—that is, Ys lacking a physical X. Freestanding Ys are not grounded in any physical structure. Rather, they consist merely in the words that create them, that is, they exist only by virtue of a declaration. The possibility of freestanding Ys is an interesting challenge to Searle's theory because it can be extended to other sorts of current phenomena, for example, electronic money, which might or might not have a physical grounding. This challenges the aspect of naturalism of Searle's theory of social construction. On this possibility, the naturalistic link between the physical world and human reality that Searle wishes to ensure is allegedly broken: Human reality appears only to be a matter of intentionality realized linguistically.

Searle points out in *Making the Social World* that although the declaration alone is capable of creating freestanding Ys, the power of the freestanding Ys is only enabled by people who can exercise that power. This has the effect of grounding the status function of the Ys in people's behavior. Declarations of the sort that create digital money or corporations state the powers of a set of people with respect to a given context. The status function then is a relation between powers and people who serve as the media for the realization of these powers.

Concluding Remarks

Searle's early ideas about the unity of the world come to fruition in his work on social reality. The link between the intentionality of human institutions and the brute physical world lies in the biology of humans. Human biology allows for collective intentionality and cooperation. Human biology allows for the creation of human power relations because it can grasp and understand concepts such as deonticity by virtue of the particularly human capacity of language. Language as a biological capacity allows humans to create a reality by representing it as such, in such a way as to be collectively believed, perceived, and accepted. The high-level facts of the human institutional world form a continuum from the brute physical world to the world of social behavior to the world of institutional life. The tie that binds the facts together, that unifies them into one physical world, is that of the human biological capacity for intentionality and linguistic representation.

Self and Essential Indexicality

What connects the topics of the self and essential indexicality is the first-person term: *I, me, mine, my,* and their cognates ("I" for short). This is because, as it is now commonly thought, (a) *I* refers to the self, (b) *I* is an indexical term, and (c) *I* is an essential term. Considerable philosophical debate has surrounded each of these ideas, and it is necessary to come at them from within that context.

Basic Claims

The idea that *I* refers to the self incorporates two claims: that *I* is a referring expression and that what it refers to is the self. In modern philosophy, René Descartes assumed both of these claims; they play an important role in the arguments of the *Second Meditation.* His immediate successors tend to agree that *I* refers, but they tend to complicate the issue of what it refers to. So John Locke drew a distinction between being a person and a human being and then floated the idea that *I* might sometimes refer to entities of the first sort and sometimes to entities of the second sort. George Berkeley narrowed the reference of *I* to the agent one is, while he conceived that agency in even more restricted terms: It is essentially the willing of ideas into existence by the imagination. David Hume denied that there is any self at all for *I* to refer to, at least if "self" means what it is usually taken to mean: something simple and continued and individual. If such an entity were to exist, Hume insisted, it would have to be observable as such when one introspects; yet no such entity is observable in this way. Immanuel Kant also doubted that *I* refers to a self, at least in the use of the term that interested him: in the phrase "I think," which, he claimed, accompanies all our representations. He even doubted that *I* is a referring expression, in this use at least. It is for him a completely empty expression, and what it represents is the mere form of consciousness.

The other two ideas, (b) and (c), arise from dissatisfaction with these disputes about (a). They must remain irresolvable until it becomes clear what precisely is at issue when one claims that *I* refers. Fairly evidently, if *I* is a referring term, it must be a singular term; each use indicates which one individual we are thinking of or speaking about on that occasion. But

this is true of a variety of terms: names, pronouns, descriptions, and demonstratives. To which category, if any, does *I* belong? Once this question was clearly and precisely formulated, two basic options quickly dominated discussion. One is that *I* belongs to the class of names. In the 19th century, John Stuart Mill thought so, and Gottlob Frege agreed, though he complicated the issue: *I* is an ordinary sort of name when we use it in a public and communicative way but a wholly special sort of name when we use it privately. The other basic option is that *I* is a descriptive term, one that is synonymous with some particular descriptive phrase. Bertrand Russell, in the early 20th century, took this view at one stage, making *I* synonymous with "the subject of the present experience." Later, Hans Reichenbach offered a language-based alternative: "the person who utters this token." Debate between these basic options quickly exposed certain features of *I,* which prevent it from belonging to either the class of names or the group of descriptions.

One set of features leads to (b), the idea that *I* is an indexical term. What prevents *I* from belonging to the class of names, at least if we focus on the paradigm case (personal proper names), is that its reference is radically context sensitive. Whereas the name "N. N." refers on each occasion of use to whichever one person was so baptized, no matter what the context, *I* may have as many different referents as it has uses. Whom it refers to depends on the context in which it is used, on who happens to be speaking, for example. This makes *I* like *here* and *now,* at least in their standard uses: The person, place, and time to which each use refers depend on the who, where, and when of that use, respectively. So it is natural to explain the feature that is common to these terms, their so-called indexicality, in the way David Kaplan does, by appeal to rules. On his view, now standard, what makes indexicals special among the varieties of referring term is that the rule associated with each indexical (he calls it its *character*) is sufficient to give its meaning and determine the reference of each use in context. These are rules like "Any use of *I* refers to whoever uses it" and (for the central cases at least) "Any use of *now* refers to whenever it is used" and "Any use of *here* refers to wherever it is used."

Another set of features leads to (c), the idea that *I* is an essential term. What makes it unlikely that *I* belongs to the group of descriptive terms is that no one has yet managed to come up with a description that is a genuine synonym for the term. One test of whether a description A is a genuine synonym for a term B is that if one knows that A is thus-and-so, one should know that B is thus-and-so. But none of the candidate descriptions passes this test. Consider Russell's option: I may know that the subject of the present experience is unhappy, without knowing that I am unhappy—if I am going on reflections of faces, for example, and do not realize that this unhappy face is mine. The reasons why *I* cannot be replaced by a synonym give it a crucial role in our thinking, as John Perry and others have pointed out. They regard *I* as an "essential" term because it has a unique role in manifesting self-reflexive self-consciousness and because such consciousness is indispensable to us. The argument for this latter claim usually centers on action—more specifically, on the relationship between such consciousness and motivation. But the evidence is precisely that to which we have appealed in discounting the description view of *I*. In the case given above, for example, I will change my expression when, but only when, I recognize that it is *I* who am looking unhappy. For any of the various candidate descriptions, I might well know that "the F is thus-and-so," without recognizing the crucial bearing of that information on me. Conversely, it makes no sense to suppose that I might know "I am thus-and-so" and fail to recognize the bearing of that information on me. And since this feat of self-conscious self-reference partly explains how and why we are regularly motivated to act as we do, *I* is regarded as an essential term.

Implications

Suppose that the uses of *I* are sufficiently determined in context by the rule that they refer on each such occasion to whomever then uses them. We may assume that in any genuine case of *I*-use, there is at least and at most one user. Then it seems to follow that every use must be guaranteed to have a referent: the user responsible for that use. This is consistent with a view that is generally held (indeed, it accounts for that view)—that it would make no sense to suppose that any use of *I* could fail to refer. There is another view, also commonly held—that it would make no sense to suppose that in using *I* to express thoughts about oneself, one would need to identify which item was being referred to. This view

is also consistent with, and explained by, the now standard view. Suppose that uses of *I* are sufficiently determined in context by the familiar rule. We may assume that in any genuine case of a person using *I* to express thoughts, that person must recognize that she is the user. Then it seems to follow that the user who knows the rule, and knows that she is the user, must know that she is the referent of the use, without having to identify herself with the item being referred to.

This is undoubtedly why the standard view is generally held—because it seems to provide a way of combining (a) to (c), arrived at after a long, historical debate, with two views that are commonly assumed to be true: that *I* is guaranteed to refer and that its use to express thoughts is independent of identification. But there are tensions within the position. The most significant concerns the relation between (a) and these two common assumptions about *I*. If *I* refers to the self, it must be a genuine singular referring expression. But if we look at the wide group of such expressions, we notice one characteristic they all have in common. Such expressions are used to single out items, and this is because their successful use represents an achievement: when the intended item is indeed identified, singled out, and referred to. Now there is no such achievement with the use of *I,* on the standard view; the intended item need not be identified by the user, and the use could not fail to refer. So it is unclear whether uses of *I* can genuinely be said to single out items, and hence whether the term does indeed share that underlying characteristic required for membership as a singular referring expression.

Current debate about *I* reflects this tension. Can what is special about the term (e.g., its guaranteed reference and identification-independence) be reconciled with what is ordinary about it (e.g., its status as a genuine singular referring term)? The range of responses reduces to four basic options. The orthodox view is optimistic: There really is a way of reconciling these apparently contradictory properties. The nonorthodox views are pessimistic and content to be so: There is no such way of reconciling these properties, and that is because there is simply nothing to reconcile. Some deny that there is really anything special about *I;* it is more secure than other terms, but it is not guaranteed to refer, and it does depend on some form of identification. This position is held by those who regard *I* as a deictic term, like the other personal pronouns (*you, he/she*). Some deny that there is really anything ordinary about *I;* it is too special to be a genuine referring expression. This position is held by some Wittgensteinians. Some deny that there is really one term at issue here; there are two types of term, and hence there is no combination problem: We simply attribute special properties to one type and ordinary properties to the other. This position is held, for example, by those who hold variations of the Fregean idea, that there is an *I* of communication (ordinary) and an *I* of soliloquy (special). These nonorthodox views will continue to disturb the peace unless and until the tensions that give rise to them are resolved.

Self and the Social Sciences

The self lies at the center of mental life. As the pragmatist philosopher and psychologist William James noted in the *Principles of Psychology* (1890/1981):

> Every thought tends to be part of a personal consciousness. . . . It seems as if the elementary psychic fact were not thought or this thought or that thought but my thought, every thought being owned. . . . On these terms the personal self rather than the thought might be treated as the immediate datum in psychology. The universal conscious fact is not "feelings and thoughts exist" but "I think and I feel." (p. 221)

Brief Historical Review

James's monumental work on the self (a chapter that covered more than 100 pages!) set the stage for much subsequent work on the topic in the social sciences. However, events taking place in the early 1900s put into play a number of assumptions about human behavior that resulted in wide-scale cessation of self-related research in academic psychology. Specifically, the behaviorist movement, primarily associated with the work of John Watson in the United States and Ivan Pavlov in Russia, came to dominate the research agenda for academicians in the psychological sciences. Behaviorists treated the organism as a "black box" that connected stimuli with responses but whose internal workings could safely be ignored. As a result, the self, clearly a part of the content of the black box, did not fit this theoretical worldview.

Fortunately, the decision to ban the workings of the black box from academic psychology did not transfer to disciplines in the social sciences outside the influence of behaviorism. For example, research on the self by sociologists was largely unabated. One prominent movement involving the self is exemplified by the work of the *symbolic integrationists*, such as Charles Cooley and George Herbert Mead, who, taking their lead from James's speculations about the social aspects of self, argued that the self was, at least in part, a social creation. Thus, Cooley introduced the metaphor of the "looking-glass self" to underscore the idea that we come to know who and what we are by seeing ourselves as reflected in the eyes of important others with whom we interact.

Another sociological enterprise focused on the self and its relation to the individual's temporal orientation. Such work (largely in the 1950s and 1960s) was characterized by a concern with (a) the factors influencing a person to temporally orient his or her self toward the past, present, or future and (b) the consequences of a temporal perspective for one's social-psychological function and mental health.

The self also was alive and well in the domains of clinical psychology and psychiatry. Starting with the far-reaching impact of Freudian thought on clinical practice around the start of the 20th century, the self (or ego/identity) assumed a central role in therapeutic thought and practice. Freudian theory and its implementation subsequently were supplemented and expanded both by Neo-Freudian perspectives on the self (e.g., by psychologists such as Alfred Adler, Karen Horney, and Otto Rank) and by competing analytic views (e.g., those of Eric Erickson, C. G. Jung, and Harry Stack Sullivan). But the ego remained a central concern. Medical schools soon became the new home, within psychology, for the study of self.

At the close of the 1950s, all this began to change as academic psychologists slowly freed themselves from the overly restrictive theoretical commitments of behaviorism. Reflecting this change, the number of research papers exploring self-related processes in academic psychology since the early 1950s has been proliferating at a staggering pace. Commenting in 1971 on the explosion of empirical articles on the self appearing in the 20 years since the behaviorist movement in American had gradually given way

to the traditional appreciation of the importance of inferring mental structures from the behavior of persons, Kenneth Gergen recorded an astonishing 2,000 studies published on the self during the previous two decades. Approximately 17 years later, John Kihlstrom and his colleagues identified dozens of "hot" research areas in which the word *self* served as a prefix (thus occupying the central position with regard to the topics addressed)—for example, self-awareness, self-concept, self-control, self-identity, self-verification, self-perception, self-handicapping, self-reference, self-regulation, self-schema, self-image, and self-stereotypes.

The Problem of Self in the Social Sciences

While it is clear that the self now has become central to the social sciences in the manner James understood it should be, it would be wrong to conclude that the intense research it receives has done much to clarify exactly what we refer to when we study the vast variety of self-hyphenated topics that populate research journals in a wide variety of domains (e.g., sociology, anthropology, and clinical, developmental, cognitive, personality, and social psychology). What is the self that regulates, references, handicaps, serves as a concept, and enables awareness?

One source of difficulty is that scientists studying the self often do not differentiate between aspects of and the ways in which they use the word *self*—that is, as an object of scientific analysis versus as first-person experience. Bertrand Russell's distinction between knowledge by acquaintance and knowledge by description provides a way to make sense of this definitional confusion. Russell proposed that we have knowledge by acquaintance when we know something by direct personal contact (sensory or introspective) and that we exhibit that knowledge by using appropriately referential terms when we communicate with others. With respect to the self, this is seen in the ease with which I talk about the self as well as understand talk about the self by others.

However, when we attempt to make explicit what it is we refer to by the word *self*—when asked to describe what the word *self* means—problems quickly arise. What exactly is the "self" that serves as the object of this diverse set of predicates? What is it that is being verified, conceptualized, controlled, esteemed, deceived, referenced, regulated, depleted, and handicapped? Although this question has led to models of the self dating back more than 100 years, it is difficult to find a coherent and convincing descriptive account of the self, per se. Rather, most papers typically describe the neurological and cognitive mechanisms that appear causally responsible for knowledge available to the self. In short, it has proven notoriously difficult to provide a set of propositions capable of transforming our acquired knowledge into a satisfying description of what a self is.

Some have argued that this really is not an issue at all. Researchers know that the object of the predicate in the relation X (self)–Y (concept, depletion, image, regulation, reference, etc.) is really a "place holder" for the modifier (Y), which is the real focus of examination. However, if that is the case, then we run into uncertainty vis-à-vis which aspect of the X–Y relation is doing the causal work. If the former (X), then in what sense is a self causally efficacious such that it can, for example, be depleted? Does it lose air, phlogiston, ether, spreading activation? If Y, then how does depletion casually work on a construct that would appear to lack substance under the physicalist principle of causal closure?

The point is that if one wishes to discuss the self and not simply see it as a slot to be filled in at some future date, then theory and research that invoke it as a causally relevant factor in psychological mechanism need to give it the respect and attention it requires.

The Neural Self of Science and the Subjective Self of First-Person Phenomenology

This section turns to what can and cannot be asserted with reasonable, empirically warranted confidence about the self. Specifically, first we discuss what Stanley Klein calls the *epistemological self*—the behavioral, affective, cognitive, and neural systems assumed to be causally responsible (at least in part) for providing the subjective self with knowledge of who and what it is. The discussion then points to an apparent incompatibility between treating the self as both the content of experience (i.e., an object) and the agent of experience (i.e., a subject). We will refer to the latter aspect of the self as the *ontological self*.

Considerable progress has been made in describing the cognitive and neurological bases of the epistemological self. This is because, unlike ontological questions, the epistemological self—that

is, the neurological bases of self-knowledge—is empirically testable and thus amenable to scientific analysis. Specifically, empirical studies of the epistemological self suggest that the singular, unified self of everyday experience actually is informed by a number of different, functionally isolable neurocognitive systems. These include, but are not limited to, the following:

1. Episodic memories of one's life events
2. Semantic memory-based summary representations of one's personality traits
3. Semantic memory-based knowledge of the facts about one's life
4. *The experience of continuity through time:* The connection between the "I" experienced now and the "I" experienced at previous points (as well as later points) in one's life—episodic memory is known to contribute heavily to this ability
5. *A sense of personal agency and ownership:* The belief—or experience—that "I" (agency) am the cause of "my own" (ownership) thoughts and actions
6. *The ability to self-reflect:* To form metarepresentations where the agent is the self and make inferences on the basis of those representations
7. *The physical self:* The ability to represent and recognize (e.g., in mirrors, photographs) one's body
8. *The emotional self:* The ability to experience and produce emotional states (both transient and dispositional) that provide value, affective valence, and evaluative direction to our actions and reasoning

Although the environment (social, cultural, and physical), and its reciprocal influence on the person, is not included in the above, this is not to dismiss its obvious relevance for what it means to have knowledge of one's self. However, the claims about the constituents of the epistemological self are primarily placed at the level of neural architecture. Accordingly, social and situational self-knowledge is folded into, and thus contained within, the neural machinery provided by systems of memory. This may be a vast oversimplification (as suggested by consideration of mirror neurons, theory-of-mind processes, and other neural structures that appear unique to social cognition rather than cognition taken more generally). It can be acknowledged that the selection criteria may be overly restrictive for some tastes.

Although the above sources (1–8) each contribute to the experience of self as a subjective singularity, taken individually they are functionally independent. That is, while in normal individuals, sources of self-knowledge work together to help create our sense of self as a subjective unity, taken separately none of these systems are either logically or empirically necessary to maintain the experience of the self as a singular, subjective point of view.

By contrast, the ontological self, the self of personal experience, is too poorly understood to bear the definitional adequacy required of the terms of a causal relation between self and memory. Not surprisingly, many researchers (intentionally or otherwise) sidestep this difficulty, relying on their readers' familiarity with the term *self* (i.e., the self of subjective experience), derived from years of knowledge by acquaintance, to confer a sense of confidence that he or she knows to what it is the author refers. But the basic problem remains—we are unclear what it is we are referring to when we apply the label *self* (nor is the term open to being grasped and thus labeled via scientific objectification). This is a serious problem.

Compounding this difficulty, researchers often fail to appreciate that the self as subjectivity—the ontological self—is *not* the object of their experimental tasks. Indeed, it logically cannot be the object of their studies. Objectivity is based on the assumption that an act or object exists independently of any individual's awareness of it; that is, it is something "other" than the self. When objectivity is the stance adopted by the self to study itself, the self must, of necessity, be directed toward what is not the self but rather some "other" that serves as the self's object. To study myself as an object, I must transform myself into an "other," into a "not-self." Thus, the self is not, and cannot, be an object for itself and still maintain its subjectivity. Paradoxically, we achieve "objectivity" of the ontological self only at the cost of losing awareness of our self as a subjective center.

The ontological self thus would seem a poor candidate for "current" scientific exploration—an enterprise predicated on understanding objects and their relations. Science is the world of publicly observable and physically measurable objects and events. Since nothing can be an object for the self unless it is "other" to the self, it follows that the self cannot objectively apprehend itself as itself. For the subjective self to become a part of the scientific world, it

would have to forfeit its subjectivity. Scientific analysis therefore has the unintended consequence of eliminating the object under discussion—the ontological self—from the discussion.

Conclusion

When social science researchers focus on the self, what they are investigating, more often than not, is actually the multiplicity of social and neural systems assumed to present the ontological self with knowledge. A tacit assumption is that there is a substantive, objective self, which, like any object (provided proper tools were available), can be treated as "other" and, thus found, grasped, and studied scientifically. While this assumption has its merits for the study of epistemological sources of self-knowledge, we often fail to sufficiently appreciate that (a) the subjective self is not an object but an awareness, a consciousness, and as such is not privy to anyone but itself and (b) there are profoundly important differences between the self as a subjective entity (the ontological self) and the self as types of knowledge available to that subjectivity (i.e., the epistemological bases of self-knowledge). These two forms, or aspects, of "self" are contingently related but are not conceptually reducible. By conflating them, we assume that we are casting empirical light on one (the assumed, causally relevant mechanism of our research endeavors—that is, the ontological self) while experimentally exploring the other (neural-based sources of knowledge about the person we are—that is, the epistemological self).

Self-Direction and Self-Ownership

The terms *self-direction* and *self-ownership* can be used in many different ways. For present purposes, it is best to take *self-direction* to refer to a possible and (putatively) morally portentous feature of persons' lives and to take *self-ownership* to refer to a central moral right that persons may be thought to possess by virtue of their respective (capacity for) self-direction and/or the value, significance, or moral import of their (capacity for) self-direction.

Self-direction is a matter of an agent's directing her life (not just her momentary behavior) on the basis of her reasons, judgments, projects, and commitments. Indeed, through self-direction, an agent in part constitutes herself as an embodiment of certain projects and commitments. However, self-direction need not take the form of hyperbolic autonomy—that is, continuous self-conscious and self-critical deliberation about the course of one's life.

Self-ownership is a matter of an individual possessing the moral *liberty-right* to dispose of herself—in other words, of the elements, attributes, and powers that constitute herself—as she sees fit and the moral *claim-right* against all others not to be prevented from exercising that liberty, that is, not to be prevented from disposing of her person as she chooses. Self-ownership is the moral liberty to dispose of oneself as one sees fit *combined with* the moral right against others that they not preclude one from doing as one chooses with one's own body and mind and one's physical and mental faculties. Many general moral rights, such as the right to determine

what one will say or the right to determine what one will ingest, are profitably seen as aspects of self-ownership. Like self-ownership itself, these rights are negative in the sense that they merely obligate others to allow one to act as one chooses with the means at one's disposal.

The thesis under consideration here is that in some way the value or significance or moral import of self-direction—or of something that is closely linked to self-direction—makes plausible the affirmation of the rights of self-ownership.

Despite claims to the contrary, there is nothing especially mysterious about the term *self-ownership*. The term is certainly no more mysterious than *self-direction*. Although the rights asserted in the name of self-ownership could be advanced without employing this locution, there is a long tradition within political thought that employs this terminology, including John Locke's *Second Treatise of Government* and Robert Nozick's *Anarchy, State and Utopia*. Moreover, the locution allows the advocate of the right to dispose of one's body and mind as one sees fit to present her position as the most thoroughgoing rejection of the idea that any person is to any degree the natural slave of others. This thoroughgoing denial of any degree of natural subordination is a corollary of the claim that no one's self-ownership imposes any positive obligations of service upon others. Finally, the employment of "self-ownership" places advocacy of persons' rights to do as they see fit with themselves within a broader program of facilitating peace and freely chosen cooperation among persons through the delineation of the moral fences that define "mine" and "thine."

If the rights of self-ownership are thought of as grounded in some yet more basic and morally portentous feature of the lives of individuals—for example, in the value, significance, or moral import of their (capacity for) self-direction—then those rights will be understood as *original* or *natural* rights. They will be understood as rights that persons have by virtue of their nature as beings capable of valuable self-direction, not merely by virtue of contract, convention, or legislative decree, or the social utility of belief in those rights. Even if human beings are not born *with* (the full range of) the rights of self-ownership, they are nevertheless, as Locke put it, born *to* self-ownership in the sense that in due course they will acquire the natural features that ground the attribution of self-ownership to them. Indeed, most defenders of self-ownership take these rights to be founded upon certain morally fertile natural features of human existence and, hence, to be original or natural rights.

In contrast to this belief in *original* or *natural* self-ownership, consider J. S. Mill's assertion in *On Liberty* that every individual is sovereign over himself, that is, over his own mind and body. Mill explicitly rejects the idea that the rights of self-sovereignty have any nonutilitarian foundation and insists instead that any ascription of moral rights must be based on a calculation of social utility—albeit a calculation that ascribes utility to individual self-direction as one of the permanent interests of mankind. However, it is precisely because Mill grounds his case for self-sovereignty on social utility that the domain of sovereign individual choice endorsed in *On Liberty* contracts steadily in the last two chapters of that work as Mill's list of socially beneficial interferences with individual choice lengthens. It seems that robust and far-reaching rights of self-ownership must be original or natural rights—in other words, rights anchored to yet more basic features of persons and, hence, rights not subject to the currents of social utility, convention, or legislation.

The affirmation of self-ownership is supposed to capture and articulate a range of our most basic intuitions about the *moral inviolability* of persons. Unless individuals have waived or forfeited their rights, they are not to be killed, struck, maimed, immobilized, or enslaved, and they are not to be coerced by the threat of such actions. They are not to be subject to such treatment even for the sake of great gains for others, for themselves, or for their righteousness. At least in their paradigmatic form, moral rights do not merely require that one be duly compensated if one is subjected to any such infringement; these rights require that one simply not be subjected to such treatment. To treat the rights of self-ownership as merely requiring that compensation be paid to those who suffer (unprovoked) infringements of them is to throw overboard the inviolability of persons that attributions of rights are supposed to safeguard.

Another important feature of robust rights of self-ownership—strongly emphasized by Nozick—is that they may not be violated even to minimize the total of rights violations. You may not kill one innocent person even if doing so will distract an aspiring evildoer who is about to kill five other innocents. Each

innocent person's self-ownership imposes upon you an obligation not to kill that innocent; with respect to each, you are subject to a "moral side constraint" against killing. You violate this moral stricture if you kill the one in order to save the five from the aspiring evildoer. But you do not violate this stricture if you abstain from killing the one. Of course, if you abstain, the evildoer proceeds to violate the self-ownership rights of each of the five. That is not a good thing; but not preventing those killings does not make you a violator of the rights of the five.

On what might robust, side-constraining rights of self-ownership rest? They cannot rest on the *agent-neutral* value of the condition that they purport to protect, that is, the lives or the well-being or the self-direction of individuals. A condition has *agent-neutral* value if and only if that value provides everyone with an equally strong reason for promoting each instance of that condition. (Different people will have different countervailing reasons of different strengths for promoting instances of competing valuable conditions.) Suppose that it is thought that the rights of individuals not to be killed rest upon the agent-neutral value of individual life or individual self-direction (both of which are eliminated by killing). On that supposition, what is really wrong with killing any individual is that this act diminishes the amount of agent-neutral value in the world. But if that is what is wrong with such killing, it is not wrong for you to kill the one to distract the evildoer from killing the five. For this act does not diminish the amount of agent-neutral value in the world. It brings about a world that is better endowed with agent-neutral value than the world would be if you eschewed killing the one. If the underlying rationale for rights were the agent-neutral value of the conditions to which persons are said to have rights, then persons will not have robust, side-constraining rights.

Robust, side-constraining rights can be a salient feature of morality only on the basis of the separate, ultimate, and, hence, *agent-relative* value of each individual's life or well-being or self-direction. A condition, say, Mary's self-direction, has *agent-relative* value if and only if the value of that condition provides the person *in whom that value would be realized,* in this case Mary, with a reason to promote it and yet may provide no other individual with a reason to promote it. Agent-relative value is decentralized value—not merely in the sense that this value occurs in many places but in the stronger sense that each person is a center of ultimate sui generis value. Only the agent-relativity of the value of persons or their lives or their self-direction explains the *irreplaceablility* of persons.

It is important to see here that the agent-relativity of the value of each person's life or well-being or self-direction serves two argumentative functions. First, it undermines agent-neutralist justifications for interfering with an individual's disposing of herself as she sees fit, namely, justifications that point to some alleged increase in the world's endowment of agent-neutral value. For instance, it undermines the assertion that your killing of the one is justified because there is more agent-neutral value in a world in which the five live than in the world in which the one lives. The agent-relativist responds that—at least in the absence of very special strong relationships of concern among some of these individuals—a world in which the five live is better for each of the five and worse for the one, period. Just as each of the five has reason to favor the outcome in which he lives, the one has reason to favor the outcome in which she lives.

However, this undermining of any agent-neutralist justification for your interference with the one does not itself establish the *wrongness* of your killing the one. It does not establish the right of the one not to be killed. The second function of the appeal to the separateness of persons—that is, to the separate importance of their lives and so on—is to provide individuals with a reason to eschew interferences with other persons and, hence, to show the wrongness of those interferences. Here is the central thought: The fact that each person has ultimately valuable ends of her own that she has reason to promote provides each *other* agent with a reason not to preclude that person from disposing of herself as she sees fit in pursuit of her ends. All other agents have reason to eschew treating this person as though she is a mere resource without purposes of her own and, hence, available for their exploitation. In more Kantian language, since persons are moral ends-in-themselves by virtue of the separate ultimate value of their lives, well-being, or self-direction, persons are not to be treated as means to the ends of others. Moral rights function to *honor* the separate importance of each person (or each person's life, well-being, or self-direction); they function to give practical effect to the moral *status* that each person has by virtue of the separate and ultimate importance of her life or well-being or self-direction.

Self-direction may enter in here in either (or both) of two ways. One may say that for each individual, value lies especially in her self-direction. It is the agent-relative value of self-direction that explains or is at the core of the agent-relative value of each person's living well. Hence, respect for the individual requires respect for her self-direction. Or one may say that for each individual, value lies especially in her living well, but a highly salient fact about human beings is that they live well through self-direction; they live well through the exercise of their ability to guide their actions by their reasons, judgments, projects, and commitments. Hence, respect for human beings as centers of value takes the form of respect for self-direction.

Self-Knowledge

Western philosophy has long treated self-knowledge as knowledge of *an inner self*. That use of *inner* is epistemic, designating a self knowable introspectively, that is, only by the same person. On that conception, even scientific knowledge of a person's nature would be incomplete knowledge of that person's self.

This entry describes the locus classicus of that traditional conception, plus a few prominent challenges and alternatives to that conception. Recently, some have argued for self-knowledge's including knowledge of the wider world.

Descartes: The Classic Conception

Modern philosophy began with René Descartes (1596–1650), especially his epistemological and metaphysical writings. *Discourse on the Method* and *Meditations on First Philosophy* exemplify *autobiographical* and *introspective* philosophy: Descartes tried to ascertain for himself what he knows, first questioning whether he knows anything at all. In "Meditation I," he wondered whether his beliefs ostensibly resulting from observing the physical world might be mistaken by being present within a dreaming experience. He then postulated as possible an evil demon deceiving him in all his beliefs, even those apparently due to reason.

This is where a concept of self-knowledge entered the story. In "Meditation II," Descartes reflected that with some of his beliefs it was impossible to be deceived. Being deceived involves thinking. So even when whatever one is thinking is the result of being deceived, one cannot be mistaken in thinking that one is thinking; and thinking includes existing. That was Descartes's *cogito*. Its most celebrated version is *cogito ergo sum*—"I think, therefore I am"—from the *Discourse*. Descartes claimed similarly invulnerable knowledge of his particular acts of thought—doubting, imagining, willing, and so forth. Thus, a self was described—known by that same self, immune from skeptical doubt. This is philosophy's locus classicus of putative self-knowledge.

Hume: The Self as Bundle

For Descartes, the known self was a mentally active substance. David Hume (1711–1776), in *A Treatise of Human Nature,* advocated a contrary picture, reflecting on how a self would be known. Hume allowed that there is mental activity with mental content. However (he concluded), no inner substance is knowable as the agent of that activity. We would know such a substance by introspectively discovering its accompanying the mental contents. Yet whenever we introspect to effect that discovery, we find only more mental contents. We do not discover also an inner substantial self. Hume did infer, nonetheless, that selves exist. But his was a distinct

conception: The self is a mere bundle or collection of those mental contents—not an entity, or substance, over and above those.

Kant: Two Selves

Immanuel Kant (1724–1804), in the *Critique of Pure Reason,* distinguished between the self as experienced (the *phenomenal* self) and the real self (the *noumenal* self). We can know only the former—one's self as involved in having experiences. There is no such experience—hence no knowledge—of a real self characterizable apart from one's having the experiences. Inevitably, though, we continue believing that such a self exists; we organize our thoughts as if it does. That is part of how we conceive even of experiencing a world beyond ourselves. You do not know your self as an object; you think of it as a subject.

Anscombe: Practical Self-Knowledge

Part of self-knowledge could be knowing oneself in action, including mental action. Elizabeth Anscombe (1919–2001), in *Intention,* highlighted a particular instance of that. Seemingly, knowing that one is about to eat an apple differs in kind from knowing that one's dog is about to do so. The latter knowledge is predictive; the former is also indicative of one's intending to act in that way. Anscombe called this *practical* knowledge. It would be practical self-knowledge. Her discussion has influenced many philosophers writing on action.

Semantic Externalism and Active Externalism

Recent philosophy poses another challenge to Descartes's classic conception. That challenge concerns the semantic content of thoughts. It reflects a view of meaning—semantic externalism (or "social anti-individualism and the mental" in this *Encyclopedia*)—associated especially with Hilary Putnam (1926–). Putnam imagined speakers on a twin of Earth—Twin Earth—using the term *wate*r as we do on Earth, responding to apparently the same sort of liquid—except that Twin Earth's "water" is XYZ, not H_2O. So their term's meaning differs unwittingly from that of ours.

This would imply that no one can know purely introspectively quite what his or her uses of such a term mean. To that extent, no one could know themselves by introspection. A person would have to know the surrounding world (e.g., whether this is Earth with H_2O rather than Twin Earth with XYZ) even to know his or her own mind. The former knowledge would depend on complex observation, even scientific theorizing. Self-knowledge would thus differ from Descartes's conception of such knowledge as immediate and first-personal. It would involve observing the wider world, even in order to know one's inner thoughts.

Maybe the self being known would actually be a part of the larger world. Andy Clark and David Chalmers propose an active externalism about mentality: One's mind is partly those aspects of the world helping one's functioning in cognitive respects. Diaries, calculators, even iPhones actively extend one's mind and, hence, one's self. Self-knowledge would include knowing one's iPhone.

Semantics and Pragmatics

Semantics and pragmatics are the two major branches of linguistics devoted to the study of meaning in language. This much is largely accepted. However, what constitutes the domain of semantics and that of pragmatics? Can semantics and pragmatics be distinguished in a principled way? Are they autonomous, or do they overlap with each other? How and to what extent do they interact with each other?

Semantic Minimalism Versus Contextualism

Currently, there is a heated debate between semantic minimalism and contextualism in the philosophy of language. The central thesis of semantic minimalism is that context is allowed to have only a very limited or minimal effect on the semantic content of an utterance. In addition, semantic minimalism holds that semantic content is entirely determined by syntax, semantic context-sensitivity is grammatically triggered, and it is not the job of semantic content to capture one's intuitive judgment of what a speaker says when he or she utters a sentence. Consequently, the object of study of semantics should be separated strictly from pragmatic intrusion. A number of variants of semantic minimalism can be identified. They include Emma Borg's *minimal semantics,* Hermen Cappelen and Ernest Lepore's *insensitive semantics,* and Kent Bach's *radical semantic minimalism.*

By contrast, *contextualism* endeavors to provide an account of contextual variations in semantic content in terms of a criterion of contextual best fit. According to the contextualist view, pragmatically enriched entities such as speech acts are the primary bearers of truth-conditional content. Only in the context of an utterance does a sentence express a determinate semantic content. In other words, semantics covers only part of the way toward the computation of utterance meaning, and it is pragmatic enrichment that completes the process as a whole. Currently, there are two versions of contextualism: moderate and radical contextualism. While the former acknowledges limited pragmatic influence on semantic content, the latter holds the view that pragmatic processes such as free enrichment play a central role in explaining contextual variations in semantic content. Furthermore, closely associated with radical contextualism is a position known as "truth-conditional pragmatics," namely, the thesis that various pragmatic processes influence and determine the truth-condition of an utterance.

Next, there is semantic relativism. Semantic relativism is an approach in the philosophy of language that falls largely in the semantic minimalist camp. While acknowledging that varying standards have a semantic role to play, proponents of semantic relativism reject the contextualist claim that the role in question is relevant to the determination of what is said by an utterance. Rather, the role played by varying standards is relevant to determining whether what is said is true or false. Some semantic relativists distinguish a context of use from a context of assessment and insist that epistemic standards, for example, are features of the context of assessment.

Finally, of some interest is what is called *indexicalism.* This is the position in the philosophy of language that assumes that there is a role for the speaker's meaning to play in the determination of the truth-conditional content of a sentence, but only when a slot is set up by the sentence itself to be pragmatically filled in its logical form. To this end, a range of "hidden" indexicals is posited to provide syntactic triggers for the additional context-sensitivity demanded by indexicalists, thus also referred to as *hidden indexicalism.* No top-down pragmatic influence is allowed to affect the truth-conditional content of a sentence. Interestingly enough, indexicalism is considered to be a version of moderate contextualism by semantic minimalists and a variety of semantic minimalism by contextualists. An alternative view is that, contrary to indexicalists, context sensitivity, called for by contextualists, lies in the circumstances of evaluation rather than being a truly indexical content for a sentence. This position is labeled *nonindexical contextualism.*

Drawing the Semantics/Pragmatics Distinction

The semantics/pragmatics distinction has been formulated in a variety of different ways. But of various formulations, three are particularly influential. First, it has been characterized in terms

of truth-conditional versus non–truth-conditional meaning. According to this formulation, semantics deals with truth-conditional meaning, and pragmatics has to do with non–truth-conditional meaning. This characterization of pragmatics is captured in a well-known formula proposed by Gerald Gazdar: Pragmatics = Meaning − Truth conditions ("Pragmatics equals meaning minus truth conditions"). There are, however, a number of problems at the very core of this approach to the semantics/pragmatics division. First, there are linguistic constructions that do not denote anything and therefore do not make any contribution to their truth-conditional content. Paradigmatic cases include greetings such as *Good morning,* conventional implicature-triggers such as *but,* and syntactic constructions such as imperatives. Second, the linguistically encoded meaning of a sentence does not always fully determine its truth conditions. This is illustrated by a sentence such as "It is snowing," which, according to contextualists, contains an unarticulated constituent, such as [in London]. Furthermore, there is often a pragmatic intrusion into the truth-conditional content of a sentence uttered. All this has led François Recanati to dub (part of) pragmatics *truth-conditional pragmatics.* If this is correct, one has to conclude that the truth-condition constraint cannot itself distinguish semantics from pragmatics in a principled way.

Second, the demarcation line between semantics and pragmatics has been defined in terms of conventional versus nonconventional meaning. On this view, semantics studies the conventional aspects of meaning and pragmatics, the nonconventional aspects of meaning. However, as pointed out by Kent Bach, this way of invoking the semantics/pragmatics division runs into trouble with the fact that there are linguistic expressions whose conventional meaning is closely associated with language use. A case in point is discourse indexical expressions. A major function of discourse indexical expressions such as *anyway, after all,* and *in conclusion* is to indicate that there is a relation between the utterance that contains them and some portion of the prior discourse. A further point to note is that the conventionality of a linguistic phenomenon may be a matter of more or less rather than yes or no. For example, of the three types of implicature proposed by Paul Grice, conventional implicature is the most conventional, hence the most "semantic" and the least "pragmatic"; particularized conversational implicature is the least conventional, hence the least "semantic" and the most "pragmatic," with generalized conversational implicature lying somewhere in between. In other words, the three types of implicature form a semantics–pragmatics continuum whose borderline is difficult to mark. From facts like these, one can arrive at the conclusion that there is no neat correlation between the semantics/pragmatics distinction and the conventional/nonconventional meaning distinction.

Finally, the semantics/pragmatics distinction has been equated with context independence versus context dependence. According to this formulation, if a linguistic phenomenon is invariant with respect to context, then it is the concern of semantics. By contrast, if a linguistic phenomenon is sensitive to context, then it is a topic of pragmatics. This characterization of the semantics/pragmatics distinction, however, rests on a mistaken assumption that context has no role to play in semantics. According to Bach, in the case of indexicals and demonstratives, especially of pure indexicals like *I, here,* and *now,* it is on the semantic side of the ledger that content varies with context. Consequently, Bach postulates two types of context: narrow and broad context. By *narrow context* is meant any contextual information that is relevant to the determination of the semantic content of, or the assignment of semantic values to, variables such as those concerning who speaks to whom, when, and where. Thus defined, narrow context is semantic in nature. By contrast, *broad context* is taken to be any contextual information that is relevant to the working out of what a speaker overtly intends to covey. It is also relevant to the successful and felicitous performance of speech acts. Hence, it is pragmatic in nature. Given that context plays a role in semantics and pragmatics as well, and that narrow and broad context cannot always be distinguished, the semantics/pragmatics distinction cannot correspond to the context independence/dependence distinction either. In summary, the semantics/pragmatics distinction does not *systematically* coincide with any of the distinctions between truth-conditional versus non–truth-conditional meaning, conventional versus nonconventional meaning, and context independence versus context dependence.

Pragmatic Intrusion Into What Is Said and the Semantics–Pragmatics Interface

On a classical Gricean account of meaning and communication, a distinction is made between what is said and what is (conversationally) implicated. What

is said is generally taken to be (a) the conventional meaning of a sentence uttered with the exclusion of any conventional implicature and (b) the truth-conditional content of the sentence uttered. However, according to Paul Grice, before one computes what is said, one has to (a) identify reference, (b) fix indexicality, and (c) resolve ambiguity. What is implicated is then defined in contrast to, and calculated on the basis of, what is said. It turns out, however, that the determination of (a)–(c) involves pragmatic enrichment of some kind. Putting it another way, it is now generally acknowledged that in working out (a)–(c), there is pragmatic intrusion of some sort into the semantic content of what is said.

Regarding what is said, what the relevance theorists Recanati, Bach, and Stephen Levinson share with Grice is that there is a level of semantic representation or linguistic meaning of a sentence and this level belongs to semantics. Next, what the relevance theorists Recanati, Bach, and Levinson have in common is the view that at least part of the original Gricean notion of what is said has to be understood as involving much more of a pragmatic contribution than Grice has acknowledged. But they cannot agree on two points. The first is that while the relevance theorists, Recanati and Levinson, believe that there is substantial pragmatic intrusion into what is said, as a semantic minimalist, Bach denies that there is such an intrusion. Instead, he posits a level intermediate between what is said and what is implicated, and he calls it the *middle ground of speaker–meaning implicature*. Second, the disagreement concerns the nature of the pragmatic enrichment under consideration. For the relevance theorists, it is an explicature; for Recanati, it is part of the pragmatically enriched said; and for Bach, it is an implicature. In other words, for these scholars, the pragmatic enrichment is of a special kind and differs from conversational implicature. By contrast, on Levinson's view, it is nothing but the same beast as conversational implicature. Consequently, these four analyses of pragmatic intrusion into the classical Gricean characterization of what is said have different implications for delimiting the respective territories of semantics and pragmatics and for the interaction between semantics and pragmatics.

To conclude, semantics and pragmatics constitute two distinct domains of inquiry, but they are inextricably intertwined in such a manner that their borderline is difficult to be drawn in a neat and systematic way.

Sen's Paretian Liberal

In 1970, Amartya K. Sen christened a simple logical impossibility "the liberal paradox." Ever since, the problem has been discussed in political economy and philosophy. Sen's short paper spread confusion by conceptualizing liberal rights as entitlements to determine *social outcomes* rather than a property of social rules. In short, political (or institutional) liberalism, concerned with liberal forms of the game of politics (game forms), does not suffer from Sen's paradox,

while philosophical (or ethical) liberalism, being concerned with the formation of ethical preferences over social states (liberal welfare functions), does.

Once the rules or "constitution" of a political interaction are defined, outcomes emerge from individual choices on the basis of given preferences. The rules of games—with which political liberalism is concerned—will always allow for an outcome however the rules are fixed (in Table 1, which illustrates a simple game, individuals *can* always choose a row or a column).

Philosophical liberalism scrutinizes the implications of forming ethical preferences over social results in a liberal way. It is not about how to fix the rules of the game but rather about *how* to evaluate the outcomes of games (i.e., how we rank order the cells of Table 1).

A philosophical liberal tries to incorporate the preferences of individuals as far as possible into her own ethical preferences (i.e., her ordering of the cells in Table 1). If an individual A prefers *x* over *y* (cell *x* over cell *y* in Table 1), then the philosophical liberal will intend to "respect" A's ranking when forming her own ethical (or welfare economic) ranking of social states. The obvious problem is that the philosophical liberal cannot at the same time impartially ratify in her ethical preferences B's preference of *y* over *x*.

How this simple point plays out may be illustrated by adapting Sen's original example of a group of two individuals, "Lascivious, A" and "Prude, B," who have diverging preferences over states of the world characterized by their (non)reading of the book *Lady Chatterley's Lover,* or LCL for short. The relevant actions are C_A: "A does *not* read LCL," D_A: "A reads LCL," C_B: "B reads LCL," and D_B: "B does *not* read LCL."

C indicates that the actor is cooperating *with* the *other* one by complying with his other-regarding preferences. D indicates that the actor defects from cooperation with the other-regarding preferences of the *other* actor. The preferences R over social states (the action combinations bringing about the states of the world) are

$$R_A: (D_A, C_B) >_A (C_A, C_B) >_A (D_A, D_B) >_A (C_A, D_B),$$

$$R_B: (C_A, D_B) >_B (C_A, C_B) >_B (D_A, D_B) >_B (D_A, C_B).$$

Prude B prefers that he himself, rather than the lascivious individual, reads LCL. For him, it would be best if neither of the two would have to read the book and worst if both read it. Though the lascivious individual A regards it best if both read LCL, he would volunteer not to read it himself if this should be necessary to induce Prude B to read it. That state of the world is better from the lascivious individual's point of view than one in which only the lascivious person reads the book, and this in turn is better than a state in which no one reads LCL.

If the two actors independently make their choices, then one of the cells of the table will emerge as a result of their actions. Since each of the actors according to his preferences prefers the D alternative, no matter what the other chooses, the (D_A, D_B) result will emerge under independent rational play (the preferences involved are the same as those in the Prisoners' Dilemma). If we identify the action alternatives open to the actors as their respective right of choice, the two actors may want to coordinate how they use their rights to choose between columns or rows independently of each other since $(C_A, C_B) >_A (D_A, D_B)$ and $(C_A, C_B) >_B (D_A, D_B)$. Yet there is no paradox but only a simple collective goods problem. Political liberalism as a mode of assigning rights to act is consistent.

The paradox of (philosophical or ethical) liberalism emerges in the example at hand when a liberal-ethical planner or welfare economist intends to respect the individual preferences of both A and B in her ethical preferences no matter what. If a mapping that ranks social outcome as a function of individual preferences over social outcomes is used to represent the value judgments of such a socio-ethical evaluator, an impossibility result can be proved.

Sen showed that such a mapping cannot conceivably meet three liberal requirements simultaneously:

1. The preferences of each individual are at least over one pair of social outcomes decisive for the

Table 1 Reading *Lady Chatterley's Lover*

B	C_B	D_B
A	*B reads*	*B reads not*
C_A, A reads not	(C_A, C_B)	(C_A, D_B)
D_A, A reads	(D_A, C_B)	(D_A, D_B)

Source: Author.

ethical preferences of the planner ("minimal liberalism," or "liberal decision right").

2. An alternative to which another one exists that is preferred by all should not be ethically preferred by the planner ("weak Pareto principle," or "social efficiency").
3. Whatever the preferences of the individuals over the social alternatives are, they will be taken into account as ethically relevant by the preference-forming mechanism ("unrestricted domain," or "individual sovereignty").

Using the preference orders of Table 1, it is obvious that it is *impossible* to ratify all preferences *over the cells* of the table simultaneously in the ethical liberal's welfare judgment and to secure Pareto optimality. Yet the problem emerges obviously quite independently from the Pareto principle.

SERENDIPITY

In philosophy, the idea of serendipity goes mostly by the title of "accidental discovery," while in the social sciences, *serendipity* is the preferred term. Whichever the nomenclature, the idea has been at most a relatively minor concern in the two fields, explained in part by its roots in a fairy tale (see final paragraph of this entry) and in part by the absence of a long-standing intellectual interest notably pursued by recognized scholars. It is, however, an important, even if unduly neglected, notion in scientific practice. It is also linked to recent attempts to study creativity.

The sociologist Robert Stebbins defined *serendipity* as the quintessential form of informal experimentation, accidental discovery, and spontaneous invention. As a method of discovery, serendipity joins several others, among them discovery by exploration, trial and error, and metaphoric reasoning. Robert K. Merton (who studied serendipity most systematically) and Elinor Barber have observed that serendipity can refer either to finding something of value while searching for something else or to finding something sought after in an unexpected place or manner.

In the social sciences, serendipity as a method of discovery comes closest to exploration and is sometimes confused with it. Exploration is a broad-ranging, purposive, systematic, prearranged undertaking. Moreover, serendipity as its usage in popular culture suggests is conceivably available for everyman, whereas exploration attracts a much more exclusive band of devotees. It is the department of those creative people who are trained to routinely produce new ideas. In certain fields of serious leisure and professional work, artists, scientists, and entertainers, for example, routinely explore, while in some forms of casual leisure, people at play (both children and adults), sociable conversationalists, and seekers of sensory stimulation rarely if ever do so. The latter set usually makes its discoveries only through serendipity. By contrast, though the routinely creative group occasionally discovers something serendipitously, it is far more likely to rely on exploration for new ideas.

Merton introduced the idea of serendipity to the social sciences. An anomalous finding during his research in the 1940s on the social organization of the suburban American community of Craftown stirred his interest in the unexpected in science. Craftown was a predominantly working-class community. There he observed that a sizable proportion of its residents were affiliated with more civic, political, and other volunteer organizations than where they had lived previously. He noted further and serendipitously that this increased group participation had occurred primarily among the parents of infants and young children. This finding ran counter to commonsense knowledge, for it was widely believed that, particularly in the lower socioeconomic levels, youngsters tend to tie parents down. Thus constrained, they are unable to participate in organized group life outside the home.

Although serendipity is not exploration, it can occur through inductive generalization. Researchers in the social sciences collecting data using a controlled study design sometimes observe regularly occurring phenomena that are fully unexpected. This is what happened during Merton's study while he was searching for something else. In such circumstances, the controls were, obviously, incomplete; despite the best intentions, a significant recurrent extraneous phenomenon found its way to Merton's attention. Furthermore, he was alert enough to recognize its importance for his investigation. This, since it is based on recurring instances, is *inductive serendipity.*

What may be called *unique serendipity* is probably the more common of the two types. Everyday life offers many examples: seeing a species of birds in a region they are believed not to inhabit; noting the improved flavor of a soup after accidentally adding a spice not called for by the recipe; and recognizing the greater efficiency of a new (auto, bicycle, pedestrian) route to the office upon being forced to abandon the old one because of repairs. Stebbins argues that one of the benefits of pleasurable reading lies in its serendipitous revelations. In unique serendipity, the discovered bird, flavor, or efficiency is a single occurrence, albeit with subsequent occurrences serving to support the conclusion about the significance of the discovery. That is, other people see the same bird in the same region, the soup continues to taste better enhanced with the new spice, and the new route to the office continues to be more efficient than the old one. *Unique serendipity* is a label for what Merton and Barber indicate is "finding something sought after in an unexpected place or manner."

Inductive serendipity might be described as the same process as exploration were it not that the former is accidental whereas the latter is planned. Both processes, when implemented in research, result in generalizations that emerge from systematic, direct observation of phenomena. But those resulting from exploration are intentionally sought by way of a study design that facilitates discovery. Not so with inductive serendipity.

Both exploratory and serendipitous generalizations emerging as inductively generated conclusions take their significance from a larger explanatory framework of some kind. The same holds for unique serendipity. Social-scientific theory, including other grounded theories from the exploratory project itself, helps exploratory investigators interpret what they have observed. In the case of unique serendipity, people experiencing such discoveries interpret them according to a related fund of knowledge and experience. The bird is identified as new to the region according to the birder's knowledge of regional avian wildlife. The cook, based on past culinary involvements, asserts that the new flavor is superior. And so on. It is against this kind of background that serendipitous discoveries derive their meaning.

Recently, in a far more detailed examination of serendipity than was found in Merton's earlier study, Merton and Elinor Barber explored its nature, history, and application in the humanities and social sciences. They observed that *serendipity* as a term first appeared in a letter written in 1754 by Horace Walpole to Horace Mann. Walpole coined the word *serendipity* based on his familiarity with the fairy tale *The Travels and Adventures of Three Princes of Serendip*. Serendip is the ancient name of Ceylon (today Sri Lanka), and the three princes were sons of Jafer, at the time philosopher-king of that country. Serendipitous discovery is evident in places in the tale.

SEXUALITY

Sexuality as a word was developed to describe a host of biological phenomena. It has also taken on a more specific meaning, indicating an individual's sexual proclivities or identity: "my sexuality." More recently, however, it has been increasingly used to

refer to the historical organization and cultural significance of erotic behavior. This points to the growing importance of sexuality in political debate on a globalizing world. It has become a crucial aspect of fundamentalist politics, and it has also given rise to a new concept of human sexual rights.

This entry presents the historical, political, scientific, and social-scientific aspects of the notion and underlines links with epistemological issues as well as with philosophical questions regarding biological kinds and essentialism.

Historical Overview

The history of the term suggests its complex evolution. The earliest usage of the word *sex* in the 16th century referred to the division of humanity into the male section and the female section. The subsequent meaning current since the early 18th century refers to physical relations between the sexes, "to have sex." *Sexual,* a word that can be traced back to the mid 17th century, carries similar connotations—pertaining to sex, or the attributes of being male or female, is one given meaning. The term *sexuality* itself emerged early in the 19th century, meaning the quality of being sexual. It is this meaning that is carried forward and developed by sexologists, who emerged as a distinct category of specialists in the late 19th century and became increasingly influential in the 20th century—luminaries such as the Austrian pioneer Richard von Krafft-Ebing, the British writer Havelock Ellis, the German author Magnus Hirschfeld, and the most famous of them all, Sigmund Freud, the founder of psychoanalysis.

Epistemological and Metaphysical Issues

Sexologists sought to discover the "laws of nature," the true meaning of sexuality, by exploring its various guises and manifestations. They all concurred that sexuality was in some ways an underlying biological essence that underlay a range of human behavior and fantasies. They sought to classify and define the various forms they discovered, and it is to this generation that we owe concepts and terms such as *homosexuality* and *heterosexuality, transvestism* and *sadomasochism, coprophilia* and *necrophilia,* and a thousand more terms in the ever-growing encyclopedia of sexual naming. Later researchers such as Alfred Kinsey and his colleagues demonstrated that sexual behavior was much more diverse than public morality and private prejudice liked to believe, and they argued that in biology, there was neither right nor wrong and neither normal nor abnormal.

To this point, sexuality was seen largely as a biological phenomenon, with crucial psychic manifestations. Since the 1960s, however, contemporary theorists have questioned the naturalness and inevitability of the sexual categories and assumptions people have taken for granted. They suggest that the sexologists did not so much discover or map the world of sexuality as help create and constitute it. The concept of sexuality, they argue, unifies a host of activities that have no necessary or intrinsic connection: discourses, institutions, laws, regulations, administrative arrangements, scientific theories, medical practices, household organization, subcultural patterns, ethical and moral practices, and the arrangements of everyday life. Nothing is sexual, the British sociologist Ken Plummer suggested, but naming makes it so. So sexuality was now seen as a narrative, a complexity of the different stories we tell each other about the body; a series of scripts through which we enact erotic life; or an intricate set of performances through which the sexual is invented, ritualized, and embodied. It is the name, Michel Foucault famously argued, of a historical construct.

Historical, Political, and Cultural Approaches

So instead of seeking the laws of nature that would explain sexuality as a universal phenomenon, the new theories suggested that we need to examine the specific historical and cultural organizations of sexualities in all their diversity. We should speak not of sexuality but of sexualit*ies,* not of sex and society but of sexual cultures. A further point follows from this: a recognition that sexualities are hierarchically organized, with some forms dominant while others have been historically subordinate and marginalized, shaped by complex relations of power. The most familiar of these relate to gender, with male domination shaping attitudes to female sexuality and homosexuality. Hierarchies around age, class, race, and ethnicity have also been crucial in shaping sexual beliefs and behavior. In recent years, there has also been an increasing recognition that sexualities, at least in the West, have been organized into institutionalized forms of heterosexuality.

Power relations structure sexuality, but uneven power relations also provide the necessary condition

for resistance and for sexual politics. The impact of feminism and of lesbian, gay, bisexual, and transgender (LGBT) politics since the late 1960s has simultaneously sharpened awareness of the arbitrary nature of gender and sexual categories and increased the possibility of changing them. New sexual identities, like LGBT, have become the basis for radical claims to equality.

At the same time, there has been a growing recognition that the meanings developed around sexual identity in the West were not directly relevant to many marginalized people both in Western countries and across the globe. This is closely related to a recognition of the growing importance of globalization in relation to the organization of sexualities. The spread of the HIV/AIDS epidemic since the 1980s to become a worldwide pandemic is a tragic illustration of this. Sexuality has become a major element in global political discourse, with new forms of conflict—over, for example, the rights and roles of women, attitudes toward homosexuality and gender nonconformity (e.g., transgender)—integral to the emergence of fundamentalist politics. At the same time, a new language of human sexual rights has emerged that provides a framework through which a necessary dialogue can develop on how to recognize and live with each other's differences and a common humanity.

Simmel's Philosophy of Society

Georg Simmel (1858–1918) is a thinker in whom the dialectic of the relationship between philosophy and the social sciences is reflected perhaps in its most refined and complex form. Nowadays, Simmel is generally perceived as one of the classics of sociology, alongside Max Weber, Ferdinand Tönnies, and Émile Durkheim. Yet Simmel did not consider himself a sociologist and even claimed on many occasions that sociology was for him merely a secondary activity. Although he published a great number of works in this field and was among the founders of the German Society for Sociology, he regarded himself (and was regarded by contemporaries) mainly as a philosopher.

This determined the character of Simmel's contribution to the social sciences. It was the place of the social and of our knowledge of the social on the map of human activity, and the human spirit in general, that preoccupied him most. Simmel was less interested in thorough and systematic empirical sociological research. His writings are full of specific observations and examples, which relate to even the minutest details of human life and interaction, yet they generally serve as illustrations of some general line of thought and are derived either from our common everyday experience or from the research findings of other scholars.

Simmel's Early Sociology

Simmel's early sociological writings, among them his first book, *On Social Differentiation* (1890), are written in the tradition of early anthropology, *Völkerpsychologie* (people's psychology), and Spencerian evolutionary sociology. The underlying motif of these works is the process of social evolution, which leads to the formation of modern, highly developed civilization. Simmel argues that modern society is characterized by growing differentiation,

leading to the development of a modern individuality, on the one hand, and to the strengthening and widening of social networks, interactions, and circles, on the other. This view is akin in many respects to those of many other classical sociologists, such as Herbert Spencer, Tönnies, and Durkheim. Simmel also shares with these thinkers, especially with Durkheim, a certain sociological reductionism. All aspects of human life and spirit appear in it as reducible to and explainable in terms of their meaning for social life. At the same time, even in his early writings, this sociological reductionism has its limits. Simmel never fully subjects spheres such as religion, art, and philosophy exclusively to sociological explanation. And in his later writings, he discards sociological reductionism even more decisively.

Formal Sociology

This turn is signified by two seemingly opposite attitudes toward the science of society that Simmel developed in his mature period. On the one hand, he completed his major work in the field—*Sociology* (1908)—supposedly his definitive statement of what sociology should be. On the other hand, this is paralleled by his reduced interest in all things social, as he turned his attention to other intellectual fields, stating occasionally that he was a philosopher rather than a sociologist. But there is no contradiction here: It is precisely the renunciation of the imperialistic claims of sociology that allowed Simmel to delineate more narrowly and, consequently, more precisely its proper field.

Simmel's vision of the proper sphere of sociology is first outlined in the 1894 essay "The Problem of Sociology." According to him, sociology must be the science of social interaction as such. Many other disciplines (e.g., economics, ethics, and jurisprudence) are indeed also related to the study of social interactions. Yet they investigate these interactions in terms of their content, which may include meanings, consequences, and so forth. Sociology, by contrast, must study the social *forms* implied in interaction. The same form may be present in social interactions of different kinds, and conversely, the same interaction may entail the whole variety of forms. For example, the form of the quantitative relation between three actors may produce similar dynamics in spheres as different as family, economic life, or international relations. Conversely, the dynamics of relationships in a certain family may exemplify a variety of forms of interaction, with respect to the number of persons involved, the structure of the inner hierarchy, the spatial relations, and so forth.

Formalism was already a familiar approach in other disciplines, such as "formal" psychology or "formal" aesthetics. Simmel appears to have been the first to introduce it in the field of sociology. His *Sociology* was an attempt to show what formal sociology may look like. Yet the book, despite its length, did not offer a complete scheme of those forms, remaining rather a collection of exemplifications of the suggested approach. Simmel himself regarded this work not as a final statement but as an illustration of fruitful directions of research in the sociology of forms.

The Legacy of Simmel's Sociology

The story of Simmel and his sociology is full of paradoxes. He was the most philosophically minded classical social thinker, yet he dethroned sociology of its philosophical claims and assigned to it a strictly scientific arena. He envisioned the future science of society in most rigorous terms, yet his own sociological works fall short of this rigor and betray him as a philosopher and essayist rather than a systematic scientist. He enjoys respect in today's sociology, usually not because of his general formal method but rather on account of his numerous essay-like inquiries into multiple aspects of modern life. Simmel is thus valued as a sociologist but not as the founder of formal sociology. Two different explanations can account for this. Some would (and often did) claim that without meaning and intentionality, the study of society would lose any significance and turn into a meaningless play of formal structures. But it is also possible that Simmel offered us a glimpse into an ideal science of society that still cannot be practiced with the tools available within the discipline. If that is the case, formal sociology may still be waiting for its great practitioner.

Simulation Theory

This entry introduces one of the alternative theories of mind, Simulation Theory; contrasts it with rival views; and presents recent developments in child psychology and neuroscience. The entry goes on to point out the resemblance of modern Simulation Theory to, and its difference from, earlier hermeneutic accounts of social sciences or classical theories of empathy.

Simulation Theory was originally developed as an alternative to a long-dominant view in philosophy of mind that our everyday understanding of human behavior is based on a tacit body of general knowledge, roughly comparable to a scientific theory, of the workings of the human mind. The alleged theory—often called *folk psychology*—posits unobservable mental states such as beliefs, desires, intentions, and feelings, linked to each other and to observable behaviors by lawlike principles. These principles, supposedly shared by people of all cultures and virtually all levels of intelligence, are applied to observable situations by way of logical inferences that generate predictions and explanations of behavior.

According to Simulation Theory, rather than having to inherit or acquire a body of general theoretical information about the mind (vide "Theory Theory"), human beings are able to use the resources of their own minds to simulate the mental states and processes of others by *mental simulation*—that is, to generate similar states and processes in themselves.

A typical method, though not the only one, would be role-taking, or "putting oneself in the other's place," and making decisions within the context of such pretense. For example, one might anticipate the product of another's theoretical or practical inferences from given premises by making inferences from the same premises oneself; or knowing what the product is, one might retroduce the premises, perhaps by something resembling unconscious Bayesian inference. To reason from the same premises would typically require indexical adjustments, such as shifts in spatial, temporal, and personal "points of view," to place oneself in the other's physical and epistemic situation insofar as it differs from one's own. One may also compensate for the other's reasoning capacity and level of expertise, if possible, or modify one's character and outlook as an actor might, to fit the other's background and behavioral history. Such *adjustments,* even when insufficient for making decisions in the role of the other, allow one to discriminate between action options likely to be attractive to the agent and those likely to be unattractive. Accordingly, one would be prepared for the former actions and surprised by the latter.

Simulation Theory and Theory Theory need not be formulated in ways that exclude one another. The resources underlying our everyday psychological understanding, or what psychologists (and others) call *theory of mind* (ToM), might incorporate both simulational and theoretical components. Indeed, a number of philosophers and psychologists have put forward *hybrid accounts,* usually with the suggestion that people rely on simulation in some contexts and theory in others.

Developmental Psychology

The theory versus simulation debate within philosophy of mind has had an important impact on research by developmental psychologists on the *child's* theory of mind. The attribution of false belief, in particular, might be conceived in two ways: (1) the young child comes to posit an unobservable internal state, belief, as intervening between the other's external situation and his behavior or (2) the young child comes to develop a new skill, that of introducing into his simulation of the other a counterfactual pretend world. Although the issue has motivated a considerable amount of empirical research, it remains unresolved.

Mirror Neurons

The discovery in the early 1990s of mirror neurons in the primate brain opened another channel of interdisciplinary research and debate. Certain neuron systems that are involved in the production of our own actions and emotions also become active when we observe similar actions or emotions in another person. A major research topic in the new discipline of social neuroscience concerns the possible contribution of mirror systems to our psychological understanding of others. Whether and how these "low-level" systems might facilitate the kind of "high-level" mental simulation that philosophers and psychologists have been discussing remain open questions.

Earlier Views: Similarities and Differences

In some respects, Simulation Theory resembles the views of earlier writers, such as the German philosopher Wilhelm Dilthey and the British idealist R. G. Collingwood, on the role of empathetic understanding (*Verstehen*) and historical reenactment in the human sciences, as well as suggestions by Immanuel Kant and Willard van Orman Quine. However, unlike these earlier theorists, simulation theorists often appeal to empirical findings, particularly experimental results in developmental psychology and neuroscience.

They also encourage speculation grounded in neuroscience about the computational mechanism that might accomplish the task of simulation: presumably one that calls up resources ordinarily used for engagement with the world but runs them "offline," so that their output is not actual behavior but only predictions or anticipations of behavior and their inputs and system parameters are accordingly not limited to those that would regulate one's own behavior.

Situated Action

Situated action (SA) is one of a set of theories in cognitive science that puts primacy on the role of context in understanding cognition. Like related theories labeled *situated cognition* and *situated learning,* foundational across these is the notion that the environment is an essential element *of* cognition.

SA is most associated with the social anthropologist Lucy Suchman, who proposed this theory to argue that cognition cannot be separated from the agent and the environment, whether it be the physical, social, or cultural environment. SA owes its scholarly roots to the anthropological and sociological accounts of culture and cognition, for example, of Max Weber, as well as the educational philosophy of John Dewey. SA posits an integrated or holistic view of cognition, where one is not *in* an environment but *part of* an environment. Against this broader theoretical backdrop, SA was developed to empirically address what Suchman referred to as "the irreducibility of lived practice, embodied and enacted." What differentiated SA was a focus on plans and their relation to cognition as it emerges in context. In SA theory, plans often bear little resemblance to the actions that follow and were more likely post hoc rationalizations for action. SA drew from ethnomethodology and the study of human activity via observations, as it arises *between* a person and the setting in which that activity takes place.

Studying Cognition in Context

SA was made most prominent by Suchman's 1987 book *Plans and Situated Action* (P&SA), written to codify her experiences studying human–machine interaction while at Xerox PARC. P&SA was meant as an alternative to prevailing views within artificial intelligence (AI) that knowledge could be adequately

represented within a system such that it could predict and manage interactions that had yet to be experienced. In particular, P&SA was a reaction to AI's overreliance on knowledge representations and control structures devised to execute goals and plans in service of intelligent interactive interfaces. SA theory proposed that such approaches could not account for the relational coupling that emerges during interaction between a human and a machine. Rather, what is required is a view that overcomes asymmetries between humans and machines as interactional partners, such that machines are able to more accurately perceive human actions as they actually occur.

Foundational to understanding SA is the role of plans in human activity. Within SA accounts, plans are not cognitive control structures that determine action. Because activity can only emerge from the interaction of the human and a situation, plans cannot be considered as fully structuring activity. Rather, planning is a type of imaginative practice producing projections that may relate to future actions. More broadly, SA was a reaction to the rational theories of problem solving prevalent in AI and cognitive science, which focused on knowledge residing within the mind of a problem solver—knowledge that was seen as deterministic of behavior. SA theory argued that plans do not fully shape behavior and that activity was more adaptive and flexible. Furthermore, SA pointed to the important role that the environment played in determining action. Thus, SA did away with the dualistic view of mind and body to draw attention to the interaction of mind, body, and environment, where plans serve as resources for action but do not fully determine activity.

Critiques of SA

SA and associated theories broadly influenced cognitive science and how cognition should be understood and studied. This influence was felt in disciplines ranging from AI to the learning sciences. SA theory was influential enough to spawn special issues in two journals, *Cognitive Science* (1993) and the *Journal of the Learning Sciences* (2003). Along with this influence came criticism from a number of perspectives. From traditional views of cognitive science and theories based on symbolic accounts of cognition, Alonso Vera and Herbert Simon argued from the information-processing perspective. They noted that symbolic theories of cognition have both substantial empirical evidence as well as the means to account for context and situated activity. An additional criticism centered on the interpretation that, as a theoretical approach, SA rejected the utility of planning entirely. From the learning sciences, researchers took issue with some of the foundational claims of situated theories concerning context and specificity of task. John Anderson and his colleagues drew from research in cognitive psychology to counter claims from SA theory and argued that abstract instruction has been found effective, that the teaching of skills in the absence of context has been documented, and that transfer of learning across contexts has been empirically verified.

From computer science and understanding human–computer interaction (HCI), others argued that SA was unable to account for the broad range of human activity and, thus, had limited usefulness as a theory. By focusing too narrowly on the interactions that emerge in specific situations, comparisons across contexts were too challenging. Rather, what was required was a means of abstracting key features of interaction that occur over many domains, and the artifacts used within domains, such that they can inform HCI design. Blending these critiques, Bonnie Nardi argued that "activity theory," emerging out of work analysis in the former Soviet Union, provides a superior means of addressing the role of context in cognition. Building on the work of Alexei Leontiev, Nardi argued that SA is unable to account for the durable and stable phenomena that consistently emerge across situations. Activity theory, though, shifts the focus from the context to the activity itself and to how artifacts mediate activity. In this way, even when conditions change, the activity is focal, and what matters is how goals and operations are modified to adapt to the conditions but still enable completion of the activity. By acknowledging that goals shape activity, as opposed to simply being post hoc descriptions of activity, Nardi argued that one can more fully account for the design of artifacts in support of goal-driven interaction.

Lasting Impact of SA

In later writings, SA theorists argued that what SA theory was meant to accomplish was to move the field toward a true understanding of the relationship between plans and the actual activity that ensued. In the 2007 follow-up edition to P&SA, Suchman noted that her initial objective was for research to move away from the view of plans as deterministic to one where plans became the actual objects of

study. Many were sympathetic to this conceptualization of SA and credit these ideas with influencing cognitive science and related fields such as HCI design and the learning sciences. William J. Clancey was a strong advocate for situated theories in cognitive science and argued against notions of stored symbols or representations in memory to suggest that situated actions are more akin to emergent neurological coordination. The overall influence of SA led the learning scientist James Greeno to propose the term *situativity* in order to acknowledge that all cognition and action are situated and that research needs to understand this relational coupling where meaning is constructed within particular contexts. The lasting impact of SA theory has been the recognition of the need to analyze the execution of actions in context so as to understand the often spontaneous adaptation of response to differing or unforeseen aspects of the situation. This, it was argued, should be the focus of how we come to understand human cognition, in general, and human–technology interactions, in particular.

Situated Cognition

The situated perspective on cognition encompasses a whole host of ideas relevant to the study of mind in the social sciences. Among the more familiar of these ideas is the principle of *environmental embedding*. According to this principle, cognitive activity depends so heavily upon an agent's interaction with the natural and social environment that it cannot be understood in abstraction from that context.

Cognition is essentially an ecological phenomenon and must be studied as such.

A second, more controversial, aspect of the situated perspective is the principle of *environmental extension.* This is the idea that the boundaries of cognition need not coincide with the bodily boundaries of the organism, since an agent's cognitive processes may literally extend into the environment—not just in principle but in practice. Though these two ideas about the context dependence of cognition—embedding and extension—are but two of many variations on a broad theme, their centrality to the situated paradigm makes them good focal points for an overview of the topic. This entry briefly explores each of them in turn.

The Embedded Mind

Perhaps the best-known exemplar of the ecological approach to cognition is J. J. Gibson's landmark work on vision, *The Ecological Approach to Visual Cognition.* On Gibson's view, vision requires the movement of an organism through the environment, as it is this movement that enables the organism to extract important information contained in the *ambient optic array,* the structure of light that impinges on the perceiver. For Gibson, the starting of vision is not the passive processing of the retinal image, something that is internal to the organism, but rather the active processing of the optic array, a part of the environment. This processing also underwrites the efficient detection of *affordances,* agent-relative functional properties of objects in the lived environment (e.g., the "climb-ability" of a ladder, the "sit-on-ability" of a chair).

Another facet of the ecological perspective on cognition involves the phenomenon of informational off-loading from organism to environment. As David Kirsh has observed, people routinely perform a variety of *epistemic actions,* that is, they modify the environment so as to facilitate problem solving by simplifying the computational task. He gives the example of a grocery bagger, who sorts items by their task-relevant characteristics (e.g., weight, bulk, and fragility) into different partitions of a spatially articulated buffer zone before packing them into bags. By structuring the local environment in this fashion, the bagger lowers her internal informational overhead—especially the load on working memory, with its severely limited capacity—simplifying the decision-making process and boosting task performance. Other examples of epistemic action come from the domain of game play. Most Scrabble players, for instance, explore the space of possible words by physically rearranging the letter tiles on the rack in front of them rather than in their heads. The general principle is this: Cognitive agents do best when they minimize internal representation and processing by using "the world as its own model" (in Rodney Brooks's nice phrase), and epistemic actions are a good way of accomplishing that minimization.

Attention to the embeddedness of mind is likewise evident in ecologically oriented research on human rationality, in general, and on judgment and decision making, in particular. The "fast and frugal heuristics" program, for example, draws heavily on the idea that the utility of simple decision-making rules depends on their fit with the environmental context. Thus, a rule that uses recognition as a guide to some criterion of interest (e.g., the relative population size of cities) will yield good results only in settings where recognition is strongly positively correlated with that criterion. A similar concern with ecological validity can be found in decision-field theory, which emphasizes the dynamic, temporally constrained, and interactive character of decision making, as well as the influence of context on preference orderings. Finally, much of social psychology, notably research in the "situationist" tradition of Lee Ross and Richard Nisbett's book *The Person and the Situation,* is concerned with the ways in which various aspects of the social environment (e.g., the communicative context, the context of personal relationships, and the context of group membership) shape our thought and action.

The Extended Mind

A more radical variation on the situated cognition theme is Andy Clark and David Chalmers's idea that cognitive states and processes literally extend into the environment. This revisionary metaphysics of mind is motivated, at least in part, by epistemological considerations of the sort mooted earlier: namely, that the deep embeddedness of mind in the world dictates that we cannot understand how the mind works without taking into account how mind and world interact. The view of the mind as a complex dynamical system, a view descended from cybernetics and control theory, also pulls in

this direction, insofar as it emphasizes causal interactions between the organism and its environment and de-emphasizes the boundary between them. But arguably, the strongest support for the extended-mind hypothesis comes from the results of clever thought experiments. The celebrated case of Otto, an Alzheimer's patient who regularly deploys information stored in a notebook rather than information stored in biological memory, is instructive here. From a functionalist perspective on cognition at least, argue Clark and Chalmers, Otto's externally encoded "memories" are the genuine item, and the differences between his cognitive profile and that of a neurotypical agent, with biological memory intact, are superficially significant at best. As for the fact that Clark and Chalmers's proposed redrawing of the boundary between mind and world runs afoul of commonsense intuitions, they say, "So much the worse for common sense."

Criticism

Whether this radicalism can be sustained is an open question. Certainly, it has its detractors. Most notably, it has been argued that the conceptual shift from embeddedness to extension rests on conflating the distinction between causation and constitution. It has also been argued that revising the metaphysics of mind in the manner suggested would have dire consequences for cognitive science, for example, rendering most if not all nomological generalizations about memory (e.g., recency and primacy effects, interference effects, etc.) null and void. But the jury is still out on this subject—and, given the history of metaphysical debates in general, is likely to remain so for some time to come.

Situational Analysis

Situational analysis (SA) is a recent extension of Straussian grounded theory (GT) for qualitative data analysis in social sciences and related research. It is also inspired by Donna Haraway's concept of situated knowledges, Foucauldian discourse analyses, and social studies of science and technology. The focus is on analysis of the situation being researched: the elements in it, the relations among elements, the conditions of possibility for action, and related discourses. SA integrates poststructural assumptions, feminist emphases on differences and complexities, and analysis of power and encourages studying narrative, documentary, historical, and visual discourses. The situation of inquiry itself, broadly conceived, is the unit of analysis.

Philosophical Underpinnings of Situational Analysis

Like GT, SA is also grounded in symbolic interactionism, a sociological tradition with roots in American pragmatist philosophy (George Herbert Mead, John Dewey) and Charles S. Peirce's concept of abduction as generative of theorizing. The fundamentals of symbolic interactionist theory, constructionist GT, and SA constitute a "theory–methods package." Ontology and epistemology are ultimately nonfungible. What can be known and how we can know it are inseparable. Such packages also include the concrete practices through which social scientists go about their work.

What is new in SA? There are three key facets. First, early-20th-century Chicago social ecologies are tap roots for Anselm Strauss's social worlds/arenas theory, which is foundational. Here, multiple collective actors—social worlds—participate in all

kinds of negotiations in broad and often contentious substantive arenas. Arenas are focused on matters on which all the involved social worlds and actors care enough to be committed to act and to produce discourses.

Second, SA draws upon the work of Michel Foucault, who challenged the social sciences by decentering the "knowing subject" (the individual human as agentic social actor) to focus on "the social" as constituted through discursive practices and on discourses as constitutive of subjectivities. Foucault asserts that framings, representations, linguistic conventions, and usages together constitute specific discursive fields or formations. Dominant discourses are reinforced through institutional systems of law, media, medicine, education, and so on. SA goes beyond "the knowing subject" to also analyze the salient discourses dwelling within situations. We are constantly awash in seas of discourse constitutive of life itself as well as individual and collective identities. SA enrolls poststructural approaches and follows in Foucault's footsteps to include analysis of historical, narrative, documentary, and visual discourses.

Third, SA requires inclusion of the *nonhuman,* underscoring the importance of understanding "things" in analyses of situations. SA takes the nonhuman elements in the situation of inquiry into account both materially and discursively. "Seeing" the agency of the nonhuman elements disrupts the taken-for-granted, demonstrating a materialist constructionism. Explicitly including the nonhuman in research also takes up the postmodern challenge of post-humanism—the idea that only humans "really" matter or "matter the most." Nonhuman elements may include cultural objects, technologies, animals, media, animate and inanimate pieces of material culture, and discourses—from cups and saucers to lab animals to TV programs. Nonhuman elements structurally condition the interactions within the situation through their specific material properties and requirements.

Three Kinds of Analytic Maps

In SA, the situation of inquiry is empirically constructed through making three kinds of maps, followed by analytic work and memo-ing in the GT tradition. The three very different kinds of "maps" are tools to provoke intensive analytical work. The first maps are *situational maps* that lay out the major human, nonhuman, discursive, historical, symbolic, cultural, political, temporal, and other elements in the research situation of focus. The goals of these maps are first to enhance research design by specifying everything about which at least some data should be gathered. Downstream, situational maps are used to provoke analysis of relations among the different elements. Working *against* simplification in postmodern ways, these maps capture and provoke analysis of the heterogeneous elements and messy complexities of the situation. Taking the nonhuman elements in the situation very seriously, materialities and discourses are also made visible in the situational maps.

Second, the *social worlds/arenas maps* lay out the collective actors and their arena(s) of commitment where they are engaged in ongoing discourse and negotiations. Such maps offer meso-level interpretations of the situation, taking up its social organizational, institutional, and discursive dimensions. They are distinctively postmodern in their assumptions: We cannot assume directionalities of influence; boundaries are open and porous; negotiations are fluid; discourses are multiple. Social worlds are universes of discourse, routinely producing discourses about elements of concern and other social worlds in the situation.

Third, *positional maps* lay out the major positions taken, and *not* taken, in particular discourses in the data. These are organized along specific axes of variation and difference, focus, and controversy found in the situation. Positions on such maps are *not* articulated with persons or groups but rather represent the full range of discursive positions taken on key issues in the situation. They allow multiple positions and even contradictions to be articulated. Narrative, visual, and historical discourses can all be analyzed.

In sum, SA offers three kinds of maps as fresh analytic devices to supplement grounded theory research. In centering on the situation, SA differs from the GT, with its focus on social processes—human action. Anselm Strauss's social worlds and arenas theory, Foucault's emphases on discourses, and the analytic centrality of the nonhuman are central to this poststructural approach to qualitative research.

Situational Logic

This entry introduces the notion of situational logic or logic of situation in its most prominent form and explains its importance in social-scientific explanation of action and agency.

Situational analysis is a simplification of Max Weber's claim that one kind of social action—"instrumental rationality"—could be explained by the aims, means, and expectations of the actors. The improved formulation is found in Karl R. Popper's classic works *The Poverty of Historicism* and *The Open Society and Its Enemies*. It is not to be confused with W. I. Thomas's "definition of the situation," although it is easy to see the latter as a part of the former.

Situational analysis is the schema with the fewest assumptions for explaining the outcome of actions of agents and/or agencies. The social situation is analyzed into agents and agencies (usually social institutions), which have aims or directions; they are enclosed by and form part of an environment both physical and social; and agents and agencies possess putative knowledge of the situation and the leeway it allows them. For example, a driver setting out on a journey will have putative self-knowledge as well as putative knowledge of the destination, the possible routes, the condition of the vehicle, the roads, the traffic conditions, the applicable laws, and the weather. Since the vast majority of journeys are completed, we can say that most of the time the agents' appreciation of their situation is sufficiently congruent with the facts to enable them to reach their destinations. This should suffice for the explanation of the driver's conduct that ends with reaching the intended destination.

Situational Explanation

Agents and agencies that successfully accomplish their aims—reaching a destination, collecting taxes, prosecuting a military engagement—pose explanatory problems that are trivially soluble. Failures and unintended and counterintended outcomes require explanations that are much less obvious. Researchers seek such explanations by conjecturing different aims, situational conditions, and actor and institutional knowledge, to see if they will explain the outcome. If such conjectures are promising as explanations, then they deserve empirical testing.

Social outcomes that no agent or agency intends intrigue social scientists: for example, suicide rates and divorce rates; actors who seemingly act against their interests in eating poisons, purchasing rubbish, voting, and so on. We can bring out the structure of situational explanations of the unintended by analyzing accidents, intended by no one, and especially catastrophic accidents, where the outcome was not even imagined.

Here is such an example. In November 1987, a fire in a small escalator at King's Cross Station on London's Underground transport system grew rapidly into a "flashover" that engulfed a ticket hall in smoke and flames, killing 31 people and injuring and maiming many others. The official investigation into the fire did not suggest that the lighted match that ignited it was intended to do so. More than likely, a smoker was "lighting up" on the way out of the nonsmoking system. The flammable mixture of dirt, grease, and fluff under the (wooden) escalator steps

was due to sloppy cleaning protocols (an unnoticed institutional deficiency). The lack of a central control room, of fully trained staff, and of working communications systems were due to neglect of the physical and social systems involved, not by design. The neglect had seemed unproblematic, since several such fires were extinguished every week and none had been fatal. While scientists and engineers theorized that the sloping tunnels caused the flames to shoot upward in search of oxygen and hence accelerate beyond all human capacity to cope, the investigation also looked at the many physical, social, and cultural configurations of the Underground system and pinpointed faults in each one that contributed to the sequence of events that constituted the disaster.

The King's Cross fire was a complex situation analyzed to find its various logics: the physical logic of fire in upward-sloping tunnels; the psychosocial logic of smokers dying for a "gasper" as they approach the surface; the social logic of lack of training, central direction, and clear priorities for members of staff; the logic of station design that showed up poorly in interrogations about fire control and evacuation; the logic of actions by staff, police, firemen, and emergency responders unfamiliar with the layout of the labyrinth of tunnels and hence of the best means of egress; the logic of the expectations of all concerned, namely, that small fires pose little threat: the result—no announcements, no fire alarm, no sprinklers activated.

The aim of passengers is to complete their journey. The aim of the divisions of the London Underground railway is to maintain its smooth, safe, and economical functioning. Of necessity, the knowledge of all participants is partial and often flawed; hence, they did not assess the developing situation correctly and acted in ways that were always suboptimal but usually not sufficiently below standard to be dangerous, until the flashover accident. Especially, all parties were unaware of the possibility of a flashover from a small fire and hence were unable to take that into account in their actions.

Critical Objections

This simple and intuitive model faces criticisms from holists, who see its individualism as superficial, and strict methodological individualists, who see it as not individualist enough. Leaving aside the former objection as transcendental, the latter stipulates that agencies such as groups (the passengers and the station staff) and institutions (the police, the fire services) do not have aims. In fact, we often speak as though such wholes do have aims—the way we often speak even of inanimate things (see the statement above about flames shooting upward in search of oxygen). Mostly, such locutions can be treated as shorthand. Institutional and group actions can be further analyzed into the actions of particular individuals playing their institutional roles, carrying out policies or instructions, or into aggregates of individual actions, for example, votes. The aggregation view of institutional actions has been criticized as being unable to account for shared or collective intentions (e.g., "We intend to have two children"), as with link couples, policemen ("We intend to get to the bottom of this"), and revelers ("We shall party"). Even more severe is the objection that situational models are static in treating the agent, the aims, and the agent's situation as fixed while the actions and their reverberations play out, when in fact, as is obvious in all three examples, they may change (two children may become three, cases go "cold," revelers get bored). John Wettersten argues that the agent's thoughts and, hence, aims are formulated within institutional constraints, institutions that are in constant flux, not the least because of the agent's thinking within and through them. This explains, he says, why Weberian models are nonplussed by social change—even social change initiated by the agents. As a result of these caveats, care needs to be taken with situational explanations not to reify institutions, not to make them into actors as opposed to enablers and constraints, and not to freeze the flux of developing situations.

Social Anthropology

Social anthropology focuses on the social, political, religious, and economic organization of human groups. It has traditionally understood these as aspects of culture, and it often emphasized the symbolic and meaningful dimensions of human activity. Within the discipline of anthropology, *social* anthropology is distinguished from physical anthropology, which studies biological variation among humans and our evolutionary history. In the United States, the term *cultural anthropology* is used to refer to the same range of concerns.

Throughout its history, social anthropology has both drawn on and contributed to philosophical reflection. In the 19th century, social anthropologists were engaged in a theoretical enterprise that was closely related to philosophical writing about human nature. Twentieth-century philosophy of language and philosophy of mind have been important sources of inspiration for social anthropologists. Philosophers have also debated the consequences of anthropological theories and empirical findings. Social anthropology has thus been an important resource for philosophical work on rationality, ethics, language, politics, the mind, race, gender, and social ontology. Finally, social anthropology has been at the forefront of the development of empirical methods for the study of humans, and it has therefore been a party to debates about the unity of science and the character of scientific knowledge.

The Philosophical Roots of Social Anthropology

Social anthropology in the 19th century had a broad historical scope. Global trade and colonization since the 16th century had made European intellectuals aware of the wide variety of human societies. Philosophers had long commented on these differences and often tried to account for them by imagining the developmental stages through which "primitive" humans became "civilized." Philosophical speculation on this topic was primarily aimed at demonstrating how human societies could, in principle, have arisen through the action of fundamental principles of human nature. The 19th-century social theorists developed these speculations into an empirical science. Lewis Henry Morgan, for instance, based his theory of social evolution on long-term interaction with the American indigenous peoples. Edward Burnett Tylor collected comprehensive information from missionaries, travelers, and colonial officials. The 19th-century anthropologists explained observed differences by treating contemporary peoples as exhibiting features of earlier stages of human development. Like their philosophical colleagues, they tended to see the evolution of more complex societies as reflecting either the development of rational thought or the victory of rational thought over superstition.

Romanticism, a broad literary, artistic, and philosophical movement, ran counter to the more rationalistic evolutionary narratives of the 19th century. Romanticism valorized folkways, and it thought of humans as naturally divided into nations or peoples. Johann Herder argued that language determines thought, and he postulated a very close relationship between languages and nations. Philosophy in the romantic spirit thus provided support for the later development of the concept of *culture.*

The Unity of Science

As the discipline of social anthropology became more empirical, it began to develop new methods. By the early 20th century, extensive fieldwork (ethnography) was regarded as necessary to any description of a culture. Ethnography relied on the method of participant observation. The anthropologist lived among his or her subjects for an extended period (typically a year or more), learning their language, participating in their daily routines, and conducting extended interviews. These methods are different from those found in the natural sciences, and they engage the question of the unity of science: Are different forms of knowledge associated with the study of human subjects and nonhuman objects?

Social anthropologists and philosophers have taken up both sides of this debate. Many have argued that anthropology is hermeneutic. It articulates the meaning of symbols, actions, rituals, and life experiences. Such meanings are always particular and, hence, not subject to generalization into laws of psychology, economics, or biology. Others have responded that emphasis on interpretation to the exclusion of causal explanation limits the interest and ambition of the field. Some, influenced by Karl Marx's materialism, have gone so far as to argue that the cultural meanings are nothing more than ideologies that hide the real mechanisms of social life. A more modest view is that hermeneutic and causal/explanatory inquiries are complementary. In practice, social anthropologists tend to be methodologically pluralistic. The philosophical challenge of such pluralism is to explain how specific methods support each other and how conflict among them is to be resolved.

Functionalism was an important theoretical position within social anthropology in the first half of the 20th century, and it is relevant to the debate over the unity of science. Functionalists explained the existence of specific social practices in terms of the benefits that the practice had for society. Accusations of witchcraft, for instance, were explained by their function in resolving social conflict; the accusation, investigation, and retribution (if any) diffused social tensions. Prima facie, functional explanations seem distinct from other causal explanations. Where a causal explanation appeals to a temporally prior event to explain a later event, functional explanations are "teleological," in the sense that they rely on goals or future goods. Philosophers of science have debated whether functional explanation is a legitimate form of scientific explanation and, if so, whether it can be assimilated to a general theory of explanation. While functionalism is largely out of fashion among social anthropologists today, it was an important element of 20th-century debates about the unity of science.

Culture

In its 19th-century form, the concept of *culture* retained its connotations of learning and high art. Social anthropologists used "culture" and "civilization" as synonyms and thought in terms of culture evolving from lower to higher forms. The 20th-century anthropologists rejected these hierarchical ideas and thought of the human social world as populated by many distinct cultures. A culture was an integrated system of ideas, norms, values, practices, decorative motifs, material objects, and so on, passed from one generation to the next. This commitment to "holism" entailed that the interpretation of any single item required reference to other items. It also entailed that cultures were relatively independent, both ontologically and historically. While there were historical relations (of trade, etc.) among cultures, each culture needed to be understood in its own terms. The idea of culture as something (a) distinctive of and shared by a particular group of people, (b) not reducible to either biology or psychology, and (c) constituted, at least in part, by holistically related meanings, symbols, and values has been profoundly influential both inside and outside the academy.

The concept of culture came under sharp attack in the late 20th century. A mix of political and epistemic arguments concluded that the portrayal of a given culture was an artifact of anthropological writing, not an object that existed prior to anthropological inquiry. In addition, anthropologists became dubious of the idea that cultures were stable and shared. Indeed, some began to doubt the analytic usefulness of the concept of culture at all.

There have been three broad responses within social anthropology. The first is sometimes identified as *postmodern*. These anthropologists tend to see human groups as fragmented, disunified, and driven by power. They often experiment with different ways of giving voice to their interlocutors. A second response is known as *practice theory*. This view dissolves cultures into multiple practices that overlap and conflict. Drawing on Ludwig Wittgenstein's work on rule following, Pierre Bourdieu conceived of practices as normative ways of acting that are passed among individuals. Practice theory in anthropology is related to the recent use of the concept of practice in philosophical accounts of normativity. In an important critique, Stephen Turner argued that practice theory cannot provide a coherent account of its central idea: practice.

The third response to the demise of the culture concept has been to look to the cognitive grounds for social phenomena. These writers treat a culture as a population of individuals who have more or less similar representations. Cognitive mechanisms for the learning, storage, retrieval, and transmission of representations explain the persistence of some ideas and the change in others. This perspective

has permitted the integration of social anthropology with cognitive psychology and has suggested provocative explanations of religious, political, economic, and other phenomena. Philosophically, this trend is interesting because it raises again the question of whether human phenomena can be explained in causal terms or whether other, more hermeneutic modes of understanding are required.

Rationality and Relativism

Social anthropology has sparked lively debates about the culturally relative character of human thought and value. Anthropological studies demonstrate substantial variation, but mere variation in avowed norms or concepts does not constitute relativism. A relativist must affirm both a descriptive thesis (that variation exists) and a thesis about the *incommensurability* of the norms (etc.) in question. Anthropological fieldwork seemed to demonstrate substantial human variation, and the concept of culture espoused by midcentury anthropologists provided a theoretical background for an incommensurability argument. The content of all norms (including our own) depends on a culture's religious, economic, political, or social institutions, and hence, there were no a-cultural (absolute, objective) norms by which to adjudicate differences in opinion. Insofar as the debate about relativism presupposed the classic concept of culture, it has been somewhat undermined by the recent critique mentioned above.

Rationality and Irrationality in Interpretation

Social anthropologists such as James Frazer and Lucien Lévy-Bruhl contended that human thought evolved from less to more rational forms. Midcentury social anthropologists rejected evolutionary claims, but some kept the idea that rationality took culturally specific forms. The philosophical debate concerned whether variation in forms of reasoning was possible or empirically discoverable. Peter Winch argued that ways of thinking were deeply related to forms of life and that a good interpretation must be sensitive to such differences. Donald Davidson argued for a "principle of charity," which demanded that an interpreter attribute true beliefs to the subjects when their utterances are, in the opinion of the interpreter, true. The principle of charity entails that any interpretation must portray the subjects as conforming to standard canons of logical inference; hence, the possibility of alternative modes of thought imagined by Winch and some anthropologists is illusory. A middle ground of the debate held that while variation in reasoning might be found in esoteric areas, such as religion or myth, interpretation of these domains required agreement in mundane areas.

Moral Relativism

Social anthropologists have often espoused (or been accused of espousing) moral relativism. While the empirical studies of social anthropologists have been taken as supporting the descriptive thesis of moral relativism, there has been some debate about the true range of human moral variation. Some have argued that there is substantial agreement on the general moral principles concerning lying, adultery, theft, and murder and that the variation concerns the justifiable exceptions. Recent work in the cognitive foundations of morality has supported this position.

Both anthropologists and philosophers have argued that cross-cultural moral disputes cannot be rationally adjudicated. In these discussions, it is important to distinguish arguments for *tolerance* from arguments about incommensurability. It is often claimed that a proper understanding of other cultures requires the interpreter to refrain from evaluation. Strong versions of this claim have been disputed by pointing out the importance of evaluation in any scientific research. A more modest claim is that recognition of cultural differences can motivate tolerant attitudes. However, tolerance of moral disagreement does not entail that there is no way to rationally resolve differences; hence, it does not lead to moral relativism. Moreover, even this weak claim about tolerance has been controversial within anthropology. Anthropologists are often concerned with human rights or the political status of ethnic minorities and, therefore, have sought to make and justify cross-cultural moral judgments.

Social Anti-Individualism and the Mental

This entry gives an overview of a powerful philosophical thesis holding that the concepts figuring in an individual's mental states are determined as to what they precisely mean not simply by what the individual believes or thinks she means by them but also by her linguistic community—that is, by the social environment. The entry distinguishes between two basic kinds of such mental anti-individualism and points out its implications for social sciences and, in particular, for one of them, psychology.

The Thesis

Social anti-individualism (also known as *social externalism*) is the thesis that relations between an individual and members of her linguistic community help determine which concepts she possesses and hence which thoughts she is capable of thinking. This means that, contrary to popular opinion, an individual's mental states are *not* determined entirely by her internal, physical states (e.g., her brain states); rather, they are determined by her internal, physical states *in conjunction with* her relations to an *external, social environment*.

The thesis is widely accepted in philosophy and has a number of important implications concerning, for example, the individuation of kinds in psychology, the nature of causation and explanation in psychology, and the relation between psychology and the natural sciences. Similar implications hold for the social sciences generally.

The *Twin Earth* Thought Experiments

Social anti-individualism is established by reflection on a certain kind of thought experiment (made famous by Tyler Burge and Hilary Putnam), an example of which runs as follows. First suppose that a subject, Sam, has a number of true beliefs about games—she believes that some games are more fun than others, that chess is a game, that children like party games, and so on. In addition to these true beliefs about games, she also believes falsely that games must involve at least two people. Further suppose that if her friends were to point out to her that patience and solitaire are games, she would accept their correction and update her use of the term *game* to match with her improved understanding of the term and to reflect her fuller understanding of the concept *GAME*.

Now consider a second scenario in which Sam's intrinsic physical states are the same while her linguistic community is different. In this second scenario, let us suppose, it is standard practice to use the term *game* as Sam does. That is, in the second scenario, the term *game* is defined to apply (roughly) to competitive, recreational activities involving at least two people. The first and second scenarios, then, have a word form in common ("game"), but the term has a different meaning in each, which is to say that it expresses a *different* concept in each. In the first scenario, the term *game* expresses the concept *GAME,* which correctly applies to activities including solitaire and patience (even though Sam does not initially realize this). In the second scenario, in contrast, the term *game* does not express the concept *GAME* but rather expresses a different concept (albeit a similar one—let's call it *SPAME*) that does not correctly apply to activities such as solitaire and patience. Consequently, while Sam possesses the concept *GAME* in the first scenario, she does *not* in the second, even though her physical states and classificatory practices are *identical* in both scenarios. According to the social anti-individualist, then, social differences—specifically differences in the way in which people around us use words, that is, our linguistic communities—can affect our mental states.

Natural-Kind Anti-Individualism

The thought experiment relies on a number of assumptions: that words express concepts; that understanding the meaning of a word is a matter of degree and, hence, that understanding a concept is a matter of degree; and that the meaning of a word is determined by the way in which that word is used by the community as a whole, rather than by the way in which it is used by any given individual. Although these assumptions are plausible, there is a different kind of anti-individualism—*natural-kind* anti-individualism—that does not rely on them.

According to natural-kind anti-individualism, it is relations between an individual and her natural environment that play a role in determining which concepts she possesses and, hence, which thoughts she is capable of thinking. Specifically, natural-kind concepts, such as the concepts *WATER, SILVER, TIGER, OAK,* and so on, are thought to be individuated in part by objective relations between the thinker and instances of those natural kinds in her environment. If an individual is related in the right kind of way to water, then she may be able to think about water by means of the concept *WATER*. If, on the other hand, an individual bears no relations to water at all (perhaps because she lives in a world with no water), then she will be unable to think about water by means of the concept *WATER,* for how could she have acquired that concept? Natural-kind anti-individualism is the more widely accepted form of anti-individualism, but social anti-individualism is the more general thesis, covering all concepts rather than merely natural-kind concepts.

The Precise Target of Anti-Individualism

It is crucial to understand anti-individualism as a thesis about the individuation conditions of concepts rather than as a thesis about the causes of particular thoughts involving those concepts. Thus, the core claim of anti-individualism is that relations between an individual and her environment play an essential role in determining not just what thoughts that individual happens to have at a particular time but the very concepts that enable her to represent the world in thought at all. Interestingly, both forms of anti-individualism have the same implications for psychology, as follows.

Implications for Psychology and the Social Sciences

First, anti-individualism rules out all forms of physicalism: Two individuals can have the same physical properties and yet have different mental properties. Second, this means that psychology is not reducible to physics. Third, this in turn means that psychological causation between psychological kinds and psychological explanation that invokes psychological kinds are to be treated as in a certain sense independent of physical causation and explanation that invoke physical kinds.

Similar implications hold for the social sciences generally since the philosophical thesis of mental anti-individualism shows that facts about an individual (in particular facts about her mental states and therefore the propositional attitudes figuring in them) cannot be construed solely as facts about that individual alone; facts *external* to the individual involving social facts about linguistic use, and so on, enter into the individuation of the concepts she uses. Hence, a social-scientific explanation of what an individual believes or not must take these social facts into account, going "beyond the individual" as such.

Social Capital

Social capital (SC) may be understood as the benefit or utility that humans may obtain by entering into ongoing social relations or social structures. This entry presents the conceptual, methodological, and critical issues characterizing the importance of SC for the social sciences.

As is often the case in the social sciences, in SC, too, there is no agreement on what the concept encompasses. While SC is perceived in divergent ways, with a plurality of approaches and empirical operationalizations being available, yet there is little discussion, let alone agreement, among dissenting viewpoints or perspectives. The postmodernist practice of allowing or elevating to equal status all variant interpretations has perplexed the issue even further. Insistence on the true meaning of the term risks falling into a kind of essentialism, something that is denounced, even if the reverse side of this appears to be methodological and conceptual nihilism. SC has thus been defined in ways that complement or conflict one another. It appears that such a definitional variance in SC is related to disciplinary-specific uses of the notion, varying from one social science to another. Such a prominent divergence among social sciences is the one separating the uses of SC in sociology and political science. Still, definitional variance is often found within a single discipline, too.

That being said, a general criticism of all the various versions of the SC notion questions its very essence, namely, its being construed as "capital." The "capital" in SC is considered by critics a travesty of the original and standard notion of "economic capital." Unlike "economic capital," which is transparent, specific, and clear, SC appears to some as meaningless or nonexistent. SC is seen as only a metaphor, and according to such critiques, it is void of meaning beyond that level.

Perspectives From Sociology

Pierre Bourdieu and James S. Coleman are the key sociologists exploring SC, albeit each perceives it differently. Bourdieu conceptualizes SC in close connection to other forms of capital, specifically the economic and the cultural varieties. The family is seen as a basic source of SC, and it is found exclusively among the socially powerful, namely, in the upper middle class or haute bourgeoisie. This happens because Bourdieu defines social class in terms of the possession or lack of capital, which assumes the aforementioned three forms (economic, cultural, and social); the dominated social classes and strata do not possess capital at all, including SC. He designates SC as comprising social responsibilities, "connections," or "linkages," and under certain circumstances, it may be converted into economic capital. For Bourdieu, SC is formed, more or less consciously, through one's integration into networks, and unlike economic capital, it has no specific material form, nor is it transparent. Instead, it is characterized by indeterminacy, so that there can be, for example, a leftover sense of an unspecified obligation. This, according to Bourdieu, is an inevitable dimension of SC. Otherwise, if it were clear and specific, it would simply be a series of ordinary nonmarket transactions. This conceptualization contrasts with other approaches to SC, particularly those suggested by Robert D. Putnam (see the next section).

On his part, James S. Coleman introduces the notion of SC as a "means of support," in the specific sense of enhancing students' performance, which will strengthen the generation of human capital—that is, of knowledge. Therefore, he aligns with Bourdieu in perceiving or using SC in connection to other, more typical forms of capital. For Coleman, SC results from the changes that take place among individuals, changes perceived to facilitate social action. Coleman thus defines SC on the basis of its function. Moreover, it is also determined by the outcome. Besides, Coleman, in agreement with Bourdieu, stresses the nonconcrete, nonmaterial, and indefinite character of SC when compared with other, more typical forms of capital. Furthermore, Coleman notes that SC is a public good and that this feature characterizes it as well as differentiates it from other forms of capital. It is seen to result from the empirical fact that the subject of generation of SC enjoys only a limited part of its overall benefits. It also implies that SC is not just or solely a property of, or benefit accrued to, the isolated individual agent who generates it, but it is also something enjoyed by other individuals as well as by the community. Furthermore, because SC operates within concrete social contexts, certain characteristics of the social relations can either facilitate its appearance

or, by contrast, impede it. Such characteristics are the availability of trust and reciprocity among the members of the inner group, as well as the effectiveness of existing normative regulations. Overall, Coleman's application of SC has been in linking the generation of educational achievement to, primarily, micro-social-level influences. Yet his rather unclear definition of SC has, arguably, opened up the way for the application of the SC label to a range of various and contradictory procedures.

Putnam's Views and Critique

In the area of political science, the key figure in SC studies is Robert D. Putnam, who explicitly draws on Coleman's characterization of the concept. However, on Putnam's conception, SC and trust are explicitly linked to each other. SC is generated by linking social trust, social norms, and social networks within social organizations, enhancing the efficiency of socially coordinated actions.

In Putnam's subsequent elaborations, there is transference of meaning; the radius of the SC notion expands from the meso level of analysis to the macro level. Thus, it comes to be formed by "features of social life." This broadening contrasts with the individual level of the actors (personal or collective, as Bourdieu and Coleman had it). What is more, the broadening of the SC notion itself has been neither explained nor justified.

On Putnam's conceptualization of SC, any differences in economic, social, or other forms of power do not raise a significant issue. What, however, is the significant element is the participation of individuals in the whole gamut of possible social groups and collective activities available in any given social context. In other words, the key feature is participation per se, as well as the extent to which it appears—participation being the underlying assumption and hence of major importance in political science. In fact, in this neopluralistic approach, a participatory attitude and activation within the context of community networks seems to generate additional forms of SC. Thus, SC can do, as well as accrue from, the "bonding," "bridging," or even "linking" of social groups. In fact, in Putnam's approach, the SC "stock" equals the degree of participation in various social activities and organizations, at all levels, such as in political organizations, scientific associations, or neighborhood choirs.

Putnam's construal of SC has attracted several critiques—some of which echo the social-scientific disciplinarity divergence between political science and sociology mentioned at the start. "Participation" is claimed as requiring to be concretized and suitably specified since not every kind of participation is beneficial; besides, the scale of groups involved is most important, and issues of size must be factored in when measuring SC. It is claimed that Putnam fails to offer a substantial distinction between various kinds of participation, so critics working in sociology reject his use of it as outright meaningless. Another critique concerns the issue of the logical circularity claimed to endanger Putnam's claims about SC, as well as the indeterminacy of causal direction: in other words, that cause and effect are entirely blurred and their order circular, rendering such an understanding of what SC is nondemonstrable. Furthermore, there are serious objections to the relevance, precision, and sufficiency of the indices used to empirically ascertain SC. Particularly, the idea of "density of relations" between the members of a network, measured, for instance, by the frequency of members' contacts, as favoring the generation of SC, as well as providing proof of its existence, has met with difficulties. Furthermore, SC, critics argue, must not be assumed to be an inherently positive social condition; it may be negative too, as in "mafia"-type criminal networks that promote members' welfare at the expense of outsiders or as in the case of groups adopting exclusionary practices beneficial to them, such as the "closed shop."

What, however, should not be ignored is that Putnam links SC to trust, and he does indeed have a notion of trust. He explicitly states that trust "is a form of SC," and indeed "an essential component of SC," and holds that trust is generated by norms of reciprocity and networks of civic engagement through socialization, an approach that relates to his being a political scientist. However, it is evident that for Putnam, largely because of the problem of causal indeterminacy (see above), SC and trust end up as near-identical notions. This is further conflated in empirical applications when trust is taken as a proxy for SC.

From a theoretical point of view, this practice is quite problematic because it disregards the sociological tradition indicated above, according to which SC is basically about in-group members accessing various resources. This process of ensuring resources is

assisted by the prevalence of trusting relations. This means that having trust relationships is a useful or even necessary, but by no means a sufficient, condition for possessing SC. Accordingly, using the latter as a proxy for the former will not do.

Nevertheless, the influence of Putnam's conception of SC has been quite significant in all social sciences, and it is to be found within sociology too. This is probably for no good analytical reason but merely for "convenience sake" as it facilitates the provisioning of findings in figures that are dear to political elites, which have been utilizing the SC notion for their own purposes almost from its inception. In this sense, this particular conception of SC operates ideologically, as Alejandro Portes has pointed out.

Alejandro Portes: An Economic Sociology Approach

For the economic sociologist Alejandro Portes, to possess SC, one must relate to others who constitute the source of SC and of the privileges it provides. At this point, however, as he notes, there appears to be confusion in the literature as the source or origin of the SC is repeatedly and falsely regarded as an outcome of the action of SC. Portes has observed this confusion in both Coleman's and Putnam's work, as well as in other writers relying on them. But in this way, causality is not defined; it becomes a vicious cycle, and eventually tautology prevails.

To deal with this problem, Portes and his colleagues urge for a clear distinction between the sources or origin, in other words, the cause of the SC, and the results or effects of its action. Thus, four sources from which SC originates are identified: (1) internalization of values, (2) transactions of a reciprocal character, (3) forms of collective solidarity, together with (4) the trust imposed by negative or positive sanctions. Besides, the sources of SC are embedded in the motives the members of a network or a group have in order to provide resources. These motives can be distinguished, on the one hand, into consummatory ones, which may derive from the initial socialization (e.g., within the family) and into the consecutive internalization of certain values or regulatory patterns, or may be cultivated, in the context of the community (hence marked by bounded rationality, i.e., by decisions that are rational given the specific constraints under which they are taken, as in the case of solidarity strikes). On the other hand, they may originate from instrumental motives, in which there is expectancy of reciprocity and trust, as when the sponsor is secured against fraud. Thus, the various sources of origin of the SC lead to its composite formation, so that SC is perceived as the ability to secure benefits via participation in networks and other social structures.

On the whole, Portes's interventions offer a more balanced understanding of SC and its potential. The notion is not rejected but specified and rationalized sociologically. The emphasis is on the need to systematically study the precise effects of SC and avoid attributing irrelevant, accidental, or spurious effects to it. This perception has led to conceptions of SC more akin to the micro level that focus on the individual's relationships to her or his network of social connections and the benefits and resources he or she may muster.

Social Choice Theory

The theory of social choice considers the problem of aggregating the preferences of the members of a given society in order to derive a social preference that represents this society or community. This entry reviews the major aspects of Social Choice Theory and explains the main theories and advances in it.

The social preference is to express the general will, the common good as it were. The general will can be viewed as the basis for the very existence of any society. Economists argue that the common good finds its expression in a so-called social welfare function, which, described more mundanely, represents a compromise among the divergent interests of those who belong to society. The market mechanism, in contrast, cannot be taken as a social welfare function, since it is not guided by moral or ethical principles in any deeper sense. A market allocation heavily depends on the initial endowments of the individuals. These possessions determine the power or weakness of the individual agents.

Influences on the development of Social Choice Theory have been manifold over the centuries. Mathematicians, social scientists, and philosophers made important contributions of different kinds. The Marquis de Condorcet (1743–1794) and Jean-Charles de Borda (1733–1799) explored the majority rule and ranking methods at the time of the French Revolution. Roughly in the same period, Adam Smith (1723–1790) elaborated the concept of an impartial observer. The utilitarian philosophy of Francis Hutcheson (1694–1746), Jeremy Bentham (1748–1832), and others has been most influential over several centuries, with its modern-day version brought forward by John Harsanyi (1920–2000) in the middle of the past century. John Rawls's (1921–2002) theory of justice, from around 1970, became a powerful contestant of utilitarianism over the past few decades. It is probably fair to say that the modern theory of collective choice started with Kenneth Arrow's (1921–) pathbreaking work on the nonexistence of a social welfare function around 1950. All these works and several more will be discussed in what follows.

Impossibilities

If a social welfare function is an expression of the general will of the populace, it should be able to deal with whatever kind of preferences the individual members of a given society have. More technically speaking, and this is Arrow's definition, a social welfare function is a mapping from the set of all logically possible combinations of individual preference relations over a given set of social states or alternatives to the set of all logically possible orderings over these states. This is the requirement of *unrestricted domain*. In other words, it should not be admissible that any individual ranking be a priori excluded, for whatever reason, from the set of preferences of the members of society. The next requirement, called *the weak Pareto principle,* says that if for any two alternatives x and y, say, all members of society agree that x, for example, is strictly preferred to y, then society should have exactly the same strict preference. Next, information gathering for the aggregation procedure should be parsimonious, that is, if society has to make a decision between two alternatives (let's call them again x and y), the individual preferences with respect to x and y only, and not any other preferences, should be taken into account in order to distil the social ranking between these two alternatives. Arrow calls this condition the requirement of *independence of irrelevant alternatives*. Last, we do not want that there exist a particular person in society such that whenever this person has a strict preference for some alternative over another, society "automatically" has the same strict preference, for any two alternatives and any preference profile of the members of society. This is called the *non-dictatorship* condition. For Arrow, these four conditions are necessary requirements for a democratic decision procedure—perhaps not sufficient since there may be other demands as well. Unfortunately, in the case of at least three alternatives, these four conditions cannot be simultaneously fulfilled by any social welfare function. In other words, there does not exist a social welfare function satisfying these four requirements. This is Arrow's famous *impossibility theorem*.

Clearly, almost everyone will agree that there should not exist a dictator in society who via his or her own strict preference over any pair of social alternatives automatically determines the social preference over these alternatives. Arrow defined social alternatives as very complex social states, which can include, among other things, the issue of waging a war against another nation or introducing the death penalty for certain crimes. On the other hand, democracies should allow individuals a certain

amount of freedom and autonomy over purely private matters. John Stuart Mill, in the 19th century, spoke about a circle around every human being that nobody should be allowed to intrude into. So "local decisiveness" to a certain degree should be permissible. In our time, Amartya Sen (1933–) was the first to integrate this idea into Arrovian social choice. He formulated that each and every individual be permitted to exercise local decisiveness over at least one pair of social states, which differ only with respect to some private matters of that particular person. He then proved another important impossibility result, "the impossibility of a Paretian liberal." He showed that the requirements of unrestricted domain and the weak Pareto principle are incompatible with the exercise of local dictatorship or individual autonomy over purely private matters. In other words, there does not exist a social welfare function fulfilling these three conditions.

Wulf Gaertner, Prasanta Pattanaik, and Kotaro Suzumura, among others, have argued that the Arrovian setup may not have the appropriate structure to formulate the exercise of personal rights; the game form structure within which individuals select certain actions that shape private features may be closer to what one observes in real life, where closeness refers to conformity with existing rights systems. Notice, however, that this alternative suggestion by no means denies that there can exist a clash between the exercise of individual rights and the Pareto principle. A reference to findings in noncooperative game theory may be adequate here, namely, the existence of Nash equilibria that are Pareto dominated.

A third important impossibility theorem in Social Choice Theory refers to the fact that it can be advantageous for individuals to misrepresent their preferences and, by doing so, to achieve an outcome that is more favorable for them than the one that would have come about if they had announced their true or honest preferences. This phenomenon is well-known in the allocation of public goods, where individuals may want to hide their true willingness to pay in order to achieve a lower contribution fee for themselves. In Social Choice Theory, Allan Gibbard, a philosopher, and Mark Satterthwaite, an economist, were the first to independently provide a deeper analysis of this phenomenon. Of course, there are social choice or aggregation rules that are not manipulable, but these are highly unsatisfactory in the sense that they do not respond at all or respond only very faintly to changes in individual preferences. The ranking rule proposed by the French mathematician we mentioned above, Jean-Charles de Borda, which we shall discuss a little later in this entry, is highly susceptible to manipulation (Borda was very well aware of this fact, so he declared that his method was only for honest men), since its aggregation scheme employs very detailed information coming from the individual rank orderings. Gibbard and Satterthwaite proved that if individual rank orderings are unrestricted, if furthermore the aggregation method is "monotonic" or responsive to changes in the individuals' preference rankings and Pareto efficient, and if there are at least three social alternatives, the only nonmanipulable or "strategy-proof" aggregation method is dictatorial.

Though there are lots of other negative results in Social Choice Theory, there is wide agreement among researchers in this area that Arrow's, Sen's, and the last result about strategy-proofness are the most important. We shall now turn to positive results.

Possibilities

We begin this section by focusing on the *simple majority rule,* which is widely applied in many committees. According to this rule, alternative x, say, is majority-wise weakly preferred to another alternative, y, if the number of voters who find x at least as good as y is larger or equal to the number of voters who find y at least as good as x. The simple majority rule is an attractive decision mechanism since it treats both voters and alternatives equally (there is discrimination neither among voters nor among the issues to be decided upon—the latter property is called "neutrality"). A simple majority decision is also responsive to changes in voters' rankings, much more than the absolute majority rule, for example.

Why is the method of majority decision not a counterexample to Arrow's famous negative result? The answer is that under an unrestricted domain of individual orderings, the majority rule may generate so-called Condorcet cycles. In their simplest form, in the case of three voters, they come about if one person prefers x to y and y to z (and also, of course, x to z, due to transitivity), the second voter prefers y to z and z to x, and the third person prefers z to x and x to y. Simple majority counting establishes a social preference for x over y, for y over z, and for

z over x. In other words, there is a preference cycle on the aggregate level so that an Arrow-type social welfare function does not exist. For three alternatives and three voters, the probability for cyclical social preferences to occur is about 5.5%, which is not very large, but this probability increases with the number of voters and the number of alternatives, so it cannot be considered as *une quantité négligeable*.

The Welsh economist and political scientist Duncan Black has shown that if the individual preference rankings are "single-peaked" over each triple of alternatives, the simple majority rule yields a Condorcet winner—that is, a candidate who is majority-wise at least as good as every other candidate. If the number of voters is odd, the method of majority decision generates a social ordering (so that the rule becomes an Arrow social welfare function). Single-peakedness as a qualitative property on preference profiles can be taken literally. Each and every voter has a most preferred alternative (in terms of ordinal preferences), and on either side of this most preferred object, the person's preference decreases. Black himself thought in terms of the political spectrum (left–right). Of course, the far left and the far right voters show declining preferences only on one side of their respective peaks.

Amartya Sen generalized Black's condition to what he called "value restriction." For each triple of alternatives, there exists one alternative such that all voters agree that it is never the worst (case of single-peakedness), that it is never the best (case of single-troughed preferences), or that it is never in the middle between the other two. Again, a Condorcet winner exists under the simple majority rule, and this rule once more becomes an Arrow social welfare function for an odd number of voters.

Single-peaked preferences have another remarkable property. Under this domain restriction, the method of simple majority decision turns out to be strategy-proof. This was shown by Hervé Moulin very generally—the position of the so-called median voter balances deviating interests to the left and to the right of this voter's peak. A strategic misrepresentation would be against the very interest of those who are involved in the decision making.

Consider a social choice rule that specifies for any two alternatives x and y that x is socially at least as good as y if and only if it is not the case that all voters find y at least as good as x and there is at least one individual who finds y strictly better than x. Sen called this rule the *Pareto-extension rule*. It fulfils Arrow's conditions of unrestricted domain, weak Pareto, the independence condition, and nondictatorship, but it does not satisfy the requirement of full rationality of the social relation. The Pareto-extension rule is not transitive with respect to the indifference part of the social preference relation. Therefore, this rule is not a counterexample to Arrow's theorem either; it "only" constitutes a social decision function. The latter is always able to provide a nonempty choice set but not necessarily a social ordering. The reader realizes that subtle differences can matter a lot. The Pareto-extension rule may be viewed as unsatisfactory for social decision making, since whenever there is at least one person who strictly opposes the strict preference of the rest of society for x over y, say, the social outcome between x and y will be an equivalence or indifference. Such a person has been called a "weak dictator." A consequence of this weak dictatorship is that the Pareto-extension rule is largely unresponsive to changes in the underlying preference profile of the members of society.

The so-called Borda rank-order method, which without any doubt is the best-known rule from the class of general scoring functions, attaches ranks to positions. If there are m alternatives on which a social decision has to be made and if all alternatives are ranked in a strictly descending way by all voters, Borda proposed to attach the rank $m - 1$ to the top-ranked element, $m - 2$ to the second element from the top, and so on, and, finally, 0 to the bottom-ranked alternative. The element(s) with the highest aggregate rank sum is (are) socially chosen. Clearly, this rule uses much more (positional) information than the majority rule, for example. The latter just registers whether x, say, is preferred to y, or vice versa. The Borda rule also considers the "distance" between options—in other words, the number of positions of the alternatives between x and y.

Peyton Young showed that the Borda rule can be uniquely characterized by being neutral, consistent, and faithful, and having the cancellation property. Neutrality has already been explained in connection with the majority rule. Consistency makes the following requirement.

Imagine that the preference profile of society is split up into two disjoint subprofiles representing two disjoint sets of voters. If the intersection of the set of elements picked by the choice rule from the first

subprofile and the set of elements chosen from the second subprofile is nonempty, consistency requires that all elements in this intersection are identical to those that would have been picked by the choice rule if there had only been one profile, namely, the union of the two subprofiles. A scoring function is faithful if "socially most preferred" and "individually most preferred" have the same meaning when society comprises just one person. Note that if a scoring function is consistent and faithful, it satisfies the weak Pareto principle. Finally, the cancellation property requires that given any set of alternatives, if for all pairs of alternatives from this set, the number of voters preferring *a* to *b*, say, equals the number of voters with the opposite preference, then all elements from this set are equally chosen.

Clearly, the Borda winner can be different from the Condorcet winner. It can be shown that a Condorcet winner is never bottom ranked according to the Borda rule, and a Condorcet loser—a candidate who loses in pairwise contest against all other options—is never top ranked according to the Borda count. The equidistance between two adjacent scores is typical of the Borda rule but by no means necessary for general scoring functions. Nonlinear transformations of the Borda rank numbers, for example, can be introduced if there are plausible reasons for doing so.

Beyond Ordinal Noncomparability

Up to this very point, we have only been considering ordinal rankings both on the individual and the societal level, with no trace of interpersonal comparability. John Rawls's approach to justice, however, presupposes that we can compare levels of well-being (strictly speaking, in terms of so-called primary goods) across persons, so that we can, for example, say that person *i* is better off under state *x*, say, than person *j* is under *y*. This kind of interpersonal comparability is called *ordinal-level comparability*. Utilitarianism, which was made well known by Jeremy Bentham, a legal and social theorist, postulates utility of action according to the maxim of the greatest happiness of the greatest number possible. In more prosaic terms, utilitarianism either maximizes the aggregate sum of utilities over all persons concerned or the average utility per society. In either case, differences in utilities must be a meaningful concept, and these have to be compared across persons. The underlying concept here is the cardinal concept comparable to temperature or weight, where we also usually measure differences.

Apart from the informational requirement, namely, ordinal-level comparability in the Rawlsian approach versus comparability of utility differences in utilitarianism, Rawls focuses in his second principle of justice on the worst-off in society, whereas utilitarianism, as just stated, focuses on the aggregate sum of utilities, which is to be made as large as possible. Axiomatically speaking, both models of distributive justice have a lot in common. Both maxims satisfy the Pareto principle, independence of irrelevant alternatives, and anonymity. The point of bifurcation between both rules is a so-called equity axiom in the Rawlsian setup, with its single focus on the worst-off (strictly speaking in terms of an index of primary goods, such as income, wealth, opportunities, and self-respect).

The modern-day version of utilitarianism was formulated by John Harsanyi. His model, based on the Bayesian rationality postulates, employs the von Neumann–Morgenstern expected utility hypothesis. In one of his models, an ethical observer evaluates different policies for a particular society in an impartial manner, thereby determining the utilities that accrue to each member of society. This approach is very reminiscent of the role that an impartial spectator plays in Adam Smith's *Theory of Moral Sentiment*. Again, as in the case of de Borda and Condorcet, a fundamental idea bridged over two centuries, receiving a modern scaffolding, so to speak.

Finally, we would like to mention Sen's capability approach. For Sen, what defines freedom, autonomy, and well-being are the functionings of a person—her achievements—and not just the accumulation of primary goods as in Rawls's theory. What a person manages to do or be (e.g., being well nourished and well clothed, taking part in community life, having access to medical care) are functionings that are important for a person's life. The total number of functionings that are available to a person or household define the advantages of that person—her real opportunities. These make up the person's capability set.

Social Cognition

The term *social cognition* has two primary referents. (1) As a subdomain within the parent discipline of social psychology, its mission is to apply the methods and models of cognitive psychology to study the mental representations underlying social behavior. (2) As a line of inquiry, heavily influenced by philosophical, neurological, and evolutionary (as well as) cognitive perspectives, its goal is to discover whether there are mental structures and processes unique to a person's knowledge of and interaction with social entities (as opposed to nonsocial objects, facts, etc.).

This entry examines these two areas of application of the notion of social cognition and ends by using memory—and in particular episodic memory, central to social interaction—as an example of certain methodological and ontological issues raised in social-scientific research. The discussion also highlights the importance of evolutionary perspectives in social cognition.

Social Cognition as a Subdiscipline of Social Psychology

Social cognition originally emerged as a subdivision within social psychology. Its defining features were that it combined (a) the parent discipline's concern with human social interaction with (b) an interest in applying models and techniques derived from the study of nonsocial cognition (e.g., memory for words) to explore the mental representations underlying social behavior. To appreciate the revolutionary nature of this convergence, it helps to review the context in which the interaction between social and cognitive psychology developed.

Starting in the late 1950s, hard-line positivism's informal ban on what the behaviorist movement had labeled "black box" psychology gradually gave way to the appreciation of the importance of inferring mental structures from observed behavior. This refocusing, first adopted by cognitive psychology in the early 1960s, did not enter social psychology until roughly a decade later. Emerging in the mid-1970s as a subdivision within social psychology, social cognition continued to focus on topics of interest to its parent domain, with the additional constraint that understanding social behavior must be grounded in an explicit appreciation of what the mind actually can and cannot do. Accordingly, social cognition proposed and tested hypotheses of mental functions (e.g., perception, memory, automaticity) presumed to underlie the overt behaviors of interest to social psychologists (e.g., impression formation, attitudes, stereotyping, conformity). This was achieved largely by borrowing measures (e.g., response latencies), procedures (e.g., priming and recall paradigms), and models (e.g., associative and computational) from cognitive psychology to serve as bridges with which to infer the underlying cognitive mechanisms responsible for interpersonal behavior. In placing a premium on inferring the content of the "black

box," social cognition helped position social psychology within mainstream cognitive science.

By the time a second *Handbook of Social Cognition* was issued in 1994, the parent field of social psychology was undergoing a gradual transition toward the "mental" side of human social behavior—thus adopting a shift toward theoretical commitments that had taken center stage in cognitive psychology 20 years earlier. Over the ensuing decades, there has been continual updating of cognitive representational theories (e.g., parallel distributed processing [PDP] models) and methods (e.g., functional magnetic resonance imaging). As the cognitive science approach became the standard paradigm across psychological domains, social cognition gradually morphed from an independent subdomain within social psychology to a set of methods, procedures, and theoretical orientations absorbed into the parent domain. Thus, the success of social cognition in aligning the study of social interaction with other areas in the psychological sciences rendered the need for a separate subfield within social psychology superfluous. Social cognition currently exists more as a set of procedures and assumptions within social psychology rather than as a separate subdivision.

Social Cognition as a Search for Cognitive Processes Unique to Social Behavior

For most of the past century, psychologists have been exploring the capabilities of mental systems, which are staggering. These mental systems can process a vast array of information, including much that is adaptively arbitrary and evolutionarily novel—from nonsense syllables and batting averages to chess moves and equations. But agnostically cataloging arbitrary samples out of the inexhaustible set of everything a memory system is capable of doing is not likely to lead to knowledge of its function. From an evolutionary perspective, the brain is a system designed to solve problems—that is, a system whose parts exist in their present form *because* that arrangement solves a problem recurrent in our ancestral environment.

A second referent of the term *social cognition* thus trades on the question "Have we evolved specialized neural structures and mental processes that enhance our ability to successfully navigate the complexities of our social world?" Current research suggests that the answer is "yes."

Take, for example, the human face. The face seems to be especially relevant to a host of basic social-cognitive process. It is the point of contact in the infant's very earliest social interactions; the smiles exchanged between an infant and its caregiver is the beginning of lifelong social bonds. Perceiving, identifying, and comprehending faces is absolutely basic to social interaction. We have to know who we are dealing with, what they are like, and how we relate to them, before we can interpret their behavior or plan our own. The face (even a stranger's) provides cues to the emotional state of the other person, as well as hints of other things, like deception, that are important in negotiating an interaction. Consistent with these considerations, several decades of study reveal that there are neural structures specifically devoted to face processing—structures that when impaired produce specific deficits in face perception (e.g., prosopagnosia, or "face blindness") but not perception more generally.

Theory of mind (TOM) is another cognitive process specifically devoted to social behavior. TOM enables its possessor to infer unobservable mental states (e.g., beliefs, goals, thoughts, motives) in others, thereby providing its owner a significant adaptive advantage in predicting and interpreting the behavior of others. This ability has no known nonsocial analog (save for the widespread anthropomorphism evidenced by our hominid ancestors) and evidences highly specific patterns of loss in neurological disorders characterized by patients' failure to participate normally in social communication and interaction (e.g., autism).

The list could be greatly expanded (e.g., mirror neurons, which respond both when an animal acts and when the animal observes the same action performed by another—accordingly, the neuron "mirrors" the behavior of the other).

Let us now consider an example of how evolutionary and philosophical considerations led researchers to rethink the origins of a classic form of memory whose status as a social adaptation became evident only after researchers began to ask questions about its evolutionary functions (rather than questions more traditionally posed by cognitive science that pertain to a system's capabilities).

Episodic memory is a subsystem of long-term memory held to consist of knowledge of a previously experienced event, along with an awareness that the event occurred in one's past. Episodic memory has traditionally been viewed as having evolved

in response to selection pressures posed by general environmental contingencies that the organism encountered—both social and nonsocial. However, evolutionary and philosophical considerations, confirmed by empirical testing, now make it appear that episodic memory is an adaptation specific to the social demands of the environment.

The fact that scientists have an abstract category—*episodic memory*—does not guarantee that an ontological correlate exists in the brain. If episodic memory is a genuine system in the biological sense, then it exists in its present form because that arrangement solved certain recurrent problems faced by the organism in its evolutionary past. Evolution does not produce by chance new phenotypic systems that are complex and functionally organized; rather, systems acquire their functional organization because they contributed to the organism's ability to survive and reproduce. In the case of episodic memory, these include, but are not limited to, keeping track of cooperative relationships (e.g., social exchange, cheater detection, coalitional allies) and reevaluating social knowledge in light of new evidence. Thus, episodic memory enables its owner to navigate more successfully in the complex world of human social interaction.

This is not to say that episodic memory is capable of performing only socially relevant tasks. Every system, by virtue of having a particular causal structure, is capable of doing an endless series of things that it was not designed to do. What research suggests is that episodic memory is the functional product of an evolved adaptation designed to facilitate interaction with other people.

In summary, a multitude of cognitive adaptations appear specific to social behavior. Social complexity being a hallmark of our species, it would be surprising if this were not the case. Adopting an evolutionary perspective as a heuristic for discovering such mechanisms is a promising direction for future social-cognitive research.

Social Construction of Reality

This entry presents and discusses the once influential theory of Peter Berger (1929–) and Thomas Luckmann (1927–) on the social construction of reality, which appeared in their classic book by that title. The entry proceeds to review some critical points about this subject and points to recent developments.

Berger and Luckmann's Theory

When it first appeared in 1966, *The Social Construction of Reality* by Peter Berger and Thomas Luckmann made a powerful impact on sociology, for several reasons: It was, as its subtitle said, "A Treatise in the Sociology of Knowledge," an area largely neglected in the contemporary sociology of the day; it brought the name and work of the social scientist, philosopher, and lawyer Alfred Schütz (1899–1959; who had taught both authors at the New School for Social Research) to the awareness of many sociologists for the first time; and it was qualitative and humanistic in its perspective, in contrast to the structural-functional and quantitative sociology of the day. It thus provided considerable support for those advocating qualitative instead of quantitative methods in sociology and, by introducing Schütz and many of his concepts, provided an impetus for those interested in phenomenological approaches as well.

The authors had undertaken to examine knowledge, commonsense knowledge as held by the "man in the street," the ordinary member of society. Their mission was to carry out what Schütz had advocated for many years—that is, a serious, intense, and detailed study of whatever passed for knowledge among ordinary persons. Schütz referred to the work by Max Scheler, Karl Marx, and Karl Mannheim as the so-called sociology of knowledge.

By focusing the sociology of knowledge on everything that passes for knowledge in society, they would thereby achieve what Peter Berger called a "democratization" of the sociology of knowledge, rather than dealing with the history of ideas, or ideology, as examined by intellectuals.

Berger and Luckmann state clearly on the first page of their work that, for them, "knowledge" and "reality," when examined sociologically, are found to pertain to specific social contexts. Any analysis of the context—that is, the study of various aspects of a society—would have to take this into account. The taken-for-granted in one society (or even subuniverse) may not be the same in another.

They further advocated that any examination of empirical varieties of knowledge has also to consider how *any* body of knowledge comes to be socially established as "reality." Those who do research, therefore, would not judge the validity or invalidity of what is taken to be known (as reality) but would rather seek to discover and describe knowledge for a particular society and/or its various subdivisions—in other words, to analyze how knowledge is socially constructed.

By *social construction,* they meant the interactive processes engaged in by the man in the street together with others, which led to commonsense knowledge—that which is known and then taken for granted by them.

They themselves "bracket" epistemological and methodological questions concerning the validity of sociological analysis. They wish to focus on what is known as "real" by members of society in their ordinary, everyday lives and not in their own theorizing about it—not only the content of what is "known" by members of society but how the known, as objective, can also be *subjective.* In this undertaking, Berger and Luckmann borrow from or modify several influential sources, including Émile Durkheim, Karl Marx, Max Weber, and George Herbert Mead, to delineate what they consider the most relevant aspects of the sociology of knowledge. These are how reality is *interpreted,* what *subjective meanings* members hold as they develop the coherence of their world, and how subjectivations (of meanings) are objectivated to produce an intersubjective commonsense world. Persons are aware of multiple realities and that, for example, the world of dreams is different from the world of everyday life (what Schütz called the "paramount reality")—in other words, that there are different "realities" and that everyday reality appears as already "objectified" to them and to others.

The mode of interaction with others, the typificatory schemes that may be used, the language available for use in interaction are all sources of objectivation of experiences and may lead to an interpretation of these as "already there," formed independent of us. Nevertheless, we also see how reinterpretations and modifications, and also actions based on these, can be made by ourselves and others. They argue that the sum total of these typifications and of recurring interaction patterns results in a social structure that forms part of the reality of everyday life as we perceive it.

One may use typifications in interactions with others, as may they, and despite the increasing anonymity of others, one may also "know" how to act in taking them into account. Such anonymity may depend on the input or presence of interest and intimacy, both of which may vary over time, since one "knows" one's predecessors and contemporaries better than one's successors (or even consociates).

Berger and Luckmann go on to discuss habitualization and its role in the formation of institutions, institutionalization and its being experienced as an objective reality, and the human or social production of a world of meanings shared with others as social relationships are formed.

According to Berger and Luckmann, sociological investigations of a phenomenon may examine how its meanings were socially produced—that is, how they came to be produced by and for the ordinary man in the street. The researcher may focus on the various aspects of production with the aim of revealing which types of actors, which settings, and which formulations or linguistic forms were/are used in their ongoing production.

One aim may be to offer critical perspectives on these descriptions and analyses in order to reveal the importance of existing persons (contemporaries) or previously present predecessors to the construction of meanings. Part of the aim may be to change the meanings and enhance the efforts of those attempting to modify or reinterpret the meanings of the phenomenon or who propose different linguistic usages for describing and analyzing the phenomenon.

The fact that Berger and Luckmann had presented a new way of examining knowledge, how they had utilized Schütz (together with Durkheim, Marx, Weber, and Mead) to do this and how they had focused on commonsense knowledge and said that the observer did not have to assess the validity of the claim to certainty with regard to the existence, shape, or meanings of phenomena, did not result in extensive studies of commonsense knowledge and the taken-for-granted or in multiple realities or in most of the conceptualizations they had introduced.

Berger and Luckmann did *not* claim that everything is socially constructed or that everything is a social construct—that is, they did not embrace a universal social constructionism.

They did say that institutional order is developed and maintained by members' knowledge of it, often by metaphor, maxims, morals, myths, and so on. Any analysis would reveal the recipe for knowledge that can provide rules of conduct for maintaining the institutional order. A focus on institutional order would show what rules of conduct were sanctioned, what was held as true, as belief, as well as what social controls were utilized for its maintenance/preservation. Deviance from these would thus be recognized, and efforts would be made to sanction those who did not conform.

A social world thus constituted would then be accepted as "the world" and utilized to assess any alternative actions or judgments. Such knowledge could then be internalized, and reference to external, objectivated structures could be assessed in relation to it.

Knowledge, in their view, provides a means for production of an objective world, uses language to order those objects that will be considered part of social reality, and, when internalized through socialization, can be accepted as valid or true. Knowledge thus serves not only to maintain but also to produce on an ongoing basis the reality accepted by members of that society.

Much of this knowledge is sedimented, remaining in memory and not requiring the individual to have to examine everything at hand. Language is the principal means of intersubjective sedimentation, which then enables all parties who have experienced particular phenomena as well as those who use the same linguistic meanings to share objectivations in the same collectivity.

They may become legitimated in the process of achieving a place in the stock of knowledge, such that one can say, "We know that there is this aspect to reality." The knowledge of reality becomes a shared and transmittable knowledge, and succeeding generations may even be seen as representative of such viewpoints. That is, a collectivity may be known for its traditions, the knowledge shared by its members, and the views and definitions of the "reality" that they share.

As Berger and Luckmann saw it, there is a dialectical relation between knowledge and the social sedimentations held by the members of a collectivity. Knowledge may be socially produced, but it also may serve to produce further social change in the meanings of the objectivated world.

Each subuniverse and institutional order may become objectified, that is, apprehended as though it is not a human product. A loss of awareness may lead persons to think that the reified social reality cannot be changed, as though one has no control over it. The objectivated meanings that lead to *reification* may be forgotten, and paradoxically, persons may interpret their own situations as being shaped by the objectivated, or reified, reality. In losing awareness of their own role in institutionalization, objectivation, and reification, they may believe that this is the way things were meant to be, that divine guidance has produced them, or that this is only natural. Here, we can see that any number of interpretations or explanations with regard to sources or causes may be made.

Furthermore, they emphasized that any theory must be *dialectical* in the sense that it should continue to examine the relation between institutionalization (and reification) and the actions and beliefs of human actors as these are continually involved in their maintenance and production. A loss of this perspective would mean that the theorist/observer would no longer see the *social* construction of reality—how "reality" is socially produced.

Critical Assessment and Current Developments

The book, *The Social Construction of Reality,* is indeed what its subtitle proposes, "A Treatise on the Sociology of Knowledge." However, adoption of the phrase, and supposedly the perspective that Berger and Luckmann presented, has led to many varied interpretations, some of them wrong or misguided, and to the identification of "social constructionism" as a perspective that is critical of existing ideas, beliefs, or institutions and, in general, conventional meanings in sociology or whatever is being examined or written about.

These developments and misconstruals of the meanings intended in the book have led Berger to "shy away" from constructionism and Luckmann to say that whenever he hears the terms *social construction* or *constructionism,* he "runs for cover." In fact, some versions of social construction(ism) do not even reference Berger and Luckmann's original formulation; for example, the *Stanford Encyclopedia of Philosophy* considers it a "metaphor."

In a close examination of the meaning and use of the terms *the social construction of reality* and *constructionism,* Ian Hacking notes that many studies have used them in their titles, ranging from the social construction of authorship, to brotherhood, danger, emotions, facts, and more, including the last on his list, Zulu nationalism. In Hacking's book on the "social construction of _____", *X* represents whatever it is that is being studied/written about, and he characterizes much of this work as having primary value for political activists and those involved in debates about race, gender, culture, or science.

Hacking distinguishes two different usages and referents (of whatever *X* is): a primary way "for raising consciousness" and a way of being critical of the status quo, that is, *X* need not have existed, is quite bad as it is, and we would be much better off if *X* were eliminated or changed. The main idea is that *X* is not inevitable and does not have a particular character or nature independent of human beings. Rather, it evolved from social situations, forces, and historical conditions that, if varied, could have resulted in a different character of *X*. This is not to argue for relativism but rather that doing social construction analysis will enable one to show how the taken-for-granted meaning of *X* emerged over time to its present state.

Social construction may then be about objects and/or ideas and the interaction between them. Objects are, in commonsense knowledge, taken for granted and assumed to be what they (currently) appear to be or are defined as being. These may be considered to be essential or inevitable for all human beings and at all times—that is, a universal constructionism.

Ideas and concepts may also be taken for granted and may appear as inevitable, whereas a closer examination may reveal how certain interpretations are used, how they have developed, and how they are related to social and historical conditions. Such revelations may be used to offer alternatives or to criticize existing interpretations and, clearly, to reveal how they are *socially* constructed.

Abstractions, or what Hacking calls "elevator words," are also shown to have similar usages and characteristics.

Social constructionism is examined by Hacking not as a theory concerning the sociology of knowledge but primarily as a critical perspective that seeks to reveal how existing ideas and meanings have evolved. Such revelations could then lead to social change—that is, to alternative interpretations (meanings).

Concluding Remarks

The idea of social construction has evolved and even changed since the original formulation by Peter Berger and Thomas Luckmann. An examination of their theory and its Schützian background reveals that they were involved in complex formulations of relevance to a theory of the sociology of knowledge. Distortions and misinterpretations have come in a variety of guises, but the original formulation remains more complex than those who claim to do social construction have ever recognized.

Social Constructivism

Social constructivism with respect to a given phenomenon is the view that the latter does not possess an independent existence but is "constructed"—that is, generated and maintained through collective human action, thought, discourse, or other social practices. Constructivism is thus antithetical to realism with respect to the same entities, which would ascribe autonomous existence to them. Social constructivism is primarily a position in philosophy of science, but it also informs and inspires a number of recently influential schools within the empirical social sciences themselves.

This entry introduces the various meanings and uses of *social constructivism* and reviews four main positions with regard to the ontological and epistemic versions of social constructivism concerning the social world and the physical world, respectively.

The term *social construction* was first used by Peter Berger and Thomas Luckmann in their 1966 work, *The Social Construction of Reality.* In this book, what is declared to be a construction is, albeit ambiguously, the social realm. Subsequently, the constructivist stance has achieved a widespread following and has been extended to other spheres. While social constructivism as defined above is trivially true for many human phenomena and artifacts, it becomes controversial when applied to areas of reality, or features thereof, that are normally held to exist autonomously.

Social constructivist positions often harbor normative or ideological overtones. As stressed by Ian Hacking, claims that a certain phenomenon is "constructed" carry the implication that the latter is not part of "the natural order of things"; it is not eternal and immutable, let alone necessary. Hence, such claims are often raised in connection with efforts to effect societal changes. Favorite areas in which constructivist claims have been raised in order to promote normative agendas pertain to divisions of gender or race.

Underneath its general nominal definition, social constructivism is a very diverse intellectual trend, and its adherents across the fields would not often claim any communality. Moreover, there is often considerable disagreement between constructivists within any particular field, as they draw upon many and diverse philosophical traditions ranging from phenomenology and Marxism (both of which inspired Berger and Luckmann's seminal effort) to philosophy of language. Still, the label is useful in identifying a characteristic collectivist and anti-realist mode of thinking, local or global, that has recently enjoyed considerable popularity.

Two intersecting distinctions among constructivist claims will help create an overview of this complex field.

The first distinction is that between the *material or physical* sphere and the *social and human* sphere, as objects of construction. The second distinction is that between *ontological* and *epistemic* constructivism. According to ontological constructivism, the object of construction is the world itself, while according to epistemic constructivism, it is our knowledge of (beliefs about) the world, including our scientific knowledge. (Knowledge, of course, also belongs to the world but constitutes a special subpart that is subject to evaluative, rational constraints and, hence, may usefully be placed in a separate category.) The import of claiming that (scientific) knowledge is a social construction is that it is shaped by societal forces rather than through a process of "tracking" the reality that is its nominal object.

When the two distinctions are combined, social constructivist positions may be organized as shown in Table 1.

Ontological Constructivism With Respect to the Social and Human World

That the social world depends for its existence on the thoughts, language, and actions of its inhabitants is hardly controversial; what is of interest is rather

Table 1 Varieties of Social Constructivism

	Ontology	*Epistemology*
The material (physical) world	The material world is constructed by collective human thought and practice	Our knowledge, including our scientific knowledge, about the material world is constructed by collective human thought and practice
The social and human world	The social and human world is constructed by collective human thought and practice	Our knowledge, including our scientific knowledge, about the social and human world is constructed by collective human thought and practice

Source: Author.

what precise mechanisms are held responsible for its generation. In recent discussions, emphasis has been lain on the linguistic sources of such construction, a development that is in line with the general "linguistic turn" in 20th-century philosophy and social science. Two major traditions may be distinguished, which may be referred to as the analytical and continental arguments, respectively.

1. The *analytical argument* is represented by authors such as Margaret Gilbert, Raimo Tuomela, and John Searle, who hold society to be constructed through the collective intentionality ("we-intentionality") of its members. Searle's version in particular utilizes and extends insights from speech act theory. The most important social facts are institutional rather than "brute" (i.e., natural), and the analysis of such facts provided by speech act theory can be extended to all societal institutions. A core notion is that of constitutive rules, which state that some person, thing, or action *counts as* something else under certain conditions. They thereby acquire a certain status that enables them to serve a certain social function, since various normative powers (rights, duties, obligations) flow from the imputed status. These powers motivate specific collective actions and thus instigate and direct social interactions. When a body of constitutive rules defining status functions is recognized in a given population (a case of collective intentionality), collective institutions and, thus, social reality are created. Money is the classical example, in which a certain power—"purchasing power"—is bestowed upon pieces of paper that are in themselves valueless.

This type of constructivism has affinities with classical liberalist political philosophy and its conception of society as formed and legitimized through a social contract. In their later work, Searle and Toumela have attempted to link their constructivism with aspects of this tradition, such as the notions of political power and human rights.

2. According to the continental argument (so called), social reality is also generated by the linguistic categories in which we talk about it, but in a less specific manner. The philosophical underpinnings of this argument are typically derived from Michel Foucault's writings. The fundamental line of thought harks back to structuralism, which holds that language (*langue*) is an arbitrary structure of differences that, when manifested in concrete discourses (*parole*), generate a semantic system—that is, a system of categories under which objects in the world are subsumed. When these objects are human actions and their products, a social reality ensues, structured according to the categories of that particular discourse. In Foucault and other continental authors, these ideas are taken through a "poststructuralist turn," which emphasizes that the linguistic structures are not completely rigid but dynamic and subject to transformations through discourses articulating social interests—interests that, however, are themselves transformed in the process. In empirical social science, this view of social reality has, for example, been adopted in the influential theory of democratic politics by the political scientists Ernesto Laclau and Chantal Mouffe. Laclau and Mouffe, along with other representatives of the continental argument, draw upon Wittgensteinian ideas as well, in particular the notion of "language–games," with its implication of an irresolvable fusion between language and social practice that makes language constitutive of social reality.

There are representatives of the same mode of thought in the anglophone academic world as well. Within philosophy of social science, it has been

articulated by Peter Winch, while Ian Hacking adopts a similar position, albeit on a rather more concrete and empirical level. This position was anticipated in a less philosophical vein by the labeling theory in the sociology of the 1960s and 1970s, for example, in the work of Howard Becker.

Epistemic Social Constructivism With Respect to the Social World

Epistemic social constructivism is, in particular, the position that social-scientific knowledge is shaped by societal forces. The classical example is Marxism, which asserts that knowledge concerning the "superstructure" of society is shaped by the class interests of societal subjects; this is in contrast to natural science, which is held to be resistant to such influence. Marx's view paradigmatically manifests the normative aspect of constructivism in that the demonstration of the ideological nature of societal knowledge is meant to generate "critical consciousness" with respect to the latter. Another classical example of epistemic constructivism is Max Weber's claim that the concepts in which we describe the social world, in the form of "ideal types," are shaped by societal "values." In recent social science, a constructivist stance is represented by "discourse analysis," which holds that the semantic system in which societal knowledge is articulated (if not its detailed content) is shaped by social interests and serves to promote the latter. The representatives of this position often go on to draw ontological implications from this argument (cf. Laclau and Mouffe above).

Epistemic Constructivism With Respect to the Physical World

This stance has been the hallmark of the recently influential discipline of *science studies,* a radical outgrowth of classical sociology of science. The founding representatives of the discipline are David Bloor (a contributor to this encyclopedia) and Barry Barnes, who are core members of the so-called Edinburgh school. According to the school's Strong Program, as opposed to the weak program of traditional sociology of science (vide Robert Merton), theories even within the natural sciences are generated and shaped by social interests (a claim that extends the Marxist tradition) or by general societal but historically variable modes of thought (the Durkheimian tradition).

This position is in part based on a number of celebrated case studies, but it also draws support from familiar critical arguments within analytical philosophy of science. Chief among these is the instrumentalism of authors such as Willard Van Orman Quine and Baas van Fraassen. While these authors are satisfied with vague references to "pragmatic considerations" in specifying what forces decide the choice of theoretical models in the absence of a decisive influence from reality itself, science studies focus upon precisely this question and deliver the answer: societal forces. Another important influence is Wittgenstein's "rule-following argument" from the *Philosophical Investigations,* which is held to show that the correct application of all descriptive terms, including those of science, is a matter of social agreement and is, hence, subject to the social interests that shape such agreements.

Ontological Constructivism With Respect to the Physical World

Epistemic instrumentalism with respect to theories of natural science is often pushed to an extreme within the field of science studies. The reality toward which natural scientific knowledge is directed is claimed to exert no epistemic pressure whatsoever upon our scientific theories; hence, the idea that experimental testing can push us toward an ever more accurate depiction of physical reality is dismissed. A radical ontological constructivism ensues, which holds that theoretical entities such as atoms and black holes are purely pragmatic posits that only exist within the conceptual frameworks and societal practices in which they are embedded. Their ontological status is thus akin, for example, to that of money, which does indeed exist within a given monetary system, where slips of paper really do possess exchange value but have no existence outside the system. A position along these lines is adopted, for example, by Bruno Latour in his actor-network theory (although, in later works, Latour objects to being labeled a *social* constructivist, since the agents of construction include nonhuman "actants," e.g., scientific measuring apparatus).

Within science studies, too, the constructivist stance often goes along with a normative agenda that is normally tacit but sometimes quite explicit (e.g., in Latour's work). The classical conception of natural science with its realist ontology and rationalist epistemology is held to bestow an illegitimate societal

privilege upon scientists; by contrast, a social constructivist interpretation is thought to lead to a more democratic way for science to function in society.

Social Contract Theories

This entry looks into the philosophical issues, especially regarding rationality, behind contractarian theories prominent in political and moral theory as well as in certain social sciences, principally in economics. It does not purport to give a historical account of all social contract theories.

Origins

A social contract account of normative rules or principles is one that seeks to justify moral or political institutions by reference to the idea of some sort of rational agreement between individuals. Such an account was first introduced in a famous passage from Plato's dialogue:

> They say that to do wrong is naturally good, to be wronged is bad, but the suffering of injury so far exceeds in badness the good of inflicting it that when men have done wrong to each other and suffered it, and have a taste for both, those who are unable to avoid the latter and practice the former decide that it is profitable to come to an agreement with each other neither to inflict injury nor to suffer it. As a result they begin to make laws and covenants, and the law's commands they call lawful and just. This, they say, is the origin and essence of justice; it stands between the best and the worst, the best thing to do wrong without paying the penalty and the worse to be wronged without the power of revenge. The just is the mean between the two. (*Republic,* 1974, 358e2–359b1)

This is, of course, a very cynical description of the theory in question. A noncynical but all too brief account is to be found in Epicurus, the Hellenistic philosopher.

The contract is only a second-best solution—not the one that anyone would prefer if they had the power to act unjustly toward others with impunity. Moreover, it implicitly suggests that the agreement reached need not be egalitarian in any meaningful sense. Some may be more powerful than others and so are in a position to threaten others who are not so powerful, unless the latter obtain special privileges in the agreement reached. That is, the contract that results may favor some more than others. Moreover, there is a natural disconnect between what a person might agree to in a general way and how he or she will choose to act in various specific circumstances. This becomes clear in the *Republic* when one of the protagonists of the dialogue, Glaucon, goes on to tell the story of the shepherd Gyges, who finds a ring that makes him invisible and proceeds to use the power it gives him to triumph unjustly over others.

In this way, Glaucon neatly argues, in addition, for the contemporary view, espoused by many economists, that such contracts are unavoidably subject to what is known as a *free rider* problem: Persons may be "willing" to agree, in principle, to certain restrictions, but in the absence of effective surveillance and enforcement mechanisms, they will be disposed to violate the rules when they can get away

with it. They will "free ride"—that is, secure the benefits of the agreement without paying its costs.

Modern Times and Critical Issues

What would a "noncynical" account of contractarianism look like? In the modern period, the clearest version of contractarianism is to be found in the writings of Thomas Hobbes (17th century), who argues in his famous work *Leviathan* (1651) that it is rational for persons to accept an extensive set of "laws of nature" that specify how they are to interact with one another. Even Hobbes, however, thinks, as does Glaucon, that such an arrangement must be backed up by an effective enforcement mechanism—the Leviathan.

Care must be taken here, however. In the famous "fools" passage of *Leviathan* (I, 5), Hobbes insists that where the other party has already performed, it would be against reason for one not to perform, even in the case where there is no Leviathan.

There are a number of issues that must be addressed if the contractarian view is to have any plausibility. In the first place, to justify a particular moral or political institution, one must presumably show that it is characterized by a rule or principle to which it would be rational for persons to agree to conform their behavior. However, is the reference here to an actual or a merely hypothetical agreement between persons?

It is not clear whether it is to an actual agreement. There is little talk among contractarians about certain rules or principles being binding because persons have *in fact* "contracted" to abide by them. However, if it is a hypothetical agreement—what persons would agree to under some specified set of conditions—one faces the objection raised in our times by the legal philosopher Ronald Dworkin (1977) that a hypothetical contract is "not simply a pale form of an actual contract; it is no contract at all" (p. 151). Moreover, just what are the relevant conditions? And what ensures that an agreement on some rule or principle under the specified conditions is also binding under any *other* set of conditions?

Another issue concerns the significance of the qualifier *rational*. The only clear and uncontroversial sense of *rational* here would seem to be "*instrumentally* rational": the doing of that which is the necessary means to the realization of one's objectives. But it is not clear that this sense of *rational* is relevant. We are presumably talking here about what it is rational for a group of interacting persons to do, where there is no assumption that they all have the same objective.

Another problem is that it might be "rational" to agree to a certain arrangement between oneself and others, but it *also* might be rational to avoid doing one's part as much as possible. This is the issue to which Glaucon refers in his discussion of the Ring of Gyges, and as we have seen, it amounts to what in the contemporary literature of economics is known as the "free rider" problem—that is, whether a given participant ought to abide by a rule or principle when others have or can be expected to do their part.

At a deeper level yet, on a social contract theory, reference to a "contract" or an "agreement" is perhaps best treated as really having only a *metaphorical* meaning, there being nothing in the theory that requires there to be either an actual or a hypothetical agreement. The social contract theory, on this account, is simply the view that it would be (instrumentally?) rational for persons to put into practice a particular kind of normative arrangement between persons—one that specifies some set of rights and duties for each of the agents. Moreover, by "put into practice," one is to understand that each of the persons in question should be committed to act in accordance with its (normative) dictates. On this interpretation of the theory, the arrangement would not be subject to the free rider problem, at least to the extent that the participants in the arrangement are instrumentally rational.

The problem of how to interpret "instrumental" in this context might be worked out along the following lines. We need to isolate a special sense of what best promotes the objectives of the agents involved, namely, one that applies specifically to interactive situations in which the persons involved do not have the same set of similarly prioritized objectives but are committed to disparate objectives. In such a situation, it could be argued, a failure on the part of the individuals involved to carefully coordinate their activities in some specific way could easily lead to a situation in which everyone does less well, in terms of the furthering by each of his or her objectives, than they could do if they were to coordinate their actions. On this view, if the manner in which the several agents interact leaves each worse off than they could have been, then the arrangement

in question is *not* instrumentally rational. We may suppose, then, that in such an interactive situation, the unanimous failure to realize as much as each could have realized counts as a failure to achieve an instrumentally rational outcome. Alternatively put, the question of the instrumental rationality of the arrangement arises whenever it can be shown that the coordination is not *maximally* mutually advantageous—that is, when there is some alternative that would benefit each even more.

This account of instrumentally rational interaction would also need to involve an important qualifier. A person would not be bound to act in accordance with a contract's normative requirements unless the person has assurance that others (at least most others) are also committed to act in accordance with those same requirements. For most contractarians, including Hobbes, it would be fully consistent with such an arrangement that some persons—specifically many of those who are less than fully rational—are committed to act in accordance with its requirements *only* because the arrangement provides motivating penalties for those who would be—by virtue of their not being fully rational—disposed to otherwise "free ride" on the efforts of others. Such penalties, of course, would not be perfectly motivating: They would work only for those who are not truly irrational. They would impose costs that a person would seek to (and could) avoid, if he or she were at least somewhat rational, but that will not move a thoroughly irrational person.

What about the content of what could be shown to be (in the sense just explained) an instrumentally rational arrangement between persons? Is the distinction between *moral* and *political* rights and duties useful here? This is doubtful. There is no reason to suppose that what is at issue here pertains to moral rather than political, or political rather than moral, arrangements. Indeed, the distinction is not very easy to make out in this context. Again, there may be many "moral" rules, and also many "political" rules, that cannot be shown to be maximally mutually advantageous (in the sense introduced above)—many rules, that is, that it may well be instrumentally rational for some but not necessarily for all persons to adopt. Arrangements that prohibit cruelty toward animals would seem to be a good example of this. One may have to appeal to special additional assumptions to establish that it is instrumentally rational to prohibit cruelty to animals. It must not be supposed, then, that a "contractarian" account can be given of everything that persons regard as normatively binding.

Where such an approach comes into its own, however, is with regard to rules or principles governing rights and duties that relate to what in our times the political philosopher John Rawls, for example, described as *primary goods*. These are goods such as income and wealth, as well as protections from various forms of interference by others and protections from a wide range of the vicissitudes that arise (especially natural catastrophes and diseases) from various events over which persons typically have very imperfect control. They can be characterized as primary goods by virtue of their being goods that virtually any person will value, regardless of the specific final objectives that they pursue. The place of these primary goods is perhaps most interestingly illuminated by a remark of Hobbes (1996), who argues in the *Leviathan* that

> felicity is a continual progress of the desire from one object to another, the attaining of the former being still but the way to the latter. The cause whereof is that the object of man's desire is not to enjoy once only and for one instant of time, but to assure forever the way of his future desire. And therefore the voluntary actions and inclinations of all men tend, not only to the procuring, but also the assuring of a contented life. (Pt. I, chap. 11, pp. 47–48)

It can be argued that possessing Rawls's primary goods makes possible not merely procuring but ensuring what is needed for a contented life.

John Rawls and the economist John C. Harsanyi are often taken to represent contemporary examples of the contractarian position. However, both are preoccupied with trying to show that under a very special set of circumstances—namely, conditions of radical uncertainty—it would be rational to adopt this or that principle of justice, and one is bound to wonder if this conclusion extends to conditions where such uncertainty does not obtain. Contemporary versions of contractarianism that are not subject to this objection are to be found in James Buchanan's *The Limits of Liberty* and also in David Gauthier's *Morals by Agreement*. Indeed, among contemporary philosophers, Gauthier offers perhaps both the most comprehensive and promising way to think about a contractarian justification of certain moral or political rules and principles.

To be sure, Gauthier's account is subject to another objection to contractarianism, to which I have already alluded: He supposes that the basic contract would be shaped by the relative bargaining power of the parties involved. Rawls's and Harsanyi's versions avoid this problem, for they insist that one must consider what persons would do when a decision must be reached under conditions of radical uncertainty (where one's relative power vis-à-vis others is unknown). A more convincing approach, perhaps, would be to argue, as this author does, that there would be significant negative long-range consequences for all if persons were to continually press whatever relative advantages they have over others.

Social Conventions

This entry reviews the major theoretical accounts of social conventions. It first introduces briefly their philosophical origin and then goes on to present the first contemporary systematic account of social conventions in terms of game theory. This is followed by an overview of some of the main theories and uses of social conventions in current work in the philosophy of social science.

Introduction

Many of our everyday social interactions are regulated by *conventions*. Eating manners, the kind of clothes we wear at the office, and the side of the road on which we drive are a few mundane examples. Roughly, a social convention is *a customary, arbitrary, and self-enforcing* rule of behavior that is generally followed and expected to be followed in a group or in a society at large. When a social convention is established, everybody behaves in a quasi-agreed-upon way, even if they did not in fact explicitly agree to do so. A social convention can thus be seen as a kind of *tacit* agreement that has evolved out of a history of previous interactions.

The study of social convention is relevant for the social sciences since much of social order can in fact be explained in terms of conventions and, thus, as social regularities that emerge and are sustained without the need of centralized planning and external enforcement by the state. In philosophy, the notion of social convention is appealing especially to those who aim to formulate naturalistic theories of normative phenomena in general (i.e., obligation, law) and of morality in particular.

Origin: David Hume

The 18th-century Scottish philosopher David Hume was the first to point to the relevance of conventional regularities to addressing both of these issues. Aiming in particular to demystify the nature of property and justice, Hume suggested that a convention corresponds to a pattern of mutually beneficial behavior that a group of agents follow when they know that such a pattern is mutually beneficial and that they expect each other to follow this pattern instead of another.

First Systematic Account: David Lewis

In modern times, the Humean approach to conventions has been revived by the philosopher David Lewis, whose theory clarifies the customary, arbitrary, and self-enforcing nature of conventions. Adopting a *game-theoretic* approach, Lewis proposed that a convention is a solution to a *coordination problem* arising in recurrent interactions. A coordination problem is considered as a situation characterized by at least two coordination equilibria. A coordination equilibrium is a combination of actions—one for each player—in which each player is strictly motivated to perform his component of the combination, conditional on his believing that the other players will perform theirs. Moreover, there exists at least one alternative combination of actions that has the same property. Finally, for each player, if a player performs his share of the combination, he prefers that the other players perform theirs. When an interaction contains at least two coordination equilibria and when coincidence of interests between the players prevails, the players are facing a coordination problem.

A classical example of a coordination problem is that of choosing the same side of the road in order to drive safely. If, in a society, a regularity in behavior in which each individual picks his share of a coordination equilibrium is established, then, according to Lewis's definition, this regularity is a convention. Since a conventional regularity is sustained if there is a system of concordant mutual expectations of conformity, a crucial component of any theory of convention is explaining the origins of these concordant mutual expectations. According to Lewis, the source of these mutual expectations is *precedent:* If the agents have a shared acquaintance with instances of successful coordination in a class of similar situations in the past, they will project this pattern into the future. Precedent is seen as a source of one kind of salience, which makes one coordination equilibrium a focal point and thus prominent with respect to any possible alternative.

Contemporary Approaches

The focus of Lewis's theory is mainly on how conventions, once established, reproduce themselves. A compatible but complementary approach addresses the problem of how conventional regularities emerge in the first place. Combining insights coming from theoretical biology, Robert Sugden, for instance, has employed *evolutionary game theory* to study the origins of conventions. The most general mechanism that has been suggested to explain their evolution is that of *symmetry breaking*. Avoiding collisions at a crossroad, for instance, requires a rule that specifies who is supposed to stop and who is supposed to move forward. Since, however, in the absence of any convention the positions of all the drivers are symmetrical, by observing each other's behavior, the evolutionary dynamics cannot converge on one of the coordination equilibria. However, if the players can also discriminate among contextual features of their situation, they might exploit an arbitrary symmetry to solve this problem. For instance, if drivers condition their behavior on who is coming from the right, they might evolve a convention that assigns priority to those coming from that side of the road. Thus, arbitrary cues can boost the evolution of arbitrary regularities.

Though the importance of conventions in solving coordination problems has been exploited in many areas of the social sciences (from economics to linguistics and law), limiting the role of conventions only to situations in which the interests of the players coincide is indeed an undue restriction. Actually, theoretical models in biology, economics, and philosophy have shown that together with conventions of coordination, conventions of *partial conflict* can also emerge and stabilize. Robert Sugden and Brian Skyrms have shown, for instance, that a convention of partial conflict in which property rights are assigned to the first person to take possession of a previously unowned item can evolve by exploiting the same symmetry-breaking mechanism sketched above.

Finally, even if a social convention is often regarded as a mere regularity in behavior, it has often been suggested that it also has a *normative* force. Margaret Gilbert, for instance, has argued that a social convention has an intrinsic normativity that can be accounted for only in terms of a holistic approach that appeals to social concepts not reducible to what the individuals are personally committed to do. In contrast, for other authors, like Robert Sugden and Ken Binmore, for instance, beliefs that one ought to conform to the prevailing conventions develop on top of such regularities and recruit natural human sentiments. In this naturalistic perspective, moral norms develop out of mere social conventions.

Social Epistemology

In simplest terms, social epistemology is the normative study of knowledge as a social product. It is a cross-disciplinary nomad, equally at home in philosophy and policy. There is disagreement over whether it is meant to be a branch of epistemology or sociology, or rather the entirety of one or the other or both of these disciplines. This entry begins by discussing three types of social epistemology that canvass these possibilities, followed by an extended discussion of the most ambitious form of social epistemology, which attempts to bridge the analytic/continental divide within contemporary philosophy, while providing an account of the social construction of intellectual progress.

Three Types of Social Epistemology

Social epistemology may be regarded in one of three ways: (1) as a branch of sociology, (2) as a branch of epistemology, or (3) as a field that transcends the difference between (1) and (2). Let us take each in turn.

1. As a branch of sociology, social epistemology asserts that social relations can be organized in terms of the differential, often hierarchical, access that a society's members have to a common reality. Plato originally advanced a static version of this thesis in the *Republic.* There, each level of human understanding—from the ideal to the base—corresponded to a stratum in a myth-based caste system. A more dynamic version, based on the stages of human intellectual progress, was advanced more than 2,000 years later by Auguste Comte in his positivist polity. In this context, earlier religious and metaphysical forms of epistemic authority served atavistic class–like functions in a science-led social order. The general idea continues to fascinate philosophers, as it raises the prospect of nonviolent, large-scale social control by deference to expertise, also known as "division of cognitive labor." Indeed, such knowledge-based politics is arguably the most Machiavellian of all, as it delegates the application of force to individuals, whose willed compliance is socially rewarded with the assignment of rationality. The history of medicine probably provides the clearest traces of this issue.

2. As a branch of epistemology, social epistemology asserts that an adequate grasp of the state of knowledge in society requires more than generalizing from what a single ideal (Cartesian) or average (Humean) mind knows. It requires recognizing the distributed nature of knowledge, either emergent on specific forms of life (i.e., folkways) or divided according to some overarching rational plan (e.g., science). But in both cases, the whole knowledge system is much more—and even other—than

the sum of what individuals know. On the one hand, theories of rationality and the scientific method—perhaps most strikingly Karl Popper's falsificationism—operate as a corrective social norm to the cognitive liabilities of individuals; on the other, no collectively agreed scientific theory of the sort that might govern a Kuhnian paradigm is likely to be known entirely by anyone or equally well known to everyone who claims adherence. In this respect, the fallacies of composition and division mark the boundary of social epistemology.

3. Finally, *social epistemology* may simply be a good contemporary name for epistemology's original project—put in Hegelian terms, to render knowledge "self-conscious." This point pertains to the English coinage of *epistemology* in the mid-19th century as a distinct branch of philosophy concerned with the conditions under which things may be known, where the very idea of the "unknowable" was treated as an oxymoron symptomatic of a (presumably defunct) metaphysics in which humanity remained permanently alienated from the divine source of reality's intelligibility. To be sure, many—perhaps even most—things remained unknown, but nothing was unknowable. Thus, alongside epistemology was christened *agnoiology,* the field that was supposed to capture the sphere of remaining ignorance in the spirit of an achievable research program. The main secular descendant was the logical-positivist aspiration for a unified scientific language in which anything worth saying could be said. By the 1960s, courtesy of Thomas Kuhn and Michel Foucault, this aspiration had become relativized to successive phases (paradigms or *epistemes*) in the history of science.

The difference between the first and second types of social epistemology is encapsulated in the chart below. The chart highlights the extent to which knowledge can be seen as either (a) a stabilizing or (b) a dynamizing force in society. The third type, to which the rest of the entry is devoted, may be seen as a synthesis of the first and the second.

Social Epistemology as the Goal of All Epistemology

An interesting story yet to be told is how epistemology—a field originally conceived of as a vehicle for achieving "absolute knowledge" (more about this is given below)—acquired a renewed taste for the problem of skepticism once it fell into the hands of post-positivist "analytic" philosophers, who have dominated the discipline in the Anglophone world since the end of World War II. These philosophers have resorted to various "foundational" moves, ranging from introspectively based indubitable intuitions, as in the case of Roderick

Table 1 Social Epistemology as (1) Sociology and (2) Epistemology

Social Organization of Knowledge	*(1) Individually Distributed and Collectively Reproduced*	*(2) Collectively Produced and Individually Redistributed*
Symbol of social epistemology	Evolution (especially irreversible specialization)	Encyclopedia (especially crosscutting referencing)
Knowledge as a principle of social order	Expertise and stratification	Research and education
Division of labor	Fixed and interdependent	Temporary and exploitative
Knowledge vis-à-vis power	Integrative ("social equilibrium")	Disintegrative ("creative destruction")
Sociological exemplar	Stable ecology	Dynamic university
Discovery vis-à-vis justification	Discovery is disparate, and justification channels to the mainstream (tributaries)	Discovery has biased origins, and justification redistributes privilege (delta)

Source: Author.

Chisholm, to more objectively determined reliable processes, as in the case of Alvin Goldman. Although they often cite Bertrand Russell's definition of knowledge as "justified true belief" as the touchstone for their approach, it is clear that Russell's default epistemic position was more positive than that of any of his analytic offspring. Whereas Russell defines knowledge so as to remove a priori restrictions (i.e., biases, prejudices, and blind spots) to our understanding of reality, which he believed the early-20th-century revolutions in mathematical logic and relativity physics had already begun to do, Chisholm and Goldman are more concerned with protecting whatever we know from contamination by error. In this respect, a latter-day concept that more closely captures Russell's original spirit is *epistemic injustice,* which aims to reduce the power effects of knowledge claims by proportioning their credibility to the weight of evidence in their favor.

One explanation for the risk-averse character of analytic philosophy is that two science-led world wars have shifted the default epistemic starting point from "how to go forward" to "how not to slip backward." That backslide in the default position had already begun in the aftermath of World War I, which by 1920 had witnessed a learned obituary on the idea of progress (J. B. Bury's *The Ideal of Progress*) and an ominous prophecy about the future of Western civilization itself (Oswald Spengler's *The Decline of the West*). Against this backdrop, the logical positivists in the following decade sought epistemic foundations based not on natural induction, common sense, or collective memory but on an agreed observation language through which knowledge claims could be verified. Their main concern was to penetrate disciplinary jargons that overstated ("totalized") the jurisdiction of their knowledge claims, reaching into areas of life where individuals were entitled to free choice. An alternative strategy at the time for dealing with this problem, inspired by Max Weber and promoted by Karl Jaspers, aimed to instil rhetorical self-restraint on academic experts by teaching them how their field's specific history has conditioned their worldview. Nowadays, this approach, especially popular in the social sciences, is called "reflexive," a word that Alvin Gouldner introduced to radicalize American sociology's self-understanding, where the generality of the discipline's discourse masked the specificity of its own history and that of the society that had shaped it.

Two other philosophers who came of age in the 1920s, but whose influence would peak only after World War II, Theodor Adorno and Martin Heidegger, proposed still more drastic solutions to the crisis of epistemic legitimacy in the sciences. Whereas Adorno proposed endless self-criticism of the power relations that normally legitimize knowledge claims, Heidegger advanced a philologically inspired strategy to recover the ground of ultimate being in its original Greek manifestation. Between them, the "made for export" market for "continental" European philosophy was defined in the postwar period. The "crisis" mentality reflected a lost sense of organized inquiry as integral to humanity's collective self-realization as a species. What before World War I had been celebrated as an increasingly rationalized division of cognitive labor had come by the end of World War II to be diagnosed as a debilitating fragmentation of inquiry. Concern about the alienating, if not outright dehumanizing, tendencies accompanying the advancement of science was given its most mature and articulate expression in a series of public lectures in the 1930s by the phenomenologist Edmund Husserl, who canonized the distinction between the sciences' rival "systematic" visions of the world and that of a presumptively coherent human *life-world*. The reconciliation of these two visions captured the imagination of postwar philosophers on both sides of the analytic/continental divide, most notably Wilfrid Sellars and Jürgen Habermas.

Social Epistemology as Bridging the Analytic/Continental Philosophy Divide

An argument can be made that social epistemology has been always central to both analytic and continental trends in modern European philosophy, despite their strikingly opposed ways of characterizing the overall social dynamic of knowledge. This contrast is epitomized in their respective signature phrases for embodied social knowledge: *common sense* and *collective memory.* The difference between the two can be explained in terms of their default theological starting points. Common-sense theorists take the reliability of our mental faculties to be underwritten by our divinely created souls, the repository of a priori knowledge, whereas collective memory theorists take those faculties to be born contaminated by our animal bodies, perhaps as living reminders of original sin. To be sure, both positions have been secularized

over the past 200 years: On the one hand, the seat of common sense migrated from a specifically Christian (as in Thomas Reid) to a more generically Platonic (as in G. E. Moore) sense of the soul; on the other (discussed in more detail below), collective memory has lost its original associations with theodicy (Hegel) to embrace more explicitly materialist conceptions of progress (Marx). The social epistemology of science can be more specifically understood as secular variants of both traditions. So-called naturalists and evolutionary epistemologists, exemplified by John Dewey, treat science as an extension of common sense, whereas self-styled critical rationalists, exemplified by Karl Popper, regard science as being in constant struggle against the errors committed in its own history.

Whereas the common-sense theorist values knowledge that enables one to come closer ("correspond") to the world as it naturally is, the collective memory theorist values knowledge that enables one to stand apart ("self-differentiate") from the world as a second-order entity—ideally, to remake the world in one's own image. The one privileges conformity, the other autonomy as an epistemic virtue: that is, getting it right versus thinking for oneself. The two social epistemologies differ interestingly on induction as a source of knowledge. For the common-sense theorist, induction is a positive mental tendency that reflects accumulated experience, whose sheer survival provides a forward momentum for future epistemic judgments. In contrast, the collective memory theorist regards induction more negatively as the path-dependent drag of the past that fails to distinguish what is truly needed for effective future action. What the former regards as wisdom, the latter treats as prejudice. Important strands of 20th-century psychology have tried to reconcile these two images: Carl Jung's brand of psychoanalysis may be seen as having aspired toward a synthesis, while nowadays it is common to adopt the usage of the cognitive psychologist Daniel Kahneman, describing induction as a "bias," that is, neutral to the two positions.

When James Ferrier, a Scottish importer of German idealism, coined *epistemology* in 1854, he was operating from a collective memory perspective, in explicit contrast to the common-sense tradition dominant in his homeland. Ferrier defined knowledge as a second-order awareness of our mental states, a conscious organization of experience into a systematic whole—recalling that the Cambridge Christian Platonist Ralph Cudworth had introduced "consciousness" into English in 1678 as the seat of personal identity (aka soul), on the basis of which we judge in this life and are judged in the next one. In other words, the mind always already contains a representation of reality's validation mechanism that enables it to recognize the truth even when it breaks with what is expected or desired, a capacity familiar in ethical contexts as "conscience." In the three centuries after Cudworth, this idea was divested first of its theological baggage and then, in the 20th century, even of its psychological baggage. Thus, with the advent of logical positivism, the philosophical logician Alfred Tarski secularized this second-order awareness as a *metalanguage,* or, more simply, *semantics,* that provides the truth conditions for our beliefs, now understood as first-order statements. By the 1970s, thanks largely to Saul Kripke, this idea became the cornerstone of the theory of reference, specifically the concept of *semantic reference.*

In terms of this overall trajectory, Ferrier is a transitional figure whose nod to theology remains in his definition of the goal of knowledge as the *absolute,* which alludes to the Christian idea of absolution from sin. Relevant here is Hegel's background in theology, especially his modeling of the progress of the world-historic spirit as theodicy played out on a temporal stage: that is, evils that God always already justifies from the standpoint of eternity, which we will come to terms with only in the fullness of time. The corresponding vision of the human knower is as an agent who proceeds through the world with, so to speak, a "dirty mind," just as, morally speaking, we proceed with "dirty hands," both of which have the capacity to become "cleaner" over time. More prosaically, epistemology is about separating the wheat from the chaff of our beliefs and integrating the former so that a larger truth emerges that gives direction to our inquiries and provides meaning to our lives. It is what Marxists call the *dialectical method.* Just as sin is inevitable in a world where fallible beings are called to act, so too is error inevitable in a world where we cannot learn anything at all without relying on our fallible senses. In this respect, the Popperian imperative to test our spontaneously formed beliefs is the epistemic equivalent of a moral conscience.

Left hanging in the balance, even in these post-theological times, is the legacy of Hegel's treatment of absolution as a self-reflexively applied process—that is, humanity's collective capacity to absolve

itself of sin/error without explicit divine guidance. This idea has proved a source of hope for ambitious politicians over the past two centuries, most notably Marxists, who have desired to build a "Heaven on Earth." But the view has also had its admirers among those more clearly associated with the canon of scientific epistemology: for example, the pragmatist Charles Sanders Peirce's self-correcting version of scientific inquiry, understood as a collective process that over time "converges" on the ultimate representation of reality—absolute truth. To be sure, Peirce's conception is ambiguous with regard to the nature of validation: Does a maximally comprehensive scientific consensus emerge from a common recognition of the truth, or is the truth itself the product of such a consensus? Put theologically, are we validated *by* or *as* God? The logic of this idea has been explored interestingly within analytic social epistemology by Frederick Will, yet it remains largely neglected by the field's practitioners.

Perhaps the issue on which analytic social epistemology comes closest to a continental sensibility is the distinction in science's contexts of *discovery* and *justification,* which presupposes that truth can be extracted from history to become part of an ongoing collective inquiry. Nevertheless, from a continental standpoint, analytic philosophers show remarkably little concern for exactly how this extraction is supposed to take place in practice. Instead, they have emphasized the output of such an extraction—namely, a canonical representation of a new discovery's place within an established theoretical framework. The overall rhetorical effect is to suggest that a discovery could have been made by other inquirers by other means—such that, say, the fact that Isaac Newton discovered the laws of motion or Charles Darwin the theory of natural selection is incidental to the validity of what they discovered—and that others with rather different training and interests may extend or apply these discoveries in the future. Indeed, such is the process by which science becomes "universal knowledge" in a sense that Hegel would have recognized.

Conclusion: Social Epistemology and the Social Construction of Progress

Analytic social epistemologists such as Alvin Goldman and Philip Kitcher act as if a rational future lies in people coming to the realization that they know more and more about less and less, which will lead them to cede more of their epistemic authority to others. Perhaps Auguste Comte would approve of this trajectory, but the implied epistemic ecology is not sustainable. For even if people are naturally inclined to defer to authority, the funding costs of indulging this inclination will become prohibitive. Put crudely, if we think that we need increasingly specialized research to solve persistent social problems, then a problem in the conceptualization of these problems is implicated—and the best place to locate the source of this second-order problem is the "politics of science." After all, an all too easy way for scientists to justify the need for more research on their own terms is simply to argue that we do not know enough to make sensible policy decisions. Yet, in most cases, we already can make perfectly decent policy decisions—provided that institutional safeguards are in place to enable those decisions to be reversed if they result in more harm than good. In this context, scientists can strategically enhance their employment prospects by playing on the perceived untrustworthiness of politicians as well as any latent aversion to risk in the public at large.

Nevertheless, as Randall Collins has demonstrated in an exhaustive cross-cultural history of institutionalized intellectual life, the levels of conceptual sophistication and empirical breadth demanded of philosophical and scientific inquiry have been subject to ebbs and flows depending on the ambient political economy. There is no unequivocal measure—other than sheer quantity of output—in terms of which it can be said that humanity, or even just the West over the past 200 years, has made progress. However, what is clear is that any expansion or contraction of the discursive space for knowledge production can be—and has been—justified as progressive. Thus, a growing research environment tends to be seen more in terms of opening up new horizons than as exhibiting a dispersion of effort, whereas a shrinking environment gets interpreted as consolidating and focusing effort instead of arresting development. Here, social epistemology could make greater use of Leon Festinger's cognitive dissonance theory of social psychology, especially its key concept of "adaptive preference formation," whereby thwarted expectations provide an opportunity for people to rethink their priorities, in the course of which they reorganize their relationships to the past so as to provide the legitimatory grounds

for embarking on a different future. Indeed, as Kuhn originally observed, this is one of the most important yet still least remarked achievements of scientific textbooks in the aftermath of a scientific revolution.

Social Facts

Émile Durkheim introduced the concept of "social facts" at the end of the 19th century to designate those forms of social thought, feeling, and action that form the distinctive subject matter of sociology. This entry considers the accounts of social facts offered by early social theorists such as Durkheim and Max Weber, notes the general neglect of the concept of sociality in later 20th-century sociology and philosophy of social science, and briefly describes the recent resurgence of philosophical interest in the analysis of social facts.

Origins

Émile Durkheim, one of the founding fathers of sociological science, claimed in the *Rules of Sociological Method* that it was important to identify the distinctive characteristics of social phenomena in order to distinguish the subject matter of the new scientific discipline of *sociology* from the subject matters of established sciences such as psychology and biology. He noted that it is not enough to characterize social facts as facts that are generally distributed in society, since many psychological and biological facts, such as reasoning and drinking, are also generally distributed in society.

Durkheim defined social facts as forms of thought, feeling, and action that are *external* to individuals and that exert a *coercive* force upon them. Unfortunately, in his zeal to validate the scientific status of the new discipline of sociology, Durkheim cited characteristics that are distinctive of the objects of scientific inquiry rather than sociality per se (hydrochloric acid and gravity are also external to individuals and exert a constraining force upon them, but they are not social in nature). Durkheim also treated social facts as statistical facts about social groups, such as the different rates of suicide between Catholics and Protestants documented in his monograph on *Suicide*, but this presupposes some independent account of social groups. However, given the examples of social facts that Durkheim discussed, such as family obligations and religious practices, it is clear that he conceived of

social forms of thought, feeling, and action as forms of human psychology and behavior normatively oriented to the represented psychology and behavior of members of social groups.

In *Economy and Society,* Max Weber, another founding father of sociology, identified its subject matter as social action, defined as meaningful behavior that takes into account the behavior of others and is oriented in its course. Weber is often misrepresented as equating social action with interpersonal action, which would include doubtful social actions such as acts of aggression and rape. Yet his own illustrative examples indicate that he considered action to be social only if it is *normatively* orientated to the represented behavior of members of social groups. Accordingly, like Durkheim, Weber denied that merely imitated actions, such as copying another's superior method of baiting a fishing line, or merely common actions, such as a crowd of people raising their umbrellas to avoid rain, are social actions. Or, as Durkheim put it, social facts are imitated or common because they are social, not social because they are imitated or common.

At the root of Durkheim and Weber's conceptions of sociality is the notion of an individual's psychological connection to other individuals represented as members of a social group, and the normative orientation of an individual's psychology and behavior to the represented psychology and behavior of members of that social group. Thus, both Durkheim and Weber were careful to distinguish between genuinely social groups, within which there is a psychological connection and a normative orientation, such as Catholics and teenage gangs, and mere aggregate groups of individuals who happen to share a common property or set of properties, such as the populations of persons who are ambidextrous or are afraid of spiders.

Durkheim famously affirmed the *supra-individuality* of social groups—the notion that social groups have properties over and above the properties of the individuals who compose them—and Weber famously denied it, leading to their historical representation as champions of *holism* and *individualism,* respectively. However, both in practice treated social groups as virtual realities, as populations of individuals representing themselves as members of groups normatively bound by shared forms of thought, feeling, and action, a view most closely associated with the sociologist Georg Simmel and the Gestalt social psychologist Solomon Asch.

While many early-20th-century social scientists did embrace this conception of sociality, later sociologists abandoned foundational questions about social facts as they focused on developing substantive *structural, functional,* and *structural-functional* explanations of the diverse phenomena they designated as social, while later social psychologists focused almost exclusively on interpersonal interaction and cognition. For many years, philosophers of social science also ignored foundational questions by equating social action with meaningful action and endlessly debating the question of whether meaningful human action could be causally explained.

Recent Developments

In recent decades, however, some philosophers have returned to foundational questions about the nature of social facts. This new focus on sociality was stimulated in large part by Margaret Gilbert's pioneering work *On Social Facts,* in which she explicates the notion of psychological connectedness between members of social groups in terms of populations of individuals conceiving of themselves as plural subjects, bound by joint commitments to beliefs, actions, and the like. Similar accounts have been developed by John Searle, Michael Bratman, and Raimo Tuomela in terms of collective intentionality, shared intentionality, and joint acceptance, respectively, although to date, these analyses have had little impact on mainstream social science compared with their influence on recent trends in the philosophy of social science.

Social Institutions

The entry focuses on a central feature of social life: social institutions. It explains their core features and their types, presents some of the theories of how they arise, and brings to our attention points of contact as well as points of divergence between social institutions, on the one hand, and rules, norms, conventions, and practices, on the other.

A social institution is a normative social structure that influences the behavior of those who participate in it. Institutions facilitate cooperation, and many institutions promote social order. Examples of social institutions are organizations such as the United Nations, the Roman Catholic Church, or the Chinese Communist Party. These structures involve people with particular tasks and roles. Social institutions that are not organizations encompass money, property, and the rules of the road. Institutions are usually closely intertwined with one another. Money and property, for instance, cannot function properly without banks and notaries. The study of social institutions plays a central role in a number of social sciences, including cultural anthropology, economics, political science, and sociology. Social scientists analyze institutions frequently as patterns in behavior or as social rules. They are social constructs that often evolve spontaneously.

Activities and Rules

The institution of money involves a number of characteristic activities, including exchanging cash for goods at a cash register. The regular performance of such an action by a number of people establishes a behavioral pattern or social practice. Institutions are sometimes identified with behavioral patterns. Such analyses leave out the normative dimension of institutions, which differentiates them from social practices. Rules are normative, and they tend to issue in the behavior they regulate. So rules account for both the normative and the behavioral dimensions of institutions. A rule is a social rule when a number of people share the belief that it is in force. Institutions are social because they consist of social rules.

Institutions cannot exist without intentional attitudes such as beliefs, desires, and intentions. They are sometimes identified with (shared) beliefs about which behavior is appropriate, permitted, required, or forbidden in a particular kind of situation, that is, with (interlocking) normative expectations. A customer would be surprised if the item she wants to buy is put behind the counter while the cashier puts the money that she hands to him in his own wallet. Her (presumably shared) expectation would be violated. There might not be more to institutions than such shared normative expectations. Note that the content of a normative expectation is a rule and that a set of interlocking normative expectations is a structure of expectations. So the claim at hand is consistent with the thesis that institutions are social rules and that they are normative social structures that affect behavior.

Social norms are social rules, while conventions are frequently explicated in terms of behavioral regularities. Institutions are similar but not identical to social norms and conventions. Suppose conventions are patterns in behavior that are arbitrary in some sense (as in David Lewis's work). Then driving on the left side of the road is a convention in this sense. This regularity need not have a normative status. So it is not the case that all conventions are social institutions. Furthermore, a rule that issues in a certain behavioral regularity can be an institution without being arbitrary. There is nothing arbitrary about being obliged to do as promised. Hence, not all institutions are conventions. It may be that all social norms are institutions, even though not all institutions are social norms. Social norms might be general in the sense that they apply to anyone in a particular situation, for instance, to anyone who has made a promise. Institutional roles apply only to those who occupy the relevant role. Only the president, for instance, has the right to veto a law. Note that institutions do not only constrain but also enable actions. Without money, for instance, we would still be operating in a barter economy.

Spontaneous Evolution and Social Construction

Institutions in general and economic institutions in particular are often said to evolve spontaneously

in the sense that they are the unintended consequences of individual actions (Friedrich Hayek is the prime exponent of this thesis). They arise and survive because they facilitate cooperation and are advantageous to their participants. This is captured by models that represent institutions as solutions to social interaction problems (game-theoretic equilibria). Such spontaneous evolution models explain how particular institutions have evolved. Many institutions, however, are deliberately created or designed. It is not obvious that spontaneous evolution models are useful for understanding those features of institutions that were deliberately created. It is sometimes argued that such a model explains how a deliberately created institution *might* arise or why it remains in existence.

Institutions are social constructs in more than one sense. They are socially caused or produced. Furthermore, they are socially constituted in the sense that an institution exists only if it is agreed or collectively accepted to exist. Money, for instance, is a social construction in that certain items are money (if and) only if they are collectively accepted to be money. John Searle argues that the very existence of institutions is to be accounted for in terms of constitutive rules. The structure of constitutive rules, on his theory, is "X counts as Y in context C." Certain pieces of metal (X) can, for instance, count as money (Y) in a particular country (C). The notion of a constitutive rule is useful for explicating how people confer an institutional status on an action, person, or object when they collectively accept that the relevant entity has that status (by virtue of which, some would say, certain regulative rules apply to it). Searle's "counts-as" locution captures the constitutive sense in which institutions are socially constructed.

Social Interactions: Individual Decision and Group Formation

This entry introduces the growing field of social interactions, created by economists and econometricians to study the effects of peer groups on individuals' decisions. The theoretical and empirical advances in this field help explain a number of otherwise puzzling social phenomena and offer empirical support to the influence of group actions and beliefs on individuals' choice. This novel approach to the study of social phenomena and individual action is an important development that enriches the philosophy of the social sciences, while at the same time showing the significance of the interconnections among social sciences.

Background

The study of social interactions phenomena starts roughly with Gary Becker's celebrated 1974 article on social interactions in the *Journal of Political Economy* but has received prominence since Charles Manski's pathbreaking elucidation, in the *Review of Economic Studies* in 1993, of the pitfalls of quantitative analysis in that area. Additional major contributions since then by William Brock and Steven Durlauf have succeeded in building new links with social capital and with the statistical mechanics, complexity, and emergence literatures.

The decisions of individuals who share a social milieu are likely to be interdependent. Recognizing the exact nature of such interdependence in various settings and measuring empirically the contribution of social interactions to observed choices poses complex methodological questions. Resolving such questions can be critical for a multitude of phenomena in economic and social life and for public policy. The variations in crime rates across cities in the same country and what can be done about influencing

them, the emergence and persistence of residential segregation, and its variation across different countries are all in principle issues that may be examined as social interactions phenomena.

Individuals care about private outcomes and consumption of private goods; they may value how their own consumption of goods influences others or care about the kinds of cars others drive, the incomes of their friends, or the education acquired by their friends' children. The latter type of effect is an interpersonal effect, known as *endogenous* social effect (or interaction), because it depends on *decisions* of others in the same social milieu. Individuals may also care about the personal and demographic characteristics of others, and the associated effects are known as exogenous social or *contextual* effects. In addition, individuals in the same or similar individual and social settings tend to act like one another because of factors they share in common. Such an interaction pattern is known as *correlated* effects. These canonical distinctions, due to Charles Manski's 1993 paper on the "social reflection problem," have helped streamline the literature.

Distinguishing empirically between endogenous, contextual, and correlated effects can be critical for policy analysis, as explained further below, and has drawn considerable attention in the literature.

When individuals belonging to the same social group are influenced by the actions of others, even if they take those actions as given, their actions are interdependent. The actions of all group members are determined simultaneously, and the actions of each group member depend on her own as well as everyone else's characteristics. The theoretical and empirical tools that economists have developed break this possibly infinite regress.

By choosing where to live or what group to belong to, individuals choose in effect their neighborhood effects, or their social context, more generally. Such choices involve underlying factors that may be in part unobservable to the analyst and, therefore, require making inferences among the possible factors that contribute to decisions.

Analytical Framework

Let individual i's decision, say years of education, ω_i //I////I//, be a linear function of a vector of observable individual characteristics, X_i, of a vector of contextual effects, $Y_{n(i)}$, which describe i's neighborhood, $n(i)$, and of the expected value of the ω_j of the members of neighborhood $n(i)$, $j \in n(i)$, that is, the expected years of education of all others in the neighborhood. It is straightforward to incorporate social interactions into economic models in a manner that is fully compatible with economic reasoning and obtain a behavioral equation such as

$$\omega_i = k + cX_i + dY_{n(i)} + Jm_{n(i)} + \varepsilon_i, \tag{1}$$

where ε_i is a random error and k a constant. Ignore for the moment the fact that individual i may have deliberately chosen neighborhood $n(i)$. The critical next step is to assume *social equilibrium* and that individuals hold *rational expectations* over $m_{n(i)}$. So taking the expectation of ω_i and setting it equal to $m_{n(i)}$ allows us to solve for $m_{n(i)}$. Substituting back into Equation 1 yields an expression for individual i's outcome in terms of all observables:

$$\omega_i = \frac{k}{1-J} + cX_i + \frac{J}{1-J}cX_{n(i)} + \frac{d}{1-J}Y_{n(i)} + \varepsilon_i. \tag{2}$$

This simple linear model confirms that endogenous social effects generate feedbacks that magnify the effects of neighborhood characteristics. That is, the effect of a unit increase in $Y_{n(i)}$ is $d/(1-J)$, from Equation 2, and not just d, as one would expect from Equation 1.

Identification

Charles Manski was the first to emphasize that the practice of including neighborhood averages of individual effects as contextual effects, $Y_{n(i)} = X_{n(i)}$, may cause failure of identification of endogenous as distinct from exogenous interactions, that is, estimating J separately from d. That is, if the neighborhood attributes *coincide* with the neighborhood averages of its inhabitants' characteristics, or $Y_{n(i)} = X_{n(i)}$, then regressing individual outcomes on neighborhood averages of individual characteristics as contextual effects allows us to estimate a function of the parameters of interest, $(Jc + d)/(1-J)$, the coefficient of $X_{n(i)}$ in a regression according to Equation 2. A statistically significant estimate of this coefficient implies

that at least one type of social interaction is present, that is, either J or d, or both are nonzero. This is known as Manski's *reflection problem,* which is specific to *linear* models: The equilibrium value of the outcome $m_{n(i)}$ is linearly related to the neighborhood attributes entering the causal model, and therefore its effect on individual outcomes may not be distinguishable from their "reflection."

Complicating the basic model in natural ways, as by assuming correlated effects—the performance of different students in the same class is affected by the quality of their teacher, which is unobservable, over and above peer effects from classmates—introduces additional difficulties with identification, even if individuals are randomly assigned to groups.

If it is plausible to exclude some neighborhood averages of individual covariates from the causal model, then identification may be possible. Also, if nonlinearities are inherent in the basic-model specification, identification again may be possible, even in the case where the contextual effects coincide with the neighborhood averages of individual characteristics. An interesting consequence of endogenous social interactions is the amplification of differences in average neighborhood behavior across neighborhoods. In their 2003 study, Edward Glaeser, Bruce Sacerdote, and José A. Scheinkman directly used such patterns in the data to estimate a *social multiplier.* This is defined, for a particular fundamental determinant of an outcome, as the ratio of the total effect of a change in its value—which includes a direct effect on an individual outcome plus the sum total of the indirect effects through the feedback from the effects on others in the social group—to the direct effect. From Equation 1,

$$\frac{d}{1-J}\,\frac{1}{d} = \frac{1}{1-J}\,. \tag{1}$$

This social multiplier is particularly useful in delivering ranges of estimates for the endogenous social effect and when individual data are hard to obtain.

Phenomena like diffusion of innovations, herding and adoption of norms or other institutions, and transmission of job-related information are conceptually related to social interactions. They can be modeled by modifications of Equation 1.

Empirical Findings of the Effects of Social Interactions

Several researchers have sought to identify social interactions by exploiting uniquely suitable features of observational data, such as so-called natural experiments. For example, Bruce Sacerdote, in his 2001 article in the *Quarterly Journal of Economics,* exploits the fact that at Dartmouth College, freshman-year roommates and dorm-mates are randomly assigned. Sacerdote applies Equation 1 and posits that an individual's grade point average is a function of an individual's own academic ability prior to college entrance (an own lagged effect), of social habits, and of the academic ability and grade point average of his roommates. He finds that peers have significant impacts on each others' grade point average and on decisions to join social groups such as fraternities. It is notable that strong peer effects in student outcomes are present even among highly selected college students in close proximity to one another, even though they may be otherwise quite homogeneous.

Education policy and the functioning of schools depends critically on whether students benefit from classmates with different characteristics and academic performance and whether the effect is different depending on whether one's classroom peers are more or less able. This is critical for deciding whether or not students should be "tracked"—that is, administratively segregated in terms of different performance. It is thus interesting to establish whether peer effects exist in classrooms and schools.

The demographic composition of classrooms matters. For example, Peter Arcidiacono and Sean Nicholson reported in the *Journal of Public Economics* in 2003, using data on all students admitted to U.S. medical schools in a particular year, that female students benefit from attending medical schools that have other female students with relatively high scores on the verbal reasoning section of the Medical College Admission Test.

Randomized field experiments, like the Moving to Opportunity (MTO) conducted by the U.S. Department of Housing and Urban Development in several large U.S. cities, have also been used to estimate social interaction effects. The experiments offered poor households (chosen by lottery from among residents of high-poverty public housing projects) housing vouchers and logistical assistance

through nongovernmental organizations for the purpose of relocating to precisely defined "better" neighborhoods. Several studies based on data from these experiments show that outcomes after relocation improved for children, primarily for females, in terms of education, risky behavior, and physical health, but the effects on male youth were adverse.

Nonrandom Sorting

The presence of nonrandom sorting due to factors that are inherently unobservable is a major challenge for the econometric identification of social interactions models. Several papers by Brock and Durlauf showed that this can be an advantage by recognizing that self-selection itself by being a decision—that is, that individuals choose their neighborhoods—makes $n(i)$ in Equation 1 endogenous. Estimating a neighborhood selection rule and correcting for selection bias by means of the so-called Heckman correction term introduces an additional regressor in the right-hand side of Equation 1, whose neighborhood average is not a causal effect. In a 2008 article in the *Journal of Urban Economics,* Yannis Ioannides and Jeffrey Zabel reported results from implementing this method, using micro data for a sample of households and their 10 closest residential neighbors from the American Housing Survey and contextual information for the census tracts in which those households reside. They report a very significant and large endogenous social effect in housing demands—individuals care about the housing consumption of their neighbors—along with very significant contextual effects in the form of unobservable group effects. Several other studies have sought to use instrumental variables to account for self-selection. Still, the identification of valid instruments is often quite hard and requires deep understanding of the actual setting.

Philosophical Issues

Recognition that social effects on individuals' decisions matter brings up a number of philosophical considerations. One is whether or not it matters for free will if individuals are influenced by the actions of others and if they have chosen to be influenced by them versus if they have not. Freedom of association leads to the deliberate formation of social groups and communities. This helps individuals benefit from associating with certain other individuals with desirable attributes and helps distance themselves from others with undesirable attributes. The existence of, say, conformism (or nonconformism) within social groups is an outcome of choice that underpins group formation. A second philosophical consideration is the possibility that social interactions are emergent properties in that they apply at an aggregate level but lack individual analogs, and therefore they are not describable at the individual level. When social interactions may be understood as emergent properties of social groups, delicate issues of causality may be raised. Causality in the presence of emergence is not well understood and deserves attention in future research.

Conclusions

Social interactions are ubiquitous, and estimating their effects has motivated important methodological advances in theory and econometrics. With ever-improving data availability, social interactions empirics will rely increasingly critically on careful theorizing that involves precise definitions of social interactions and also utilizes tools and results from psychology and sociology to define appropriate boundaries and to exploit data from different sources.

Social Networks

As with other social-scientific terms, there is a degree of definitional ambiguity, debate, and dissonance about the exact meaning of "social networks." The term *social networks* refers to individuals linked to each other by specified social relations. Social networks are of interest because they imply that social connections among people do matter and, accordingly, have to be studied by social science. For instance, while "personalized exchange among many agents" may encompass the idea of a network, at a more general level, *networks* are understood as visualizations of association that aim at mapping social relations and eliciting social structures and their properties. Accordingly, social networks have been applied not only as analytical devices but also, more descriptively, as ways of organizing relations among agents. This is being done in increasingly complex as well as interesting ways.

The notion of social networks has been, explicitly or implicitly, one of sociology's foremost concepts. Starting with classical sociology (the work of Émile Durkhein and Georg Simmel) and drawing on similar interests in social anthropology and social psychology, the concern with social connections and social interaction to which social networks refer has remained unbroken. Social "networks" draw from a metaphor that has to do with the imagery of "fabric." A fabric owes its unitary appearance and properties to the tightly interwoven threads that constitute it. The metaphor extends this idea to social relations among humans: The invisible but nonetheless real and meaningful social relations and social interactions, in threadlike fashion, are interwoven in the form of social networks. They may form smaller or larger groups in variable ways and manage to structure them. In this sense, social networks are but a shortcut for visualizing and conceptualizing social relations. Obviously, social networks differ fundamentally from other kinds of networks, whether these are technological in character, for instance, the Internet, which has a network-type architecture and operation, or biological, for example, the circulatory and nervous systems.

The study of social networks, with its beginnings as a useful metaphor, has developed into a recognizable subfield with its own specialized terms, methods, and literature. As examples of specialist terminology, it is worth mentioning the use of concepts such as the *ego* (meaning the focal individual) and the *node* (meaning intersections or points of contact that link [*tie*] two or more egos together by one or several types of *social relations*). In addition, terms and notions such as those of *point centrality* (local, global, and betweenness), *transitivity, homophily, bridge, clique,* and several others have been developed and deployed to describe the state of affairs within small-scale and large-scale social networks and the relations and influences exerted within and between them. Thus, for example, homophily, which refers to the tendency to associate with others who share similar traits, has been used to indicate similarity that has consequences in terms of the connections that it helps breed. It inheres in network ties of every kind, as in marriage or friendship, and renders them homogeneous in terms of

several of their features, as Miller McPherson and colleagues have shown.

Furthermore, to facilitate the study of social networks in the handling of relational data, several statistical packages have been developed, such as UNINET, STRUCTURE, and PAJEK. These form part of the trend toward mathematized structural analysis of social relations (something that not everyone welcomes).

Social Capital, Trust, and Network Society

One area in which nonmathematized social networks exert their influence has been that of social capital. According to Robert Putnam, social capital requires a continuous effort of "sociability" and continuously repeated contacts during which mutual recognition by the group members is confirmed in order to sustain the group's cohesion. Thus, social capital and its formation are perceived to be based on social networks. Social capital is involved in the density of ongoing and permanent social relations within social networks and in the prevalence, more or less conscious, of a trusting environment and relations, which themselves are generated by functioning institutions. Besides social capital, trust, too, is operative in analyses of social networks: Trust is conceived as something that operates as a functional prerequisite for the unfolding of social life organized within networks, in the absence of which it would not ensue. Thus, the "network form" emerges as quintessential for continuing human social interaction.

Social networks are the bedrock of another idea that has been advanced by Manuel Castells, namely, that of a "network society." Castells links the social network character of human social activity and organization with the network structure of many of the contemporary digital networking technologies that have become available over the past 25 years. The ensuing human–technological complex empowers social networks in new and unanticipated ways; it allows the overcoming of the limitations of older forms of network organization by expanding the horizon and enabling a variety of reconfigurations that transcend nation–state borders, thereby making possible the globalizing and global expansion of this network society. Hence, Castells claims that the human–technological interface now sets the tone of a new, evolving kind of society. This view has been criticized, however, as one that invites the fallacy of technological determinism.

Social Networks and Economic Sociology

A renewed interest in social networks has surfaced with the re-emergence of economic sociology since the 1970s. Social networks and their analysis have been utilized widely in studies as thematically varied as those on business and work organizations, processes of innovation, markets (in particular labor markets), entrepreneurship, interfirm relations, and socioeconomic development, and in eliciting the role of social capital and trust for economic purposes. Nor has the level of analysis been unitary. Consequently, it may assume diverse forms, such as analysis at the level of the individual actor around whom the network revolves (actor centrality), that of the networks' structure (systemic), or that concerned with the flows within social networks.

An example of the use of social network analysis in teasing out regular structures of social ties, and hence social-structural patterns of social behavior, is found in the work of Mark Granovetter, who studied patterns of job searching. Subjects were asked how they managed to obtain their regular job and were required to list a number of channels through which they obtained the relevant information for applying for the job, such as recruiting agencies, official announcements, ads in the press, and so on. It became apparent, however, that a considerable number of interviewees mentioned obtaining the relevant job-related information from a person who was close to them—a "strong tie" in social network terminology. Hearing about the job through an intermediary—a person little known to them, a "friend of a friend," in other words, a "weak tie"—was another important way to elicit such information. Accordingly, the social networks into which one is embedded offer opportunities but also may block them by imposing constraints. Thus, job seekers of low socioeconomic status (SES) cannot utilize their strong or weak ties, which also are low SES, to identify and safeguard a high-level job; here, social class acts as a filter or barrier.

On the whole, social networks that express patterns of social interconnection and interaction imply that social structures—repeated social

practices—take precedence over the individual, exerting not an absolute but still a constraining influence.

Social Neuroscience

Neuroscience refers to the collection of disciplines concerned with the structure and function of the brain and, more generally, the nervous system. The topic of study is so complex that it requires disparate basic, clinical, and applied disciplines to cover the terrain. Within neuroscience are crosscutting paradigms—general perspectives that underlie a range of theories and methodologies in the field. The fulcrum for some of these perspectives rests squarely under constituent structures at different levels of organization, whereas the fulcrum for others emphasizes the functions of the brain and the nervous system. Illustrative of the latter are the complementing and increasingly complex fields of (a) behavioral, (b) cognitive, and (c) social neuroscience.

In (a) behavioral neuroscience, the nervous system and brain are viewed as instruments of sensation and response. Research representing this perspective tends to focus on topics such as learning, memory, motivation, homeostasis, sleep and biological rhythms, and reproduction—and on the neural mechanisms underlying these behavioral functions. (b) Cognitive neuroscience emerged as a distinct functional perspective in which the brain is viewed as an information-processing organ, with a focus on topics such as attention, perception, representations, decision making, memory systems, heuristics, reasoning, and executive functioning—and on the neural mechanisms in the human brain that underlie these representations and processes.

(c) Humans are fundamentally a social species, however, and social species, by definition, create organizations beyond individual members. These superorganismal structures evolved hand in hand with psychological, neural, hormonal, cellular, and genetic mechanisms to support them because the consequent social behaviors helped these organisms survive, reproduce, and care for offspring long enough so that they too reproduced, thereby ensuring their genetic legacy. Social neuroscience represents yet another broad perspective that seeks to understand these neural, hormonal, cellular, and genetic mechanisms and their relationship to psychological, behavioral, and social levels of organization.

For instance, according to the "social brain" hypothesis, the complexities of the social environment contributed to the complex structure and function of the primate brain. As such, the perspective of social neuroscience extends the traditional approach in the neurosciences, in which the solitary organism has been the focus of investigation, by additionally examining the social entities and systems of which the organism is a member. In order to accomplish this goal, social neuroscientists apply a multilevel approach to examine factors at levels of organization ranging from the molecular to the cultural.

In this entry, we will discuss some of the methodologies and disciplines utilized in social neuroscience,

while highlighting some of the current research in the field.

Interdisciplinary Perspectives

Given the complexity of the subject matter, social neuroscience is an inherently interdisciplinary field that emphasizes animal models as well as studies of humans. Through studies of nonhuman social animals such as honey bees, rodents, and primates, social neuroscientists have examined the biological mechanisms of social behavior through a range of manipulations, including pharmacological, neurophysiological, and genetic. Owing to the common dependence of members of social species on extraorganismal structures, the neural and neuroendocrine mechanisms that have been shaped by social demands are often conserved across species. Animal models, therefore, play an important role in the field because they permit a broader manipulation of biological factors and the collection of brain data than would be possible in normal human participants. For example, studies of the monogamous prairie vole and the highly related, but polygamous, montane vole have led to the discovery that variations in neuropeptide systems, specifically the oxytocin receptor system, mediate the variation in social structure between the species of vole, such that the higher the receptor density in reward areas in the brain of prairie voles, the more monogamous their behavior. This work has led to research indicating that polymorphisms in genes coding for the oxytocin receptor play a role in the sociality of numerous organisms, including birds, primates, and humans.

Humans are also a unique social species in that our social institutions, civilizations, and cultures are highly developed; our territorial reach knows few boundaries; and our selection of and impact on the environment in which we live constitute an active and purposeful process. Studies of humans, particularly those that permit calibration with animal models, also play an important role in the field. For instance, human studies often utilize neuroimaging techniques, which are correlational in nature, or lesions, which can lack specificity. To address these limitations, teams of investigators using both animal and human participants to test theoretical hypotheses are increasingly common in the field. Admittedly, this integration is sometimes made difficult by differences in methodology and in the levels of organization that are investigated. Moreover, a biological mechanism underlying a social behavior in an animal model may be only a part of a more complex, multifarious mechanism in humans, which means that the differences as well as the similarities between human and animal research have the potential to advance our understanding.

Research on the neurotransmitter oxytocin is illustrative. As previously noted, the role of oxytocin in social interaction was observed in a number of animal studies prior to its being investigated in human studies. In animal studies, oxytocin has been observed to play a role in a wide range of social behaviors, including pair bonding and social recognition. The research in animals provided an initial understanding of the mechanisms through which oxytocin acts in neurological systems. Human studies now indicate that oxytocin is an integral part of a large number of behaviors, including trust, perceived social threats, and reactivity to stressors. These findings, in turn, have raised new questions regarding the actual neurological mechanisms that can be addressed in animal research.

Constructs, Component Processes, and Computations

Social neuroscience is complex, in part because it entails analyses across multiple levels of organization. Such analyses bring not only opportunities but also challenges. One such challenge is that there is more than one sufficient cause for many of the phenotypes or social behaviors that are of interest. Studies that focus on single causes can appear to have large effects in controlled experimental paradigms but later can be found to have small effects in naturalistic settings or when other factors are no longer controlled. For example, in studying drug abuse, the effects of opiates on an individual are dependent upon both genetic factors, such as individual variance in the opioid receptor system, and environmental factors, such as the social context in which the drugs are administered. Both factors have been found to interact with drug abuse at the level of opioid receptors in the brain, and thus both must be considered in order to fully understand the construct of interest.

The biological mechanisms underlying many social-psychological constructs, such as empathy,

attachment, or the "self," are not instantiated in the activity of a dedicated neuron or even of isolated neural regions but rather involve multifarious circuits of neural activity. This is due, in part, to differences in what constitutes a category across levels of organization. For example, lesion studies of the concept of the self have revealed that some lesions compromise episodic aspects of the self whereas others affect semantic summaries of traits. Similarly, neuroimaging studies of self-awareness and self-referential processing reveal widely distributed regions of neural activation, including the medial prefrontal cortex, ventrolateral prefrontal cortex, dorsolateral prefrontal cortex, bilateral temporal poles, and insula. Improvements in our understanding of the neural mechanisms underlying the construct of the self will likely be advanced by a better specification of the component processes that go into this complex psychological construct. For example, even a concept as specific as self-referential processing is likely to need to be decomposed into component processes (e.g., self–other differentiation, similarity to self) and neural computations before the underlying neural mechanisms are clearly delineated.

The Prospects of Social Neuroscience

Social neuroscience is a growing field with exciting potential for research that affects all aspects of life. There are clear commonalities between social neuroscience and other fields in the neurosciences, and the former provides a unique perspective in which multilevel analyses are utilized to understand the complex relationships between social behaviors and the underlying neurobiological mechanisms. The perspective of social neuroscience, which focuses on interacting brains, provides insights not apparent from analyses of a solitary brain. For instance, the notions of determinism and monism when applied to a solitary brain lead to the conclusion that consciousness is epiphenomenal. The premise of social neuroscience is that the study of the human brain is incomplete when treated as a solitary organ. When the brain is viewed within a social context—that is, within a context of interacting brains—the material mechanism by which consciousness plays a role in subsequent brain states is revealed. From the perspective of social neuroscience, language evolved to communicate and coordinate with conspecifics rather than simply to talk to oneself. When communicating with others, our brain spontaneously attempts to predict the present and future behavior of others through certain processes, such as social cognition, mentalizing, and theory of mind—although, but perhaps better than chance, we are far from perfect mind readers. This imperfection means that when we communicate our conscious states to others, our subsequent brain states are not entirely predicted by the brain states that gave rise to our conscious expression. Specifically, our subsequent brain states are in part determined by our prior brain states and in part by the brain states that result from interactions with other brains—other brains whose influence on our subsequent brain states are themselves determined in part by the communication of aspects of our consciousness. One might counter that a person's communication is itself the result of prior and ongoing brain states, so that it is the brain states, and not aspects of consciousness, that are being communicated. The case of the display screen on a computer helps clarify why this output is instrumental, even if its influence is mediated through interactions with other humans.

Thus, because our brain underlies communication with other brains, that is, because it is social, the conscious beliefs and intentions we communicate to others have an impact on the brains of others that was not entirely predictable by their prior brain states, and their responses to us influence our subsequent brain states in ways not entirely predictable by our prior brain states. Consciousness in this social context may therefore have the potential to serve a functional role through a mechanism that adheres to the principles of monism and determinism.

Social Norms

The Latin word *norma* appears in slightly varying orthographic forms in many languages: in Spanish and Portuguese as *norma;* in Russian as норма; in English, Swedish, and German as *norm* or *Norm;* and in Finnish as *normi*—with the sense of a rule, standard, pattern, or model. Social norms are rules; in a wide sense, they may be defined as patterns of behavior accepted, expected, or required in a certain group. Social norms determine how a citizen or a member of a group may act or ought to act in various situations. Norms do not exist in isolation but as elements of norm systems, whose function is to guide the behavior of a population of norm-subjects.

This entry first introduces what norms and norm-contents are; then focuses specifically on social norms, reviewing various kinds of norms; and ends by explaining social norms in contradistinction to social conventions.

Norms and Norm-Contents

Conceptually, we should distinguish between a norm, the content of a norm, a norm-formulation, and the way the norm-content is presented to a norm-subject or some other audience. Norms are temporal entities that begin and cease to exist within a population of norm-subjects, but a norm-content is an abstract entity, a normative (*deontic*) proposition that can be shared by different norms belonging to different systems of norms. A norm-content is expressed in a norm-sentence (norm-formulation), and it can be presented in different ways—normatively (prescriptively), to direct the norm-subjects' behavior, or descriptively, as information about the content of a system of norms in force in a certain group.

Social Norms

Social norms are distinguished from legal and moral norms, and they must also be distinguished from practical norms, which inform an agent about the necessary or best means of achieving his or her objectives and satisfying his or her interests. Social norms are informal rules; unlike legal norms, they lack an authoritative codification and are not created by governmental acts of promulgation. In this respect, they resemble moral rules. There is a great deal of overlap among social, legal, and moral norms; both social scientists and moral philosophers are interested in the *mores* of societies, and socially significant norms tend to acquire an authoritative codification in the legal system of a society. Social scientists are interested in providing descriptive and explanatory accounts of the norms in various groups, and books on etiquette and good manners are attempts to formulate a code of behavior for the "best society." The author of such a book may acquire the status of an authority on good manners, and the book is then regarded as if it were an authoritative codification of socially acceptable or desirable forms of behavior.

Cristina Bicchieri has defined the concept of social norm in terms of two conditions, which may be called the *belief condition* and the *conditional-preference* condition. According to these conditions, a rule of behavior R is a social norm in a population or group P if and only if (1) almost all or sufficiently many members of P believe that almost all members of P comply with R and (2) almost all members of P prefer to comply with R, provided that almost all other members of P comply with R. The belief in the existence of a norm may also involve the belief that other members of P prefer one to comply with the norm and that failure to comply may engender

sanctions. This account shows two significant features of social norms. First, social norms, like many other social entities, are partly constituted by the shared beliefs and intentions of the members of a population or social group, the norm-subjects. And second, a norm can exist in a group even in the absence of general compliance if each subject expects and prefers the other members to comply with the norm and believes them to have similar beliefs. For example, there is a strict social requirement for marital fidelity among U.S. politicians, even though most of them might in fact be unfaithful to their spouses.

Kinds of Norms

Norms can be divided into mandatory norms, permissive norms, and power-conferring norms. *Mandatory norms* are requirements (obligation norms) or prohibitions; the content of such a norm is an ought-proposition, a proposition to the effect that the subject ought to or has an obligation to do or not do something. Noncompliance with a mandatory norm is associated with a ("negative") sanction or a threat of a sanction; the sanctions may be severe or not more than expressions of social disapproval, and they tend to become internalized among the norm-subjects. Mandatory norms can be said to function as exclusionary reasons, that is, reasons for disregarding other possible reasons for action in a situation to which the norm applies; thus, they help coordinate behavior in a group and increase its predictability. Social scientists often use the term *sanction* for "positive" sanctions, that is, rewards, as well as "negative" sanctions. If there is a reward attached to the performance of an action (type) A but no negative sanction attached to its omission, A cannot be said to be governed by a mandatory norm: In such a case, A is a meritorious action, not a required action. We might say that A is governed by a *merit norm* and regard merit norms as a subclass of permissive norms.

Bicchieri's characterization of social norms applies to mandatory or quasi-mandatory norms, that is, norms according to which a certain action is required by R in a situation S. *Permissive norms* may provide exceptions to mandatory norms or simply describe socially acceptable courses of action. Both permissive and mandatory norms are often associated with certain positions or roles; for example, only parents may punish their children for bad behavior. A *power-conferring norm* gives a norm-subject the normative power to create norms for other subjects. These norms are also usually attached to certain positions or roles; for example, according to some systems of social norms, people can create new rules of behavior for their own children, but they do not have the same normative power with respect to the children of others.

Social Norms and Conventions

The concept of social norm is closely related to that of social convention, and it has been argued that social conventions are norms, regularities to which the subjects who follow the convention believe they ought to conform; thus, conventions have normative force. According to David Lewis's (1969) well-known analysis of the concept of (social) convention, a convention is an equilibrium solution to a coordination problem, that is, a combination of the actions of different agents (subjects) in which each agent has done as well as he can, given the actions of the other agents. Once such an equilibrium has been established, it tends to become a norm: As Lewis argues, "One is expected to conform, and failure to conform tends to evoke unfavorable responses from others" (p. 99). On the other hand, not all norms are conventions. The existence of a convention requires general (but not necessarily universal) compliance with the convention among the subjects, but as was pointed out above, a social norm can exist without general conformity. Thus, conventions, unlike social norms, can be said to be essentially *behavior dependent*. Moreover, it is clear that not all social norms can be seen as solutions to coordination problems. For example, some dietary norms may have originated from the practical interest to avoid illness, and such practices tend to retain their normative force even when the original reason for them has ceased to exist. There are a multitude of theoretical models based on rational choice theories and evolutionary game theory for explaining how norms and norm systems emerge, are preserved, and change (see, e.g., Axelrod, 1986; Bicchieri, 1993 & 2006; Skyrms, 1996; Ullman-Margalit, 1977).

Social Objects Versus Technical Objects

The category of *objects* has received much attention in recent years. Various contributions, such as the actor-network theory of those such as Bruno Latour and the object-oriented philosophy of Graham Harman, have done much to return objects to the very center of social theorizing.

The specific focus of this entry is on the terms *technical object* and *social object*. Each of these terms has been used in various ways. For example, the term *technical object* features prominently, if quite differently, in the works of philosophers of technology, such as Martin Heidegger and Gilbert Simondon, while the term *social object* appears in a range of accounts from symbolic interactionism (referring to objects that we "give meaning to in our interactions") to marketing (where social objects are those objects that "bring us together").

The focus of this entry is specifically upon uses of the terms *technical object* and *social object* that have come to the fore in attempting to capture, or elaborate, a particular distinction, namely, that between activities such as using a hammer to mend a shutter and using a passport to gain access to another country. Although both kinds of activity involve the use of material objects for some clearly defined purpose, the first activity involves only, or primarily, the use of the physical properties of the object itself (e.g., the weight or hardness of the hammer), whereas the second activity involves the use of something other, or much more, than this.

In considering the nature of this distinction, two main questions arise. First, exactly what kinds of *causal* powers and properties are we drawing upon when objects such as hammers, nails, machinery, passports, identity cards, money, and so on, are used, and where are such powers and properties located? Second, are such objects the same kinds of things, being used in different ways, or is there a useful *distinction* to be made between the *kinds* of objects that can be captured by the terms *technical objects* and *social objects?*

This entry identifies three strands of social theory that either directly address or have important implications for the nature of the distinction noted above

and the questions raised. These strands are distinguished by a focus upon each of the following: (a) the intrinsic and extrinsic causal powers of objects, (b) the technical and social function, and (c) the signaling properties of different objects.

Intrinsic and Extrinsic Causal Powers

In the first strand, it is argued that we use objects by harnessing their causal powers or properties and that different objects can be distinguished in terms of the kinds of causal powers they possess. Thus, when we use a hammer to mend a shutter, we are primarily using powers *intrinsic* to a hammer to perform the task at hand, such as its weight, the proportion of its handle to its head, and so on. Crucially, the properties of the hammer that we are harnessing, such as the hardness of iron and steel relative to wood or plastic, are pretty much the same in all cultures and at all times; these properties do not depend upon social relations.

In contrast, when we use social objects, we appear to be drawing upon much more than the object itself. Using a passport to go through customs involves the harnessing of *different* powers from those possessed by the passport as a physical object; whole sets of relationships (between citizens and nation-states, between states, between the particular traveler and the customs official at the gate) are drawn upon when using a passport. In this sense, we can say that much of what is harnessed is *extrinsic* to the object itself; the user harnesses properties that some object has by virtue of its relation to other things, people, collectivities, and so forth.

One particularly developed example of this position is to be found in the work of Clarence Ayres. Ayres, drawing upon the work of Thorstein Veblen, is primarily concerned with the role of technology in economic progress and, in particular, with a "dichotomy" between technology and institutions. At the heart of the dichotomy is a distinction between what Ayres terms *tools* and *icons* (or sometimes *fetishes*). Whereas tools and icons are similar in that they are material "things" used to accomplish certain ends, the "effectiveness" of an icon depends upon the social status, standing, or relationships of the tool user, while a tool is an artifact that will perform in much the same way whoever uses it.

From this basic distinction, Ayres elaborates an ontology of objects, which he uses to account for differences in growth and development. Technical objects (tools) have a range of properties (combinability, travel, durability, etc.) that give them a transcultural and dynamic character. Social objects (icons and fetishes) have properties too, which can be harnessed in a variety of different ways, but the (extrinsic) causal powers of such objects are not isolatable from the communities within which they have meaning and potency. For Ayres, the use of social objects tends to put a break on economic development, where their use entrenches conservative and "past-binding" attitudes and ways of doing things. In contrast, the use of technical objects, much more conducive to recombinability and so increased technological dynamism, tends to lie at the heart of increased technological and economic development.

The focus in Ayres's account, however, is primarily upon technical objects, and the particular manner in which the extrinsic power of social objects is thought to operate is left largely unaddressed.

Technical and Social Functions

A second, quite different strand maintains that the difference between activities such as mending shutters and passing through customs is to be understood in terms of the different *uses* of such objects rather than in terms of differences in the objects themselves. More specifically, such activities can be distinguished by the kinds of *functions* (in particular technical functions and social functions) that are ascribed to the different objects in use. A well-known example of the different kinds of function ascribed is provided by Lewis Binford. The crucial point here is that the same object can always be viewed under the aspect of its technical, social, or ideational functions. However, the problem of specifying the differences between these kinds of function (under what circumstances and why one function should be understood as technical and another as social) is left unresolved.

In this context, it is worth noting the work of John Searle on social institutions. For Searle, the attempt to maintain a distinction between social and technical *objects* leads to a series of contradictions. If we admit that the £5 note is at the same time a piece of paper and legal tender, Searle argues, then we must accept that we do not have two kinds of objects but rather that there are different "facts" that we might give about a particular object.

When we use a £5 note to buy a sandwich, we are not using the powers or properties of the £5 note; rather, the power at work is what he calls "deontic power," the power of rights, obligations, and so on, which are ultimately the properties of the community within which the £5 note and the user are situated. The £5 note just happens to be something that we have given a "status" to, which allows it to *perform* a particular function. Although there may be a minimal physical requirement for an object to be given some status or function, the object has no general characteristics that might form the basis of a separate category of social objects. Rather, objects have different functions, and where the function depends upon the status we attribute to the object, we have a social function. Relations are not constitutive, and causal powers are not extrinsic (in the sense that the properties of a thing do not depend on the relations in which it stands); rather, these causal powers are external to the object and not something *possessed* by it at all.

Signaling

The third position, unlike the second, does maintain that there is a distinction to be made between social and technical *objects,* but this distinction depends upon the *signaling* capacity of the former. For example, the power of money to facilitate buying something may well be grounded in the relations of credit and debt that hold between individuals in the community, but for money to be used, it must be able to *signal* the kinds of credit relationships that exist within the community itself, and it is only on account of this ability to signal that money can be so used. Indeed, most of the examples given of social objects (passports, driving licenses, deeds, money, etc.) do seem to signal something (citizenship, the ability to drive, ownership, credit, etc.).

If it is an object's ability to signal that sets it apart as a social object, what are the implications for our attempts to locate the powers harnessed when we use such objects? Even though Searle talks of objects symbolizing or counting as other things, to talk of the power residing in the community, as he does, surely misses something. Similarly, it is not clear either that this something is well captured by the idea of extrinsic powers. In this case, we need to talk of powers that are initiated, triggered, or set in play because of the object's ability to signal, properties that depend on the kind of signaling made possible by that object. Such an effect is perhaps best captured by the idea of emergent powers that arise through signaling.

It should be clear that however intuitively plausible the distinction between social and technical objects might be, invoking the distinction raises a range of ontological issues that are both complex and central to much of the philosophy of social science.

Social Ontology, Recent Theories of

Social ontology asks in what sense, if any, social entities exist and what the basic nature of social entities and social relations might be.

Recently, the focus has been on whether a social group or institution amounts to anything over and above its individual members or functionaries and their psychological attitudes and actions. This

question has been pursued in two ways. One way, which may be called *the ontology of social entities and relations,* sharpens the question of whether a group is anything over and above its individual members by using concepts of traditional and recent metaphysics to ask whether a group is identical with, reduces to, supervenes on, or is constituted by its members. The other, and currently more popular, way, which may be called *analysis of social concepts,* asks whether our everyday concept of a social group can be analyzed in terms of concepts of the individual group members and their psychological attitudes and actions. Regarding social relations, recent studies have asked whether these can be reduced to the psychological attitudes and actions of the related individuals. Can friendship, for instance, be understood as a composite of the actions, expectations, and desires of friends?

In the following sections, we will discuss these two approaches in turn.

The Ontology of Social Entities and Relations

Ontological individualism regarding groups holds that a social group amounts to nothing over and above its individual members, and group beliefs, intentions, and actions amount to nothing but admissible composites of the singular attitudes and actions of the members—the sorts of attitudes and actions recognized by belief–desire–intention psychology, for example. This thesis becomes controversial when applied to groups of the sort we would commonly call "social entities" and think of as agents—associations and social organizations—as opposed to pluralities of individuals that we do not think of in this way, like genders or ethnicities. Many individualists would allow that members of a group of the former sort act jointly, but all individualists would deny that such a group resembles a single human being in being a single subject of thought or a single agent. If groups are nothing over and above their individual members, they are not plausibly taken to achieve the unity of attitude and action required of a single agent. Although individualism is the orthodox view among analytic philosophers, it has proved challenging to formulate a defensible version of the view.

If a group is a single entity, whether understood as a single agent or not, then it cannot be identical with each of its members, since by the transitivity of identity, this would entail that each member is identical with each other member—an absurd result. This observation suggests a *plural-identity view* of a group. The suggestion is that we rely on the logic of plural terms and the notion of plural identity to identify a group with the plurality of its members. The sentence "Batman and Robin captured the Joker" does not analyze as "Batman captured the Joker, and Robin captured the Joker," since the former sentence is true and the latter sentence is false. Evidently, we should not understand the subject term "Batman and Robin" as consisting of two referring expressions, one of which, "Batman," refers to Batman and the other of which, "Robin," refers to Robin. But we may instead understand the subject term as referring plurally to Batman and Robin *as two*. A term referring to a group refers plurally to several individuals as several and not to any one of those individuals. The suggestion is then that despite appearing to be a singular subject term, "the group" does not refer to one thing but refers plurally to the members of the group. The group is plurally, not singularly, identical with these members. The plural-identity view does not by itself offer an account of the conditions under which groups remain the same in counterfactual circumstances, and until the view is supplemented with such an account, it remains unclear whether it qualifies as an individualist account treating a group as nothing over and above its members. One difficulty with the plural-identity view of a group is that distinct groups can have the same members. The members of the Library Committee and of the Food Committee of a college can be numerically identical, even though these are distinct groups. Then, identifying each group plurally with its members will violate the transitivity of identity. Plural identity might be defended here by employing the concept of relative identity rather than absolute identity: A member of the Library Committee is not identical with a member of the Food Committee relative to the sort "being a member of the Library Committee."

On the *mereological-sum view,* a group is a mereological sum of its members, where such a sum is one or another of the smallest objects that has as its parts each of the members. This view escapes the preceding difficulty with the plural-identity view if the same individuals can form distinct mereological sums. But a consequence of the view is that being a member of a group entails being a part of the group. And this leads to this implausible reasoning: My toe is a part of me; I am a member of the Chess Club

and so a part of the Chess Club; hence, by the transitivity of the "part of" relation, my toe is a part of the Chess Club—a counterintuitive conclusion. David-Hillel Ruben has given the mereological-sum view sustained critical scrutiny.

Christian List and Philip Pettit have defended the view that there are group agents quite analogous to single human agents. They focused on groups formed as a result of the prior joint intentions of individuals, such as governments and economic firms. A group counts as an agent under these conditions: Attitudes can be attributed to it under the intentional stance (i.e., its behavior is sufficiently predictable given the attribution of these attitudes); these attitudes are capable of sufficient coherence (attitude-to-fact coherence, consistency of beliefs and preferences, and attitude-to-action coherence); and there is something amiss—a fault is attributable—when these attitudes fail to be coherent. The literature on collective decision making shows that many common rules for aggregating individual beliefs and preferences, such as majority rule, lead to incoherent aggregate attitudes. Pettit and List argue that certain procedures, such as straw polling, can enforce coherent attitudes and thus provide the coherence necessary for a group agent. Furthermore, Robert A. Wilson has defended the *group mind hypothesis* in cognitive science, on which a group mind is attributed to explain behavior and cognitive capacity.

David-Hillel Ruben has argued that not all social relations can be reductively identified with nested systems of the interlocking singular beliefs, expectations, and actions of individuals. What it takes to be the mayor of a town, for example, cannot be so identified because it varies conventionally from town to town. This is a multiple-realizability objection to a property reduction, analogous to a common objection to the psychophysical identity theory in the philosophy of mind. Moreover, any specification of a candidate-nested system with which to identify being a mayor must be circular in a way that prevents a reductive identification.

Analysis of Social Concepts

Conceptual individualism is the view that talk of groups and joint activity can be analyzed as talk about individual members and their singular attitudes and actions. Seumas Miller has offered an individualist account of joint action as *interdependent interpersonal actions under a common end: A*'s action *x* and *B*'s action *y* constitute a joint action only if *x* depends on *y,* and conversely; *A* and *B* have a common end for which each performs the relevant action, and this end cannot be realized by one of the agents without the action of the other. This account leaves undefined the constitution relation between the joint action and the individual actions *x* and *y.* If that relation is simply the plural identity of the joint action with actions *x* and *y,* then it does not by itself provide the resources to explain the counterfactual conditions under which the same joint action occurs. The account would have to be supplemented with a specification of when the same joint action could be performed by more or fewer individuals than actually perform it. Without such a supplemental definition, we cannot be sure that the account remains within individualist resources.

Michael Bratman has proposed an account of shared cooperative activity, a species of joint action. Our *J*-ing (e.g., our painting) is a shared cooperative activity only if I intend that we *J* and you intend that we *J*. Bratman restricts *J* to a "cooperatively neutral" action type, excluding reference to an essentially joint action type (like playing tennis), because referring to intentions about a specific action type of this sort would employ the conceptual resources of the notion defined, shared cooperative activity, thereby introducing a circularity into the definition. This limitation on *J* raises the difficulty, like that noted for Miller's account, that the analysis does not by itself explain the counterfactual existence conditions of shared cooperative activity. Moreover, the limitation entails the risk of preventing the account from giving conditions for shared cooperative activity of all types, including essentially joint types. Under this limitation, the account will be fully general only if for every essentially joint action type, there is a cooperatively neutral action type such that satisfying the conditions is enough for a shared cooperative activity of this essentially joint type. But there is the danger that in a case like playing tennis, there is no cooperatively neutral activity *K* such that our satisfying the conditions for *K* is enough for our playing tennis. The difficulty has also been raised, by J. David Velleman among others, that my intending that we *J* must settle that we *J* for purposes of my practical reasoning, but it cannot do so because, at least when our *J*-ing is a joint action, I cannot think of myself as controlling whether we *J*.

John Searle has argued against an individualist account of collective intention. Searle allows that individuals are the only subjects having minds and the only agents, and every intentional state is a state of an individual mind. But he maintains that for a plurality of individuals to have a collective intention to perform a collective action, it is not enough for each to have a singular intention to act. Rather, each must have a "we-intention" to perform the collective action, where a we-intention is an intentional state of the individual but not a singular intention of that individual to perform any action. In addition to we-intentions of the participants, a collective intention to perform a collective action also requires that each has a singular intention to do his or her part in the collective action. Since a we-intention is an attitude of an individual, an illusory we-intention is possible: An individual can have a we-intention even though no one else has a similar we-intention and there is thus no collective intention. Margaret Gilbert has objected to Searle's account on the ground that it assigns collective intention even when coincident individual we-intentions arise from an illusion of collective intention, but such cases are not cases of collective intention. Ben and Elaine each individually thinks, "We intend to get married," and each says so to his or her parents; each assumes that the other would sincerely say this is true if questioned; thus, each has a we-intention that, on Searle's account, should together suffice for a collective intention. But if their parents discovered that the two had not even discussed the matter with one another, they would correctly conclude that there was no collective intention. Searle builds an account of status functions (e.g., a piece of paper's counting as money) and of social institutions on his account of collective intentionality by making these rest on the collective acceptance of deontic propositions (that we are enabled or required to act in certain ways).

Margaret Gilbert's early account of how a group forms supplied an item missing from Searle's account of collective intention—communication between the participants. On her account, a group forms when each of several individuals is, independently of the others, "quasi-ready" to share in an attitude or action as a body (where quasi-readiness is readiness conditional on the like readiness of others and their expression of willingness to share), and each expresses this willingness to the others. Once such an expression of willingness is secured, the individuals are jointly ready to share in the attitude or action as a body. This joint readiness is then sufficient for the existence of the group. Joint readiness entails an espousal of the goal of performing the action, and individuals act jointly just in case each acts in light of this espousal. It has been objected that the notion of sharing employed in this account of group formation is that of joint or participant action, since nothing less than a positive attitude toward such sharing would be sufficient for joint readiness; and for the same reason, the notion of action as a body must be a general notion of action that in this case is potentially instantiated by a joint action. Although this circularity parallels that of Bratman's account of shared cooperative activity, it does not similarly threaten Gilbert's account of a group, since her account does not aspire to remain within the conceptual resources of individualism.

In later work, Gilbert employs a primitive notion of joint commitment that is explained in part by elaborating on the obligations such a commitment entails. She offers an account of group formation that begins not with an individual's quasi-readiness to share in an attitude or action as a body but with an unconditional personal readiness to enter with others into a joint commitment (to hold an attitude or to act). A group forms when individuals who are personally ready in this way express this readiness with the understanding that, provided that others express their like personal readiness to enter a joint commitment, such a commitment is formed. The existence of such a joint commitment is sufficient for the existence of a group. A joint commitment to believe a proposition or intend an action is sufficient for a group belief or intention and does not require that any member of the group also believe that proposition or intend that action.

Gilbert proposes further that a joint commitment is at its core normative in entailing obligations of (and reasons for) the members to do their part in performing the relevant joint actions. A joint commitment is distinguished from a personal commitment by the fact that an individual can unilaterally form and rescind a commitment of the latter sort but not of the former sort. A joint commitment with others gives individuals a participant, as opposed to a singular, reason for following through in doing their part. Such reasons override singular reasons arising from an inclination to the contrary. Thus, for Gilbert, a key function of group membership

is to provide individuals with overriding reasons to participate in cooperative activities even when they are personally disinclined to do so. Michael Bratman has argued for the alternative view that individual obligations to participant actions arise not from joint commitments but from each participant's purposive creation in others of an expectation of the participant's participation, a creation that has value because there is value in having a certain matter settled. Caroline Baumann has argued that, contrary to Gilbert's proposal, the obligations that arise from joint commitments do not differ fundamentally from singular reasons arising from inclination: They do not derive from the will but instead create reasons for following through that weigh against those of personal inclination by raising the cost of not participating. Gilbert builds an account of political obligation on her account of joint commitment.

Raimo Tuomela has developed an account of collectivity that employs a distinction between having an attitude or acting in the we-mode and in the I-mode. The former is a matter of an attitude or action as a member of a group, the latter as a private person. Tuomela has offered an extensive taxonomy and detailed analyses of collective attitudes and actions in terms of we-attitudes and we-actions. He has given particular attention to group belief. He has also employed the concept of collective acceptance to account for social practices and institutions.

Social Perception

Social perception, an element of social cognition, refers to the set of processes by means of which we perceive others—individuals, groups of individuals, as well as symbols—in our social world.

Social cognition, in turn, refers to the ways in which we understand our social world. Thus, social cognition refers to cognitive manipulation of information regarding conspecifics. The nature of social perception is a much debated issue, and there are views that even question its very existence, given that it is not always clearly distinguished from social cognition.

This entry looks at the nature of social perception and tries to demarcate its borderlines by focusing on its relations to social cognition and sensory perception. It ends by drawing the relation between social perception and related areas such as empathy, Simulation Theory, as well as recent uses of mirror neurons in motor- and action-cognition.

Social Perception and Social Cognition

Sensory perception, regardless of particular sensory modalities (visual, tactile, olfactory, etc.), is often understood as occurring at two stages, a passive and an active. The passive stage of visual perception, for instance, is what occurs at the peripheral parts of the human brain dedicated to perception, while the active stage involves processes of understanding what is out there. Even though no highly sophisticated cognitive processing is involved in the passive part of perception, it is widely accepted that memory, in other words, stored mental representations, does play a significant role in perception.

In an attempt to distinguish social perception from social cognition, it could be argued that a relation analogous to the one holding between passive and active perception also holds between social perception and social cognition. In this sense, social perception could be seen as part of social cognition. But that does not imply that for social perception to earn its keep, there have to be special sensory-perceptual channels dedicated to social stimuli, as, for instance, in the case of visual perception (a kind of "social sense" as it were, akin to the "moral sense" championed by the moral philosophers of the Scottish Enlightenment in the 18th century or, more recently, by contemporary philosophers like Jesse Prinz). It suffices to say that social perception occurs on the basis of a stimulus triggering our perceptual apparatuses, which then triggers deployment of a proprietary set of representations acquired during experiences with our social environment.

Clearly, in real-life situations, it is very hard to isolate social perception from social cognition, and it seems far more useful to examine the two together. But this should not be taken to mean that social perception does not exist or that it is not useful in its own right in understanding social behavioral patterns. For instance, waiting for your turn patiently instead of jumping the queue does not have to occur by virtue of sophisticated reasoning processes such as "Respecting others is generally good, therefore I should wait for my turn patiently." Most often, information acquired during social perception, for example, a set of representations of previous queuing experiences in this case, suffices in order to explain the occurrence of social behavioral patterns like the one described above.

Social Perception and Sensory Perception

In order to further understand the nature of social perception, we must have a thorough understanding of the relationship between sensory perception and cognitive processing. However, the distinction between perception and cognition is not a clear one either, and this unavoidably allows space for a "gray area" between the two. For instance, even though it is widely accepted that the way in which we get to perceive the world around us is not isolated from previous experiences, it is still intuitive to assume that there are stages of the perceptual process that are clearly noncognitive.

But is it plausible to assume that early, noncognitive, perceptual stages suffice in order to perceive social features, or is it that social perception requires more sophisticated cognitive processing?

Perception of our social world occurs in the same way as sensory, for instance, visual, perception of our physical environment occurs, namely, by virtue of light reflecting on the surfaces of objects (or other agents in the case of social perception) and exciting our sensory apparatus. During perception of a given object, a representation of that object is formed in the perceiver's mind. A plausible way to distinguish between sensory and social perception is to assume that representations of conspecifics or of social processes either bear a different weight or are tagged as different from sensory perceptual representations and are in turn stored in a distinct locus in the mind or forwarded toward distinct cognitive processes.

If this is accepted as plausible, then it could be argued that social perception differs from sensory perception. Furthermore, if it is shown that social perception occurs precognitively, then it could be said that social perception is clearly demarcated and distinguished from social cognition.

The above suggestion seems to enjoy support from independent evidence from researches on facial recognition. In particular, Edmund Rolls and colleagues showed that certain groups of cells in the inferior temporal (IT) cortex of primates are responsive to faces. Interestingly, they also found that single cells responded strongly to a few faces and showed little response to certain other faces or nonfacial stimuli. Martin Tovée and associates also found face-selective cells in the IT cortex and the cortex in the banks of the anterior part of the superior temporal sulcus of macaques. Furthermore, Edmund Rolls and colleagues found that certain neurons in the cortex in the anterior part of the superior temporal sulcus in primates responded to facial expressions and to facial movements involved in gesturing. Crucially, they also found that neurons in the temporal area were more likely to have responses related to the identity of faces. Finally, Robert Desimone and colleagues, who also studied face recognition in primates, found a population of cells in the IT cortex that responded selectively to faces, and their response patterns did not alter over changes in the stimulus's size or position in the visual field. Note that these neurons did not respond to other complex objects such as flowers and snakes.

Further evidence of the "special nature" of social perception can be found in the literature on gaze following. Among others, Rechele Brooks and colleagues found that at nine months, infants do not respond differentially to the perceptual status of the eyes. They merely follow the adult's turn of the head toward a target. In contrast, older infants sharply differentiate these two conditions and closely monitor the adult's perceptual organs.

In light of the above evidence, it could be said that there are neurons in the brain that respond selectively to "social stimuli." Note though that this does not imply that our social world is perceived, in the broad sense of the term, without deployment of cognitive processing. Rather, it suggests a way on the basis of which the raw materials of social cognition are formed. In this sense, it is plausible to assume that social perception could be seen as a part of social cognition that is distinct from sensory perception.

The Role of Social Perception

Social perception contributes greatly to our understanding of others. It does this by providing the representational inputs to processes of attributing beliefs and desires to others. In turn, this attribution process occurs by virtue of simulating the mental states of others. Simulation processes are often seen as underlain by brain areas associated with the human mirror neuron system (neuronal groups in motor cortical areas that get activated both while perceiving and while performing a given action, and are thus seen as not differentiating between specific agents). Furthermore, simulating the mental states of others involves empathizing with them. For instance, when an agent perceives a subject's facial expressions, she visually represents the expression in question, and the emotional states associated with these expressions also get activated in the beholder's mind. That is, the subject empathizes with the perceived agent by virtue of the neurons underlying the appropriate emotional state that would have caused the subject herself to draw similar facial expressions getting activated. In a sense, social perception is the starting point of all of the above processes that are involved in understanding others.

Social Practices

The concept of social practices has recently become important in discussions of the nature of social life and ongoing human existence. Theories employing the concept also typically embrace an account of activity that forsakes traditional subject–object ways of thinking. Theorists of social practices have offered novel accounts of society and human existence that challenge reigning approaches, inform empirical research, and contribute to the integration of philosophy and social inquiry.

Social Practices and "Practices"

Since the 1980s, the expression *social practices* (or usually just "practices") has widely appeared in theoretical accounts of social or human life. The expression and word are sometimes used almost unreflectively to name a general type or realm of phenomena that is central to the topic under discussion. This usage signals that theorists construe their subject matters as rooted in or as forms of human activity—for common to practically all theories utilizing either term is the notion, often unarticulated, that (social) practices are bundles of actions performed by different people. A long line of key topics in the human sciences have been analyzed on the assumption that bundles of different people's actions are crucial to them. Examples are reason, mind, normativity, language, identity, science, the society–nature relationship, learning, communication, gender, organizations, consumption, and social change.

Because practices are bundles of activity, attention to them perpetuates the long-standing belief in social thought that activity is central to social life. Attention to practices is also one stream in a wider intellectual development that promotes activity as equally, or even more, central to human life as mind. Theories of social practices thereby link up with other accounts that make action central to human existence, for example, post-Husserlian phenomenology, pragmatism, and even behaviorism.

There is little to unify theories that marshal the term *practices*. Many such theories have no articulated conception of practices. Significant differences, moreover, mark different explicit conceptions: The relationship of practices to actions, on the one hand, and to social phenomena, on the other, can be variously understood. Still, conceptions of social practice exhibit common themes and have arisen on the background of particular philosophies and paradigmatic social-theoretical and philosophical accounts.

Social Life

One of these themes is the centrality of practices to both the constitution of—what they are made of—and the causality responsible for social phenomena. Theories championing this theme represent an alternative to reigning social theories that treat individuals, interactions, language, structures, systems, and so on, as the principle generic phenomenon in social life. Against, for example, those forms of individualism that build up social phenomena from the actions and mental states of individual people, theorists of social practices argue that actions inherently belong to activity bundles (practices) and only as such help constitute social entities. Almost all social theories that wield an explicit conception of practices uphold this theme, though individualist analyses of something called "social practices" also exist.

The two paradigmatic theories of social practices are those of Pierre Bourdieu and Anthony Giddens. Bourdieu conceived of society as composed of fields

of practice, where a field is a bounded domain such as agriculture, politics, recreation, or education. Practices in a field pursue the specific matters at stake in it, drawing on material, symbolic, and cultural capitals accumulated there and arising from subconscious generating mechanisms (habitus) that, in mirroring objective properties of that field, ensure that practices perpetuate those properties. Giddens, meanwhile, analyzed a slew of prominent social phenomena, including institutions, change, systems, power, and ideology, by reference to practices, which he understood as structured by sets of rules and resources.

Philosophers, too, have advocated the constitutive and causal centrality of social practices. Examples are Charles Taylor's doctrine that social reality *is* practices and Theodore Schatzki's claim that social phenomena are slices or aspects of nexuses of practices and material arrangements.

Human Activity

Theorists of social practices also usually sport a particular philosophical conception of human activity. Since the 17th century, philosophical discussions of human activity have been structured by the dichotomy between subject and object. On the background of the ideas of the celebrated 20th-century philosophers Martin Heidegger and Ludwig Wittgenstein, philosophers of a practice persuasion, such as Taylor and Hubert Dreyfus, have made two important claims. The first is that action rests on something nonpropositional, something that cannot be put into words, for example, skills or practical understanding. This nonpropositional know-how is embodied, as opposed to contained, in a subject or its mind. The second claim is that activity so understood both is conceptually prior to and underlies the traditional division between mind and the world. This claim fosters the philosophically important conception of practices as constellations of doings and the nonpropositional understandings underlying them, which form the background on which—the place where—states of mind, human activities, rules, and interpersonal relations receive determinate content—that is, are the states, activities, rules, and relations they are.

This picture of action also characterizes social-theoretical practice theories, paradigmatically, those of Bourdieu and Giddens. In Bourdieu, the nonpropositional phenomenon that underlies action is habitus: arrays of subconscious bodily structures that generate activity, thought, and perception. Meanwhile, according to Giddens, "practical consciousness"—what a person knows but cannot say—is the central agency responsible for human activity.

Theories highlighting practices share the conviction that prominent features of human or social life not previously so conceived are best understood as constituted or rooted in bundles of actions resting on embodied know-how. As the above discussion shows, the concept of social practices also joins philosophy and social theory. Practically all theories that make the concept central are resolutely multidisciplinary.

Social Rules

Social rules are the rules of social groups. Different groups may have different rules. A possible social rule is the rule that one is not to talk on a cell phone while dining with friends. Although such rules are commonplace, theorists disagree on what precisely they amount to. There is pointed disagreement over the attitudes individual members of a social group must have if there is to be a social rule. One account

argues that there is a social rule when members *personally* accept a certain pattern of action as a standard for the group. Another account argues that *joint* acceptance by the members is required. The joint account claims to explain better how people respond to rule breakers.

This entry briefly reviews three prominent accounts of social rules and highlights their differences.

H. L. A. Hart on Social Rules

According to the British legal philosopher H. L. A. Hart, there is a social rule within a group if and only if, roughly, all or most group members (a) regularly conform to a particular pattern of behavior; (b) consider this pattern a standard to which group members *ought* to conform, all else being equal; (c) pressure one another to conform to the rule; and (d) think that such pressure is justified. Though influential, Hart's account is open to criticism. The necessity of each of his conditions has been questioned. Furthermore, it seems that there are situations that meet all of his conditions but do not instantiate the concept of a social rule.

Thus, consider the following case: All members of a particular group are regularly truthful, they consider *not lying* to be a standard to which group members ought to conform, they pressure one another not to lie, and they believe that such pressure is justified. As described, not lying seems to meet all of Hart's conditions for a social rule of this group. But though each group member *individually* considers not lying to be a standard to which group members ought to conform, it is not clear that it is a rule *of the group*.

It has also been argued against Hart's account that the kind of pressure put upon rule breakers, including demands for conformity and rebukes for nonconformity, requires a special standing or authority. Hart's conditions could be satisfied without group members having that authority.

David Lewis on Social Convention

Some see *social conventions* as a species of social rule. According to David Lewis, conventions are patterns of behavior conformed to by members of a given group within a recurring *coordination problem*. Here is a sample coordination problem: Sue and Tom agree to meet at "the Greek restaurant downtown." Later, both realize that there are two Greek restaurants downtown. They have no way to contact one another. Tom and Sue have a coordination problem. Each wants to go to the same restaurant as the other, and neither cares which restaurant that is, but where should each one go?

According to Lewis, a group has a convention if and only if, roughly, there is a pattern of behavior in the context of a particular coordination problem such that all or most members of the group conform to that pattern, expect one another to conform to it, and prefer to conform to it on condition that the others do, and all of this is known to all.

A clear case of a Lewisian convention is driving on the right side of the road. When all relevant persons prefer to drive on the side everyone else drives on, everyone expects everyone else to drive on the right, everyone does so drive, and all this is known to all.

Driving on the right may have become the convention by chance. Perhaps some people started driving on the right for no particular reason and others took it from there. Lewis emphasizes that there need be no explicit agreement in order to start a convention, nor need the parties be moved by a sense of their obligations to others. Group members conform to conventions given their personal preferences and their personal expectations that others will conform.

Does Lewis's account of convention capture our everyday understanding of social rules? One problem with the account is that not all social rules seem to be grounded in coordination problems. The cell phone rule imagined earlier seems to be an example. It may simply make sense to some people to have such a rule. If that is right, Lewis's account is in at least one respect too narrow to account for social rules generally.

Another problem is that Lewis's account seems unable to explain important aspects of social rules. People think of the rules of their group as something that members should conform to regardless of personal preference. Furthermore, Lewis's account seems not to entail that group members have the standing to rebuke one another for failing to conform to an established convention.

Margaret Gilbert on Social Rules

Margaret Gilbert's account of social rules differs from those of both Hart and Lewis in significant ways. It does not appeal to what individuals personally

accept, expect, or prefer from others. It invokes the *joint* acceptance of a rule and explains this in terms of something akin to an agreement.

If two individuals make an agreement, then if one violates the agreement without release from the other, that other has grounds for rebuking the violator. In other terms, agreements create obligations of the parties, one to another. When there is a social rule in Gilbert's sense, the parties are in this way obligated to conform to certain standards of behavior.

Gilbert's account of social rules is not in terms of agreements as such but rather in terms of something she takes to be the result of agreement making. It can also occur independently of the making of an agreement strictly speaking. This is what she refers to as *joint commitment*.

According to Gilbert's account, in her technical terminology, a given pattern of behavior is the rule of a particular group if and only if members *jointly commit themselves to accept as a body* that they are to conform to it. Those who make such a joint commitment are said *jointly to accept* that they are to conform to the said pattern. As a result of this process, each member of the group is committed to conform to the rule in question, and no one is in a position unilaterally to rid oneself of this commitment; the permission of the other group members is required. Furthermore, Gilbert argues, each member is in a position to rebuke other members for nonconformity to the group's rule and to demand conformity when it is threatened. Thus, she sees her account as an improvement over that of both Hart and Lewis in this respect.

Social Studies of Science and Technology

Social studies of science and technology is a field of scholarship that has developed in its current form only in the past 40 years or so; it is often referred to as STS, for science and technology studies. In its broadest sense, STS is concerned with the conceptual and empirical analysis of science and technology in their social context.

Orthodox philosophy of science and STS are clear contenders with regard to the study of science, and to a large extent, STS has challenged received assumptions about science and technology. Equally, STS can be seen as important for the development of the philosophy of the social sciences, as certain social-scientific disciplines, notably sociology, have been expanding their erstwhile domain by looking at science, the role of scientific theories, and scientific production, while at the same time positing interesting philosophical questions about science and the way it should be studied. In this vein, the reader may also look at a parallel development, the study of the economics of scientific knowledge (see entry in this encyclopedia), as an offshoot of modern developments in the philosophy of science and of social science.

Though there are many reasons for being interested in the social context of science and technology, there are three analytical issues that are most prominent and of conceptual importance for philosophy and the social sciences.

(1) The first of these revolves around the question of the extent to which science and technology—but especially science—are bound up with or independent of their societal context. As will be explained below, this issue was the central point of contention in early scholarly debates around STS in the 1970s and into the 1980s. (2) The second analytical issue relates to the growing importance of science and technology for the social and human sciences, given the extent to which contemporary political and

policy issues themselves hinge on scientific matters. Perhaps, the key global policy issue of the 21st century is climate change, and of course, policy debates on climate change revolve precisely on scientific models and the credibility of scientific expertise. Unanticipated to an extent in the early years of STS, the social role of science and technology is now at the center of politics and socioeconomic analyses. Finally, and in some ways linking the previous two points, (3) there is a major academic and policy debate about the extent to which science and technology can (or should) be democratized and opened up to public participation.

Strong Programs and the Distinctiveness of Science

Sociological interest in science and technology can plausibly be traced back to the early 20th century and before. Certainly, public and scholarly debates in the 1930s and 1940s concentrated on the extent to which developments in science were driven, and indeed molded, by changes in society and the economy. But the work that is now taken as the core of "modern" STS was produced some three decades later. The pivotal arguments at the time were directed against prevailing assumptions in the philosophy and history of science.

The then-orthodox position was that science fundamentally progresses in a rational manner—following the precepts of the scientific method—and that the path of scientific development is significantly immune from social or cultural influence. Of course, a hostile cultural environment can slow the advance of science. On the other hand, exceptional support for research in one area (astronomy perhaps) can influence the relative development of different scientific disciplines. But scientific methods disclose the nature of the material world in objective ways, so that one would not expect sociocultural influences on the content of scientific claims themselves. Similarly, in cases of scientific disagreement—controversies have broken out frequently in the history of science—one would expect the controversy to be ultimately resolved by the production of the better evidence. In these ways, science was taken to be exceptional among humans' intellectual products. Theological study has, for example, been undertaken for millennia, and there are countless works of theological analysis. But theological knowledge is not cumulative in the way science is taken to be; on the contrary, it is assumed that cultural influences can be detected in the way theological views change. The same would be true of metaphysics or aesthetics but not of science.

Philosophers of science generally subscribed to one variant or another of this orthodox view, a view with which many practicing scientists were also content. The history of science tended to be conducted in isolation from other historical scholarship, and it charted the way in which the forefront of scientific understanding advanced through time.

Perhaps the most telling challenge to this orthodoxy came not from a social scientist or anyone committed to founding STS but from an unusual historian of science, Thomas S. Kuhn. Most celebratedly, in his 1962 book *The Structure of Scientific Revolutions,* Kuhn presented historical material arguing against key aspects of this exceptionalism (of science vis-à-vis the rest of human knowledge) on the orthodox view. He proposed that scientific thinking was characterized not by steady, cumulative advance but by the existence of *paradigms:* fundamental commitments and exemplars that framed how knowledge was made. Paradigms—such as Newtonian physics—organized what it was possible to think at any particular period. And, according to Kuhn, the move from one paradigm to another was more like a political revolution than a scientific debate. Although Kuhn famously used the term *paradigm* in a number of differing ways and although he offered no strict methodological basis for his studies, his fundamental insight took hold.

Launching Programs

In the following decade, two sets of British sociologists began setting out their standpoints. Both were Kuhn-friendly, though not precisely Kuhnian. Both developed programmatic positions. And both were more radical than Kuhn. Probably, the more well-known position is the "Strong Program" set out by David Bloor at the University of Edinburgh (also a contributor to this encyclopedia). His arguments were generally supported by other scholars who were then based in Edinburgh, for example, Barry Barnes and Steve Shapin, who were clearly within the Strong Program, even if they did not follow Bloor's preferred route in doing the sociology that followed from the Strong Program. What was

strong about Bloor's Strong Program was its insistence that sociology should treat all kinds of knowledge equally. The social scientist should adopt the same "impartial" approach to explaining people's beliefs about science or mathematics as he or she would adopt for analyzing ideas about religion or political ideology. Even more radically, this equality of treatment should be extended to the explanation of beliefs that come to be regarded as true or as false. For Bloor, the sociology of knowledge would be "symmetrical" in its style of explanation, although Bloor was clear that this meant that the same *types* of cause would explain true and false beliefs. He did not assert that it was only sociological or cultural factors that explained beliefs.

The other programmatic position was associated with Harry Collins and his then-colleagues at the University of Bath, and was known as EPOR, the Empirical Program of Relativism. Collins developed his position in relation to the analysis of contemporary, not historical, science. His fundamental argument is that if one studies any live scientific controversy or dispute, the facts of the matter are precisely what is up for grabs. Therefore, the truth of beliefs cannot be part of the explanation of the outcome, since the truth is not known by anyone until the outcome has been determined. If the scientists involved in a controversy do not know the truth (and they wouldn't be having a controversy if they did), the sociologist plainly has no way of knowing what the truth is either. By necessity, sociologists will thus have to be impartial and symmetrical. Similarly, in Collins's view, good historians studying past controversies will interpret them in terms of the knowledge available to the participants at the time and not by reference to views that subsequently come to be taken to be correct. Accordingly, the only appropriate stance for the sociologist is a relativistic one, treating the competing views as equally legitimate. However, this is only a *methodological relativism,* a position appropriate to the study of controversy. It does not imply that the sociologist is necessarily a thoroughgoing relativist.

Collins and colleagues generally chose to study controversies in the physical and experimental sciences, suggesting that if their approach was successful there it was assured of success in "softer" knowledge domains. The EPOR view was developed on the basis that studies of scientific controversy indicated that scientific data can always be interpreted in differing ways (this came to be called "interpretative flexibility"). Given that, in principle at least, this interpretative flexibility would allow disputes to carry on indefinitely, EPOR proposed that controversies are in practice resolved through social processes (referred to as processes of "closure") and not through evidential necessity. Roughly speaking, closure occurs when people choose not to carry on arguing or they run out of the resources needed to do so; this point was similar to Kuhn's views on the succession of paradigms. Finally, it may sometimes be the case that there is a connection between these processes of social closure and social forces beyond the immediate community of scientists; closure may, for example, be related to a broader struggle for power or credibility, though the process is always social, even when not societal in this broader sense.

Both of these positions, the Strong Program and EPOR, joined Kuhn in making the very content of scientific knowledge the subject of social-scientific study. Both, thereby, lent credence to a kind of constructionist view in the analysis of science. Scientific beliefs emerged historically not as the gradual disclosing of the underlying makeup of the natural world but as versions of nature assembled out of cultural resources.

This broad constructionist position was firmly in place by the 1980s, even if some of the conceptual issues around the meaning of relativism or about Bloor's "causes" of belief were unresolved. Several contemporary authors were critical of the relativist or perceived antirationalist approach implied; they argued that the programmatic Edinburgh and Bath views were not as compelling as their proponents suggested. Others tried to offer compromise positions—including a proposed "weak program."

Similar arguments were applied to the field of technology studies. In the 1980s, Trevor Pinch, a colleague of Collins, applied the EPOR approach directly to the analysis of technology, swapping EPOR for SCOT (the Social Construction of Technology). As with EPOR, he argued, when there are disputes over rival technologies, it is not simply the case that the objectively superior technology wins out. Rather, "closure" around a technology, while apparently driven by technical considerations, is a social process. This argument was in some ways regarded as less radical than EPOR since it is hard for anyone to maintain that technologies are free of

societal influences. All technologies are, by definition, constructed, if only in an everyday sense, so a constructionist position on technology is less counterintuitive than one on science.

After, or in Place of, Constructionism

In practice, many analysts in social studies of science and technology have settled for less strident versions of constructionism than those apparently offered by Bloor and Collins. Such authors are somewhat relaxed about the symmetry and impartiality demands and are content to argue that there are elements of construction in the bits of science they are concerned with, without necessarily maintaining that scientific beliefs are just as constructed as beliefs in other fields. For example, detailed studies have lately been completed of current disputes over "infanticide" among primates. The idea here is that in the wild, newly dominant male primates may kill the offspring of former rivals. This is a controversial idea since it suggests that humans' near-relatives may be routinely murderous. But the controversy persists—pretty much as EPOR proposes—because such killings are hard to observe and because those episodes that stand the best chance of being observed relate to primate populations that are living in the least natural circumstances. In this case, there are compelling reasons for impartiality and symmetry between the two possibilities (that infanticide is "normal" or that infanticide occurs only by accident or because of abnormal circumstances), but there is no need for analysts of this case to advance general claims about relativism in relation to the rest of science.

Mild constructionist views have also been adopted in practice by many adherents of actor-network theory (ANT), an approach devised in slightly differing ways by Bruno Latour and Michel Callon in Paris. In its programmatic versions (popularized in the 1980s), ANT made its own radical turn. It introduced a further kind of symmetry, arguing that there is no inevitable validity in distinguishing between human and natural actors (an asymmetry that is central to both EPOR and the Strong Program). On this ANT view, controversies are to be understood as conflicts between competing heterogeneous networks—that is, networks indiscriminately made up of "social" and "natural" elements. In Latour's celebrated study of Louis Pasteur and anthrax, this meant that Pasteur's views won out because Pasteur created successful alliances with vets and some farmers, and with livestock and vaccines. He defeated human opponents and microbes. ANT very cleverly draws attention to the way in which scientific claims are enmeshed in institutions and relationships. But in the hands of lesser exponents, the ANT approach amounts to little more than the retelling of customary stories about the history of science, decorated with some apparently radical terminology. The fundamental issue of what accounts for the strength of strong alliances is seldom confronted.

A further strand of work in social studies of science and technology, also distinct from the constructionist approaches, comprised studies of scientific knowledge from the feminist and political economy standpoints. Such approaches were typically in agreement with the overall notion that scientific knowledge was constructed, but they were opposed to the requirements of symmetry and impartiality. However, their opposition to impartiality was not the usual, realist one (that scientific knowledge is manifestly correct, so that there are no grounds for treating claims symmetrically) but an ethical or political judgment. Scientific claims were of most interest to such authors insofar as such claims tended to legitimate social inequalities (scientific assertions about the supposed naturalness of, say, male infidelity or of female lack of competitiveness). And it was this diagnosis of the legitimatory power of science to which they could not be impartial.

By the early 1990s, this loose federation of science studiers had become well institutionalized in many U.S., Canadian, and European universities, and particularly in North America, the overarching claims about the constructedness of scientific knowledge came to the attention of some high-profile, established natural scientists. Dismayed at what was apparently being taught about the nature of science, under their very noses on campus, these natural scientists launched a counterblast that initiated what came to be known as the "Science Wars." Despite some tactical successes (including a notorious episode in which a spoof science-studies paper, admitted by its [physicist] author—Alan Sokal—to be nonsensical, was accepted for publication in a peer-reviewed cultural studies journal), the Science Wars came to no definitive resolution, though the conflict may have made STS scholars more careful about their academic practices and ambitiously general

claims. Since the 1990s, detailed and academically robust work on the sociology of science and technology has continued to thrive.

Social Studies of Science and Technology in the "Knowledge Society"

As mentioned above, there is a kind of irony in the fact that despite sociologists having been very influential in the post-Kuhnian version of STS, their concerns were not those of the sociological mainstream at the time. Bloor and Collins, for example, had their most famous arguments with philosophers of science and rationalist historians. And the subsequent Science Wars also drew attention away from societal issues to questions about the truth and rationality of science. Yet, at the same time and to an extent apparently unanticipated by nearly all the leading figures in STS, it was becoming clear that many of these concerns about scientific rationality or about the resolution of scientific controversies were being played out at a practical level in emerging policy issues.

A series of major, yet contested, policy issues arose from around this time that very frequently looked like public manifestations of the very issues that sociologists and philosophers had been fighting over. There was of course nuclear power and efforts to demonstrate its safety (or dangerousness) in objective terms. In the United States, in particular, more and more complex calculations of risk were used to regulate policies for exposure to potentially harmful substances, from industrial solvents to electromagnetic radiation. There were lengthy international arguments over the scientific causes of "acid rain" and a parallel set of negotiations over ozone depletion. These controversies intensified in the 1990s with contests over "mad cow" disease and genetically modified crops and food, and with the gradual march of climate change to the center of global public policy. As suggested above, these debates represented an adapted and public form of scientific argumentation. Sociologists of science began to see that the strategies they had devised for analyzing disputes over 18th-century optics or farm animal anthrax in the Victorian era applied also to controversies over the ways in which genetically modified crops might or might not be a source of environmental or dietary harms.

Sociologists have always been attracted to the aspiration of typifying the age in which they live. And several sociological labels for society at the close of the 20th century picked up on society's scientific and technological aspects. People wrote widely of the knowledge society, and as early as 1986, Ulrich Beck (a contributor to this *Encyclopedia*) had characterized modern society as a "risk society." Anthony Giddens and Beck both developed this idea into a focus on society's increasingly reflexive character, with—for example—older questions about whether something was safe being replaced with arguments about how safety is proven. In this context, social studies of science and technology were clearly in the sociological mainstream in an unprecedented way, even if some STS authors were not.

As indicated above, there are almost countless examples that demonstrate how STS has impinged on current policy issues, but perhaps one stands out. This stems from a legal case that arose late in the 1980s, when a suit was filed against the pharmaceutical company Merrell Dow by two children and their parents, alleging that the children's birth defects had been caused by the fact that, during pregnancy, the mothers had taken a prescription antinausea drug (Bendectin) manufactured by the company. The company produced scientific experts who argued (essentially on epidemiological grounds) that there was no rigorous evidence that the harms were caused by the drug; it was unfortunate, they said, but such birth defects do occur occasionally. The families wanted to introduce different scientific experts, bringing alternative forms of evidence, for example, about the pathways through which such a drug would be likely to cause developmental abnormalities. The judge had to decide whether to admit the families' experts; they were excluded. The case ended in the 1990s, after being appealed all the way to the U.S. Supreme Court, which was asked to determine not the facts of the case but the correct basis for admitting scientists into court. The Court was essentially faced with a classic question in STS: What are the identifying characteristics of science?

A great deal of advice was offered to the Court, including some by STS scholars, though in the end, the Court appeared to take the most heed of the affidavits of leading scientific institutions, coming up with four indicators of scientific standing. These indicators included the idea that scientific views will typically be testable and will have been subjected to peer review and publication. Anyone familiar with the STS literature will have worked out that these

indicators are unlikely to provide much assistance. In scientific controversies—even in the public disputes over genetically modified organisms—both sides typically favor testing, yet they disagree about what makes a good test. And, as anticipated, what has happened is that the four indicators—now more commonly known as "criteria"—have themselves become the focus of a whole new paralegal industry advising on how to make one's evidence fit the criteria for legal admissibility.

In this example of reflexive modernity (the application of law to science), it turns out that STS has particularly acute insights to offer.

Public Participation in Science and Technology

STS has brought important new insights to one further public policy issue, the issue of the extent to which science and technology can or should be democratized. Since the middle of the 20th century, there has been a major presumption in favor of democratization wherever possible in Western, liberal societies. But certain areas have been exempted from this trend, notably those where scientific (or similar) expertise is taken to be crucial. Loosely expressed, nearly everyone agrees that democratic methods are appropriate for selecting the government, but more or less, no one thinks that these methods should be used to vote on the value of the gravitational constant. But the late 20th century (and the start of the present century) witnessed numerous cases that fall uncomfortably between these paradigmatic instances.

There are those examples where the scientific community wishes to do something—such as to create "admixed embryos" for medical and biological research—where the ethical desirability of doing so is contested. These cases are complicated and important in a substantive sense, though they are not particularly intricate at an epistemological level, since they tend to leave the technical aspects of scientists' expertise unquestioned and focus instead exclusively on the legitimacy of their ethical reasoning.

More philosophically complex are those cases where there is uncertainty or disagreement about how to arrive at legitimate, publicly important knowledge. Under such circumstances, neither paradigmatic possibility may apply. For example, it may turn out that the presumed scientific experts are not as well informed as they believe themselves to be. Numerous studies in STS have documented cases where the established scientific authorities have had limited insights and where, by contrast, local people with experiential knowledge or activists with a commitment to rival approaches have in some senses known better. On the other hand, there are numerous cases—particularly in the biomedical field—where nonscientific citizens have claimed a right to speak, not out of general arguments about democratic entitlement but because they have privileged access to some phenomenon, as sufferers from a chronic condition or as full-time carers. In practice, one can say, experts are less expert than they assume, and certain ordinary people are often more expert than is presumed.

Such cases are commonly presented as focusing on opening up science to more public participation, but this "opening up" is not primarily on democratic grounds but, rather, because of the acuity of the understandings that lay actors may have. STS has provided a rich analytical vocabulary for making sense of this move toward participation in science and technology. It has contributed to the major academic and policy debate about the extent to which science and technology can (and should) be democratized and opened up to public engagement and has provided practical insights into the methods that can appropriately be used.

SOCIOBIOLOGY

Sociobiology is the study of social behavior, including human social behavior, from an evolutionary perspective. It is grounded in the theory of evolution presented by Charles Darwin (1809–1882) in his *Origin of Species,* published in 1859, but it came to fruition only 100 years later, in the 1960s. It proved to be highly controversial, particularly as applied to humankind, but it survived the onslaughts and today is a flourishing part of the evolutionary spectrum.

Background

In his *Origin of Species,* Darwin presented his theory of evolution through natural selection. First, relying on the ideas of the political economist Thomas Robert Malthus (1766–1834), Darwin argued that there is a universal population pressure, leading to an ongoing struggle for existence or, more particularly, to a struggle for reproduction. Darwin argued further that this struggle leads to an ongoing winnowing of organisms, or natural form of selection, and given enough time, this eventuates in permanent organic change. Most important from the Darwinian perspective is the fact that organisms develop characteristics, known as *adaptations,* that help them in the struggle. Paradigmatic examples are the hand and the eye.

Darwin recognized from the first that behavior is part of the evolutionary scenario. It is no good being big and strong if you do not have the inclination to fight as needed or perhaps to flee in the face of predators. Of particular interest to Darwin was social behavior as evinced in social insects like the bee and the ant. It is well known that these organisms have sterile castes of workers. How could natural selection, which is brought on by the struggle for reproduction, produce animals that do not reproduce at all? Eventually, Darwin argued that at some level, it is the nest or family that counts. Sterile workers are rather like parts of the whole rather than entities entirely unto themselves.

In the *Origin,* Darwin said virtually nothing about humankind, but some 12 years later, in the *Descent of Man* (1871), Darwin turned to our own species. He made it clear that he thought that we are the product of selection—although, increasingly, he relied on a secondary form of selection, sexual selection (involving the struggle for mates)—and he included here our social behavior and inclinations, including our moral inclinations; our religious yearnings; our aggression; as well as our sexual behaviors and dimorphisms.

For a number of reasons, Darwin's thinking about the evolution of social behavior went essentially undiscussed and unexplored for 100 years. First, there was little interest in natural selection generally, and it was not until the coming of Mendelian

genetics (developed by Gregor Mendel (1822–1884), the Austrian scientist and friar) at the beginning of the 20th century that evolutionists finally could see how selection is the overwhelming force of evolutionary change. Second, behavior generally raises a number of particular problems, not the least of which is the problem of observation and experiment. It is much easier to study the morphology of an already dead organism than the activities of organisms in nature, and it is notorious that organisms in captivity often do not behave as they do in the wild. Third, the rise of the social sciences and their somewhat jealous attempt to claim the study of behavior entirely for themselves meant that evolutionary approaches were viewed unfavorably and dismissed.

Emergence of the Field

Nevertheless, even by the 1930s, especially on the continent, things were beginning to change. The so-called ethologists started to take an interest in the evolution of social behavior. However, their work was sadly marred by a naive understanding of the working of natural selection. The reason why Darwin agonized over the social insects was because he could see that selection will almost always favor the individual over the group. This is not ideological but simply that selfishness pays over being helpful (or what biologists call being "altruistic"). The selfish individual exploits the altruist. Thus, it does better in the struggle; and so then the altruist goes extinct. Darwin, as we saw, got around this problem by considering the group of relatives—the family—as one unit. The ethologists ignored these worries and so plunged into "group-selective" explanations rather than "individual-selective" ones, thus vitiating much of their work.

It was not until the 1960s that the importance of an individual-selectionist approach was fully appreciated, and as soon as this happened, especially given that by now the general theory of selection leading to adaptation was on an increasingly firm theoretical and empirical foundation, things took off in a major way. Most significant were a number of new models showing how natural selection can promote social behavior. First, the then-graduate English student William Hamilton developed his idea of *kin selection*. Relatives share the same genes, and thus inasmuch as a relative reproduces, one reproduces oneself. Hence, help given to relatives—in other words, altruism—can in fact be a form of evolutionary enlightened self-interest and promoted by natural selection. Second, the then-graduate American student Robert Trivers developed his idea of *reciprocal altruism*. Basically, you scratch my back, and I will scratch yours. Help given to others can be of value if it ensures that at times of need others will help you.

With these models in place, as well as (thanks particularly to the English evolutionist John Maynard Smith) a growing recognition that game theory (developed in the Cold War to anticipate the moves of the enemy) has much to say in the study of animal social behavior, the way was now opened for empirical workers to search nature and start experimenting to see if indeed social behavior can be brought about by natural selection working at the individual level. There were a number of outstanding achievements in this direction, notably the studies of Geoffrey Parker on the mating behaviors of dung flies and the studies of Tim Clutton Brock and his associates on the social behavior of the red deer on islands off the coast of Scotland.

By the mid-1970s, it was apparent that finally social behavior had been brought fully within the Darwinian paradigm. As if to celebrate this fact, the subject was given its own distinctive name of *sociobiology*. Two outstanding works of synthesis and explanation appeared at this time. First, there was the magisterial overview of the subject, *Evolution: The New Synthesis,* by the Harvard entomologist Edward O. Wilson. He discussed in some detail the new models of understanding and the need for them and then gave a magnificent overview of the new subject, starting with the slime molds and then moving up through the insect world to the reptiles and then on to the mammals and birds. (Birds were becoming a particular subject of interest, given both their ease of study and the recognition that the dangers of breeding in trees meant that the males necessarily made a much greater contribution to social life than do mammals.) Second, there was the outstanding popularization of the subject, *The Selfish Gene,* by the Oxford-trained behavioral biologist Richard Dawkins. He proved particularly skilled at explaining complex notions, for instance, those drawn from game theory, without the need of heavy-duty mathematics.

At first, work in the blossoming field of sociobiology did not focus on humankind, but it was not long before students of the subject were

extending their vision to our species. The final chapter of Wilson's *Sociobiology,* "Man: From Sociobiology to Sociology," dealt explicitly with *Homo sapiens*. Wilson argued that human social structure is, for instance, a reflection of the fact that males tend to be more aggressive and females more domestic, more "coy." And this is a direct function of Darwinian selection. Then, three years later, Wilson devoted a whole volume to our species. *On Human Nature* was a full exposition of the worth of using natural selection to explore topics such as religion, ethics, and aggression. Thus, for instance, Wilson argued that religion has a biological function, namely, that it promotes group cohesiveness. Likewise, following Darwin himself in the *Descent,* Wilson argued that morality has no further basis than cementing the social bonds between fellow members of the human species.

Dawkins also extended sociobiology to humankind, although, unlike Wilson and others, he did not remain exclusively at the biological level. Rather, he suggested that there are units of culture, which he called *memes,* analogous to the units of heredity, genes. He argued that we have a form of Darwinian evolution operating pretty much exclusively in the cultural realm, somehow above and sitting on Darwinian evolution in the biological realm, and that this explains human nature and belief. Unlike Wilson, who although not personally religious appreciates its social value, Dawkins denies that religion has any social or cultural value. He explains it in terms of memes that hop from human to human, parasitically as it were. He has indeed likened religion to a disease, a form of unfortunate cultural virus.

Criticism

It was not long before critics started to appear. Expectedly, some of the objections came from social scientists. Sociobiology, especially as applied to humans, was threatening to their own autonomy and activities. Perhaps somewhat less expectedly, some of the objections came from the sociobiologists' fellow biologists—in Wilson's case, even from fellow members of the same biology department at Harvard. These biologist critics had a number of motivations, but two of the most prominent, Richard Lewontin and Stephen Jay Gould, were open in their Marxist affiliations. They clearly thought that the biological approach to humankind was threatening to their philosophy.

The criticisms generally fell into one of two camps. First, there were the epistemological objections. These included worries that there is insufficient evidence for much that is claimed by sociobiologists, especially in the human realm. Connected to this objection—perhaps not entirely consistently—was the charge that, in any case, sociobiology is unfalsifiable. Notoriously, Gould argued that sociobiologists simply provide stories akin to those fabulous tales invented by the English writer Rudyard Kipling. Gould opined that much of sociobiological thinking failed to rise above the level of "Just So" stories. You think of an idea and simply make up the evidence for it.

Also at the epistemological level were the twin objections that sociobiology is unduly reductionistic (in the sense of focusing on the part and not the whole) and deterministic (in the sense of seeing all as predetermined). Too much emphasis is put upon the gene and not enough on the whole organism, and organisms—particularly humans—are being portrayed as marionettes on the end of strings controlled by genes. (Actually, the favorite image was of a gray-suited, White businessman, on strings manipulated by the double helix.) Most particularly, the implication of human sociobiology supposedly is that we can never escape our genetic destiny. Things like IQ are fixed, and no amount of social engineering is going to change them.

The second kind of criticism was more social or moral. It was argued that human sociobiology is a thinly veiled excuse for the worst excesses of capitalism; it is grossly sexist inasmuch as it gives females very different and inferior roles to males; and worst of all, it is grotesquely racist. Gould, particularly, was eloquent on this last charge (a charge incidentally closely connected to the epistemological charge of determinism). In his book *The Mismeasure of Man,* Gould claimed to show that human sociobiology is but the end point of a dreadful tradition of putting down people who are not pure Anglo-Saxons. He disliked, particularly, the ways in which biology had been used to denigrate Jews.

Counters

Naturally enough, the sociobiologists gave back as good as they got. Studies in the nonhuman world grew apace, backed by increasingly sophisticated theoretical models. A good example, combining

theory and observation, was work done on "local mate competition," another idea from the ever-fertile mind of William Hamilton. If the offspring of one sex (probably males) compete for mates, then from the parental perspective, one needs fewer of that sex—after all, when it comes to grandchildren, one son is generally as good as another—and one should skew the sex ratio in favor of the other sex. Extensive work on the Panamanian fig wasp, where males emerge before females and brothers do gather and compete for the chance to reproduce, shows that Hamilton's prediction proves true. There are fewer males than expected and more females. Multiply this many times—and sociobiologists would argue that they have done just this in the past 30 years—and the critics' claims about "Just So" stories simply are not true.

Nor are the claims about falsifiability. Hamilton himself thought that one can explain the sociality of bees and ants by virtue of the fact that here one finds that females have both mothers and fathers, whereas males are born from unfertilized eggs and thus have only mothers. This means that sisters are more closely related (75%) than mothers and daughters (50%), and Hamilton thus thought that kin selection suggests that worker females are better off sterile and raising fertile sisters than fertile themselves and raising daughters. Now, however, we know that this is generally not true—queens are often multiply fertilized, and this destroys the expected relatedness ratios. Other explanations have had to be sought to explain sterile workers. (A favorite one is—given the dangers from without—in terms of the advantages of working harmoniously with relatives.). So falsifying is possible.

There is much work also on humans. One of the most rightly celebrated studies, by Wilson's student Sarah Hrdy, looks at family relationships. There is a well-established theorem (chiefly attributed to Robert Trivers) that suggests that high-status females will tend to have sons whereas low-status females will have daughters. The reasoning behind this is that females in nature almost invariably are going to get fertilized, whereas males will have to compete with other males. Females will therefore tend to have some limited guaranteed offspring, whereas males may have many offspring but also may have few or none. Hence, if you can guarantee your son a good start in life, you might skew toward sons, but if not, you will skew toward daughters. Hrdy shows, in some detail, how this theorem explains some otherwise puzzling behaviors in the Indian caste system. High-status families tend to have sons (presumably because of infanticide of the females), whereas low-status families tend to have daughters—or at least, they care for the daughters and leave the sons to fend for themselves.

What about reduction and determinism? Someone like Dawkins, who focuses on the gene, is a reductionist and is proud of it. On the other hand, he and his fellow sociobiologists would argue that this is hardly something that occurs at the expense of the whole. Work like Hrdy's may start at the level of the gene, but it rapidly expands to cover the whole of society. Moreover, Dawkins and his fellows would warn that uncritical enthusiasm for the whole over the part can lead one badly astray. Group selection in some sense clearly favors the group or whole over the individual or part, but generally it is not the right explanatory strategy. As far as determinism is concerned, one must tease apart the various meanings of this term. If one means some generally metaphysical thesis about the whole of nature being determined, then this may be true, but it is accepted by the Marxist as much as by the sociobiologist. If one means that in some extraspecific sense humans are determined, then it is by no means clear that sociobiology implies that this must be so. We may perhaps be biologically determined in something like our sexual orientation (this is controversial, but many sociobiologists would accept that this is so), but it does not follow that we are determined always to act on our inclinations. Sometimes people decide to have sex, and sometimes they don't. That is our individual choice.

What of the moral issues? No one can deny that sometimes some pretty hurtful and hateful things have been said in the name of biology. Darwin's views on the sexes in the *Descent* make for embarrassing reading in our age. But again, the response is that this is not necessarily always the case when one uses biology to explore human nature. Hrdy, for instance, rather reverses the role of the sexes in her analysis of human beings. In a book provocatively and informatively titled *The Woman Who Never Evolved,* she argues that the concealed ovulation of the human female means that males can never be sure that they have fertilized their mates and that therefore there is a biological reason for them to stay around, both protecting their investment as it were and then raising the offspring. If anything, it is men who are being manipulated, not females. Analogous arguments can

be brought to bear on other cases. Referring again to sexual orientation, the fear might be that if one finds gay genes, this will open the way to selective abortion of future folk with a same-sex orientation. On the other hand, equally, one might suggest that since the orientation is God-given—more precisely, evolution-given—it is hardly a matter of shame or moral condemnation and that one should simply recognize it for what it is, namely a nonmoral variant like hair or eye color (and probably a lot less easy to change or likely to infect others).

Conclusion

At the animal level today, everyone accepts that sociobiology is a straightforward and thriving part of the evolutionary spectrum, along with other areas such as biogeography, paleontology, and systematics. At the human level, undoubtedly, there is still controversy, so much so that practitioners now tend to conceal their activities under other more neutral names like "evolutionary psychology" and "human behavioral ecology." Perhaps, given human nature, this kind of tension will long endure. The only firm forecast one can make is that, like it or not, the Darwinian evolutionary approach to humankind is here to stay. The aim now must be to improve rather than refute.

SOCIOLINGUISTICS

Sociolinguistics is the branch of linguistics that explores the *social significance of language variation.* It examines the influence of membership in social categories, such as age, gender, social class, and ethnicity, on the use of language. One of its achievements has been to show that much of the linguistic variation that is found in all communities is

not random but systematic. Although no two individuals are identical, we share some characteristics with other family members, with people of our own age and sex, with members of our surrounding community, and so on. For many people, the way we dress, the food we eat, the ways in which we amuse ourselves are likely to be fairly consistent with how others in our community behave. In the same way, how we speak is affected by our place in society, and this often makes it possible for a stranger to draw some inferences about our social background simply from hearing us speak. The study of linguistic differences related to social factors is the province of sociolinguistics. This entry first introduces the use of quantitative methods and goes on to present the main domains of sociolinguistics.

Quantitative Methods in Sociolinguistics

In 1963, William Labov published in the journal *Word* an article titled "The Social Motivation of a Sound Change." Labov showed that on the island of Martha's Vineyard, off the Massachusetts coast, there was a change taking place in the way in which the inhabitants pronounced the vowels in words such as *tide* and *house*. Labov found differences in the extent to which different categories of the speakers he interviewed participated in the change. Factors such as the age of the speakers, where they lived, and which ethnic group they belonged to affected their participation in the change, though attitude toward life on the island turned out to be the factor that had the strongest influence.

Labov was able to show this because of the way in which he quantified his results. He developed a scale that assigned a numerical value to each example of the relevant sounds in all the words on the tape that included these sounds. He then obtained a score for each speaker. He could then calculate an average score for a social category—for example, those of a certain age or those who lived in a certain community or were of a certain ancestry. These group scores could then be compared with those from another category. This quantitative approach allowed comparison on a range of social factors and provided a model for future investigations of linguistic variation.

Labov followed up on his own example by conducting a large-scale investigation in New York City. This became the model for other investigations of urban speech in Detroit (Michigan), Anniston (Alabama), Reading (England), Montreal (Canada), Glasgow (Scotland), Sydney (Australia), and Bahia Blanca (Argentina). These studies revealed the systematic nature of linguistic differences related to age, gender, social stratification, and ethnicity.

Age Differences

Age differences in language use have been reported in a number of sociolinguistic studies. Young people are often in the vanguard of linguistic change, though some of their innovations are not adopted by adults. Ethnographic studies of adolescent speech behavior have shown girls making greater use of language differences to establish their identity in school-based groups or street gangs. Membership in these groups is influenced by social class categories, but participation in certain group activities has more impact on girls than on boys.

Gender Differences

Early sociolinguistic discussion of gender differences occurred in the context of investigations that focused mainly on social class differences. In a number of studies, it appeared that women used more of the standard variants than men, and different explanations were offered for this. One was that women were more concerned with respectability, while men, particularly lower-class men, were more anxious to assert their toughness, perhaps as a way of distancing themselves from a feminine world. Later studies have shown that women are often the leaders in linguistic changes, thus contradicting the notion that women are generally more conservative in language usage. In one study, the females used many more pronouns than the males, in particular the pronoun *she*. This is probably related to the fact that the women talked more about people, while the men made many more references to places.

Social Class Differences

Social class has been shown to be related to differences in the pronunciation of vowels in a number of studies in New York City, Reading (England), Glasgow (Scotland), and Londonderry (Northern Ireland) and to differences in the pronunciation of consonants in studies in New York City, Detroit, Reading, Glasgow, Cardiff, Newcastle, and

Londonderry. Most of the early work investigated differences in pronunciation, but more recent works have investigated other aspects of language. A study in Glasgow found that working-class speakers used fewer adverbs (e.g., *definitely, seriously,* and *very*) than middle-class speakers. The middle-class speakers used more examples of passive voice and more evaluative adjectives, as well as the expressions *sort of, kind of,* and *quite.*

Ethnic Differences

Much work has been done on what is now called African American Vernacular English (AAVE). The early work on AAVE was to some extent motivated by a desire to show that vernacular forms of speech are as regular and systematic as the standard language. William Labov investigated the speech of African American males aged 8 to 19 years who participated in the street culture of New York City, and he was able to show that grammatical patterns not found in the standard language were used consistently and systematically by these speakers. Despite this work, it has been very difficult to persuade many members of the public (including teachers) that these apparently ungrammatical forms are not simply mistakes.

Studies of Latino English have shown that many of its features are not typical of the forms used by native speakers of Spanish who are learning English, so Latino English is not simply a version of a foreign accent. There are Puerto Rican, Cuban, and Dominican forms of Latino English, and they all have distinct characteristics.

Sociology of Knowledge and Science

This entry gives an account of the domain of the sociology of knowledge and the special subdomain of the sociology of scientific knowledge, clarifies the precise kind of sociological approach involved, explains what "evidence" means in this area, distinguishes the sociological from the philosophical questions, and finally pinpoints misconceptions about the task and goals of the sociology of science. A number of concrete examples are offered.

Introduction

The sociology of knowledge is a discipline devoted to investigating the role played by conventions, institutions, traditions, and interests in the creation and evaluation of knowledge, including scientific knowledge.

Knowledge is a complex, real-world phenomenon, and it can only be addressed as an object of study with the cooperation of specialists from a range of empirically grounded disciplines, such as biologists, physiologists, psychologists, sociologists, historians, and anthropologists. No single approach can offer a sufficient account of knowledge, but all the contributions can be seen as necessary components of an adequate, "naturalistic" picture of knowledge—that is, a picture that securely grounds knowledge within space and time and sees its origin and development as a causal process on a par with any other natural phenomenon.

The Task of the Sociologist of Science

To identify the kind of contribution made by *sociologists of knowledge* when looking at, say, the achievements of scientists, it will be useful to start with a special case and then show how it can be generalized. Suppose that scientists have developed two rival theories, T1 and T2, which cover some range of phenomena, for example, rival theories in genetics or in fluid dynamics. As a result of their investigations, suppose that the scientists have accumulated a considerable body of evidence but the evidence proves to be equally balanced and supports both theories to an equal degree. A number of different things could now happen. The community could split into

two subgroups G1 and G2, with the members of G1 expressing a preference for T1 and the members of G2 for T2. The scientists in these respective groups could continue to develop and apply their preferred theory and evince confidence in its ultimate triumph. Or the scientists could maintain their unity and attempt to pursue the study of both theories while waiting patiently for any evidence that might help decide between them.

These possibilities bring to the surface a number of questions. If the original group splits, why do some scientists prefer T1 and some T2? Can these preferences be explained in terms of the properties of the two groups? For example, the sociologist may discover that most of the members of G1 are British while most of the members of G2 are German or that the G1s are physicists from elite universities while the G2s are engineers from provincial technical colleges. Further analysis of the reasoning of the scientists concerned might reveal how the intellectual traditions of these institutions find expression in divergent technical preferences and decisions. Whatever the outcome of such investigations, it will be apparent that, in the circumstances described above, the original group will have to reach some accommodation with the situation. Whether its members divide up or stay united, that accommodation will involve some form of coordinated behavior and will necessarily involve some manner of social organization. It is the sociologist's job to find out what happens and why. What contingencies of power, status, influence, solidarity, and social organization determine the accommodation that is arrived at?

It is now time to acknowledge the limitations of the example. In the hypothetical scenario described above, it might appear that the experimental evidence for T1 and T2 "underdetermines" the choices that the scientists make and this is why it is necessary to bring in "social factors." The expression *underdetermination by the evidence* suggests that "evidence" is one (perhaps partial) determinant while "social factors" constitute a second (perhaps partial) determinant. This understanding has informed many of the critical responses to the sociology of knowledge offered by philosophers. Philosophers have enjoined sociologists to "disentangle" the rational from the social and to confine themselves to those cases where the evidence and reason are insufficient to determine scientific judgment. For example, sociologists are encouraged to study cases where "social factors" are said to override "cognitive factors," as in the notorious examples of the ideological distortion of science in totalitarian states. The philosopher is thus proposing a division of labor: The philosopher will address "rational causes," and the sociologist will address "social causes." There are, however, good reasons for believing that there can be *no* such division of labor, or *none* that makes sense within the naturalistic framework identified at the outset. To establish this conclusion, it is necessary to relax the idealizations in the example and focus attention on a category that has so far been taken for granted, namely, that of *evidence*. It is necessary to press the sociological analysis into the realm of the undeniably rational in order to break down the idea that rational and social "factors" are qualitatively different kinds of thing operating in competition with one another.

"Evidence"

Sociologists and historians have examined the role of *evidence* in scientific reasoning with great care, and one result stands out clearly. No theory is ever confronted with the totality of putative evidence that is available. Evidence is always used *selectively*. Some evidence is deemed better than other evidence, some evidence is counted as more important than other evidence, some evidence is described as misleading or as coming from unreliable sources, and some claimants to the role of evidence are dismissed as mere artifact or error. And *all* evidence involves some element of *theoretical interpretation*. In other words, evidence always operates by virtue of the exercise of judgment, and the judgment is constitutive of what counts as evidence.

Just as sociologists ask why the members of one group prefer one theory to another (when the evidence is balanced), they can now ask what influences the judgments that go into the selection, interpretation, and evaluation of evidence, that is, into the *construction of the evidence itself*. Here is an example. In the 1910s and 1920s, British physicists working in aerodynamics were worried about the implications of a theorem about the behavior of an ideal fluid. Lord Kelvin had proven mathematically that a pattern of flow called the *circulation* could neither be created nor destroyed. On that basis, the British experts rejected an account of the lift of an aircraft

wing that depended on the wing creating a circulation. German engineers knew all about Kelvin's result but were unworried by it and continued to develop the circulation theory with considerable success. For them, the result was not evidence that their approach would fail. Why did the two groups react so differently? The sociologist will explore the possibility that the divergent evaluations derived from the different disciplinary traditions involved. Of course, the evaluation of a piece of evidence may involve the use of further evidence, but this only raises the same questions again. It delays but cannot evade the need to take judgments into account and to explain their covariation with social categories such as nationality and academic discipline.

Misconceptions About the Sociology of Science

Unfortunately, it has become routine for certain scholars to talk of sociological "critics" of science, as if sociological enquiry was an exercise in denigration. In reality, the attempt to answer sociological questions does *not* amount to an attack on science, nor does it show that evidence is necessarily distorted by the exercise of judgment. The rooted conviction that sociologists of knowledge are expressing hostility to science derives from a failure to understand the naturalistic perspective. From a naturalistic and scientific perspective, all knowledge claims are part of the causal nexus. To locate the causes of a belief, including, of course, sociological causes, does not permit the inference that the belief is compromised. If causation implied error, then all knowledge would be defective. Such considerations also show that the timeworn claim that the sociology of knowledge is self-refuting is wrong. It rests on the false premise that causation implies error.

To drive these points home, it is worth recalling the outcome of Rudolf Carnap's attempt to develop an account of the process of scientific confirmation. He wanted to know how much support a given piece of evidence provided for a given theory, and he wanted to analyze the relation in purely logical terms. Here, we can see the philosophical ideal of *disentangling* the social from the rational in action. Carnap would surely be able to give a nonsociological analysis of the nature of inductive evidence. To develop his argument, Carnap postulated a simplified model "world" with a limited number of properties and a simplified formal "language" containing a limited number of predicates. After a strenuous mathematical analysis, he was forced to conclude that there was no unique definition or measure of the degree of confirmation but an infinite continuum of confirmation functions, so that some element of *choice* was unavoidable. Furthermore, to arrive at a determinate measure of confirmation, it was also necessary to assign a value to an intriguing parameter that Carnap called λ. It transpired that λ symbolized an inductive strategy and corresponded to the willingness to take risks when making generalizations. Here, then, was the inescapable element of *judgment*.

What might be understood as an attempt to remove human agency from the process of scientific reasoning finished up as a demonstration of its irreducible presence. Carnap himself identified λ as a psychological variable, but it is not difficult to see that in the history of science, inductive strategies are properties of *groups* of persons and are maintained, monitored, and sanctioned at the level of the group, not at the level of the individual. Inductive strategies are *institutions* sustained by the *group*. Now the sociologist can complete the process of bringing the analysis back to earth by asking, in real cases, how a group implicitly or explicitly arrives at its risk-taking strategy.

Concluding Remarks

The aim in this entry has been to describe the general principles behind the sociology of knowledge rather than the results of particular empirical case studies, though it must be emphasized that these studies represent the true center of gravity of the field. Many of them concern episodes in the history of science—for example, early scientific disputes about the interpretation of experimental findings derived from the air pump, disputes over the proper scope of genetics, or disputes in the history of aerodynamics. Their practical value is like the practical value of all studies in history, in whatever field: They increase self-awareness. Contemporary judgment can be both challenged and refined by appeal to analogies between past episodes and present problems.

Clearly, philosophy, which is not an empirical discipline, stands in a problematic relationship to the sociology of knowledge. The idea of a division of labor between the study of rational and social causes has been discussed above and rejected.

In confronting the problem of finding a role for philosophers, it is often argued that philosophers are concerned with what ought to be believed rather than what is actually believed; in other words, philosophers' concerns are exclusively evaluative. From the naturalistic standpoint, however, such a position is untenable. Why are the evaluations made in one way rather than another? Could it be that they are simply rationalizations of current practice and therefore, as justifications, wholly circular? If not, then what is the source of their credibility and authority? It would seem that from a naturalistic standpoint, philosophers can neither work alongside sociologists, dividing different aspects of knowledge between them, nor transcend the sociology of knowledge.

SOLIDARITY

The word *solidarity* derives from Roman law, where *obligatio in solidum* referred to the group liability of joint debtors. This is the sense of the French word *solidarité* in the *Encyclopedia* of 1765 and in Napoleon's Civil Code of 1802. Around the 1840s, the term was adopted in German and English, was politicized, was adapted to the social sciences, and came to be used in the broader sense of emotionally and normatively motivated readiness for mutual support, as in the slogan "One for all and all for one."

Given its widely different meanings, the concept has been used in four main contexts. First, it is employed in the context of explaining or understanding the nature of social cohesion, social order, "groupness," or the "glue" that keeps societies or groups together (in the sense of social solidarity and group solidarity). Second, it has been linked to the ideal of *fraternité,* as a desirable feature of societies, political communities, or welfare states (in the sense of social solidarity and civic solidarity). Third, it denotes an attitude or demand relevant in struggles for liberation and against injustice or oppression (in the sense of political solidarity, workers' solidarity, Black solidarity, and women's solidarity). Fourth, it is employed as a universalistic ethical ideal of responsiveness to the human moral standing (in the sense of human solidarity, moral solidarity, and global solidarity).

This entry focuses especially on the first use—more relevant to the theme of this encyclopedia—and then briefly discusses the other three.

Group Solidarity and Social Solidarity

In sociology and social psychology, solidarity has been conceived either as an irreducible macro-level phenomenon of group cohesion or order or as a micro-level behavior, namely, in the form of emotions and attitudes explaining such a cohesion. The macro-level cohesion or unity can be sustained, for example, by coercion, by self-interest, or, as in the case of social solidarity, by a commitment to shared norms and valued social bonds. While it is irreducible to self-interest, the degree to which the social norms and institutions are seen to benefit oneself (and one's kin) and the degree to which one's own fate depends on that of the whole group may, nonetheless, partly explain the strength of the commitment to the social norms and institutions.

The term was introduced to sociology by August Comte, but the classic treatment is Émile Durkheim's distinction between the "mechanical" solidarity of traditional communities and the "organic" solidarity of modern societies. Mechanical solidarity is based on the similarity of the members and the dominance of collective consciousness over individuality.

Organic solidarity is based on the interdependence of different individuals and on the social division of labor. The Durkheimian distinction makes it possible both to acknowledge that traditional social ties are eroding (while not fully disappearing) as an effect of industrialization, urbanization, individualization, or democratization and to see a different basis for social life emerging, consistent with these processes, leaving room for individual differences.

As a micro-level phenomenon, solidarity has been conceptualized as prosocial behavior across different situations: helping and supporting in situations of need, doing one's share in situations of cooperation, showing fairness in situations of distribution of goods, avoiding breach in situations of trust, and facilitating moral repair when violations have taken place. The sociologist Siegwart Lindenberg sought to explain what makes people act in such a solidarity-based manner, as opposed to hedonistic or gain-seeking ways, in certain situations but not in others. In addition to the general formation of character or behavioral dispositions, situational cues have been shown to make a difference to behavior by affecting the salience of the solidarity frame, as opposed to those of immediate gratification or long-term gain. Solidarity is thus precarious and needs to be supported by factors that increase the salience of the solidarity frame.

For methodological reasons, such focus on behavior, excluding emotional or attitudinal elements, is adopted in empirical research (e.g., by Michael Hechter and Siegwart Lindenberg). Most theorists argue that behavior is not enough, as acting out of solidarity requires the presence of attitudes or emotions such as a sense of belonging, concern for the others' well-being, commitment to shared norms, valuing the social bonds in question, or identification with the group. As a distinct motivational pattern, solidarity combines elements of (extended) egoism and (restricted) altruism. It can be seen as a form of "we-thinking" based on collective intentionality, whose nature has been studied in recent social philosophy.

Civic Solidarity, Political Solidarity, and Human Solidarity

Solidarity has been taken to be one important evaluative feature of good societies (complementing social justice, democracy, and autonomy). "Solidarity" has made its way into the European Union Constitution and has been promoted by rival movements such as Marxism, Social Democracy, French Solidarism, Liberalism, Roman Catholicism, and Neo-Fascism. The classical Liberal and Catholic approaches stress interpersonal responsibility and solidarity as a private or personal virtue, while Marxists and Social Democrats typically stress structural obstacles, institutional solutions, and shared responsibility, so that solidarity can equally be a virtue of institutions. A moderate view is that institutional arrangements can promote and realize genuine group solidarity (e.g., via progressive taxation and social services), but if the institutional arrangements are obeyed for solely coercive or self-interested reasons, they fall short of genuine solidarity. In social policy research, the European welfare states have been seen as realizing, via institutional means, relatively high degrees of social (or "civic") solidarity and distributive social justice.

A third type of solidarity has been at stake, for example, in the international workers' movement, the Polish *Solidarność*, and various new social movements. In political solidarity, activists and members of the movement join to oppose the injustice or oppression of some group and possibly to seek support from outside (out-group solidarity). Fourth, the term is sometimes used very broadly to refer to the basic ethical concern for others, as in the work of Richard Rorty. In this context, it is often called *moral* or *human* solidarity. While solidarity is typically seen as a positive quality, various forms of solidarity have been criticized for their tendency to lead to the exclusion of outsiders, perhaps represented as enemies, or for the internal repression of individuality, autonomy, or personal responsibility.

Space, Philosophical Theories of

From antiquity through the Scientific Revolution, a major controversy was whether extension can exist without body. Although this is sometimes still debated, the original *Problemstellung* has been eclipsed in three respects: first, by the emergence of the field concept in physics; second, by the assimilation of space into space-time; and third, by the geometrization of gravity in the general theory of relativity. This entry traces the history of concepts of space and the philosophical debates concerning the nature of space.

The beginnings of the concept of space in Greek thought are not clear, since the term *space* is of Latin derivation and has no direct Greek origin. Plato's notion of the receptacle in his dialogue *Timaeus* played too much the role of Aristotle's later concept of prime matter to be considered to refer to space itself. Aristotle went to great lengths to develop a notion of place (*topos,* or τόπος) but never wove these places together in order to arrive at a doctrine of space. Earlier, the Greek atomists Democritus and Leucippus, in response to the single, changeless being of Parmenides, had introduced the notion of the void (*kenon,* or κευόυ) in which atoms can move. By the time of Epicurus, a global notion of space clearly emerged, according to which *kenon* refers to unoccupied locations, *topos* to a part of space occupied by a body, and *chôra* (χώρα) to a region of space through which a body is moving. This became standard in later atomism.

The word *diastêma* (διάστημα), which refers to (a finite) extension, led to the division of Greek and Latin philosophers into two camps. On the one hand were those, including Plato, Aristotle, and the Peripatetics, who rejected the possibility of *diastêma* without body, and on the other hand, were the atomists and the Stoics, who allowed for unoccupied extension. For the former camp, the universe is a finite material plenum. For the latter, the universe is infinite in extent. (The atomists believed the number of atoms to be infinite as well, while the Stoics took the world to be a finite plenum embedded in an infinite void.)

Descendants of these views emerged in the 17th century. René Descartes identified matter with extension, and hence by definition, there can be no empty space. The pivotal innovation was that Descartes permits the parts of space to move among themselves. Indeed, all physical phenomena are to be traced to the motions of this material plenum. Stationary space, in which this motion takes place, is only a mode of thought.

Following Descartes in the 17th century, Pierre Gassendi and Walter Charleton revived a Christianized version of the Epicurean worldview. To address the Aristotelian objections, they held space to be neither a substance nor an attribute but rather something with its own nature of being that arises of necessity from the existence of God, who is literally omnipresent. Isaac Newton took over this concept, calling it *absolute space.* Famously, he argued in the "Scholium" to the definitions of his *Principia* that the definition of the state of true motion or rest of a body requires the existence of absolute space. He also likened absolute space to the sensorium of God. This drew the ire of Gottfried Leibniz, who like Descartes, was a material plenist and believed in a transcendent God. For Leibniz, a body's true motion is internal to it and cannot be known (although there cannot be true motion without relative motion between bodies). Space is something ideal and relative, arrived at by hypostatizing the locations of bodies at relative rest.

The success of Newton's mechanics led to the widespread acceptance of absolute space, although it had its frequent critics. In the 18th century, Immanuel Kant initially thought that the existence of incongruent counterparts (left hands and right hands) supported Newton over Leibniz, only to argue later that space is the a priori form of outer perception. But Kant was unable to go on to develop

a natural philosophy of motion capable of bearing fruit for physical science.

Changes in physical theory led to new conceptions in the 19th century. It was primarily due to Thomas Young's and Augustin-Jean Fresnel's resuscitation of the wave theory of light in the early 19th century that the world became a plenum again, with an omnipresent optical ether conceived as stationary en masse in absolute space. The Scottish physicist James C. Maxwell, by identifying light with electromagnetic radiation, converted this into an electromagnetic ether, which in the hands of the Dutch physicist H. A. Lorentz at the end of the 19th century became dematerialized to the extent that one has an everywhere stationary ether, at each point of which exists an electric and a magnetic state. As such, it is difficult to discern whether this is a material plenum or rather Newton's absolute space endowed with further physical qualities. Max Abraham is representative in suggesting that the difference is but a choice of one's *façon de parler.*

Special relativity brought further changes by wedding space with time as a consequence of the relativity of distant simultaneity. Events simultaneous for one observer are not simultaneous for another observer moving relatively to the first. Thereby, spatial extension also becomes relative. The more natural physical ontology becomes one of space-time events rather than of spatially extended substances enduring over time. Yet further change appeared with general relativity. For one, the metric of spatial hypersurfaces of space-time no longer needs to be Euclidean but may have variable curvature, either positive or negative. For another, the metric tensor also serves as the gravitational potential, making it unclear whether space-time is an arena in which physical events occur or whether it is a kind of four-dimensional ether, as Albert Einstein sometimes described it. Other fields exist in space-time, and the metric field can exchange energy with them. However, gravitational energy cannot be localized as an energy density, as can the energy of other fields. By Einstein's famous formula for the equivalence of mass and energy, this entails that the gravitational metric can possess mass, only one cannot say how this mass is distributed. The best one can say is that the nature of space in general relativity is unprecedented. The introduction of quantum gravity promises to bring yet further modifications by giving space a granular structure at the extreme micro level of Planck length, 10^{-33} cm.

Space, Social Theories of

This entry provides an introduction to a number of key social theorists who address the *production of space* and its implications for the analysis of social relations. It will thus show the importance of a renewed, radical reconceptualization of "space" in social science.

Space as a directly theorized concept has been, until relatively recently, a neglected and underaddressed aspect of social theory. The reprioritization of space as a fundamental element in the organization, structure, maintenance, regulation, and experience of social relations and of social life has generated interest within a number of social science disciplines. Space is no longer assumed to be a mere backdrop to social life, as something merely there, as natural, a void, a container, a vacuum waiting to be filled by objects or social activity. Instead, space is increasingly analyzed and understood as a product of social relations and as such is a contingent and complex process that not only reflects the needs, priorities, ideologies, aims, and practices of power per se (whether individual, institutional, or structural) but is also potentially in conflict with everyday uses, activities, and practices. Space as a product of social relations then operates in all spheres and at different scales, from the personal and micro to the macro and global levels.

Classical Social Theory and Space

The origin of much of social and especially sociological theory resides in the works of Karl Marx, Max Weber, and Émile Durkheim. Despite their ontological and epistemological differences, a recurrent theme in all their works was the attempt to make sense of the new social and material landscapes of modernity and industrial capitalism. However, the consideration of space as a fundamental factor in their analysis of the transition from feudalism to capitalism and its establishment as the dominant mode of production are implicitly, rather than explicitly, addressed in their works.

Weber, in his emphasis on the development of a rational organization of production, market, state, and bureaucracy, observes that all presuppose spatial organization. Similarly, the separation of work/household as a precondition for the emergence of capitalism and its extension to the separation of the public and private spheres have an implied spatiality. However, similar to his investigation of the role of the medieval city as a combination of fortress and market, a precursor for modern rational and urban industrial capitalism, the role of space is not developed.

Durkheim, in his treatment of the transition from feudalism to capitalism, focuses on the change from mechanical to organic social solidarity and emphasizes changes in the *spatial* organization as well as social division of society. Durkheim uses the spatial metaphors of material and moral density to explain the increasing distancing and isolation (resulting in egoism and anomie) of individuals who are cut adrift from traditional kinship ties and networks in increasingly concentrated urban centers. However, space is not explicitly theorized by Durkheim.

It is possible to identify in Marx's voluminous writing on capitalism an implicit, if not explicit, acknowledgment of space and spatial relations as a feature of the specificity of its operation and alienating experience. This includes space as a force of production, the destruction of previous spaces associated with the feudal mode of production and the creation of new spaces of capitalist production and circulation, the spatiality of the detailed division of labor (in society, in industry, as well as in the reproduction of labor, especially the spatial form of the industrial city, leading to what Engels describes as socio-spatial segregation), and capitalism as a world system.

For all these founders of social science, there is an *implicit* acknowledgment of the role of space, in their analyses of various factors, features, processes, and effects of the transition to capitalism, as the dominant mode of production but one that is not developed explicitly or in detail.

Simmel and the Sociology of Space

Georg Simmel (1858–1918) may be said to be the first sociologist of space in that in much of his work, not only in sociology and urban analysis but also in philosophy, literature, art, aesthetics, social psychology, and cultural analysis, there is a clear focus on space as a fundamental feature of the analysis of modernity through formal sociology. His essay "The Sociology

of Space" is an early contribution to the social theory of space, which, in keeping with his conception of society as reciprocal interaction, presents his five "aspects of space" (exclusivity, boundaries, fixity, mobility, and proximity and distance) as a means for investigating the significance of space for social forms. Simmel acknowledges that space shapes, and reciprocally is shaped by, the forms of social interactions that occur within it. This is a dynamic symbiotic relationship between social construction and environmental—that is, geographical—determinism, which has significance for subjective experience as well as the structural and spatial organization of the city as a whole or specific spatial forms within it, including the streets, squares, buildings, and places and spaces of consumption, leisure and recreation, or escape. Space thus features prominently and explicitly in Simmel's work on forms of social interactions as networks that constitute society.

Henri Lefebvre and the Production of Space

Henri Lefebvre (1901–1991) is considered the most influential theorist in the recent "spatial turn" in the interdisciplinary studies of space. His corpus of work on various aspects of modernity, particularly that relating to the urban, asserts the need to understand space both as a product (a thing) and as a determinant (a process) of social relations and actions. Space, for Lefebvre, is both a means and a mode through which and in which social relations and actions occur. Space therefore cannot be separated from social relations and is the product of ideological, economic, and political forces (the domain of power) that seek to delimit, regulate, and control the activities that occur within and through it. In this, Lefebvre emphasizes that space is subject to conflict and contestation over the meanings and values that are represented by and attached to it.

Lefebvre's analysis of the production of space centers on the interplay of everyday experience and interactions within historical modes of production. Forms and arrangements of space (spatial practices) as well as representations of space (maps, designs, plans, signs, symbols, regulations, etc.) and the lived experience of space (spaces of representations) exist for Lefebvre as a dynamic interrelationship that collectively produces space. However, for Lefebvre, under capitalism, representations of space dominate the other two elements in that ownership infers control and regulation, that is, the power to delimit and delineate what actions, activities, social practices, and so on, are permitted or allowed in specific spaces.

For Lefebvre, there is a need to understand all three elements in that form, structure, and function alone cannot provide a comprehensive understanding of space. There is a need to ask who produces what forms/kinds of space, why and for what purposes, and whom are they for? But space as a social product is not only the domain of power. Space is also where the lived experience of everyday life takes place, though its inhabitation and colonization is invested with meanings and values that may conflict with the designed intentions of planners, architects, the state, and so on. Space then is the product of social relations and as such is not only a constraining factor, a structuring element, but also the means by and through which we make sense, understand, and invest meaning in our everyday lives.

Space and Place

There is a need to distinguish between the interrelated concepts of *space* and *place*. Often, the two are viewed and used interchangeably, but there is a need for more precision in understanding spatial theories and their application to the analysis of social life. *Space* refers to the abstract conception of physical location and its contents. Spaces become places when individuals and groups assign meanings and social significance to them. Michel de Certeau (1925–1986) argued that space is the effect produced by those processes that seek to define, functionalize, and situate it, while place signifies attachment through uses and practices of meanings and values that confer stasis, value, and importance in everyday life. Similarly, the geographer Yi Fu Tuan (1930–) associates space with mobility, movement, and flow, while place is endowed with values accomplished by pause and immobility through knowledge and use. Thus, there is a distinction between abstract designs and plans, and lived experiences, in which meanings and values change space into place through everyday practices and uses.

David Harvey and the Political Economics of Space

David Harvey (1935–), geographer and influential social theorist, has extended aspects of Lefebvre's thesis on the social construction or production of space as a means to expand Marx's historical

materialism to include a geographical or spatial element. Harvey's initial concentration on the creative destruction and reconstruction of the built environment emphasizes the conflict and contestation over space, which involves not only class conflicts over the allocation and distribution of services and resources but also competition and cooperation between capitalists (through the state) in a profit-oriented market. What Harvey asserts is that space is capable of being shaped and formed by human actions and that such actions do not belong solely to those with power. Command over space involves conflict and contestation over meanings and between exchange and use values. In later work, Harvey extends his analysis beyond the city to focus on the produced space of globalization, particularly that dominated by neoliberal economics, which creates an interrelated network of production, circulation, and consumption of services and commodities, requiring the creative destruction and production of a new global spatial order.

Foucault: Space, Knowledge, and Power

Michel Foucault (1926–1984) did not propose a general theory of space, but his well-known proposition concerning the emergence of a dispersed system of spatial sciences in Europe in the 18th century resulted in what he considered to be the formation of modern disciplinary society. Most of his focus in this respect has been on those technologies of surveillance, in particular the celebrated *Panopiticon* (of Jeremy Bentham), in which architecture and design were applied to the carceral space of prisons to discipline and train prisoners as well as to inculcate in them appropriate moral and physical norms and values that would ensure their rehabilitation before their return to society. The application of architecture and design in which the "eye of power" was used to create "docile bodies" was, according to Foucault, used in other disciplinary institutions, such as schools, hospitals, and barracks. Foucault's writings on space and geography provide a more nuanced understanding of the relationship between power and knowledge as an interlinked concept applied not only in these institutional settings but also to society at large. The organization and control of space for Foucault was a fundamental strategy of bio-politics and "governmentality" in the creation of docile bodies and populations. Foucault singles out the medical profession, in particular public health officers, as the "first specialists of space" who required knowledge of the physical landscape of expanding towns and cities as well as their populations to plan and design social and physical infrastructures to ensure both a more hygienic and a safe urban environment and society.

Spatial theories and analyses have led to an increased interdisciplinary acknowledgment of the importance of spatiality for understanding and research in a variety of spheres and areas. For example, spatial theories have been applied to space and gender (Massey), sexuality (Bell & Valentine), social divisions and fear of crime (Caldeira), postmodern architecture and urbanism (Soja & Gottdiener), landscape (Cosgrove), globalization, and risk.

Speech Acts

The study of speech acts arose in part as a challenge to a dominant philosophical assumption that the primary purpose of language is to describe the world. In the middle of the 20th century, philosophers such as Ludwig Wittgenstein, J. L. Austin, Peter Strawson, Paul Grice, Gilbert Ryle, and John Searle began to undermine that assumption by arguing that even a grammatically indicative sentence may be used for many other purposes besides description. Describing is now seen as one of a great variety of things that can be done with words, such as defining, promoting, excommunicating, and promising. This new perspective has enabled students of language from many fields (including philosophy, linguistics, social psychology, computer science, literary theory, and law) to appreciate how language use is ineluctably bound up with intentions, interpersonal relations, and social institutions. The last reminds us that speech acts play a crucial role in our social life and, for some, a constitutive role in creating social institutions. In the case of Searle, in particular, something akin to the functioning of speech acts has been put forward as the foundation of the construction of social reality. Speech acts have thus occupied a crucial position in some theories in the philosophy of social sciences.

Speech Acts, Acts of Speech, and Performatives

Many types of action can be performed by the uttering of words. I might startle you with my loud "Boo!" or offend you with my atrocious singing. However, these acts of speech are to be distinguished from speech acts in the semitechnical way in which this expression is used in the philosophy of language. According to that usage, a *speech act* is any act that can be performed by, or in, saying that one is doing so. Growing an inch taller is not a speech act because I cannot do so by, or in, saying so, and likewise for adding a sum to the amount in my checking account. However, I can promise to meet you tomorrow at noon by saying, "I promise to meet you tomorrow at noon," and if appropriately empowered, I can declare the proceedings open by saying, "I declare the proceedings open." Part of the interest of the topic of speech acts derives from our ability to achieve momentous nonverbal effects by verbal means.

Theorists of speech acts typically distinguish among levels of linguistic analysis. On the semantic level, one can string together meaningful words according to grammatical rules to produce a meaningful sentence. "The proceedings are open" is such a case, as is "I promise to meet you tomorrow." Both sentences have fairly determinate meanings, but those meanings are independent of their use to perform a speech act. After all, I might utter either of these in my sleep or while delivering the lines in the play in which I am acting. In neither case do I literally mean what I say (declare any proceedings open or promise to meet you). Thus, uttering a sentence with a semantic content will not ensure that it has been used to perform a speech act. Since the theory of speech acts is a part of the *pragmatics* of language, this is to say that semantic meaning leaves pragmatics underdetermined. A full account of the import of an utterance must attend not just to its semantic meaning but also to its pragmatic significance.

Sometimes, as in the last two examples of promising and declaring open, we make explicit what speech act we are performing. In such cases, we use sentences that one of the pioneers in theorizing about speech acts, J. L. Austin, called *performatives*. On this usage, a *performative sentence* is any sentence that makes explicit the speech act it is characteristically used to perform. Speakers sometimes additionally insert "hereby" to draw attention to the fact that their utterance is accompanied by carrying out the act, as in "I hereby declare the proceedings open."

One can perform a speech act by using a performative sentence. However, we also perform speech acts without making explicit what act we are performing. One can assert that it is raining by saying, "I assert that it is raining," but one can also do so by simply saying, "It is raining." In the latter case, the speaker relies upon the context of her utterance to make it clear that her act is an assertion rather than some other kind. So too in saying, "I'll be there tomorrow," one might count upon context to ensure that

one's utterance is a prediction rather than a promise. However, when something of value is on the line, it can help to make explicit what speech act one is performing with the use of a performative sentence.

Infelicities

Only those appropriately empowered can declare proceedings open. More generally, many speech acts can only be performed by speakers possessing a certain status. Lacking that status, the speaker will perform an act of speech but no speech act—a case Austin termed a *misfire*. For instance, strolling up to the Taj Mahal, I announce, "I hereby declare this the Babe Ruth Palace." Here, I have uttered words with determinate meaning, and I've performed an act of speech but no speech act: I have not endowed that palace with a new name. Austin and his student Searle have detailed the conditions that various acts must meet if they are not to misfire.

Among the conditions that must be met to avoid misfire is the requirement of an appropriate response from the addressee. I might try to bet you $100 that it will rain tomorrow, but I won't succeed unless you accept that bet. Responses such as these are known as *uptake*. Some, but not all, speech acts will misfire unless they are followed by an appropriate uptake.

Austin's doctrine of infelicities in speech acts included not just ways in which they may misfire but also ways in which they may be abused without misfiring. I make a promise I have no intention of keeping. In that case, I have committed myself to carrying out the promised act even though I do not plan to do so. So too, a child might assert that he's done his homework, although he has not done so; here too, a speech act of asserting has been performed, but its insincerity makes it infelicitous. Given the importance for social life of our ability to make agreements, convey information, and modify one another's roles by means of speech acts, we find a common temptation to abuse these institutions for our own gain.

Illocutions, Perlocutions, and Implicature

Austin's term for speech acts was *illocution,* and he distinguished illocutions from what he termed *perlocutions,* which are those effects characteristically brought about by illocutions. Persuading does not fit our definition of a speech act given above, but a characteristic effect of an act of *urging* you to leave the room is persuading you to leave the room. Persuading is thus a perlocution. So too, I cannot impress you by saying that I am doing so, but I may do so with a series of eloquent promises, assertions, appointments, and even denunciations.

Perlocutions are generally effects on addressees. However, speakers often achieve more in a speech act than a perlocution. Often we are able to "mean more than we say" by virtue of the phenomenon known as *implicature* (described and analyzed by Grice). In answer to your question "Where is Susan?" I reply that she is either in the toolshed or in the garage; in so doing, I convey that I do not know which of these two it is. Or you ask me whether I can join you for a movie this evening, and I reply that I have a major deadline tomorrow. I mean, without saying so, that I cannot attend the movie. Grice posited a number of principles (enjoining speakers to be relevant, truthful, adequately informative, etc.) that, as rational interlocutors, we implicitly follow, and he used these principles to explain how we can mean more than we explicitly say. In some cases, this further meaning is a speech act as well. For instance, my remark "You're standing on my foot" is naturally construed not just as a statement of fact but also as a request that you remove your foot from mine. Implicated speech acts such as this are known as *indirect speech acts* (discussed by Searle).

Speech Acts and Norms

Language relates to reality in many more ways than simply describing it, and when it is used to describe reality, it can do so by various illocutionary means. We may appreciate this by noting that different types of speech act are governed by distinctive sets of norms. It is a norm of assertion that one who *asserts* a proposition P should be in a position to respond properly to challenges of the form "How do you know?" By contrast, one might *conjecture* P; and while both assertions and conjectures of P stand to be right or wrong depending on whether P is true, it is not appropriate to call out a conjecture with a challenge to the speaker's knowledge. Rather, an appropriate challenge to a conjecture would be a request that the speaker give *some* basis for what she says; another appropriate challenge would simply be to show that what has been conjectured is untrue. Other speech acts might have the same propositional content P while being governed by yet different norms: Guesses, presumptions, suppositions for the sake of argument, and presuppositions are examples.

Norms governing speech acts evidently overlap with moral norms but are not reducible to them. The injunction that one who asserts that P is to believe that P on pain of being a liar is likely a moral norm. However, one who attempts but fails to name a famous building after himself has done something silly rather than immoral. Norms governing speech acts are perhaps best construed analogously to norms of etiquette. In one society, the "done thing" is to burp loudly after a meal, while in another, this is considered inappropriate. So too, if one is to *assert* or *promise*, certain standards are to be adhered to, but this leaves open the possibility of another culture or group developing its own set of verbal institutions with a unique set of norms.

A twinkle in an eye can speak volumes among sensitive interlocutors. So too, an implication of the theory of speech acts is that the utterance of an innocuous-seeming sentence can be momentous, committing its speaker to a policy or course of action, modifying the social status of the addressee, or forging a bond, for good or ill, between the two. Study of speech acts has and will continue to illuminate the rich communicative content thriving under the grammatical surface. Speech acts are therefore a crucial element of the social world.

Spontaneous Order

A spontaneous order refers to a pattern, regularity, or structure generated without conscious design or explicit agreement. Sometimes referred to as self-organizing systems, complex adaptive systems, or emergent, endogenous, or polycentric orders, these phenomena may be found in both the natural and the social realms. For example, a particular ecosystem may reflect spontaneous ordering forces within

nature. Such orders may also be found within societies or across societies.

Examples of spontaneous social orders include the emergence of money, social conventions and norms, language, as well as economic patterns and institutions (including, e.g., the division of labor and prices). That a complex ordering might emerge without design, intention, or agreement requires explanation. Social science may explain such orders by using "invisible hand" explanations to explore how a complex pattern might arise from initial conditions in which individuals, bearing certain properties, act so as to bring about the pattern without either intention or design. It is often argued that spontaneous orders coordinate disparate knowledge and generate a complex set of interactions not otherwise attainable by design.

In this entry, we characterize the nature of a social order, discuss how it may be spontaneous, and set forth some of its significant implications.

Order and Spontaneity

To refer to an "order" of things, elements, particles, or persons is to suggest that these manifest relations allow one to make predictions from one part of the order to another. Thus, an order is constituted by relations among parts or elements, a subset of which allows one to form predictions or expectations about other parts or elements. A *social* pattern or order would, therefore, be a complex pattern of actions of human agents whose relations allow a participant to form predictions or reliable expectations about elements of the whole not currently experienced by that person. Within society, the agents may be understood as individuals or as groups (institutions, organizations, firms, etc.). Such a social order is spontaneous insofar as the set of relations emerges, without design or intention, from the actions and interactions of individuals. A spontaneous order is framed by rules, either explicit or implicit. The framework of rules allows agents to respond to and adapt to one another and to changing circumstances; as the agents act on their knowledge (or information) and react to the activities of other agents, new patterns of conduct emerge that were not originally present or part of the intentions of the acting individuals. Such an order may emerge over a relatively short period of time (e.g., an aggregative pattern of market prices), or it may occur over a long period of time (an accumulative order, as exemplified by structures or institutions that evolve over time).

Relevance to Social Science

A number of thinkers have appealed to the idea of spontaneous order. Michael Polanyi was one of the first to employ the terminology, describing the enterprise of science as one such order. In various works, Friedrich A. Hayek has articulated the significance of spontaneous order to an understanding of liberal and commercial societies. For Hayek, a genuinely spontaneous social order emerges out of purpose-independent rules, universally applicable, that provide for plural or private property. Out of these rules, an extended social order will emerge, to include the order of the market as well as overlapping orders, such as those of morals and social norms. The overall spontaneous order (and particularly the market order) will allow for the generation and coordination of more knowledge and information than could have been devised and implemented by a centralized authority or designer. For Hayek and other advocates, a spontaneous order enables individuals to generate and utilize more knowledge, both propositional and practical, than would otherwise be attainable.

Other important social theories bear resemblances to spontaneous order theories. The theory of symbolic interaction, following from the work of George Herbert Mead, suggests that social phenomena emerge as individuals respond to situations, circumstances, and other persons. Recent elaborations of systems theory, in particular the self-reproducing or *autopoietic* theory of Niklas Luhmann, explore how society incorporates a collection of differentiated systems—say legal, economic, or artistic—that function in a decentralized manner.

Relevance to the Philosophy of Social Science

The theory of spontaneous order sets forth salient issues for the philosophy of social science. The very idea of a spontaneous order raises questions of social ontology. Is the order of society to be understood in terms of the behavior of persons? Or is order, in fact, a phenomenon of the mind, constituted by the beliefs and expectations of those who navigate and act within the society itself? The idea

of spontaneous order also broaches significant issues regarding the coordination and utilization of dispersed knowledge. Insofar as such orders allow for a degree and kind of complexity not otherwise attainable, then so should models of regulation and public policy take into account how ever-more precise and determinate rules and regulations may serve to inhibit the growth and utilization of knowledge and information.

Straussian Critique of Social Science

The Straussian critique of modern social science originates in the writings of Leo Strauss (1899–1973), who sought to restore an appreciation of classical political philosophy as a superior mode of addressing fundamental human questions. This entry reviews Strauss's thought on the primacy of political philosophy, his sustained critique of "new" or "behavioral" political science, and shows its continuing importance for recent developments in political theory.

Strauss criticized the social science of our time as *insufficiently scientific* or precise, as the result of the misguided attempt to apply the methods of modern natural science to phenomena that do not lend themselves to understanding through that approach. Strauss regarded the recovery of the classical perspective as particularly urgent in our era, owing to the crisis of modern Western civilization, which was both articulated and deepened in the thought of Friedrich Nietzsche and Martin Heidegger. Strauss's aim was not to secure agreement on all of the specific political judgments made by the greatest classical writers, such as Plato, Aristotle, and Xenophon—judgments that would certainly need to be revised in light of subsequent political, religious, and scientific developments. Nor did he deny the utility of quantitative scientific methods in a field like economics (the one area of social science that has clearly profited from that approach). But he argued for the *primacy of political science or political philosophy* over the other human sciences (as Aristotle suggested in calling politics the "architectonic" study, or *technê*, situated at the summit of all others and directing or "governing" them all) and for the necessity that the student of society *begin* his inquiries, as the classical philosophers had done, with the perspective of the concerned citizen, who seeks clarification of the nature of his own and his country's good and makes claims on his government based on opinions about justice. It is the fundamental task of the political

philosopher, Strauss maintained, to clarify the issues raised in such civic debates, with a view to both promoting practical political improvement and achieving greater understanding of the human condition itself.

The chief obstacle to social science's furthering such goals in our time, Strauss contended, was the supposed distinction between "facts" and "values," developed most profoundly by the great German sociologist Max Weber and adopted by the 20th-century theorists of "logical positivism." According to that distinction, it is the duty of the social scientist to limit his judgments to matters of fact, eschewing evaluative claims, since the latter are incapable of being verified by reason. In the second chapter of his most influential book, *Natural Right and History,* Strauss challenged Weber's argument, contending that it is impossible to provide meaningful, empirical descriptions of social or political phenomena without evaluating them; that the supposed incapacity of reason to arrive at objective evaluations is itself incapable of being demonstrated; and that the fact/value distinction, contrary to Weber's intention, inevitably leads to outright moral relativism, or nihilism, according to which the basest of human deeds must be accorded "objectively" equal status with the noblest.

Although Strauss addressed the problems of social-science relativism in several of his other writings, his most comprehensive critique, outside of the chapter in *Natural Right and History,* was the "Epilogue" he composed to *Essays on the Scientific Study of Politics,* edited by Herbert Storing, in which four of his former students offered critical assessments of leading examples of the "behavioral" approach to different areas of contemporary political inquiry: voting studies, public administration theory, group politics, and "scientific propaganda." Summarizing and elaborating the findings of those studies, Strauss identified several defects of the "new" political science, including the following.

First, despite their profession of relying only on information about politics derived from "scientifically" verifiable research, "behavioral" political scientists are "constantly compelled to borrow from common sense knowledge" both to identify and understand objects of knowledge and in order to make their findings intelligible—thus attesting to the fact "that there is genuine prescientific knowledge of political things" possessed by the unscientific citizen that "is the basis of all scientific knowledge of them" (Strauss, 1968, p. 214).

Second, in its attempt to uncover "universals" that are assumed to be common to all political regimes, the "new" political science obscures the true universals in light of which political phenomena need to be understood: the differences *among* political regimes, which in turn shape the character of subpolitical associations. Thus, it misleadingly reduces distinctions of kind (e.g., between liberal democracy and communism) to mere differences of degree.

Third, because the chief techniques of contemporary, "empirical" social science research can be applied only to human beings now living, in countries where governments tolerate such research, its supposedly universal findings tend to be parochial in both time and place.

Fourth, in its attempt to replace "the political understanding of political things" with a "scientific" language, such as the substitution of "power relations" for "politics" and of Sigmund Freud's "superego" for conscience, behavioral political science obscures crucial distinctions (e.g., between a bad conscience and "guilt feelings") as well as the more general complexity of political life that is captured in ordinary speech.

Fifth, and most important, having ostensibly expunged "values" from their descriptions of political things, the new political scientists are compelled to smuggle evaluations in through the back door (e.g., through terminology like "the open society"); but unlike the practice of the classical political philosophers or intelligent modern historians, these evaluations are never subjected to rational assessment. Hence, they remain mere prejudices.

Although fads in the social sciences have partly changed since Strauss wrote, his criticisms apply *mutatis mutandis* to more recent movements like "rational choice theory" and the "new normativism," typified by the writings of John Rawls and Robert Nozick, which constructs utopias ungrounded in political fact or in critical assessment of the author's value preferences. While Strauss recognized that a considerable amount of valuable work is done by genuinely empirical political scientists—on topics such as the operation of American political institutions or problems of contemporary international relations—he tried to rescue such practical political analysis from subsumption under abstract theories that obscure rather than

clarify the nature of political phenomena. Without denying the achievement of the great modern political philosophers whose thought generated America's constitutional-liberal regime, he maintained that Aristotelian political philosophy—which bears certain resemblances to the political science of Alexis de Tocqueville—offers the best theoretical foundation for political inquiry.

Strong Program in the Sociology of Scientific Knowledge

This entry explains the basic theses of the influential "Strong Program" in the sociology of scientific knowledge, also known as the "Edinburgh school," whose main protagonists were Barry Barnes and David Bloor.

Supporters of the Strong Program argue that both true and false, and rational and irrational beliefs are open to sociological study and that the same general explanatory processes and causes are at work in the analysis of both cases. The principle that sociological curiosity should apply equally to all knowledge claims is called the *symmetry postulate*.

The Strong Program is best approached via the position that its supporters reject—a position that may be called the "weak" program. The weak program is based on the idea that sociological causes may explain (a) the conditions that promote or inhibit science and (b) any deviations from the operation of the rational principles that should govern the growth of knowledge. Sociologists can be given the task of explaining why science developed in Europe and not in China or the job of explaining why science is distorted by political interference in totalitarian states, but that is all. According to the weak program, the normal, rational activity of science calls for a nonsociological explanation in terms of the reasons advanced by scientists themselves.

The weak program rests on an allegedly fundamental distinction between the *rational* and the *social*. Society can, at most, propagate rationality but cannot constitute it. Society is the cause of facilitation or deviation but not the immanent working of rationality itself. The weak program has clear implications for history and sociology: It is necessary to disentangle the social from the rational and exhibit each playing its proper, but different, role. The attractions of this view may derive from its roots in daily life. What is normal and routine becomes taken for granted, and only deviations seem to call for explanation. Commuters want to know why the train is late, not why it is on time. In reality, there is a cause for the train being on time just as much as for its being late. This may arouse no interest in the tired traveler, though it should be highly interesting for experts who want to keep the system running. The weak program, as formulated, for example, by Imre Lakatos, involves turning this commonsense asymmetry and lack of curiosity about routine into a philosophical principle.

The weak program may be superficially attractive, but there is a price to be paid. The most cogent criticism of the weak program derives from Ludwig Wittgenstein's analysis of rule following. He took the example of following an arithmetical rule: for example, "add 2" in order to generate the sequence

2, 4, 6, 8, and so on. Critics of the Strong Program argue as follows: Surely the behavior is governed by the rule, and as long as the rule is followed, the rule itself explains the behavior. What is there for the sociologist or psychologist to explain except (a) how the follower came to be in a position to understand the rule (e.g., schooling) and (b) deviations from the rule (e.g., lapses of attention or inadequate training)? It should be clear that on this view the operation of the rule "itself" remains mysterious.

Wittgenstein sought to provide a more revealing "strong" account of rules by examining the resources available when training a rule follower or when correcting errors in performance. He found, of course, that reasons come to an end. Any correction offered by a teacher will be a rule for following a rule or an interpretation of the rule. To avoid a regress, a tenable explanation must ultimately depend on there being ways to follow rules that operate below the level of reason giving. The process ultimately depends on ways of aligning behavior at the causal level. Everything depends, as Wittgenstein put it, on something animal. We are social animals susceptible to one another through the influences generated by our interactions. Thus, *the rational depends on the social* and cannot be disentangled from it. This amounts to accepting that rationality is indeed a natural phenomenon (nothing supernatural about it) and that rules are conventions and social institutions. Wittgenstein's work thus destroys the most cogent supporting example of the weak program. It shows that there is an *irreducible* sociological dimension to correct rule following, not just to incorrect rule following, just as there is a sociological dimension to trains that run on time.

Two further points need to be stressed. First, the Strong Program is not just concerned with examples of the kind given above. It also applies to empirical knowledge. Contrary to the claims of critics, the program does not imply that knowledge arises from scientists responding to society *rather than* to the material environment. Scientific knowledge of the material world is indeed about an independent reality, but the knowledge is always shared and collectively constructed. As Thomas Kuhn demonstrated in his *Structure of Scientific Revolutions,* these sociological characteristics apply to good science just as much as to bad science. Notice, though, that it is *knowledge* that is socially constructed, *not* the ultimate constituents of the material world.

Second, the Strong Program is *relativist*. Relativism simply means the rejection of any claim to absolute knowledge and derives from an awareness of the natural origins of all processes of cognition. Relativism must not be confused with idealism ("the material world does not exist"), irrationalism ("anything goes"), or the idea that humans are imprisoned in inherited conceptual schemes ("the myth of the framework"). As Wittgenstein's arguments show, conceptual schemes (like rules) are the product of social life, not its determinants, just as the shared use of a word determines its meaning, rather than meaning determining use.

Structural Functionalism, in Social Theory

Structural functionalism became one of the most influential theories in the history of sociology and also figured quite significantly in that of anthropology. Structural functionalism is not to be confused

with *structuralism,* for which there is a separate entry in this encyclopedia.

Origins

Structural functionalism originated in the work of some of the founders of sociology—Auguste Comte (1798–1857), Herbert Spencer (1820–1903), and Émile Durkheim (1858–1917). It reflected their interest in seeing society as in many ways being analogous to a biological *organism,* with its separate parts each fulfilling necessary *functions.* So just as the stomach performs a digestive function and the heart the function of pumping blood about the body, so in the social body the family would fulfill the functions of procreation and socialization, schools an educational function, and so on.

Of the three, Durkheim's work was by far the most influential. In addition to his sociological influence, his writings profoundly affected the functionalist leanings of *social anthropology* through the work of Alfred Radcliffe-Brown (1881–1955) and Bronislaw Malinowski (1884–1942). Durkheim's own position may be more complicated with regard to his espousal of functionalism, but it may be safe to say that his book *Division of Labor* is the inspiration for functionalism and functionalist interpretations of him. In addition, Radcliffe-Brown has some claim on the title of "founder of structural functionalism" (though he was not happy with the label).

These latter two social anthropologists, through their disagreements over what is perhaps the central concept of structural functionalism—that of *function*—provided deep insightful thought into the philosophical foundations of their discipline and perhaps, ironically, the grounds for later critique.

Radcliffe-Brown, in keeping with his desire for scientificity, wished for conceptual precision with regard to the notion of function. He thought that with regard to the two ways science had used the term—as the physiological contribution a particular organ made to the continued healthy working of an organic system or with the quite different meaning and context of a mathematical function—the former, but not the latter, should be developed analogously. Thus, the notion of function for Radcliffe-Brown should refer to the contributions made to the persistence of the entire system of social relations. Malinowski criticized this both as unnecessary abstract formalism and as problematic in terms of the role of analogies in social science derived from the natural sciences. In this latter point, he presaged quite important thinking in the philosophy of social science, though, at the same time, espousing a slightly naive dependence upon the "concrete" in fieldwork.

One could make the argument, however, that Malinowski won this debate because whatever the theoretical merits or not of Radcliffe-Brown's position, the actual history of usage of the term *function* shows considerable slippage and imprecision, which we shall briefly consider later in this entry.

Neither the early sociologists nor the anthropologists fully developed the systematic body of theory known as structural functionalism. Rather, they should be seen as progenitors, as the theory awaited a later thinker for its full development: Talcott Parsons (1902–1979). Ironically, Parsons was not particularly happy with this as a label for his theory, but be that as it may, it is the label that is indelibly associated with his name.

Talcott Parsons

Sociology is often described as a discipline lacking a paradigm. That is, it lacks a common philosophical foundation, methodology, and dominant mode of theorizing. It even lacks an agreed-upon definition of its subject matter and what its most important questions are. This is truer than ever today; and though this lack of foundational consensus has been a historical constant, it did at one time come close to a paradigm. That was during the 1940s and 1950s and reaching into the early 1960s, when structural functionalism was the dominant sociological perspective, less so in Europe but particularly so in America.

A good example of sociology lacking consensus can be seen in the work of two of its three most important classic thinkers: Max Weber and Émile Durkheim (the other being Karl Marx). Durkheim believed that society had a sui generis reality, whereby it existed in its own right and was not reducible to the sum of its constituent parts. Weber not only disagreed with this perspective but considered it an error—the error of reification—made not only by social theorists but by ordinary people as well. The error of reification, according to Weber, is to conceive of collective entities, say, a team, as really existing as something in their own right. Rather, a

team should be thought of as a convenient linguistic fiction; the reality of the team is the individual people: the coach and players who compose it. Weber's theoretical emphasis was upon social action, while Durkheim focused more upon *social structure*.

It is the latter emphasis that structural functionalism tends toward, but it was Parsons's conscious intent to combine the best insights of *both* Weber and Durkheim. We can see this intention in the title of one of his most famous works, *The Structure of Social Action*. We can also see that structural functionalism leans toward the structure side of the equation from the title of another of his most famous works, *The Social System*.

The first step in the scientific investigation of any social phenomenon, Parsons argued, is the identification of the *unit acts* of which it is composed. The unit act is the most fundamental concept of all social analysis and is analogous to an elementary particle in physics. The second step is to describe their features in terms of the *action frame of reference*. This regards actions as being organized over time and involves the purposive use by people of means to attain goals.

From this perspective, we can see our social system as being an action system and, thus, a system of interrelated parts. These parts *function* in relation to the needs of the whole that is society. These parts not only perform some very specific functions, but, as Parsons argues, every element also contributes to the stability of the system as a whole. In this regard, we can see Parsons's thought as being consistent with that of Radcliffe-Brown.

In order to maintain order and reproduce themselves, societies have *functional prerequisites*. They all have fundamental needs that must be fulfilled. Any action system (that lasts) will have these, and only these, four main functions successfully fulfilled: (1) a set of adaptive processes, (2) a means for attaining goals, (3) a set of institutions performing an integrative function, and, last, (4) the somewhat oddly named *latent pattern maintenance* function. These fundamental functional requirements form the famous acronym AGIL, through which students have been memorizing Parsons's ideas for generations: *A* is for adaptive function, *G* for goal attainment, *I* for integrative function, and *L* for latent pattern maintenance. The following discussion examines each of these in turn. But, first, we must note here the previously mentioned conceptual slippage of the term *function*. Are these "functions" need-fulfilling ends in themselves for Parsons? It would seem that something more akin to fundamental subsystems would be the intended meaning.

First, the social system must adapt itself to its external environment, its physical environment. This *adaptive function* is performed (primarily) by the various economic institutions. The economy *adapts* the environment to our social needs through the production and distribution of goods and services.

Second, society needs institutions and processes whereby people can be mobilized to attempt to attain collective goals. This *goal attainment* function is principally fulfilled through political institutions. By this is meant political institutions in the broadest of all possible senses. Trade unions, for example, are perfect examples of such institutions.

Third, the *integrative function* is fulfilled by the institutions and processes whereby social cohesion and solidarity are achieved. These are the institutions that allow for the coordination of different activities and functional units. This coordination, Parsons believed, very importantly included principles of social stratification. The people with the right set of skills and abilities needed to be recruited to the appropriate jobs.

Finally, there are the institutions and processes that function to ensure the continuity of fundamental normative values. The processes whereby this is achieved are usually latent and underneath the surface, rather than explicit (hence the word *latent* in the term *latent pattern maintenance*). These processes are found in the institutions that socialize us (e.g., the family and the education system). Such processes are among *the* most crucial.

The social system is a *dynamic* system, and though always tending toward stability, it nonetheless evolves. An adaptive-upgrading process thus accompanies society's evolution. The theory assumes that the new subsystems that develop will be more adaptive than the earlier ones. Society becomes more and more differentiated, particularly in the economic realm. This differentiation leads to new problems of integration and creates new needs—and the corresponding development of appropriate skills and abilities. New subsystems thus emerge.

An important way of conceiving of society as a social system is to see it not as a collection of

individuals but rather as an interlinked system of positions. Each position possesses one or more functions and has *roles* corresponding with them that the individuals who occupy the positions must fulfill. Any given individual will have a number of different roles according to the different positions he or she occupies in the system. Thus, a woman may be both mother and daughter, with correspondingly different roles for each position. A person may be a student *and* an employee. And so on. There are myriad positions and roles possible, limited only by the complexity of the particular society.

Some of the roles are permanent, even though they may change over time. For example, a daughter's responsibilities change as she gets older, until perhaps later on in life she might assume a caregiver's role with respect to her own mother. Many other roles are by their very nature temporary. For example, Parsons describes what he called the "sick role." When we are sick, this discharges us from the usual responsibilities of our job and domestic chores. However, with this role come responsibilities, the responsibility to heed the doctor's advice, for example, as part of the overarching responsibility to get well. It is clear with this example that the concept of roles embodies considerable expectations of behavior from individuals.

Individuals are not generally coerced into conformity with these expectations. Rather, as part of a lifelong process, they are socialized into the roles they occupy. From a structural-functionalist perspective, the *self* is an *evolving collection of positions and roles and responsibilities,* a changing set of patterns of behavior that form a personality. In this way, Parsons demonstrates the important influence of Sigmund Freud upon his work.

Criticism

There have been many criticisms of Parsons. George Caspar Homans, Parsons's colleague at Harvard, felt that Parsons had failed to explain social structure because the overly elaborate and abstract structure did not properly take into account the *actions of individuals*. In their ongoing debate, they thus reproduced to some extent the ontological and epistemological differences of Weber and Durkheim—precisely what Parsons hoped his own work would transcend.

This debate also occurred within the anthropological tradition of functionalism and its critics. Is there a different order of reality beyond the actions of individuals? Given that social structure is not immediately visible, is the empirical study of it possible even if it does exist? The ontological questions of existence translate into epistemological questions as to the possibility of knowledge, which in turn translate into some practical difficulties of methodology. While you reach a dead end with Parsons from this perspective because he always stayed at the level of grand generalizations, Radcliffe-Brown and most particularly Malinowski *did* translate a functionalist perspective into an empirical investigative methodology—only to encounter the same charges of reductionism voiced by another major figure in anthropology, Edward Evans-Pritchard.

There seems to be an implicit *circularity* in the basic premise of functionalism. An institution exists in order to fulfill certain functions—therefore, if it exists, it must be functional. It should be noted here that it was precisely this point that Radcliffe-Brown objected to in some notions of functionalism.

In addition to this circularity, there is also an inherent *ahistoricism*. Parsons seems to have taken the existing American status quo and universalized it as applying to societies everywhere and always. Parsons's theory precludes questions (standardly voiced against structural functionalism) as to whether any other, *different sort of institution* could fulfill the same function as the one carried out by any currently existing institution. The (nuclear) family, for instance, fulfills the functions of procreation and socialization. However, it is apparent that other, very differently organized institutions could as easily fulfill this function.

One of the most sympathetic of Parsons's critics was Robert K. Merton (1910–2003), who also pointed to philosophical contradictions with functionalism. His principal contributions are twofold. First, Merton introduced the distinction between *manifest* and *latent* functions. The former are related to the conscious intentions of actors, and the latter deal with the unintended consequences of action. The actor may not be aware of all the functions of his or her position or what the actual consequences of an action may be in this regard.

Second, Merton argued that while elements of the system sometimes function in relation to preserving

the overall unity of the system (a primary argument for Parsons), this is not always the case. Elements can be functional for some yet highly dysfunctional for others. Unemployment, for example, may economically function to keep wages down, because the greater insecurity about their jobs felt by the workers makes them reluctant to demand improvements. While obviously this is not functional for the unemployed themselves, it may also be doubted that it is functional for society as a whole. Is it really a good thing for the economy that wage demands are kept low? While it could benefit some employers, it is not beneficial to those whose wages are driven down.

Through this sort of example, power and conflict are admitted to the structural-functionalist schema. The emphasis upon social order and social stability inevitably gave way to perspectives of conflict and change.

While there has been *relatively* little sociological interest in structural functionalism and Parsons since the 1970s, there has been a more recent revival, primarily in the Neo-functionalism of Jeffery Alexander (1947–).

Structuralism and Poststructuralism

Structuralism and, subsequently, poststructuralism were key components in what became known as the "linguistic turn" in 20th-century social theory. Both are less accurately described as theories; they are, rather, broadscale theoretical orientations, each of which served as a foundation for a rich and diverse number of thinkers and researchers.

This entry provides an overview of structuralism and poststructuralism and how they relate to both social science and philosophy.

Structuralism

Structuralism originated in the work of Ferdinand de Saussure (1857–1913). Seldom in the history of thought has there been a single book so influential as *Course in General Linguistics* (published posthumously by his students from their course notes). With this work, the *synchronic* study of language and meaning generation truly began, and Saussure is thus credited as the "father of modern linguistics." Previously, language was mainly studied diachronically; that is, the evolution of words and grammatical construction, and so on, was traced over time.

It is difficult to overstate the revolutionary nature of Saussure's work. His synchronic study of language focused upon the manner in which meaning is generated *structurally* through an arbitrary "sign" system of differences (as described below). The realization that meaning is structurally generated through *sign systems* took his linguistic analysis beyond the study of the spoken and written word to embrace potentially *all* sign systems (of which our spoken and written language is merely a subset) involved in human communication. Thus, an entire new discipline was born—*semiology*—and once again Saussure is credited as the "father" of it.

Through semiology, the entirety of human culture—and each and every aspect of it, from architecture to literary criticism to the unconscious mind—can be analyzed in terms of its being a structured sign system. A plethora of famous thinkers (though many did not accept the structuralist label) applied this methodology to a diverse range of human phenomena, for example, Roman Jakobson

(linguistics), Claude Lévi-Strauss (social anthropology), and Jacques Lacan (psychoanalysis). Louis Althusser (Marxism) and Roland Barthes (literary criticism and cultural analysis) are perhaps the most famous.

The technical fundamentals of semiology are fairly simple. Language (or any meaning-generating sign system) can be broken down into two categories: *langue* and *parole* (or in English, "language" and "speech"). Parole is what is happening for me now as I type this and for you as you read it. When in speaking you utter a command or ask someone a question, that is parole, too. When they hear and understand you, that is also parole. One way of putting it is to say that parole (or speech) is any *particular* usage of language. Saussure's great insight was to realize that for *any* particular instance of language usage to potentially work in terms of intended and received meanings it must depend on the underlying system of linguistic rules or structure of language, that is, on *langue*.

A sign is composed of two elements, a *signifier* and a *signified,* which fit together as the two sides of the same coin, of the sign itself. In written or spoken language, the signifier is the written mark or sound, respectively, and the signified is the mental image associated with the mark or sound.

A more naive view would be to see the essential meaning-generating relationship as between a word and a thing. So there is something out in the world, a chair, for instance, and we label it with a sound or set of marks: *c h a i r.* But this is a highly inadequate theory of meaning. For example, understanding the relationship between particular entities and categories of entities would be doomed to confusion with such a naive, pointing-and-labeling theory of meaning. The signified is *not* any real-world referent but rather the *image in the mind* (of both speaker and listener, writer and reader) provoked by the signifier. Exactly where real-word referents stand in this understanding of meaning and language is discussed later in this entry.

Crucial to this theory of meaning is the thesis that the relationship between signifier and signified is *arbitrary.* What is meant by this can be most clearly demonstrated by a consideration of nonarbitrary examples. Onomatopoeia is one such case. The word *moo,* meaning in English the sound a cow makes, has some similarity to the actual sound a cow makes; though as Saussure wittily pointed out, apparently the sounds French and English animals make must be different as they have different words for these sounds. Another case would be pictogram writing. In such forms of writing, the symbols resemble, usually in highly stylized ways, what they mean. An example would be a pictogram resembling a house and meaning the same.

Saussure stresses that such cases are the *exception*s to the crucial rule of meaning and sign systems—namely, that the relationship between signifier and signified is *arbitrary.* The very importance of this assertion warrants its repetition. What is meant by this is often illustrated in the famous example of the "cat" and the "mat." What makes the former signify a four-legged feline creature and the latter something you wipe your feet on is nothing more than the fact that a *c* is not an *m*. The written alphabet is nothing more than a system of arbitrary differences. So too is the sound system of "c" and "m" sounds.

Meaning is generated through a series of "syntagmatic" and "paradigmatic" choices. Structural analysis in semiotics takes place along two axes of meaning: On the horizontal plane, a *syntagm* is a combination or concatenation (chain) of several successive linguistic units of the same level, thus forming a meaningful whole, for example, a sentence, while on the vertical plane a *paradigm* is a class of linguistic elements grouped together according to a certain principle. Signs make sense—have meaning—only because they are situated within the structure of these two axes or planes, that is, they are nodes in a system or structure, namely, the system of language.

So, as we are speaking the sentence <the cat was asleep on the sofa>, we are choosing the sound signifiers of the "c," "a," and "t" sounds (combined to form the "cat" sound) and also making a series of other choices. We choose *c* instead of *m* or *b*, *cat* instead of *lion* or *tiger* or *cheetah* or *moose*. We choose the sound order "the cat" rather than "cat the." And so on. The *conventions* of syntax and grammar in language, along with the *arbitrary conventions* of the signifier and signified relationship, are what enables meaning to be produced. The syntactical and grammatical choices are, of course, going to be different in different languages (or any sign system). Foreign learners of English, for example, make different common errors depending

on their native language. They do so because they incorrectly apply in English the grammatical conventions of the other language.

What holds the system together and allows it to generate meaning is thus nothing more than *social convention*. However, that "nothing more" is actually a very great deal theoretically. In this regard, we can plot a trajectory leading back from Saussure to Émile Durkheim's sui generis *social facts*. Language, Durkheim asserted, was one of the most crucial *social facts* and illustrated an independently existing *different order* of reality—a level of reality not reducible to a physical materiality.

Poststructuralism

It is such ontological questions as the preceding that one sees as constituting one of the crucial launching points for the birth of poststructuralism. Another concerns the referent question. That is, if a sign consists of a signifier and signified and the latter is *not* an actually existing object in the world but rather an image in the minds of the message instigator and recipient (that this is the same image is guaranteed by the social conventions of the sign system), then the question arises as to the ontological (existential) status of the referent. When we are talking about a cat, for example, the sound signifier of "cat" provokes in us the same signified image; and if we are talking about a particular cat, "this cat" in the room, it is no less true that what is provoked by the signifier is a signified, an image—not the independently existing (i.e., independent of our discourse) particular animal in the room. It only remains to point out that to say "independently existing" is an ontological position consistent with the philosophical realism that appears to be implicit in structuralism, but *not* with poststructuralism. Saussure himself does not provide a definitive answer to this question; one could classify him as an agnostic in this regard.

While Saussure can rightly be considered the founding father of structuralism (and thus indirectly of poststructuralism), it was left to others to develop it further. While modern linguistics derives from Saussure, it has long since moved on; he would only get a passing mention in a contemporary linguistics course. He has actually probably been more influential on other disciplines.

In social anthropology, for example, the work of Claude Lévi-Straus had considerable impact for a time and intellectually popularized the term *structuralism*. He provided a structuralist analysis of both kinship relations and mythology. His analysis of both these disparate areas of investigation can be seen to directly connect with Saussure. For example, the empirical variety of tribal myths found in the world can be analyzed according to a system of elements combined and recombined to produce different meanings. Similarly, we can see the emphasis on the relational formation of meaning in his perspective on kinship systems. An uncle, a nephew, a brother, a sister and so on, are individual positions in a system and find their significance and prescribed roles not in and of themselves but rather in their *relations* to the other positions in the system.

The most direct intellectual descendant of Saussure, however, is the discipline of semiology as applied to cultural analysis and literary criticism. Later, this was developed in a variety of ways by poststructuralists, and we can find both semiology's structuralist origin and its basis for this later development in the work of Roland Barthes. Barthes made the observation that we frequently find in bourgeois culture (Barthes was a Marxist as well as a structuralist) a variety of *levels* of signification. So on one level perhaps we have a simple denotation. The words *red* and *rose* are the signifiers for our mental image of a particular colored flower. On another level, the signified red rose is itself a signifier in another signifying system: a red rose signifies love.

The example given in the preceding paragraph may seem perhaps rather banal and obvious, and through its very banality thus inherently *innocent*. This is very much the point of the sort of analysis Barthes engaged in. Our culture is precisely *not* innocent. The levels of signification serve to create a false naturalness with regard to the many, extremely politically nuanced meanings it is constantly producing.

Barthes demonstrated the above in a variety of diverse contexts: in literary works, in the language of fashion, and in the spectacle of professional wrestling (one wonders if the founders of today's WWE studied Barthes's work!). However, the structuralist analysis of culture opens up some questions concerning its own assumptions that almost beg for their transcendence. If language, if culture, is a structured system of oppositions, then what guarantees the necessary stability of meaning for successful communication to occur?

We may recall here that the essential arbitrariness of the signifier–signified bond means that at the root of all meaning is merely social convention. But

societies are fluid and changing. It follows that meaning is never absolutely fixed; there is no transcendental signifier to ground it; meaning is also fluid and ever-changing. Ergo, poststructuralism was born. Important contemporary thinkers working within the poststructuralist paradigm are too numerous to mention, but Jacques Derrida and Michel Foucault are seminal original influences.

Derrida embraces the contradictions implicit in structuralist semiology and both celebrates them and puts them to work. He further develops the notions of meaning fluidity and textual convention as the only grounding for meaning. The idea is that there are levels of signification—that every signified is itself a signifier—reaching to infinity, an "endless chain of signification," where there can never be true denotative meaning. What this last thought means is that in order to understand a word requires context—the context of the sentence. But the sentence too requires contextualization—the contextualization of the paragraph, the page, the chapter, the book, the history of thought. So meaning is never fixed but rather interactively produced and reproduced between reader and text.

Commencing with such premises led Derrida to produce not a philosophy or even, as some would have it, an "anti-philosophy" but rather a method of textual practice: *deconstruction*. It is a very particular kind of method and one with profound philosophical implications, but at root it *is* a method. Deconstruction begins with the idea that among the paired oppositions through which much meaning is generated, that between *core* and *peripheral* is of particular importance. It is where the innocence of language is lost and power becomes integral to meaning itself. In Derrida's deconstruction of many of the seminal texts of Western philosophy, for example, he takes as his starting point not the central arguments but rather apparently peripheral notions implied by the texts. The marginal becomes the main line and in doing so undermines the force of the original argument by showing that somehow its conclusions were already inherent in the presuppositions made (which were concealed but made apparent by the process of deconstruction). It is Derrida's argument that the texts *already always* contain their own deconstruction. One of his metaphors for deconstruction is that of a computer virus.

Foucault's work has perhaps the least *semiological* focus of poststructuralist thinkers, and yet his fascination with *discourse* is central. Foucault, in a variety of quite different (and highly original) ways, works around the relationship between power and knowledge. He actually hyphenates the two—*power-knowledge*—to emphasize their inextricable interconnection. All disciplines of knowledge have institutional manifestations of power relations, and of course, these institutions—the psychiatric clinic and the prison are two of the institutions he analyzed—are also based upon discursive structures of knowledge.

SUPERVENIENCE

Supervenience, as a philosophical term of art, describes a relation between sets of properties. The central idea is that properties belonging to a set *A* supervene on properties belonging to a set *B*, the so-called supervenience base, iff any two individuals or possible worlds that are exactly alike with respect to *B*-properties are exactly alike with respect

to *A*-properties. In other words, any two things that differ with respect to *A*-properties must differ with respect to *B*-properties. Mental properties can be said to supervene on physical properties, for instance, iff any two individuals who instantiate exactly the same physical properties instantiate the same mental properties.

The supervenience relation in its contemporary use first rose into prominence in metaethics. According to the British moral philosopher Richard M. Hare, any two persons or actions satisfying exactly the same nonmoral description have to be ascribed the same moral attributes; otherwise, the logical rules for the use of terms like *good* would be violated. Thus, supervenience is employed to formulate adequacy conditions on the use of moral terms. Later, Donald Davidson introduced the notion into the philosophy of mind to describe the controversial relationship between the mental and the physical. Nowadays, philosophy of mind still is one of the most important fields of application of the supervenience relation. However, the notion also plays a central role in various other fields of analytic philosophy. In contemporary metaphysics, there are debates on whether modal properties supervene on nonmodal properties and whether dispositions supervene on categorical properties. In ethics and aesthetics, supervenience is used to describe the relationship between normative and descriptive properties as well as between aesthetic and natural properties.

Definitions of Supervenience

Weak and Strong Supervenience

The intuitive definition of supervenience given above leaves it open whether the supervenience relation relies on comparisons between single individuals or between whole possible worlds. Depending on how this issue is decided, one can spell out the definition of supervenience in different ways. If supervenience is taken to rely on comparisons between single individuals, the two standard notions are weak supervenience (WS) and strong supervenience (SS), usually defined in the following way:

> *Weak supervenience:* *A*-properties weakly supervene on *B*-properties iff for any possible world w and any individuals x and y, if x and y have the same *B*-properties in w, then x and y have the same *A*-properties in w.

> *Strong supervenience:* *A*-properties strongly supervene on *B*-properties iff for any possible worlds w_1 and w_2 and any individuals x and y, if x in w_1 has the same *B*-properties as y in w_2, then x in w_1 also has the same *A*-properties as y in w_2.

To illustrate the intuition behind WS and SS, suppose that mental properties weakly supervene on physical properties and that x instantiates the mental property of *being happy* in some possible world w. Then, it follows from WS that all individuals who inhabit w and have the same physical properties as x are happy, too. The crucial difference between WS and SS is that the former only requires that individuals inhabiting the same possible world and having the same *B*-properties are alike with respect to *A*-properties, whereas SS involves cross-world comparisons between individuals. Accordingly, mental properties strongly supervene on physical properties iff any two individuals, whether they are world-mates or inhabit different possible worlds, have the same mental properties if they are alike in any physical respect. SS hence implies WS—that is, whenever *A* strongly supervenes on *B*, then *A* weakly supervenes on *B*, but the converse does not hold.

Global Supervenience

In contrast to WS and SS, which rely on comparisons between single individuals, the notion of global supervenience takes into account the distribution of properties over whole possible worlds. The underlying idea is that *A* globally supervenes on *B* iff any possible worlds w_1 and w_2 that are exactly alike with respect to *B* are also exactly alike with respect to *A*. Suppose that Φ is a set containing properties and relations of a certain type, for example, physical properties and relations. Then, the claim that w_1 and w_2 are exactly alike with respect to Φ is typically interpreted as the claim that there is a Φ-preserving isomorphism between w_1 and w_2, that is, a one–one mapping, Γ, of the inhabitants of w_1 onto the inhabitants of w_2, such that for any Φ-property F, an individual x has F in w_1 iff $\Gamma(x)$ has F in w_2 and for any Φ-relation R, the tuple $\langle x_1, \ldots, x_n \rangle$ instantiates R in w_1 iff $\langle \Gamma(x_1), \ldots, \Gamma(x_n) \rangle$ instantiates R in w_2. Accordingly, w_1 and w_2 are alike with respect to B iff there is a *B*-preserving isomorphism between them. The three

standard definitions of global supervenience all rely on this notion:

> *Weak global supervenience (WGS):* *A*-properties weakly globally supervene on *B*-properties iff for any possible worlds w_1 and w_2, if there is a *B*-preserving isomorphism between w_1 and w_2, then there is an *A*-preserving isomorphism between w_1 and w_2.
>
> *Intermediate global supervenience (IGS):* *A*-properties intermediately globally supervene on *B*-properties iff for any possible worlds w_1 and w_2, if there is a *B*-preserving isomorphism between w_1 and w_2, then there is a *B*-preserving isomorphism between w_1 and w_2 that is also an *A*-preserving isomorphism.
>
> *Strong global supervenience (SGS):* *A*-properties strongly globally supervene on *B*-properties iff for any possible worlds w_1 and w_2, any *B*-preserving isomorphism between w_1 and w_2 is an *A*-preserving isomorphism.

The notions of global supervenience are all logically weaker than the notion of SS. This becomes evident, for instance, if it is assumed that externalism about mental content is true. According to externalism (also called "social anti-individualism" and dealt with in a separate entry in this encyclopedia), mental states, such as beliefs (and other propositional attitudes entertained by a speaker/thinker), do not solely depend on an individual's intrinsic physical states (and their properties), but they also depend on the environment in which the individual is placed, that is, on the kinds of concepts available in the linguistic or conceptual environment in which the speaker finds herself (i.e., concepts or linguistic terms that appear in the propositional attitudes in question). In other words, if externalism is true, mental states (and their properties) fail to strongly supervene on intrinsic physical states (and their properties). To see this, suppose that John living on Earth and Twin-John living on Twin-Earth instantiate exactly the same intrinsic physical properties. If then John and Twin-John both believe that the transparent liquid called "water" in their community quenches thirst, John has a belief about H_2O, whereas Twin-John has a belief about XYZ. According to externalism, this means that John and Twin-John are in different belief states and consequently have different mental properties. Thus (leaving aside the fact that John's body partially consists of H_2O, whereas Twin-John's body partially consists of XYZ), John and Twin-John have exactly the same intrinsic physical properties but different mental properties, and so SS fails. The criterion of global supervenience is not violated, however. Earth and Twin-Earth, which can be considered as two different possible worlds, are radically different in some physical respect, namely, the chemical structure of the transparent liquid called "water." Therefore, there is no isomorphism preserving physical properties between them, and none of the three criteria of global supervenience will be violated if John and Twin-John have different mental properties.

In general, as long as there is no formal restriction on the structure of the properties contained in *A* and *B*, the three notions of global supervenience are logically distinct from WS and SS. Karen Bennett shows, however, that each of the definitions of global supervenience is equivalent to SS if *A* and *B* contain intrinsic properties only. Moreover, Robert Stalnaker proposes a proof to the effect that if the supervenience base contains properties involving complete *B* descriptions of possible worlds, SS is equivalent to SGS. Yet both Bennett's and Stalnaker's arguments are restricted to the case where *A* and *B* contain properties only. Oron Shagrir argues that if *A* and *B* contain relations, SGS is crucially distinct from SS, since SS is defined for properties only and SGS can make claims about dependence relationships between sets of relations, which cannot be made using SS.

Supervenience and Other Relations

Supervenience is a term of art that does not correspond to any commonsense notion. In particular, it cannot be equated with a causal or explanatory relationship. That supervenience cannot be equated with a causal relationship follows directly from the observation that supervenience is a synchronous relation whereas causality is a diachronic relationship. That supervenience claims alone are not sufficient for grounding an explanatory relation becomes clear in view of the fact that supervenience is a reflexive relation—each set of properties trivially supervenes on itself according to all the notions of supervenience specified above. However, identity does not count as an explanatory relationship. If Peter has the mental property of *being happy,* for instance, this cannot suitably be explained by the fact that Peter is happy.

Given that supervenience is not a causal or explanatory relationship, many authors claim that supervenience expresses a dependence relation: If *A* supervenes on *B,* then the properties contained in *A* are dependent on the properties contained in *B*. It is questionable, however, whether supervenience is strong enough to ground a dependence relation. If dependence is understood as an ontological priority relation, that is, in such a way that *A*'s supervenience on *B* implies that the *B*-properties are ontologically prior to or more fundamental than the *A*-properties, supervenience cannot be equated with dependence. Suppose, for instance, that *A* = {*being a father*} and *B* = {*being male, having at least one child*}. Then, *A* supervenes on *B,* and vice versa. But the mutual supervenience relation holding between *A* and *B* does not imply that the properties contained in *B* are more fundamental than the property of *being a father* or that the latter property is more fundamental than the properties contained in *B*.

It is possible, however, to interpret supervenience as a certain kind of functional dependence. Consider a complete physical description of an individual (or a possible world). Supervenience of the mental on the physical then implies that there is exactly one mental description such that any individual (or possible world) satisfying the physical description under consideration also satisfies this particular mental description. Accordingly, the supervenience relation between the mental and the physical can be interpreted as a function from combinations of physical properties to combinations of mental properties: Any possible combination of physical properties instantiated by an individual or possible world will be mapped onto exactly one combination of mental properties.

Applications

Physicalism

One major field of application of supervenience is the definition of physicalism in the philosophy of mind. Physicalism is usually understood as the thesis that fixing all the physical facts is sufficient for fixing *all* the facts. Thus, physicalists claim that the nonphysical, particularly the mental, is necessitated by and systematically covaries with the physical. This implies, for instance, that zombies, creatures that are physically like us but have no mental properties whatsoever, are metaphysically impossible. On the basis of this intuition, several authors, notably Frank Jackson and David Lewis, propose a definition of physicalism according to which physicalism is true in a world *w* iff any physical duplicate of the actual world is a duplicate *simpliciter* of *w.* This condition can be interpreted as a global supervenience claim: Physicalism is true in *w* iff each possible world that is like *w* in all physical respects is also like the actual world in all nonphysical respects. Thus, for example, if physicalism is true in the actual world, then there are no metaphysically possible worlds that are like the actual world but in which the physical duplicates of some humans are zombies. According to this definition of physicalism, humans and their physical duplicates are also alike in all nonphysical respects.

The intuitive definition of physicalism leaves open how the underlying global supervenience should be interpreted. It is widely agreed, however, that WGS and IGS are too weak to ground physicalism since they are compatible with what Karen Bennett calls *intraworld variation,* that is, two individuals inhabiting the same possible world and having exactly the same physical properties but different mental properties. Yet if there can be two individuals inhabiting the same possible world who are in exactly the same bodily state but have radically different mental properties, such that one of them feels happy, say, whereas the other feels sad, the requirement that mental properties systematically covary with physical properties is violated. The notion of SGS excludes intraworld variation. Accordingly, if physicalism is to be understood as a global supervenience claim, then global supervenience should be interpreted as SGS.

It is controversial, however, whether physicalism can adequately be defined in terms of supervenience. We will mention here two challenges. One is that a global supervenience requirement might be too strong. It captures the intuition that zombies are not metaphysically possible. However, it rules out that there are worlds that are very similar to the actual world but contain extra entities, such as angels or ghosts. Yet physicalists do not have to rule out nonphysical entities, for example, angels or ghosts, as logically or metaphysically possible. The central tenet of physicalism is restricted to the thesis that in worlds like our world, all nonphysical entities are necessitated by and systematically covary with the physical ones and therefore our world is not inhabited by any angels or ghosts. Jackson therefore proposes to restrict the supervenience thesis to worlds that are *minimal* physical duplicates of *w,* that is, worlds that are like *w* in all physical respects

and that do not contain any extra entities (a similar approach was proposed by David Lewis, Terence Horgan, and Chalmers). If only such worlds are taken into account, the definition of physicalism is compatible with the assumption that angels or ghosts are metaphysically possible.

Another challenge is that a supervenience-based criterion of physicalism might be too weak. One problem is that global supervenience theses cannot rule out the existence of necessary nonphysical beings, for example, the assumption that God exists in every metaphysically possible world, which is incompatible with physicalism. Moreover, it can be argued not only that physicalism requires the existence of an ontological covariance relation between nonphysical and physical properties but also that this covariance can be explained in a physicalistically acceptable way. Horgan therefore proposes to replace the ordinary notion of supervenience, which cannot ground an explanatory relationship, by the stronger notion of superdupervenience—a supervenience relation that does not just hold for metaphysical reasons but is in addition explainable in a physicalistically acceptable way.

However, even though it is controversial whether supervenience alone is sufficient for defining physicalism, it is widely agreed that some supervenience requirement is a necessary condition of physicalism. Even proponents of opposing views take it for granted that if there is a systematic relationship between mental and physical properties at all, then it must obey some supervenience principle. This is the reason why supervenience has a crucial role to play in the debate on physicalism and the mind–body problem.

Coincidentalism

Another important application of supervenience pertains to the debate over coincident entities. Coincidentalism is the view that there are pairs of numerically distinct entities that are made of the same parts. Coincidentalists argue, for example, that a statue and the lump of matter from which it is made are coincident yet numerically distinct entities, since they differ in their modal properties: The lump but not the statue can survive being flattened. A pattern of supervenience argument against coincidentalism is that their modal properties cannot differ. The modal difference between the statue and the lump must be grounded in qualitative nonmodal properties and relations (call it BASE), such as their subatomic structure. Modal properties, in other words, supervene on nonmodal, BASE, properties and relations. But given that the statue and the lump—as coincident entities—share exactly the same BASE at the time they coincide, we must conclude that the statue and the lump cannot differ modally.

Coincidentalists can reply that there are understandings of supervenience under which the alleged conclusion does not follow: The statue and the lump can still differ in their modal properties. Assume, for example, that modal properties weakly globally supervene on BASE. Weak global supervenience requires that BASE-indiscernible worlds be modal indiscernible. It requires that in a BASE-indiscernible world, one object has the modal properties of the statue and another the modal properties of the lump. But this requirement is certainly in accord with the entities' coincidence, as the statue and the lump can have different modal properties.

In responding, some have pointed out that not every notion of supervenience counts as an adequate notion of dependence. We must be sure, for example, that weak global supervenience relations reflect adequate grounding relations. However, Bennett's intraworld variation example (above), among other examples, gives us reason to think that weak global supervenience is not a notion of dependence and thus cannot establish the grounding of the modal in the nonmodal. More recently, Theodore Sider suggests that there is a fundamental modal *relation* between the statue and the lump of matter. This relation, of *opposite-possibly surviving being squashed*, means exactly that one might have survived being squashed. It strongly globally supervenes on BASE. The strong global supervenience of the modal (monadic) properties (*surviving being squashed*) on BASE fails. But these monadic properties are artifacts of the language we ordinarily speak, and so the failure of supervenience does not indicate a real metaphysical nondependence. Here too, supervenience does not settle the metaphysical debate, but it advances our understanding of unsettled issues.

Symbolic Interactionism

Symbolic interactionism is a major theoretical tradition in sociology. The term was coined by the American sociologist Herbert Blumer (1900–1987) in a 1937 essay on debates in social psychology: He later described it as a "barbarous neologism" that stuck. It may be understood as the product of the encounter between American philosophical pragmatism, sociology, and social activism. This entry traces the development of symbolic interaction, the history of its older intellectual precursors, and more recent developments.

Social Behaviorism

Blumer and his closest followers identified their principal philosophical inspiration as that of George Herbert Mead (1863–1931), a close associate of John Dewey, who joined the University of Chicago's philosophy department in 1894 and remained there until his death in 1931. Mead's own preferred description for his work was *social behaviorism,* contrasted with the radical behaviorist psychology of his Chicago contemporary John B. Watson. Watson argued that "mind" was a redundant metaphysical notion. All action could be explained in terms of responses to stimuli, without the need to posit some intervening process. Mead objected that there was an important difference in the processing of incoming stimuli by humans, compared with the animals studied by behaviorist psychologists. Animals treated stimuli as *signs,* information about the world that directly triggered behavioral responses. Humans mostly responded to stimuli as *symbols,* signals that required cognitive transformation before becoming the basis of action. Mead also stressed the extent to which the meaning of acts was *not* derived from the actor's intention. An actor would design an act in *imagined* anticipation of the response of its projected recipient or audience. However, the meaning of that act would only emerge from the *actual* response and might be further revised by the producer's subsequent self-correction. The act of speech, for example, involves organizing the range of sounds producible by the human body into blocks that stand for, or *symbolize,* the actor's imaginative projection of a hearer's response. For these blocks to function as potentially shareable communicative symbols, they must form part of an *intersubjective* cultural system: Words and language would be the most familiar example. I find out who I am and what I meant from your response: This involves the so-called looking glass self, in the terms of an earlier American pragmatist, the sociologist Charles Horton Cooley (1864–1929). Each of us would ultimately be constrained by our understanding of what an idealized citizen, the *generalized other,* would be doing through the use of this symbol, given its place within our shared system. This system is a social phenomenon, something that we learn in the course of socialization.

(In this respect, Mead has an extensive discussion of children's games and their contribution to the development of skills necessary for successful interaction.)

Similar arguments were used by sociologists such as Ellsworth Faris and Luther Bernard against those who argued that all human behavior could be reduced to inherited biological drives, an early-20th-century version of genetic determinism and evolutionary psychology. Although these writers acknowledged the importance of understanding human embodiment as a material constraint on action, they argued strongly against any suggestion that biology could be preeminent.

The Wider Tradition

The emphasis on pragmatism does not do full justice to the philosophical traditions on which symbolic interactionism is based. The citation conventions of 19th- and early-20th-century academic writing have obscured the influence of ideas from Scottish Enlightenment writers, especially Adam Smith (1723–1790). Key concepts like the *looking glass self* and the *generalized other* derive from Smith's *Theory of Moral Sentiments*. This connection locates symbolic interactionism in a lineage to the ancient Stoic philosophers and also draws our attention to another line of descent from the Scottish Enlightenment: through Kant to Austrian philosophers, like Alfred Schütz and Ludwig Wittgenstein, and economists, like Friedrich Hayek and Ludwig von Mises, with their interest in language, in the nature and distribution of knowledge, and in the communication of information. This line results ultimately in symbolic interaction's sociological cousin, *ethnomethodology*.

Recent Developments

Since the late 1980s, the unity of symbolic interactionism has split along three axes: ontological; epistemological; and political. One group has tried to identify symbolic interactionism with a postmodernist version of social constructionism as a basis for critique and action. In response, many "realists" have discarded the label, while continuing to draw on its tradition in their studies of social organization. They accept Mead's analysis of the constraints created by the material world, even if this is knowable only through cultural symbols, and of the importance of true representation as a regulating ideal for inquiry, even if practically unachievable. An overlapping division is between those who accept the ethnomethodological argument that, since we cannot know another person's mind, we should not speculate about this and should only study his or her practices, and those who retain the view that empathic understanding allows us to induce the meaning of actions for participants. This is often seen in disputes over the legacy of Erving Goffman (1922–1982), whose work has influenced both symbolic interactionists and ethnomethodologists. Finally, there is division over symbolic interactionism's politics. The original Chicago work was closely associated with the social activism of Jane Addams (1860–1935) but did not follow her radical turn in the late 1920s. Contemporary symbolic interactionists have often been associated with "standpoint" research, using empathic analysis to recover the moral and cultural integrity of socially marginal or excluded groups and to challenge their "outsider" status. This sits uncomfortably with the degree to which symbolic interactionism can also be seen as part of the "spontaneous order" tradition in political thought.

SYMBOLISM

This entry presents the various meanings of *sign, symbol,* and *symbolism*; charts various approaches to them; and highlights the manner in which the social sciences have approached the use of signs and symbolism as central to their domain.

Signs, Symbols, and Semiosis

Ways of perceiving symbolism range from a concept so broad that it encompasses the entire human world of meanings to one that narrows the term solely to representations of the transcendent sphere. If, thus, the word *symbol* refers to every element endowed with a meaning, then the entire sociocultural human reality may be considered in terms of symbolism.

The terms *sign* and *symbol* are often used interchangeably in the study of *semiosis,* that is, the formation of meanings. The object, fact, or event that functions as a sign or symbol refers to something other than itself. Contemporary *semiotics* or *semiology* (from the Greek σήμα), stemming from the work of Charles S. Peirce and Ferdinand de Saussure, has its roots in the ancient and medieval concepts of *signata* (from Latin *signum*—"sign") and *sumbolon* (from the Greek *σύμβολον* and the verb *sumballein*—"to put together").

The typology of signs proposed by Charles S. Peirce, who distinguished indexes, icons, and symbols understood as conventional signs, has become widespread in the theory of *semiosis* that relates to the use of signs. Semiosis implies a continuous interpretation of signs in communication. The sign in the process of semiosis is based upon its triadic structure of *representamen, object,* and *interpretant*. For Peirce, no sign is exclusively a symbol, an icon, or an index, but every sign contains—in various proportions—elements of them all.

Sign and symbol are sometimes differentiated on the ground that a sign indicates something, whereas a symbol stands for, or takes the place of, another thing. A trail marker, for example, points in a direction, and money represents a value. The emphasis in the case of the former term is put on that which is pointed out and signified and in the case of the latter is placed on the signifier, which functions as a substitute for something.

Natural language is the primary or most basic form of symbolic system. Words can be considered as linguistic signs or symbols. The common function of signs and symbols is invoking something else to come in mind. The nature of *meaning* is here the central point. A broad range of views may be categorized as either cognitive or pragmatic standpoints focusing on thought and action, respectively. The modes of signification or symbolization vary depending on the kinds of things functioning as signifiers, including discursive symbolism, symbolism of objects, and behavioral symbolism.

The symbolic functioning of things as representations has been analyzed in terms of *natural* and *conventional* signs or symbols.

Natural Signs

Natural signs enable inferences about the cause (e.g., fire) on the basis of the effect (e.g., smoke). Historically, natural signs or natural meanings were taken as the foundation of the premise about the symbolism of the whole natural reality conceived of as God's Book of Nature expressing meanings. This view has reappeared as the Romantic understanding of symbols epitomized by Friedrich Schlegel, with hieroglyphs carrying the sense of a higher reality, and likewise by G. W. F. Hegel, in his *Aesthetics,* for whom the Sphinx was a symbol of symbolization, imparting a mysterious meaning. This ontological or metaphysical understanding of symbols can also be found among the American transcendentalists, as well as the French symbolists. Of the former, Ralph Waldo Emerson stated that we are symbols and inhabit symbols, while of the latter, Charles Baudelaire used, in his *The Flowers of Evil,* the famous metaphor of the human journey through the forest of symbols.

The romantic conception of symbolism permeates the humanities, as exemplified by hermeneutics (Paul Ricoeur), religious studies (Mircea Eliade), history (Eric Voegelin), and even semiotics (Umberto Eco). A similar stance has been taken by the social phenomenologist Alfred Schütz, who placed symbols in provinces of meaning that transcend everyday life. Following this approach, the sociologists Peter Berger and Thomas Luckmann adopted a narrow conception of symbolism in the form of symbolic universes—in other words,

systems of meanings that link symbolic reality with transcendent reality.

Conventional Symbols

The *arbitrary* relationship between a symbol's meaning and the symbolized thing consists in the fact that the meaning is not contained in the symbol itself but in the symbolized thing. Furthermore, the symbol has no causal connection with its meaning and, thus, with the symbolized thing: The relationship is purely conventional.

Unlike natural signs, conventional signs or symbols are intentionally devised by human beings to signify. Linguistic symbols are particularly important because other modes of meaningful expression may be converted into words but not vice versa. Words may signify real things or name them, as well as signify ideas by expressing their meanings. Ideas as mental images are meanings and were treated as symbols of things or thoughts. Multiplicity of meanings is characteristic of linguistic symbols and allows for the ambiguous or equivocal use of words, particularly the invention of metaphors. Signs, on the contrary, are unequivocal (e.g., a red traffic light for "Stop").

Literal and metaphorical meanings provide a ground for arguments to narrow the notion of symbolism to the latter. Such an approach has its roots in the interpretation of religious sacred texts in a multiplicity of senses beyond the literal or historical, considered as spiritual meanings. The symbolic mode operates through a pragmatic decision to interpret the text symbolically beyond the literal level.

A narrower definition of the term *symbol* relies on the differentiation between two types of meaning: *denotation* and *representation*. A person's given name denotes (refers to him or her) but does not represent; in contrast, a national emblem represents the state but does not name (denote) it. Symbols represent that which they substitute for. Symbols thus defined may differ in arbitrariness. Words are generally considered wholly arbitrary symbols of ideas. Words do not denote ideas but represent them. Both words and the ideas they represent denote reality. In other words, individual terms (names) in language denote, whereas symbols represent.

Symbolism is frequently linked exclusively with complex and unobvious meanings; that which is symbolic may be contrasted with that which is real, since a symbol can substitute for something that doesn't really exist. Different conceptions of symbolism stem from research on mythology, on the one hand, and from the theory of language, on the other. Expressive symbolism conveys a meaningful emotional experience. Its antithesis is the symbolism of the completely abstract categories of scientific language. Relating to these cognitive and emotional dimensions, Edward Sapir distinguished between referential symbols and symbols of condensation. Ernst Cassirer, in his theory of symbolic forms of culture, such as language, myth and religion, art, history, and science, distinguished three types of symbolism: expressive, conceptual, and representative. The third one, characteristic of social phenomena, combines and balances the functions of the two previous ones.

The Social Sciences

Symbolic Action and Symbolic Interaction

Ways of understanding symbolism and defining symbols reflect the diversity of views about the nature of reality and cognition. The differences also stem from specific features of the studied realms of sociocultural reality, on the grounds of which conceptions of symbolism develop. Symbols and symbolic actions were especially closely studied by social and cultural anthropologists, in the field of rituals and religious myths, notably in symbolic anthropology, where symbols are not purely conceptual but have a dramaturgical and performative character, as shown by Victor Turner. Clifford Geertz says that symbols represent models of reality and models for patterned acts. Ritual remains the prototype of symbolic action, that is, of the symbolic performance, which in its elementary form is an action dealing with something that serves as a symbol and represents an analogous action dealing with the symbolized thing.

Studies on the social function of symbolization were initiated by social anthropologists such as Alfred Radcliffe-Brown and Bronisław Malinowski, as well as by cultural sociologists like Florian Znaniecki, Pitirim A. Sorokin, and Robert M. MacIver, and afterward by symbolic interactionists, who followed the American pragmatists. Among the latter, George H. Mead's notion of the conversation of gestures and significant symbols has been

particularly seminal. According to this approach, symbolism is examined in the context of coordinated actions. Symbols make it possible to anticipate the future course of interaction.

Social Symbolism and Collective Action

The analysis of symbolism's functions extends beyond linguistic theories focused on the cognitive function of language. Referring to the significance of symbols for social relations, Raymond Firth distinguished between expression, communication, knowledge, and control. The 18th-century Scottish moral philosophers Adam Ferguson and Adam Smith argued that symbols indicate social relations, consolidate social order, and represent power and wealth. It was Émile Durkheim who most persuasively claimed that social life in all its aspects is possible only due to a vast symbolism. Researchers from the Durkheim school focused not only on functions but also, and to a greater degree, on the identification of symbolic forms. Albert Salomon showed that Durkheimian collective representations include three forms: symbolic collective representing, symbolic affecting, and symbolic recollecting (collective memory).

Pierre Bourdieu developed a theory of the social symbolic system that is organized according to the logic of difference, beginning with basic categories such as gender, social hierarchy, or fellow men and strangers. It presents the problems of symbolic power, symbolic violence, and symbolic conflicts.

When one assumes the social character of language, symbolism is not contained in an autonomous, semiotical-linguistic system but is socially produced. The main focus of attention is not on social knowledge but on systems of action. The functions of symbolization in social practices are constitutive and transformative of social order. Symbolic boundaries are demarcated, abolished, or transcended.

Symbolization is not limited to writing and speaking but is contextualized in action and in acts of communication. This entails investigating symbolic practices constructing the framework of collective action and social movements—that is, the symbolic constitution of the objective of such actions and of the identity of collective agents. Power is symbolic and is accompanied by a symbolism of power. Methods of action are a variation of basic forms such as coercion and the influence through which power is manifested. Both coercion and persuasion require symbolization as a tool of influence. Power, in the sense of influencing, dominating, manipulating, or transforming collective life, remains a central problem for the sociology of symbolic processes.

Meanings are products of social acts as signifying acts and generated through interacting. Symbols are studied as instruments or tools of action where their use is decisive for the reproduction or transformation of social relations and involves strategies or politics of symbolization. Social symbolism has three basic functions—constitutive, conservative, and transformative—with respect to individuals and to collectivities.

Symbolism belongs to the anthropological order and constitutes the human sociocultural reality. It is a research subject in many of the cultural sciences, which uncover the symbolic constitution of culture. Studies of the functioning of symbols have proven significant for the basic problem of liberty, both in the private and in the public sphere.

Systems Theory

Systems theory is a multifaceted, transdisciplinary approach to the study of complex systems. Although it has roots in earlier philosophical traditions, such as the process philosophies of G. W. F. Hegel and Alfred North Whitehead, it emerged as a distinct field in the mid 20th century. It encompasses a number of different schools of thought, and the term *systems theory* is often used interchangeably with *systems thinking* or the *systems approach*.

Systems theory grew out of a recognition of the limitations of classical science in dealing with complex systems, such as biological organisms, social systems, and the increasingly sophisticated organizational and technological systems of the 20th century, often referred to as "socio-technical systems."

Building on the work of René Descartes, classical science emphasized the analytical method, breaking things down into their component parts in order to understand the whole. Because complex systems involve highly interdependent interactions among their parts, systems theorists argued that this reductionist approach was inadequate in explaining the dynamic behavior exhibited by these systems and that such systems must be understood as whole systems, as reflected in the often-quoted maxim that "the whole is greater than the sum of its parts." Systems theory, then, provides a holistic framework for understanding the organizing relationships within and among such systems, highlighting as well the relationship between any system and the environment within which it exists.

Systems theory is an inherently interdisciplinary orientation, emphasizing the need to integrate perspectives from different fields. As a result, it has contributed significantly to the evolution of both theoretical and applied social science, in addition to providing new conceptual frameworks for philosophical inquiry. It seeks to articulate principles that are common to all types of systems and to create a framework for dialogue among scholars from different disciplines in order to overcome a perceived fragmentation in knowledge that undermines humanity's ability to address the problems confronting society.

This entry provides an overview of the evolution of systems ideas, a summary of the key concepts to emerge out of this tradition, and an examination of the implications of systems theory for philosophy and the social sciences.

A Brief History of Systems Theory

Systems theory emerged in the mid 20th century, drawing on parallel developments in the fields of biology, psychology, management, engineering, information science, and ecology, as well as on a trend toward increasing interdisciplinary collaboration in the social and behavioral sciences. The broad range of perspectives that scholars from these various fields brought to their understanding of systems resulted in an enormous variety of interpretations of systems theory, leading to multiple and often contradictory implications for philosophy and the social sciences.

Ludwig von Bertalanffy (1901–1972) is generally recognized as the father of General Systems Theory, which is one of the key strands in the threads that have been woven into the systems field. He introduced the term in a seminar at the University of Chicago in 1939 to describe an approach to studying the nature of organization in all types of systems.

A *system* can be defined as any entity that is composed of parts whose interactions form an integrated whole. It is characterized by a particular structure that constrains the relationships between the elements that constitute the system and a boundary that delineates the system in the context of its environment. Systems can be either open or closed; open systems allow for the exchange of matter, energy, and information with the environment. The elaboration of the concept of open systems was one of Bertalanffy's most important contributions to the development of systems theory.

Bertalanffy believed that all phenomena could be understood as systems and that all systems (physical, biological, and social) displayed common patterns, behaviors, and properties. At the same time, as a theoretical biologist, he also believed that there were properties unique to biological systems that could not be explained according to (or reduced to) purely physical and chemical interactions. Similarly, he argued that human systems (psychological, social, and cultural) could not be explained in purely biological terms. The potential contradiction between these two positions—that all systems contain similar properties and that biological and social systems possess unique characteristics—reflects the underlying tensions between various interpretations of the systems field. In order to understand this tension, and the implications for the application of systems ideas in philosophy and the social sciences, it is helpful to explore the properties that all types of systems share in common, the most significant of which is the idea of self-regulation through feedback.

Homeostasis and Feedback: Nonlinear or Circular Causality

Another limitation of classical science, according to systems theorists, is its emphasis on linear chains of causality. Developments in the fields of biology, neurophysiology, engineering, and information science highlighted the significance of recursion and self-referentiality in the organization and function of living organisms as well as in the newly emerging technologies. There are several different schools of thought that grew out of different ways of understanding this phenomenon, and different branches of systems theory evolved out of these various formulations.

One of the most influential concepts to come out of the study of biological systems was the notion of *homeostasis,* which is the ability of living organisms to maintain themselves in a steady state, despite constantly changing internal and external conditions. This ability depends upon a system of communication among the various organs in the body that allows it to maintain constant levels of critical factors such as blood sugar, pH balance, and temperature. If any of these factors deviates from the optimal level, the body is able to respond to restore the balance. The existence of such mechanisms implies a kind of goal-directedness or purposefulness that does not exist in closed systems and depends not only upon the exchange of matter and energy in the system but also on the exchange of information. This organismic model of feedback was central in the development of James Grier Miller's (1916–2002) formulation of systems theory in his massive tome *Living Systems Theory,* as well as in the development of Talcott Parsons's social system theory.

Miller's work grew out of a decade-long collaboration among scholars from biology, psychology, and the social sciences at the University of Chicago, inspired in part by Bertalanffy's proposal of a general theory of systems. In an effort to articulate similar processes at different levels of organization in living systems, Miller identified 20 different subsystems that processed the input, output, and processing of matter, energy, and information at the level of the cell, organ, organism, group, organization, society, and what he called the supranational system. The concept of organizational levels is another important insight—namely, that living systems, as well as complex technological systems, generally consist of nested systems, with smaller systems existing within the context of larger systems, which are themselves part of systems at an even larger scale of organization.

Cybernetics

A parallel development that influenced the community of scholars at the University of Chicago who provided the foundation for Miller's work was a series of conferences sponsored by the Macy Foundation. These conferences, held in the late 1940s and early 1950s, brought together scholars from the social sciences, neurophysiology, and systems engineering, including figures such as Gregory Bateson, Margaret Mead, John von Neumann, and Norbert Wiener. The working title of the conferences, "Feedback Mechanisms and Circular Causality in Biological

and Social Systems," evolved over the course of the conferences. At one point, the group adopted the term *teleological mechanisms,* underscoring the potential for purposive activity in biological and even technological systems. Later, they proposed the term *cybernetics* to characterize the phenomena they were exploring.

Specifically, the participants in these conferences were exploring parallels between neural networks in the brain and recursive operations in the newly emerging field of computer science. This led to a growing emphasis on the role of information and communication in complex systems. In 1929, Leo Szilard had suggested that information was distinct from matter and energy; while the latter can be neither created nor destroyed, information has the potential to increase over time, providing an explanation for the phenomena of evolution and learning in living systems. The cybernetics group sought to understand the mechanisms of information processing, exploring the ways in which information is embedded in the dynamic processes that give rise to complex patterns of organization.

As might be expected, there were significant differences between the orientations of the social scientists and the engineers. Bateson and Mead, in particular, were interested in the unique role of language in the creation of social structure in human communities. In contrast, Weiner emphasized the similarities between organisms and machines. Although his view does not accurately reflect the general orientation of the field as it evolved, his name is perhaps the one most commonly associated with the concept, and the title of his book, *Cybernetics: Or Control and Communication in the Animal and the Machine,* reflects a mechanistic and reductionist orientation that was not shared by other researchers. Many cybernetics scholars were closely affiliated with the general systems community and tended to focus more on the concept of second-order cybernetics, which emphasized self-referentiality, or the importance of including the observer in the system being observed.

System Dynamics

Somewhat distinct from the cybernetics and general systems orientations, *system dynamics* emerged in the 1950s as another approach to understanding feedback processes. Based on the work of Jay Forrester, system dynamics was rooted in the circuitry models of electrical engineering and emphasized the internal dynamics of organizations rather than the exchange of information in systems. Specifically geared toward applications in management, it tended to focus on the input, processing, and output of material in production processes and to highlight the importance of understanding stocks and flows of materials in such systems. Unlike the models of feedback based on the concept of homeostasis, which only focused on negative feedback (or deviation-minimizing feedback), system dynamics identified both negative and positive (or deviation amplifying) feedback in the dynamics of systems.

Open Systems and Emergence

While feedback processes can be found in all types of complex systems, some systems thinkers were more concerned with the unique characteristics, or emergent properties, that can be found at higher levels of organization (i.e., biological organisms, human personality structures, and social systems). Bertalanffy's conception of open systems is the foundation for the concept of *emergence,* which is central to his understanding of General Systems Theory. According to the second law of thermodynamics, the entropy of any closed system will always increase. Because it takes energy to maintain any kind of organizational structure, the infamous second law implies that all systems will tend toward greater disorder. While this seems to contradict the evidence of evolution, since life has evolved increasingly complex forms over time, Bertalanffy's insight was to suggest that living organisms are open systems and are thus able to import energy from the environment and to export their entropy (or waste), allowing them to maintain complex organizational structures and, more important, to develop increasingly complex structures.

Open systems provide a context in which qualitatively new properties can emerge from the interaction of components within the system, which cannot be predicted or explained based on understanding the components alone. This perspective allows for creative and spontaneous activity in living organisms and suggests that systems at higher levels of organization possess qualities and capacities that do not exist at lower levels. Bertalanffy contrasted his theoretical orientation, which emphasized the self-organizing nature of living systems, with Miller's

organismic model, which emphasized equilibrium models of feedback and did not allow for the possibility of change. Instead, Bertalanffy argued, living organisms exist in a dynamic steady state, with the potential to adapt to changes in the environment. Ilya Prigogine (1917–2003), the Belgian physical chemist, built on this concept of open systems, suggesting that the further systems are from equilibrium, the greater the potential for more complex forms of organization to emerge. He introduced the concept of *bifurcation,* which described the tendency, as systems become increasingly unstable, to either reorganize into more complex structures or collapse into less highly ordered structures.

Relevance in the Contemporary World

Since its origins in the mid 20th century, systems theory has influenced a broad range of disciplines. Bertalanffy distinguished between three major strands of systems thinking: systems technology, systems science, and systems philosophy. As systems technology, it has been a central framework for the emergence of information technology and systems engineering in general, which has recently launched a new field of study known as "system of systems," acknowledging the highly interdependent, nested, and networked nature of current technological and organizational systems. As systems science, it articulated a more holistic paradigm for research, influencing recent developments in systems biology, as well as chaos and complexity theories. Although his work originated in the context of theoretical biology, Bertalanffy was particularly concerned with the philosophical and social implications of systems theory and emphasized the holistic and humanistic orientation of General Systems Theory as he conceived it.

Philosophical Implications of Systems Theory

The systems perspective offers significant insights into the ontological, epistemological, and ethical dimensions of philosophical inquiry. As ontology, it suggests that phenomena must be understood in terms of whole systems, in contrast to the reductionist and mechanistic orientation of classical science. Echoing insights from the field of quantum mechanics, it emphasizes the interconnected and interdependent nature of reality, proposing a cocreative relationship between the whole and the parts and integrating both upward (from part to whole) and downward (from whole to part) causality. It is process oriented, highlighting the emergence of organization out of the dynamic patterns of relationship between the components of a system.

The various traditions of systems thinking offer a variety of interpretations of the epistemological implications. Reflecting further parallels with emerging understandings from quantum mechanics, some schools of systems thought highlight the active role of the observer in the system being observed, leading them to embrace a constructivist epistemology. Other schools of thought, such as Miller's living system orientation and the system dynamics tradition, embody a more objectivist epistemology. Nevertheless, most systems thinkers emphasize the importance of integrating multiple perspectives in understanding any system, arguing that no single lens can provide a comprehensive and accurate representation. In addition to the implications of this orientation for education, there are significant ethical consequences that inform contemporary applications of systems thinking in social organizations. Proponents of this view consider an ethic of inclusiveness and collaboration to be essential in the application of systems thinking in the social context.

Systems Theory in the Social Sciences

The concept of emergence is central in understanding the implications of systems thinking in the social sciences. It informed Bertalanffy's views on psychology, which had a significant impact on the evolution of the fields of humanistic psychology and family systems theory. He was particularly opposed to the behaviorist model of stimulus and response as the primary motive forces in human behavior, which he saw as a reductionist approach rooted in a homeostatic model. Instead, he saw human consciousness as an emergent property characterized by self-reflective awareness, highlighting the importance of considering the role of subjectivity and autonomy in understanding humans as active agents. At the same time, he rejected the individualistic conception of identity and motivation, which conceived individuals as separate from the entire web of relations in which they are embedded.

In contrast to Bertalanffy's view, some systems models, paralleling structural and functionalist schools of thought, tend to minimize the autonomy

of the individual, emphasizing instead the structure of the social system as a whole. This orientation can be traced back to Herbert Spencer's organismic understanding of the social order and is reflected to some extent in Miller's living systems model and Talcott Parsons's social systems theory, both of which were rooted in organismic models that tended to emphasize homeostasis. Parsons's theory of social action described the interrelationships between organism, personality, culture, and society, portraying society as an autonomous system with the goal of maintaining stability, order, cooperation, and consensus through the communication of values and cultural norms. As a result, it tended to downplay the autonomy of the individual, and critics argued that the model ignored the role of conflict, did not adequately account for change, and tended to reinforce the status quo.

Building on Parsons's model, Niklas Luhmann is the most well-known contemporary social systems theorist, whose work is further informed by the conceptual framework developed by Humberto Maturana and Francisco Varela. They coined the term *autopoiesis* to refer to the process of self-creation or self-production in living systems. Although echoing earlier work on the concept of self-organizing systems, they argued that the organization of a system could not be changed without destroying the integrity of the system. In their view, living systems were closed in terms of their internal organization but open in terms of their structural composition and metabolism, reproducing themselves through a process of structural coupling with their environment. Based on this understanding, Luhmann conceived of society as an autopoietic system of communication. Like Parsons's model, this conception tended to privilege the social system as a whole over the autonomy of its individual members.

In his work on the role of communication in society, Jürgen Habermas voiced concerns that many scholars shared about the eclipse of subjectivity—or what he called the *lifeworld*—in systems models, and he engaged Luhmann in an ongoing debate about the relative significance of lifeworld and system concerns. While both addressed the source of meaning and motivation in human behavior, Habermas argued that Luhmann placed too much emphasis on the structure-maintaining role of the autopoietic social structure, emphasizing instead the generation of the social world through the evolving process of discourse. Habermas's critique was particularly influential in the application of systems thinking in social organizations.

Applied Systems Theory

While systems thinking has informed the evolution of disciplines across the spectrum, it has perhaps had the most influence in the applied social sciences. Beginning in the 1940s and 1950s as systems engineering, systems analysis, or operations research, it embodied a positivistic orientation, using systems principles to maximize performance in socio-technical systems. These approaches, which were characterized by top-down decision making and control, later became known as *hard* systems methodologies, in contrast to the *soft* systems approaches that emerged in the 1970s and 1980s, which sought to integrate the experiential, subjective (or lifeworld) dimension of organizational systems.

Soft systems approaches emphasized the active inclusion of all parts of the system in the decision-making process, recognizing not only the goal-seeking but also the relationship-maintaining function of organizations and embodying a shift in emphasis from structure to process. A critical insight to emerge from the soft systems orientation, reflecting the interpretive orientations in the social sciences, is the importance of surfacing the various beliefs, assumptions, and frames of reference—or mental models—that members of organizations bring to their participation. This has resulted in the understanding of organizations as learning systems, highlighting the potential for the emergence of new forms of social organization. More recent developments in applied systems thinking, described as *critical* or *emancipatory* systems approaches, suggest that soft systems approaches have failed to address underlying issues of power, privilege, and domination, with the ultimate goal of facilitating the design of human systems that effectively serve the whole system, while acknowledging the integrity and autonomy of the individual.

Tacit Knowledge

The term *tacit knowledge* was coined by Michael Polanyi to describe the elements of scientific knowledge that cannot be, or normally are not, set out explicitly but that are nevertheless essential to the activity of science and indeed all other human activity. Polanyi's slogans included the statements "We know more than we can say" and "All knowledge is either tacit knowledge or rooted in tacit knowledge." The range of application of the concept and the ground for tacit knowledge are matters on which users of the term differ, but the starting point—the most common motivation—is this: Some activity, inference, or communicative act depends on both the user and the recipient possessing some skill, inferential element, or mechanism that allows them to understand, anticipate, cooperate, or coordinate with another.

The standard example of tacit knowledge is the knowledge one needs to ride a bicycle. It is essential to the activity: Some people acquire it, and others do not acquire it. We normally use questions like "Do you *know* how to ride a bicycle?" so it is not odd to call this "knowledge," however much it departs from the paradigmatic definition of knowledge as justified true belief. We cannot articulate this knowledge and therefore cannot transmit it through words, though we may be able to coach a person learning to ride a bicycle.

Tacit knowledge is itself a paradoxical term. Standard philosophical usage treats knowledge as "true belief." But tacit knowledge is neither belief, which implies something explicit or self-conscious, nor necessarily "true"—indeed it is odd to think of calling something that cannot be derived from or contradict a true statement either true or false. The term itself is an analogical term, which likens the content in the tacit background to content whose character we understand, namely, explicit belief. Yet the term has caught on, for good reasons. The paradoxical language points to the fact that this kind of "knowledge" is unlike other "beliefs" in many ways *because* it is tacit: It cannot be examined and revised in the same way, it is not open to discussion, and it is not open to justification.

The term is an attempt to designate something that is familiar and difficult to deny. Consider a simple example: The police stop me after I thread my motorcycle through traffic and ask, "Do you know how fast you were going?" I cannot tell what was on the speedometer, but I had to know how fast I was going to successfully negotiate the traffic—if I didn't know, I would have crashed. This is not only tacit but also "nonconceptual" knowledge. In this, case, what I know is not something I could articulate even if I wanted to. These cases, which might be called the "bicycle cases"—after their paradigmatic instance, knowledge of how to ride a bicycle—constitute a large class. There is a dispute about whether this class should be taken as a model for other forms of tacit knowledge. But the existence of this kind of knowledge and its external properties, for example, the fact that it is learned as a skill, with some coaching or interaction but largely through experience, is not a matter of dispute.

The oddity of the notion of tacit knowledge is illustrated in the problem of the ambiguity between

psychological and logical notions of tacit knowledge, which bears on the question of what one is doing when the tacit is articulated. On the surface, when one explains something by making it explicit, one is dipping into one's mental world to pull out something that is already there but not attended to, on the analogy of the distinction between occurrent and dispositional belief. But the bicycle-riding case does not fit into this: There, the problem is that there is no way to formulate the knowledge in words. But there is also a problem with cases of articulation.

When we explain ourselves to someone who does not understand us, are we articulating something that we think our audience will understand better, which is to say inventing a new articulation for a new audience—in short, is our statement of tacit knowledge, as in the syntactic structure case, like a theory of the content? Is the "content" relative to our idea of the audience, not something fixed that is accessed in the mind, or is it merely a kind of comment on the failure of inference on the part of the audience, with no psychological significance? Answers to this question differ. One line is that there is a psychological fact and that it is in more or less the same form as that which is articulated. Another is that there is some psychological fact, as there is with the bicycle case, but there is no close connection between the psychological fact and the articulation, which merely patches up the inference.

The role of tacit knowledge is acknowledged in a large set of literatures, notably the construction of expert systems in artificial intelligence, in the economics and social studies of science (because of the need and, therefore, the economic value of specialized tacit knowledge in science), and especially in organization studies, where the growth and sharing of tacit knowledge in an organization is seen as a valuable benefit realizable only in social networks. Ikujiro Nonaka developed the socialization, externalization, combination, internalization model for the process of one of the most widely cited theories in knowledge management to account for the interactive sharing of tacit knowledge and the growth of tacit knowledge in organizations.

Team Reasoning

In Decision Theory, it is almost universally presupposed that agency is invested in individuals: Each person acts on her own preferences and beliefs. A person's preferences may take account of the effects of her actions on other people; she may, for example, be altruistic or have an aversion to inequality. Still, these are *her* preferences, and she chooses what *she* most prefers. Opposing this orthodoxy is a small body of literature that allows *teams* of individuals to count as agents and that seeks to identify distinctive modes of team reasoning, which are used by individuals as members of teams.

This entry explains the motivation for and the general principles of team reasoning. It then presents the two leading theories of team reasoning, those of Michael Bacharach and Robert Sugden, which differ in important ways regarding how group agency comes about, what happens when there is no common knowledge of group membership, and what the group agent should take as its goals.

Team Reasoning

One motivation for theories of team reasoning is that there are games of cooperation and coordination that are puzzles for orthodox Decision Theory,

in the sense that there exists some strategy that is at least arguably rational and that a substantial number of people play in real life but whose rationality Decision Theory cannot explain and whose play it cannot predict.

One such puzzle is the game of Hi-Lo. In Hi-Lo, both (*high, high*) and (*low, low*) are *Nash equilibria*; each player has achieved the best possible payoff for herself given the action of the other player (see Table 1). Intuitively, it seems obvious that each player should choose *high* because both prefer the outcome of (*high, high*) to that of (*low, low*); but that "because" has no standing in the formal theory. Standard game theory has no way of recommending or predicting one equilibrium over the other.

The source of the puzzle seems to be located in the mode of reasoning by which, in the standard theory, individuals move from preferences to decisions. In the syntax of game theory, each individual must ask separately, "What should *I* do?" In Hi-Lo, the answer to this question is indeterminate. Theories of team reasoning extend game theory to allow the players to ask, "What should *we* do?" In Hi-Lo, the answer to this question is surely "Choose (*high, high*)."

The basic idea of team reasoning is that when an individual reasons as a member of a team, she considers which *combination* of actions by members of the team would best promote the team's objective and then performs her part of that combination. It is still *instrumental practical reasoning,* where conclusions about what an agent ought to do are inferred from premises that include propositions about what the agent is seeking to achieve, but it allows that groups can be agents with group goals that provide their standards of success. When a group of people team reason, the rationality of each individual's action derives from the rationality of the joint action of the team.

Bacharach's Circumspect Team Reasoning

Bacharach presents the most comprehensive, formal theory of team reasoning. For Bacharach, people "team reason" when they "group identify," that is, see themselves as strongly embedded in, or identified with, a group; whether a particular player identifies with a particular group is a matter of "framing." A *frame* is the set of concepts a player uses when thinking about her situation. To team reason, a player must have the concept "we" in her frame. Bacharach proposes that the "we" frame is normally induced or *primed* by games like Hi-Lo.

Although Bacharach proposes that some games increase the probability of group identification, he does not claim that they *invariably* prime the "we" frame. The "we" frame *might* be primed, but alternatively, a player may see the game as one to be played by two separate individual agents. Bacharach models the psychology of group identification as a random process that, independently for each member of the group, determines whether or not that individual identifies with the group. Then an individual who group identifies will maximize the expected value of the group payoff function given the probabilities that other group members fail to identify. This means that a player may find ex post that she has team reasoned when the other player has not, leading to a worse outcome for herself than if she had not team reasoned—as sometimes happens in the experiments whose results Bacharach sought to explain.

Sugden's Mutually Assured Team Reasoning

On Sugden's account of *mutually assured team reasoning,* a person will not commit himself to team reasoning unless he has assurance that others will also act on team reasoning. Sugden uses a theoretical framework in which the central concept is *reason to believe.* To say that a person has reason to believe a proposition *p* is to say that *p* can be inferred from propositions that he accepts as true, using rules of inference that he accepts as valid. In mutually assured team reasoning, team members will not act on the results of team reasoning unless each has reason to believe of all the others that (a) they identify with the group and acknowledge the group payoff function as the objective of the group and (b) they endorse and act on mutually assured team reasoning. So if Sugden's group members are not sure that they will

all cooperate to achieve what they all take to be best for the group, then they will not team reason.

Because Sugden's team reasoners cooperate in a mutually advantageous enterprise, he would also constrain the group goal so that team reasoning is welfare increasing for its members, by their own individual lights.

Technological Convergence

This entry presents a very recent phenomenon, technological convergence, and the key epistemological and policy issues it raises. The term *technological convergence* describes the merging of different fields of technology as a result of scientific-technological progress. This entry describes the differences of vision between philosophy and nonphilosophical standpoints and highlights the importance of recent developments in the philosophy of technology and the significance of technological convergence for a novel understanding of technologically changing societies.

The currently dominant convergence story concerns the so-called NBIC convergence, referring to the synergistic combination of *N*anotechnology, *B*iotechnology, *I*nformation technology, and *C*ognitive neurosciences. Nanotechnology would provide the necessary key competence and play the role of an "enabling technology." According to this line of thought, convergence would mean providing a common ground for the scientific disciplines involved (or for science generally), so that all four elements converge in an engineering science working at the level of atoms and molecules. Far-reaching futuristic expectations are associated with this convergence, from "human enhancement" via an almost complete elimination of aging to the solution of virtually all sustainability problems.

In philosophical terms, the main idea behind this image of technological convergence can be called *atomic reductionism*. Operating with atoms and molecules thus becomes an engineering version of a "theory of everything." It would not be a theory of physical fundamentals providing explanations at an abstract level but a practical theory of operation and manipulation. Its subject would be constructing matter in a targeted fashion at the level of its building blocks—atoms and molecules, independent of whether these would be parts of crystals and metals or of living systems. In a radicalized version of 19th-century materialist reductionism, the spheres of the living and of the social are supposed in this perspective to be explained and made the object of technical manipulation starting from their atomic basis.

This concept of technological convergence not only expresses the scientific-philosophical viewpoints of its authors and exponents but also is an instrument of research policy and the subject of political dispute. The American perspective on technological convergence, which emphasizes the momentum of scientific development as a driving force, has been confronted with a European point of view that places the *design* of the convergence process for the achievement of societal goals at the center. The idea of technological convergence has also had an impact in terms of ideology. The transhumanist movement perceives the convergence hypothesis as offering a key possibility to technically improve humans from their condition as, in Arnold Gehlen's phrase, "deficient beings," first with converging technologies and eventually to overcome many human limitations

altogether in the course of the further development of a technical civilization.

An effect of the rapid and worldwide spread and discussion of controversial notions of technological convergence has been to raise interest in the field of science and technology studies (STS). Owing to technological convergence, it has been possible to observe concretely how futuristic visions have exercised real power and have practical effects—for example, for the promotion/funding of research or in structuring societal debates about the future.

In this way, visions of the future as a medium of societal conflicts, for the preparation of future-relevant decisions, and as a tool for societal self-understanding became a focal point of STS studies. Researchers have focused mainly on the emergence conditions, spread, real impacts, and strategic roles of these visions.

In contrast, the philosophical research interest is focused on questions of validity and on the contents of the visions of technological convergence. As an element of vision assessment, the hermeneutics and epistemology of these visions play a part in any reconstruction of the vision's contents and backgrounds and thereby contribute to an increase of transparency in societal debates on scientific-technological progress in the field of NBIC convergence. This enlightenment sometimes involves the formation of new and cross-sectional subspecialties of philosophy, such as neurophilosophy or nanoethics. In general, technological convergence forces the cooperation of philosophical subdisciplines that have hitherto been operating more or less separately: applied ethics, philosophy of technology, philosophy of mind, anthropology, epistemology, and hermeneutics.

The fascinating new opportunities of manipulating matter by converging technologies in abiotic and biotic systems have also motivated thinking about possible deeper changes in human civilization and its relationships to nature and technology. Technological convergence can allow disruptive increases of the agency of human beings and thereby abruptly raise the contingency in the *conditio humana*. What this may mean is the subject of philosophical debate. Roughly, three different positions have been expressed so far. First, there are assumptions that a new wave of Baconism is arising. Nanotechnology assumed that the ability of "shaping the world atom by atom" could be interpreted as a new manifestation of optimism by making everything appear to be technically possible and controllable. Second, the opposite story starts from the "enabling" character of nanotechnology and assumes creation of the greatest uncertainty imaginable: Everything could be possible, and probably nothing could be controlled. The third story regards nanotechnology as a "cipher of the future" that serves as a catalyst for societal, philosophical, and scientific debates on issues such as the future relationship between humans and technology and the future of human nature in avoiding strong substantial claims about controllability or other issues.

These debates are useful for the self-understanding of modern society regarding its transformation through converging technologies. They require philosophical reconstruction as well as socio-scientific analysis of the different forms of (mostly visionary) communication. In this way, hermeneutical reflection based on philosophical and social science methods, such as discourse analysis, can prepare the groundwork for applied ethics and for technology assessment. Ultimately, this promotes a democratic debate on scientific-technological progress by investigating alternative approaches to the future of humans and society with or without different techno-visionary developments.

Technoscience and Society

Technoscience as a label highlights the fluidity of the interactive process of science and technology and the ways in which it permeates every facet of our life—from transportation and communication to health and entertainment. Technoscience can be understood historically, sociologically, and ethically. This entry reviews all three standpoints from which technoscience can be viewed.

The scientific revolutions of the 16th century, especially Francis Bacon's concern with observation and experimentation as the proper scientific method, as well as the concerns with the power that is embedded in scientific knowledge, can be seen as forerunners of the term *technoscience*. Some early-20th-century thinkers, such as Gaston Bachelard, used the term, and others, notably Karl Popper, later linked the scientific method with political views of an "open society" while retaining the difference in aims that science and technology have.

More direct uses of the term are associated first with the Belgian philosopher Gilbert Hottois and the French philosopher Jean-François Lyotard, who used the term to combine the social, political, and economic activities within which science and technology operate. The Paris school (Bruno Latour, Michel Callon, Steve Woolgar) and the Edinburgh school of the Strong Program in the Sociology of Knowledge (David Bloor, Barry Barnes) in their sociological insights into the social construction of scientific knowledge in modernity made use of the term as well. From its European origins, the term is simultaneously sociological and critical, contextualizing the acquisition of knowledge, meaning, and truth.

Historically, the standard notion has been that science is theoretical and therefore pure or that technology is simply the application of scientific theories and principles, hence practical and messy (even when philosophically the aims remain distinct). In fact, theoretical insights arise out of experimentation just as much as out of contemplation. Isaac Todhunter has documented a series of historical moments wherein great thinkers were commissioned to find a theory, principle, or equation that would explain and predict how to win at gambling, ensure financial solvency in cases of overseas transportation, and collect the right premiums for life insurance. More recently, it is recognized that technical testing informs scientific research just as much as hypotheses inform practical trials. The Manhattan Project itself could be seen as a case study of the mixture of engineering prowess and theoretical insights that brought about the creation of the atomic bomb.

The social contextualization of technoscience in its various communities represents a sociological rather than a philosophical designation of a changed worldview regarding the evolution of our process of acquiring, disseminating, and consuming knowledge claims. Instead of characterizing the history of ideas (including science and technology) as Kuhnian "paradigm shifts," the process is understood in terms of the social conditions (World War II and the Cold War) that led to Big Science, the military–industrial–academic complex. From this perspective, technoscience is also informed by Marxist as well as feminist critiques, since they all contribute to a fuller recognition of the inherent biases that inspire or motivate researchers in their respective communities.

Ethically, there is a significant concern that if science remains theoretical and pure, on the one hand, and technology (or engineering) remains practical and applied, on the other, the former may be exempt from ethical considerations while the latter will necessarily bear the brunt of all moral condemnation (when catastrophes erupt). But if all of these activities are combined in technoscience, all those involved will be praised or condemned depending on the consequences of their work. This designation puts added pressure on all participants to prefigure the implications of their ideas (or research), rather than presume that they work in a shielded political vacuum because of its academic prestige or industrial wealth.

As the constellation of science, technology, and engineering, technoscience is best understood in terms of the activities of a whole community, and therefore this critical approach has been supported primarily by sociologists of science. Their work should be understood as following other European movements, such as deconstruction and hermeneutics. While the latter two were concerned to find the ultimate truth hidden beneath a structural understanding of objective knowledge (Truth), the sociological turn in science studies insisted that all scientific knowledge is always already socially constructed. Any claim to objectivity or truth was false. The reductionist move to a single prism through which to look at all scientific activities was toned down in the United States with the rise of the discipline of science, technology, and society (STS) studies, which includes a stronger focus on policy implications. The relative success of

the American counterpart has been seen in government agencies that have enlisted the help of these scholars (e.g., Virginia Polytechnic Institute and Rensselaer Polytechnic Institute).

While attempting to debunk the authority of science and technology, sociologists of science may have inadvertently privileged technoscience instead. Seen as interdisciplinary in nature, technoscience is not limited to sociology but extends to other disciplines and to the critiques of science by postmodernists as well, where a plurality of perspectives and multiple interpretations are encouraged (as Raphael Sassower argues). This plurality allows us not to lose sight of the importance of science and technology in our daily life and of the different philosophical and practical aims they have. Science and technology have the potential, in concert or separately, to remain open-minded to the contribution of various quarters in the construction of knowledge, however objective and universal it may eventually become.

TELEOSEMANTICS

This entry offers an overview of a relatively recent approach, called *teleosemantics*, that has become prominent in philosophical accounts of mental representation. The entry first explains what teleosemantic theories aim at and proceeds to present varieties of such theories. Teleosemantics adds an important dimension to what constitutes representation, intentionality, and perception in humans when they relate to the outside world and can thus be seen to have fruitful applications in the social sciences, too, and in particular in cognitive psychology.

What Are Teleosemantic Theories?

Teleosemantic theories try to explain, in a way that fits into the natural sciences, the relation that meaningful mental states, such as perceptions, beliefs, and desires, have to the things they are about. They are theories of what mental representation is. Teleosemantic theories may also be extended to explain what it is for communication devices such as animals' danger signals, bee dances, and human language to represent. Distinguishing teleological theories from other naturalistic theories of representation is a certain approach to the problem of misrepresentation, a problem often overlooked by other naturalistic theories. Misrepresentation is taken to be constituted by a failure to fulfill a natural *purpose* of some kind, hence to involve teleology, though of a naturalized kind.

Consider the problem of what it is for something to be a representation but a false one—a misrepresentation. Although a false representation does seem to represent something, it does not represent anything real. How can the representation relation be a real relation yet one of its relata sometimes be unreal? If I think it is raining but it is not raining, my thought is "about" something, namely, current rain, yet there is no current rain. What then is this "about" relation that is able to obtain between a representation and something that doesn't exist?

According to teleosemantics, the answer is that representations are items that have natural purposes or *functions* that require them to represent, but these natural functions can fail to be performed. Eyes have as their function to produce sight, but they can fail in this purpose when conditions are not right, for example, when the eyes are damaged or when there is no light. Representations that are false are representations that have failed or would fail to perform their natural functions. If we were to insist on using the word *represent* in only one sense—represent—it might be said that although to fulfill their natural purposes they would have to represent, false representations do not in fact represent. They fail to represent. But the word *represent* has another use that confuses us. "It is raining," we say, means or represents the same as "Es regnet" (in German) and the same as "Il pleut" (in French), and it represents "that it is raining" (putting things in English). These are all good translations of "It is raining" (the last being homophonic). Telling what something represents is, in this sense of "represent," giving a translation. But the fact that I can give a translation of a representation into another that would represent the same thing, if it did represent, does not entail that the translated sentence *does* represent. Basic representing—representing—is bearing an actual relation of a certain kind to something in the real world. There is no need to reify unreal things for false representations to correspond to. (This way of formulating the central thrust of teleosemantics is idiosyncratic but nevertheless, perhaps, accurate.)

The natural purposes or functions invoked by teleosemanticists are taken to be derived from selection processes: natural selection, or the selection that is learning, or, in the case of language forms, social selection or meme selection. The functions that characterize representations are, intuitively speaking, survival values—what a thing or its ancestors did that ultimately accounted for its existence or continued existence. Thus, teleosemantics involves the claim that what makes an item into a representation is partly a matter of its history. Just as memories have to have the right sort of history to be real memories, so perceptions, thoughts, and sentences have to have the right sort of history to be perceptions, thoughts, and sentences. If they were to manage to serve the same sort of functions as do representations, even though they had not been designed to do so, though failing the right history, they would not be representations in the core sense. Similarly, a gadget that can nicely be used to open cans but was not designed to do so is not a can opener in the core sense. This can be supported by noting that something not designed for opening cans and hence bad at it would not be a defective can opener, nor would something not designed to represent be a false representation.

Because teleosemantic theories require that representations have the right kind of history in order to be representations, when applied to mental representations teleological theories are what are called *externalist theories of content*. They imply that the content of one's thought—what would make that thought true (or satisfied)—is not determined by anything before one's mind or within one's consciousness or even within one's head. Nor is it determined merely by current dispositions that one has to make inferences or to act.

Different Kinds of Teleosemantic Theories

Teleosemantic theories differ in what they take the functions defining representations to be, hence in what they take the representing relation to be. It has often been said, for example, both by others and by teleosemanticists themselves, that the function of a representation is to (correctly) represent or to "indicate" something else. But this tells us little, unless it is also explained what (correctly) representing or indicating is supposed to be—for example, whether representations are supposed to covary with what they represent, whether they should be lawfully caused by what they represent, or whether they must "picture" or be isomorphic to, in accordance with semantic rules of a certain kind, what they represent, and so forth. The challenge has often been construed as that of creating a description that not only characterizes all representations (at least of a particular kind) but is also not too broad, implying that certain things are representations that do not seem, intuitively, to be representations or implying that what these representations represent is not what they seem, intuitively, to represent. However, a recalcitrant problem in the background concerns just what such a theory should be expected to explain. Should it be taken as a project in conceptual analysis, an attempt to capture what the outlines of our ordinary usage of the terms *represent* and *representation* are, or perhaps of the cognitive scientist's usage of these terms? Or should it be taken as a project in theoretical science,

an attempt to describe a certain kind of important phenomenon or principle that turns up in nature in many forms and that can be appealed to for explanatory purposes? Some of the differences between teleosemantic theories can be traced to this difference in aim, the exact relevance of prior intuitions about which things are representations and of what depends, in turn, on this aim.

We can roughly classify teleosemantic theories by what they take the relation to be between a true representation and its represented. What defining function is bearing a representation relation to something else supposed to have? How does this relation come about, or how is it produced when the system that produces or employs representations functions properly? Answering this question should also answer the question of what determines what a given representation represents, that is, "what its content is."

Dennis Stampe, who may have been the first to propose a teleosemantic theory, and Jerry Fodor, who proposed one but almost immediately repudiated it as "viciously wrong," offered theories that required representations to be caused by the things they represent. For Stampe, a mental representation represented whatever caused it when it was produced by devices that were functioning properly; otherwise, its content was what probably would have produced it had it been functioning properly. Fodor claimed that various kinds of external conditions could in principle be specified under which normal perceptual/cognitive systems would operate optimally in accordance with design and that what a belief state in the brain represented was whatever would always cause it under these epistemically optimal conditions. Under these conditions, the occurrence of the represented would be sufficient for occurrence of the representation. Karen Neander proposes a causal requirement on representation, at least for ordinary perceptual representation, and for simple cases such as the impulse in the optic nerve of the frog that has often been called a "fly detector." Neander takes it to be the job of such representations to represent that which they were selected for responding to, hence that which causes them when the system operates in accordance with its design by natural selection. She recognizes that a consequence of such a causal theory is, for example, that what the "fly detector" really represents must not be flies but small, moving dark things, since these properties are the proper *causes* of the frog's response.

Fred Dretske introduced what is sometimes called an "informational" teleosemantic theory, claiming that the function of a perceptual representation is to "indicate," or to carry "natural information" about, the represented. He described a signal or representation as carrying natural information if whenever the representation is present, there is a probability of 1, in accordance with natural law, that the represented is there also. Occurrence of the representation would thus imply occurrence of the represented. A representational system was a system designed to bring this kind of relation about. Notice that this kind of relation might occur for other reasons than the representation being caused by the represented. Dretske claimed, controversially, that the representational functions of belief-like states were derived only from learning, not from natural selection.

Dretske was explicit that representations have the "function" of carrying information owing to their situation in some larger system that makes use of the information to guide behavior, thus looking beyond the causes or correlates of representations to their effects to help determine content. David Papineau and (originally) Ruth Millikan claimed that it is only the uses to which mental representations are put that are relevant to determining their content. Millikan claimed that representations emerge when two systems (or one system in two capacities) are designed to cooperate with one another, one producing representations that correspond to aspects of the world by certain (semantic) rules, the other varying its activities as guided by these representations, perhaps first in the making of inferences but ultimately always in the production of behavior, taking account of what has been represented. The emphasis here is on the relation that the interpreting or "consumer" side of the system requires between representation and the represented if it is to perform whatever functions it has in the way it was designed to.

Papineau has sometimes said that the function of a belief is to be copresent with its represented. But he also says that what a belief represents, its truth condition, is the condition that would guarantee that actions based on that belief, plus other true beliefs one has, will satisfy one's desires, the function of a desire being to produce what it represents, that is, its satisfaction condition. For both Papineau and Millikan, then, a useful "correspondence" between representation and the represented does indeed occur when the biological system functions properly,

but how this correspondence is brought about is not definitional of the representing relation.

Ruth G. Millikan

Theory of Teams

Teams are a subject of investigation in many branches of social science, and *theory of teams* has different connotations in each. In some areas, the concept of a team may be "thick," specifying features that a group must possess in order to be a team, while in others it may be "thin," referring merely to a collection of individuals. This entry will present teams in various social-scientific guises, will explain why we might consider teams to be agents, and will consider the place of teams in our social ontology.

The thinnest use of "team" occurs in economics, where it is most often used to refer to the problem of how to incentivize individual members of a workgroup who each want to maximize their own pay and minimize their effort when the employer can only observe aggregate output. The team is just a group of individuals who each has her own goals but who are all subject to the same payment schedule. Also in economics, the Marschak-Radner theory of the team is a model of individual agents with a common goal. The theory concerns how best to communicate in order to implement the optimal collective action given that agents have private information and communication is costly. Thicker still is the concept found in the management literature on organizational behavior, which explicitly differentiates teams from mere groups. A team has features such as a common goal, interdependence, and synergies between members. Researchers in this area may focus more on specialization within teams, optimal team structure, and interactions between team members. Finally, in game theory, the theory of team reasoning takes a team to be a group with a common goal and proposes a special mode of reasoning used by individuals as members of teams. This approach overlaps with the two economic theories and explains some of the phenomena discussed in the management literature.

Team Agency

In the thinnest theories of teams, the team is not an agent but merely a collection of individuals. These teams are not of much interest to philosophers of social science.

Thicker theories may allow that a team can be an agent. There are some prima facie reasons for thinking that team agency is possible. It has been proposed that teams are agents because this explains how people can solve problems of game theory and because we might attribute to a group a pattern of beliefs, desires, and judgments that are held by none of the members.

Whether or not teams are agents ultimately depends on the criteria for attributing agency. In game theory, the key characteristic of agency is *instrumental rationality*. Agents have a preference ordering that represents what they want to achieve, and they

seek to be as successful as possible according to that standard. So a minimal condition for being an agent is having an end that is pursued. In the case of a team agent, this implies that there is a group goal.

A stronger characterization of agency requires that agents have a commitment to *rational unity.* Agents are any entity that has the ability to form states that play the role of intentional attitudes, such as judgments and beliefs, and that can take steps to ensure that these states are consistent with each other. If the defining feature of agency is the ability to engage in rational deliberation, then the bounds of agency need not coincide with the individual.

These two characterizations of agency need not coincide. Under the second characterization, ephemeral groups, such as two strangers pushing a car, will not exhibit agency. But these groups have a common goal and hence may be agents according to the theory of team reasoning.

Ontological Status of Teams

A related but separate question is the ontological status of teams. In the early 20th century, an *emergentist* tradition, inspired by Georg W. F. Hegel, considered teams to be transcendental entities over and above their individual members. Advocates of this approach were happy to countenance the possibility of "group minds" and tended to support more holistic explanations in social science. Others have found the idea of a group mind mysterious or problematic.

More recently, the dominant paradigm has been *eliminativist,* asserting that groups are reducible to individuals and that any property ascribed to a group can be reexpressed in terms that refer solely to the individuals who constitute it. Eliminativism is associated with methodological individualism in philosophy of social science, which denies that groups are a part of good explanations of social phenomena.

A middle road has been offered by Christian List and Philip Pettit, who argue that groups "supervene" on their members. The notion of supervenience is familiar from other areas of philosophy. As applied to teams, the idea is that facts about the individual members determine facts about the team. There is no additional factor required for the constitution of a group agent, over and above those about the collection of individuals who constitute the team. However, the relation between the agency of the individual members and the agency of the group may be very complex, and features of the group agent are not easily reducible to those of its members. Hence, talk of team agency is nonredundant, and teams may be a part of good social-scientific explanations.

Theory Theory

This entry introduces one of the alternative theories of folk psychology, the so-called Theory Theory, presents its main features, and reviews criticisms of it.

The main competitor of the Theory Theory is the *Simulation Theory.* They are both alternative accounts of what are known as ToM, that is, *theories of mind:* theoretical accounts explaining how people ordinarily understand each other's beliefs and actions in everyday settings by ascribing psychological states to them, without any prior scientific schooling in the notions people employ in doing so. The Theory Theory is thus a philosophical-psychological theory about a "theory" people apply in order to understand each other—a kind of mind reading.

The Theory Theory holds that knowledge of a (certain) "theory" helps us (the "folk") understand, predict, and explain the actions of others in terms of their psychological properties, such as the beliefs, desires, and intentions we ascribe to them. For instance, we explain why George went to the tavern by reference to his wanting a beer and believing that he could get one in the tavern. The theory has been very influential both in philosophy and in psychology.

In developmental psychology, a Theory Theory approach has been championed by Alison Gopnik and Andrew Meltzoff in relation to the child's cognitive development. The child is seen as a "scientist in the crib" constructing a "theory" about the world. The basic idea is that children do so by using the same cognitive tools that adult scientists use in constructing scientific theories. Children develop theories enabling them to predict outcomes and others' actions and assess evidence, and they even "experiment" and "test" in exploring the world around them. Thus, we grow up developing and employing a theory to understand others.

What Does the Theory Theory Hold?

The motivation behind the Theory Theory is the following problem. Though we are familiar with what people do and say and how they express themselves, we never have any *direct access* to the internal psychological states that we assume cause their observable behavior. It therefore stands to reason that we *infer* the existence of such mental states. But to do that, we must know which psychological states go with what behavioral manifestations, hence the need for a *theory*.

Many have thought that the situation here is no different from what we are faced with when attempting to understand natural phenomena. We need something like a scientific theory to understand others. In physics, we often posit so-called unobservables to explain the behavior of observable objects. For instance, we can observe the effects of gravity on how objects move but not gravity itself. It is sometimes thought that the same is true of mental states. Because we cannot observe them in others, but nevertheless assume that they cause their behavior, they gain a status similar to that of unobservable entities in scientific theories.

Problems With Theory Theory

One problem with thinking about mental states as *unobservables* is that most people believe that they have direct access to their (own) mental states. If they do, it is hard to see how they could be unobservables. Many theory theorists, however, think we do *not* have unmediated access to the contents of our own minds. Only by learning about other minds do we get to understand our own, suggesting that our knowledge of our own minds is *mediated*. Some of the developmental literature in psychology supports this idea. Not all theory theorists deny, however, that we have more direct access to our own mental states than those of others.

When queried, most people (including philosophers) are unable to produce anything like the *law-like* generalizations that the Theory Theory leads us to expect that they know. Most theory theorists, in fact, maintain that our knowledge is *tacit,* much like our knowledge of grammar in a Chomskian framework. The assumption is that we can know a theory and apply it without having conscious access to it and with it playing only a limited inferential role in our general reasoning. There are issues with this interpretation, however. We consciously know much more about the principles of psychology than we know of Chomsky-style grammar, *and* we seem to possess, and use freely, the concepts that are involved in folk psychology but not grammar. We have, and use, concepts such as belief, intention, desire, and fear freely but not artificial concepts such as *wh*-traces, a technical item of the complicated Chomskian theory of generative grammar.

The classic version of the Theory Theory holds a Hempelian-Nagelian view of scientific theories, according to which a scientific theory is a coherent body of knowledge containing theoretical terms that refer to unobservable entities or properties that are defined in terms of one another and are related in terms of laws. The theory provides explanations and predictions in terms of these laws. Using such a picture of our folk psychological knowledge, Paul M. Churchland has argued that our standard ToM is false and should be discarded like any other false theory. His reasons are that the theory is stagnant, insofar as it is no different from that held by the Ancient Greeks; it is explanatorily deficient—it fails to explain important psychological phenomena such as mental illness, creative imagination, and learning—and it shows poor prospects of being integrated into the natural sciences, none of which operate with intentional properties, such as believing that *p* or desiring that *q*. People have responded that folk psychological theory is the only game in town and

that although parts of it may be false, it is unlikely to be false in its essentials.

Alternatives

Other versions of the Theory Theory suggest that rather than think of our knowledge of folk psychological theory in terms of knowledge of lawlike relations, we should think of it as knowledge of *models*. Models are like exemplars, which we apply to real-life situations, assuming that the principles that guide the workings of the model apply to reality in certain respects and to a certain degree. We often use ideas of what ideally rational agents would do to understand other less rational agents.

Daniel Dennett's so-called intentional stance may be understood as a version of the Theory Theory. Taking the intentional stance on others is to *assume* that they have the beliefs and desires that it is rational to have—in other words, that they have intentional states. Doing so helps us do explanatory and predictive work that purely physical or functional frameworks cannot provide. Dennett believes that mental states as we conceive of them do not exist, but he thinks we need to think of others in intentional terms nevertheless. By contrast to both Churchland and Dennett, Jerry Fodor has argued that we should expect any future science of mind to retain the central categories of folk psychological theory. So far, both psychologists and philosophers have continued to work with categories that are essentially those of folk psychology.

Therapy, Psychological and Philosophical Issues

The entry discusses therapy as understood by psychology, in the form of psychotherapy, and concentrates on the two main kinds of philosophical issues surrounding it: first, the issue of values involved in psychotherapy, or in general the normative challenges unavoidably related to it, and, second, the issue of its epistemic status, that is, the question of the evidential support the outcome of psychotherapy may be said to enjoy.

At one time, only the so-called insight therapies, those heavily influenced by the views of Sigmund Freud, were classified as psychotherapies. Today, the term *psychotherapy* is used in a wider sense to include any sort of psychological therapy, including the behavior therapies and the cognitive therapies. In this wider usage, there are more than 400 different types of psychotherapy. The question of which forms of psychotherapy are effective, for which clinical disorders and under what conditions, has been an enduring topic of controversy.

At first appearance, the issue of effectiveness is straightforwardly empirical. We are asking about a causal connection between treatment and outcome. How else are we to answer this causal question except through empirical inquiry? Yet, when we press further and ask about the kind of empirical evidence that is needed and what the evidence shows so far, various deeper questions emerge, some of which are clearly philosophical.

The Values Question

The picture of psychotherapy accepted by many is of an enterprise that is through and through *value-laden*. It is not merely that psychotherapists sometimes make ethical judgments in their practice but that such judgments are everywhere and are

unavoidable. Here is one illustration of this view discussed in the literature.

Bob is suffering from anxiety and depression. Part of his problem is that his wife has moved in with a much younger man. Bob wants help, and he wants advice. The wife's new relationship is not working out, and there is a good chance that she is willing to go back to her husband. Bob, apparently seeking moral advice, asks the therapist if he should forgive his wife and if he should try to work out the problems in their marriage.

As the therapy progresses, the therapist must make more ethical decisions in deciding the goals of the therapy and the best means to achieve them. The therapist decides that the therapeutic goal should be for Bob to gain insight into the unconscious and childhood roots of his current difficulties, but Bob just wants to be less confused, less anxious, and less depressed. The insurance company, on the other hand, wants the focus to be on a quick, cost-effective reduction in symptoms. Further ethical decisions must be made when the therapist realizes that others, including Bob's children, have a stake in the therapeutic outcome. The therapist reasons that he must make an ethical decision concerning the weight of their interests compared with those of the client and the insurance company.

Some who see the Bob case as a model for psychotherapy reach provocative conclusions such as this: Psychotherapy research and practice are essentially expressions of moral principles, the practice of psychotherapy is not in any way separable from the practice of ethics, and the psychotherapist is someone working in applied ethics.

Many cite the value problem as the main impediment to developing a natural science account of psychotherapy, but they need another premise. It is not enough to say that psychotherapists must make value judgments in their research and practice. That is consistent with a natural science view of the field. The needed additional premise is that there is no way to establish the truth or falsity of value judgments.

The issue of explaining how value judgments can be proved is a difficult one (and is, of course, central to philosophy in general), but what might help is to split the value problem in two, reflecting the distinction philosophers draw between theories of the nonmoral good and theories of the morally right. Traditional hedonism, for example, treats pleasure as the only intrinsic good, but it is silent on the moral issue of whether and under what conditions agents ought to seek their own pleasure. In contrast, Kantianism and Mill's utilitarianism do talk about what is morally right or wrong.

The evaluative questions that arise in psychotherapy's outcome research are generally not moral questions; they are questions about whether treatment effects are beneficial, neutral, or harmful to individuals. Moral issues, when they do arise, usually come up in choosing therapeutic goals or when clients seek moral advice from a therapist.

Although not everyone agrees to this, explaining how a treatment effect can be shown to be beneficial for an individual may be easier than showing how moral judgments can be proven true or false. Assuming that Bob is not being irrational or misinformed in wanting to be less depressed, it seems, at least before we wade into the philosophical issues, that one can make the case that satisfying his desire to be free from depression would be a benefit for him. Some philosophical theories try to explain how judgments about what is beneficial to someone can generally be warranted by linking beneficial outcomes to the satisfaction of an agent's desires, provided that certain conditions are met, such as the absence of irrationality and relevant ignorance.

There are likewise cognitivist moral theories that try to show how moral judgments can be proven or disproven. If one of these can be warranted, then the moral component of the values problem can also be handled; but if moral skepticism is true and no moral judgment can be proven, then we might try a different option and argue that the extent to which psychotherapists must make moral judgments, at least of a categorical kind, is greatly exaggerated.

Disagreements about the proper goals of therapy are often about likely consequences and not about moral issues. For example, the debates between psychoanalysts and behavior therapists about making symptom remission the goal of therapy has mainly been about the symptom substitution hypothesis, with psychoanalysts contending and behavior therapists denying that the elimination of symptoms without a resolution of underlying unconscious conflicts generally causes worse symptoms to develop. The Bob case is fictional, but if his therapist is appealing to the symptom substitution hypothesis or merely claiming that the most efficient way of solving Bob's problems is to gain insight into their underlying cause, then he is making an empirical, not a moral

point. If, rather oddly, the therapist were making the moral claim that it is better on moral grounds to seek insight into unconscious causes, then the therapist's behavior would be atypical and could not be reasonably taken as a model of what psychotherapists generally do.

Even where therapists give moral advice, and even if we count this as part of the psychotherapy and not something merely added on, the judgment is often conditional, not categorical. If the therapist were to tell Bob that he ought to reconcile with his wife, the therapist might well mean that Bob should do this on condition that he wants to be happy or wants his children to be happy. Conditional moral judgments of this sort can often be proved or disproved empirically. The question of whether Bob's reconciling with his wife will increase his happiness is a causal question that can be answered by finding the right sort of empirical evidence.

Psychotherapists do sometimes give categorical moral advice—"You ought to do this no matter what your goals are"—but it remains to be shown that this fact creates a serious problem for the general practice of psychotherapy or for a natural science approach to researching its effects.

Standards of Evidence

Many of the controversies about what has, and has not, been shown to be effective reflect different approaches to standards of evidence. The issues are partly empirical; but when disagreement extends to basic standards, they are also partly philosophical.

Many psychotherapists have followed Sigmund Freud in relying on uncontrolled clinical case studies. The idea is that by the time the therapy is terminated, the therapist can often see that the treatment has brought about a reduction in symptoms or some other beneficial result. The standard objection to this idea is that at most the therapist can determine by observing the patient that improvement has occurred, but she cannot know the cause of the improvement without ruling out a credible rival hypothesis: Spontaneous remission has taken place, which means that events occurring outside the therapist's office were causally responsible for the beneficial outcome. Even if this can be ruled out, there is the problem of discounting another credible rival hypothesis, that the main curative element was not the therapy but the patient's belief that the treatment would be effective—in short, that there was a placebo effect.

These twin problems also arise when pharmaceutical treatments are studied for their effects on psychological problems such as depression or anxiety. The standard way to deal with them is to use randomized clinical trials with a credible placebo. However, many psychotherapists object to such trials on ethical grounds—patients in the placebo group are deceived about the treatment they are receiving—or because they believe that they are unnecessary.

Whatever the merits of these objections, it still has to be explained how credible rivals to a hypothesis of therapeutic effectiveness can be ruled out without employing randomized clinical trials or how we can obtain credible evidence without ruling out credible rivals. The first option has been explored recently in the medical literature, where some have argued that certain types of observational studies, such as sophisticated cohort and case–control studies, can take the place of randomized clinical trials, but neither of these sorts of trials has been widely used in psychotherapy research.

If, contrary to what many psychotherapists believe, randomized clinical trials are ultimately necessary for establishing effectiveness, then as of now, most of the 400 or so psychotherapies have not yet been shown to be effective. As more and more randomized clinical trials are carried out, and providing they are of high quality, the quality of the outcome evidence will improve.

But there is another problem: the *integration problem*.

The best evidence that a medical treatment is generally effective for a certain malady is a megarandomized clinical trial with 50,000 or more subjects. No such trial has ever been done in the field of psychotherapy. When smaller trials are done, it is very common, partly because of the great variability in responses to treatments, for the results to disagree. Some studies show positive results, some negative results, and some neutral results. This gives rise to the integration problem: the problem of putting all of the evidence together, analyzing it, and reaching a reasonable causal verdict.

The standard way of dealing with this problem in psychotherapy and medicine is to use *meta-analysis*. A statistician collates the results of all the relevant studies and calculates an "effect size," assuming

that there is a quantitative measure of a therapeutic outcome and at least one control group, by subtracting from the mean score for the treatment group the mean score for the control group and dividing the result by the standard deviation for the control group. An average of the effect sizes for all the studies is then calculated and is said to be the average effect size for the treatment. This may work if all the studies are high-quality randomized clinical trials, or some adequate substitute, but in much of the psychotherapy outcome research, the studies are uniformly inferior, or there is a mixture of good and bad studies. In such cases, doing a standard meta-analysis will not by itself permit the inference that a therapy is effective.

One possible solution tried in medical research, but not in psychotherapy research, is to develop a quantitative system for rating design excellence. Many such systems have now been developed, but the philosophical problem of validating the numerical values for a system has so far not been solved. The upshot of this is that even where psychotherapy has been the subject of experimental studies, there is often good reason not to trust the meta-analyses that have been done to integrate the conflicting evidence and reach a causal verdict. The main exception is where all the trials are of high quality and the results are in agreement. This, unfortunately, is not the standard case in psychotherapy research.

Thought Experiments

There is no agreed definition of the term *thought experiment*. However, two important strands of usage may be discerned. In one usage, *thought experiment* refers to imaginary or hypothetical examples used to bolster, illustrate, or convey a theory. In another, narrower usage, it refers to the use of such examples to *test* a theory and thus provide evidence for or against it. There is no need to choose between these usages, but it is fruitful to keep them apart. This entry will discuss each notion in separate sections. For brevity, the term will be understood below in the sense indicated by the respective headings.

Thought Experiments as Examples

Sometimes, imaginary examples are used simply to illustrate an abstract theory or concept in a textbook or a classroom setting in economics, jurisprudence, or the sciences. Their utility for this purpose is due to the fact that they are free to abstract from messy, distracting detail and to idealize away nonsalient causal factors that would always be interfering in an actual case.

Thought experiments used for this purpose may draw on analogies or use extrapolation. Albert Einstein and Leopold Infeld illustrated the equivalence of gravitational and inertial mass with the famous case known as *Einstein's elevator,* in which a person will observe light bending whether the

elevator is accelerating in an inertial frame or subject to gravitation. Isaac Newton imagined a cannonball's trajectory gradually widening or extending to the point where it doesn't come down at all, thus illustrating how gravitation keeps the moon in orbit.

Thought experiments may also be used to bolster a theory—without, strictly speaking, testing it—by showing its explanatory potential. Darwin had no access to the historical evidence that would go into a detailed explanation of the evolution of biological variation. But in *The Origin of Species,* he invites the reader to imagine various scenarios in which selection would lead to what we now observe, thereby establishing his theory as a *potential* explanation, contrary to creationist objections. Such use of thought experiments to show a theory's explanatory merits is not sharply distinguishable from mere illustration. In both uses, the point of the exercise is to see what would happen in the scenario on the assumption that the deployed theory is true.

Thought Experiments as Tests

Sometimes, however, hypothetical cases are invoked to check whether a theory yields the right result in them. This outcome, in turn, is taken to indicate whether the theory is true. This use of hypothetical cases for providing evidence is very common in philosophy, but it also occurs in the sciences. Galileo asked what would happen if a cannonball and a musket ball were connected by a string and then dropped. In Aristotle's theory, the speed of a falling body is proportional to its weight. Galileo argued that, in his hypothetical scenario, Aristotle's theory implies that the composite body should fall both faster than the cannonball on its own (since it is heavier) and slower (since the small musket ball should act as a drag), which is absurd.

In ordinary testing by experiment—in a wide sense, covering not only laboratory experiments but also observational testing in, for example, astronomy and sociology—a theory is tested by its logical consequences: If the theory is true, certain observations will be made given certain initial conditions. The experiment then proceeds by establishing that the initial conditions hold and checks whether the theory's predictions are right. (This simplifies matters a bit.)

Correspondingly, thought-experimental testing proceeds by establishing that a hypothetical scenario is possible and checks whether the theory is correct about what would be the case in that scenario. In conventional experiments and thought experiments alike, an outcome at odds with the theory counts as a prima facie counterexample, indicating that the theory is false; an outcome in accordance with the theory may be some evidence that it is true. Thought experiments parallel ordinary experiments but differ in being *modal*—that is, in dealing with possible, rather than actual, cases.

The modal character of thought experiments arguably brings the parallel with ordinary experiments to a halt. For thought experiments, three questions loom: (1) How can merely possible cases be evidence? (2) How do we know whether a scenario is possible, and what would be the case in it, given that we do not empirically observe this? (3) What is the relation between the particular test case and the theory that is tested?

These questions are interrelated. Consequently, various attempts to answer any of them tend to either address or presuppose certain answers to all three. Some theorists take the epistemological puzzle raised by Questions 1 and 2 to motivate skepticism about thought experiments (they do not give evidence) or reductionism (thought experiments give knowledge but may be reconstrued as general arguments that do not invoke case particulars). Others take it to motivate Platonism or rationalism, according to which thought experiments employ intuitions, understood as a nonperceptual, a priori analog of observation. Some argue that although modal and particular, thought experiments don't require any peculiar a priori cognitive capacities. Still others hold that the use of thought experiments as tests should be restricted to the testing of distinctly a priori theorizing.

Advocates of these various positions tend to adduce very different instances as examples bolstering their own interpretation. In discussions of thought experiments in the philosophy of science, Galileo's case has become a standard instance of a successful thought experiment. Recent debates of thought experiments in philosophical methodology often treat Gettier cases (undermining the standard definition of knowledge as justified true belief) as paradigmatic. The latter debate is currently engaged in the question of what the content of thought-experimental claims (or intuitions) is.

Various suggestions seem to accommodate the wish to render thought experiments epistemically respectable by construing the content as something both plausibly accessible to intuition and relevant to the theory under testing. This has in turn led many theorists to construe the tested theory as a (universal) necessity claim. But it is worth noting that when historians invoke hypothetical scenarios—alternative histories—to argue for or against claims of causal relations, they seem to be engaged in thought experimentation as testing. Yet the theories they test by means of thought experiments, while modal, seem to be making neither universal nor necessity claims.

Recently, experimental philosophers have challenged the very appeal to intuitions as evidence. Current work—both experimental and theoretical—on intuition should prove relevant to the status of thought experiments as tests.

Time, Philosophical Theories of

The nature of time has puzzled philosophers throughout history. Time pervades our lives and experiences. The notion of an indeterminate or "open" future contrasting with a determinate or "fixed" past has seemed essential to certain views of free will, and more generally, our views about time are likely to be central to our views about reality as a whole. Yet there is something deeply puzzling about time. The puzzle is usually thought to have something to do with the notion that time *passes*. This entry discusses philosophical theories concerning the passage of time, along with some related views about the existence of the past and future.

McTaggart and the A and B Theories of Time

Current theories of time are divided into two varieties, known as *A theories* and *B theories*. These names are derived from J. M. E. McTaggart's notions of the *A series* and *B series* of time. Let us use the term *A property* to denote temporal properties such as *being present, being past to some degree,* or *being future to some degree*. Then an A series is a time series in which times are ordered according to their A properties. One time is present, and all other times are past or future to differing degrees. As time passes, a different time becomes present, and a new A series arises; or to put it another way, the position of each time along the A series constantly *changes*. In a B series, by contrast, times are arranged in an order, but no time is past, present, or future, and nothing about the B series ever changes. Instead, times are ordered according to the relations in which they stand, eternally, to one another—relations of being *earlier than, later than,* or *simultaneous with*.

McTaggart held that only the A series truly described time; change, he held, was essential to time, and only where there are A properties can there be genuine change. Yet McTaggart held the A series to be paradoxical. Because time passes, every time has its turn at being present and, similarly, every time has its turn at being past and being future. Yet no time can be past, present, and future; these properties are incompatible and hence the paradox. The obvious response is to accept that every time has every A property but to deny that any time is past, present, and future all at once. Instead, the year 2100, for example, is *presently* in the future, it *will be* present, and it *will be* past. So a given time has only a series of compound "tenses," such as *presently future, future past,* or *past past future;* it does not have the simple properties *past, present,* and *future* all together.

Much debate has arisen over whether the move to compound tenses removes the paradox; McTaggart

thought not. McTaggart's own radical conclusion was that since, according to him, there can be no real A series, time itself is unreal. During the latter half of the 20th century, however, a number of philosophers have drawn a quite different conclusion from McTaggart's paradox. Advocates of the B Theory agree with McTaggart that there is no real A series, but they hold that real time is adequately described by the B series. Thus, they hold that no time is really past, present, or future, and along with this, they deny that there is any real passage of time. All locations in time have the same metaphysical standing, much like locations in space. Just as no single location in space is really, objectively *here* (it is only said to be "here" by a person at that location), similarly no location in time is really, objectively *now*. Some B theorists are motivated by McTaggart's paradox, but others have arrived at the view for independent reasons. Advocates of the A Theory, by contrast, hold that there is a real A series and that time passes.

Versions of the A Theory

A theories and B theories come in a number of different versions. Most B theories are broadly similar, differing mainly in what they say about the relation between time and space. The B Theory holds that all times are equally real; the only reason why the present seems special to us is that we happen to be located there. Others (or other temporal parts of us) are located at other times, which they describe as "now" with equal justification.

Different A theories, however, are associated with very different views about reality. The traditional "moving-spotlight" A Theory holds that all times are equally real but the present "moves" along the time series much like a spotlight moving along a line, illuminating one location after another. The "growing-block" theory, by contrast, agrees that the past and present exist but denies that the future exists. According to this theory, reality consists of a space–time "block" consisting of all past and present entities but no future entities, and the block grows as time passes and more of reality comes into being. Hence, the past is "fixed," whereas the future, which is yet to come into existence, may be seen as "open" (insofar as the laws of physics allow for different possible futures). Another theory, sometimes known as the "shrinking-tree" theory, agrees that a single past and present exist but holds that all possible futures also exist. As time passes, a single state of the world comes to be present, then passes into the past. Reality is thus like a tree whose lowest branches continually fall off as time passes.

Currently, however, the most popular version of the A Theory is *presentism,* according to which reality consists only of the present. The past and future do not exist. But the nature of the momentary reality constantly changes as time passes. Strictly speaking, presentists need not accept that there are A properties at all; there are no past or future times that could instantiate properties of pastness and futurity, and presentness is therefore redundant. Many presentists do hold nonetheless that there are irreducibly tensed facts about the present (e.g., the present fact that there were dinosaurs in the past); and almost all presentists hold that time passes.

One advantage of presentism is that it clearly avoids McTaggart's paradox. If reality consists of a single present time, then no time ever instantiates pastness or futurity, so no paradox arises. But presentism also faces problems. The problem that has received the most attention is that of explaining what makes past or future tensed utterances true. Consider, for example, the claim that there were once dinosaurs. If the past exists, then the claim that there were once dinosaurs is made true by the dinosaurs themselves, located in the past; as philosophers sometimes say, the dinosaurs are the *truthmakers* for the claim that there were once dinosaurs. But if there is no real past, then there are no truthmakers for claims about the past; so presentists must either deny that all truths require truthmakers or else find an unexpected truthmaker residing in the present.

Fatalism

If, as presentists and growing-block theorists hold, the future does not exist, this makes it easier to defend the view of free will, according to which the future is open and our free choices help determine which of the possible futures comes to be. But if, as B theorists and moving-spotlight theorists hold, there is already a single determinate future, just as fixed as the past, then, on the face of it, this notion of free will must be abandoned, for there is only one possible future course of events (this is the view sometimes known as *fatalism*). Views about the metaphysics of time thus tend to constrain views about free will,

and vice versa. It is important to note, however, that the problem of reconciling free will with an already existing future is distinct from the problem of reconciling free will with determinism, the view that the current state of the world, combined with the laws of nature, determines all future events. Determinism could be true even if presentism were true; for example, the fact that no future yet exists does not entail that there are many possible ways for the future to turn out.

Problems for the Passage of Time

The notion that time *passes* is at the root of the disagreement between the A theorist and the B theorist. The notion of passage is at once familiar and elusive; we think we know from experience what it means for time to pass, yet it is notoriously hard to explain what this amounts to. We seem only to be able to describe it using puzzling metaphors such as *passage* or *flow*.

These metaphorical descriptions have led to challenges. One of these concerns the *rate* at which time passes. It is sometimes claimed that if time passes then it must pass at some rate. But at what rate does time pass? A standard answer is that it passes at the rate of 1 second/second. There has been much recent debate over whether this is a possible rate. Moreover, even if we can make sense of a rate measured in seconds per second, it sounds worryingly as though there would have to be two distinct time series for the rate of time's passage to be a ratio between two quantities measured in seconds. But the notion that time passes is clearly not equivalent to the claim that there are two different time series, the units of which stand in a one-to-one ratio to each other. Much clarification is needed here.

It is open to the A theorist to reject these puzzles as simply taking the metaphors too literally. Perhaps, they may say, the notion of passage is indeed rather mysterious and cannot easily be explained in terms of anything else, but this is not an adequate reason to reject it; for these are mere quibbles when set against our immediate familiarity with the passage of time in experience. The B theorist must hold that our apparent experience of time passing is an illusion and must therefore explain the nature of the illusion and the reasons why it occurs. The A theorist, it is assumed, has no such problem with experience. This has often led to an assumption that the A Theory is the default theory and the B Theory is a counterintuitive theory for which strong arguments must be given.

Recently, however, some philosophers have challenged the assumption that experience gives us any reason to accept the A Theory. If we experience time passing, then presumably the passing of time must have a role in making our experience the way it is. Yet when one starts to consider possible mechanisms whereby the passage of time could bring about the experience of it, problems loom. All other kinds of experience seem to involve a unique causal chain leading from the experienced phenomenon to the experience itself; at any rate, there must be something that makes it the case that the experience and the phenomenon are uniquely related to one another. The experience is of passage, not of another phenomenon; and no other kind of experience is an experience of passage. Giving an account of what makes this the case promises to present a significant challenge to the A theorist.

Time, Social Theories of

Time is our self-conscious awareness of change. We can measure such changes by means of the shadow that moves across a sundial, the sand that falls through an hourglass, the hands that traverse the face of a clock, or the vibrations of a cesium atom. Human societies create divergent ways to understand time, and in turn, the rhythms of activity in these societies are shaped by their respective systems of time reckoning. Social theories of time attempt to explain or account for some aspect of this reciprocal relationship between time and society. For all human beings, however, death is a fact of life; we know our days are numbered. The essence of human existence is temporal because our consciousness of impending mortality brings about a uniquely human concern with time itself. Consequently, theories that address time or temporal experience are important issues in the humanities and social sciences. These theories form two principal lines of inquiry: (1) *the social construction of time* and (2) *variation in temporal experience.*

The Social Construction of Time

The predominant theoretical perspective emerged at the beginning of the 20th century with the idea that time is a *social institution.* Like religion, family, and government, time is a social institution because it represents a culturally specific solution to one of the challenges that confront all human societies: the temporal organization of social rhythms in our behavior. Systems of temporal organization vary historically and culturally. Unlike hunting and pastoral peoples, for example, agrarian peoples typically establish a regular day of rest. Time reckoning is also variable. The people in one society may agree to meet at a certain hour, but in a society without clocks, people may agree to meet when the sun is at a certain point in the sky. The people in one society may estimate intervals of time in terms of minutes or seconds, while those in another society use the time it takes to cook rice or fry crickets.

The social construction of time entails the *creation* of temporal systems that are products of human ingenuity and artifacts of social interaction. These temporal systems have histories, and they are *culturally relative;* they are neither natural nor inevitable. Yet they are also real or objective features of cultural arrangements, and once they have been established, it is very difficult to alter them. Indeed, subsequent to their establishment, these temporal systems act back on the individuals who enact them with exteriority and constraint.

The 7-day week is a prime example of these social conventions. It is so familiar that we take it for granted, but its arbitrary origins are rooted in the seven "planets" of Babylonian astrology and the creation stories of the ancient Hebrews. Nonetheless, the week structures the rhythm of our activity. Each day of the week seems to have intrinsic qualities, yet these characteristics quickly evaporate when we go on vacation or extraordinary circumstances free us from our usual schedule. The 7-day week is certainly not universal. Cross-cultural research reveals that various societies have had weekly rhythms that are 3, 4, 5, 6, 7, 8, 9, 10, 12, 13, 19, or 20 days in length. Those who espouse radical philosophies have tried to abolish the 7-day week because of its religious roots. Following the French Revolution, the new regime attempted to enforce a 10-day week, and 140 years later, Soviet Bolsheviks tried to establish a 5-day week. Each of these efforts lasted for more than a decade, and each of them offered a feasible alternative, but the people of both societies rejected these revolutionary temporal systems because of their cultural commitment to the traditional 7-day rhythm.

The international standardization of time is another socially constructed temporal system. The decision to place the prime meridian at Greenwich, England; the number and width of the time zones; the location of the international dateline in the Pacific Ocean—these are social conventions negotiated at an international conference during the latter part of the 19th century. Although it is not easy to revise temporal conventions, they are subject to change. In the 20th century, for example, the international community agreed to redefine a second. The older (but now too imprecise) definition was one 86,400th of 1 day. As of 1967, however, 1 second is defined as exactly 9,192,631,770 oscillations of the cesium atom.

The social distribution of time is a function of relative power and status. If we define time as a scarce and valuable resource, then we can see how waiting and delay are structured by a temporal system

of inequality. We are willing to wait for what we want, and the more we want it, the longer we are willing to wait. It follows that powerful and prestigious people demand that others wait for them as a form of deference and avoid waiting by hiring others to stand in lines for desired goods and services. An emerging *theory of temporal politics* elaborates on these principles to explain how ruling regimes in Latin America construct their own authority by making citizens wait interminably for various governmental services. A related theory concerns postindustrial nations, where politics and economics are increasingly desynchronized because the legislative processes of liberal democracies cannot keep pace with the market's technologically driven acceleration. There is, then, a *sociology of time and power.*

A society's *future* is another socially constructed facet of its temporal system. We can conceptualize the relationship between our past and our future in terms of temporal depth. This variable concerns the distance into the past or the future that people in a given society typically imagine as they go about their daily lives. Moreover, we can hypothesize that, on average, the further backward in time a people look, the further forward they look—that is, the larger a society's past, the larger its future. This theory has practical and quite important implications for our problems with environmental hazards. As a young society with an emphasis on the short-term future, our difficulty in dealing with threats to the environment is related to the fact that they tend to develop so slowly and over such long periods of time that we have trouble perceiving them.

Variation in Our Experience of Time

Despite the standardization of time, there is *subjective* variation in our temporal experience. We may perceive time passing slowly or quickly relative to the standard temporal units of clocks and calendars. And, of course, there is the third possibility that we may experience a rough synchronicity between subjective and objective time. This form of temporality may involve subjectivity, but it is no less social in its etiology than the International Date Line. Our perception that time is passing quickly or slowly always occurs against the backdrop of standard (i.e., socially constructed) temporal units and a normal, albeit approximate, synchronicity between subjective and objective temporality. Furthermore, variation in the perception of time is conditioned by our social circumstances, and this causal impact is mediated by a thoroughly socialized entity—namely, self-consciousness. Several theories link the social structure of self-consciousness with variation in temporal experience.

In any given society, one learns to negotiate multiple forms of reality. A person in our own society, for instance, must recognize that art, religion, science, play, and dreams are different realms of meaning. They represent unique worlds of experience. Each of them is characterized by an internal consistency of meaning and experience that is divergent from what we find in the other realms. A theatrical production, novel, or film may use flashbacks to create scenes that occurred prior to the present action in the plot. Our religion may ask us to contemplate a god who exists outside time in an unfathomable eternity. Scientists examine processes that transpire in nanoseconds or billions of years. Children at play may lose all track of time as they are absorbed by a fanciful game of make-believe. Our dreams are marked by temporal experience that is wildly unfettered by any of the usual restrictions. We experience the self and time differently in these (and other) worlds, which enables us to recognize transitions from one realm of reality to another.

Another theory posits that our sense of duration results from the self's ability to integrate recollection and anticipation. According to this theory, variation in the perceived passage of time reflects the density of experience per standard temporal unit. Time is perceived to pass slowly when the density of self-conscious information processing is high. The circumstances that occasion this experience include intensely pleasant or unpleasant emotions, violence or danger, waiting and boredom, altered states of consciousness, concentration and meditation, or shock and novelty. Time is perceived to have passed quickly when the density of self-conscious information processing is low. These circumstances are brought about in two different ways. First, one is confronted by a challenging but unproblematic situation (i.e., a busy night at work). Given some familiarity with, or training for, this situation, one can act with little self-consciousness or attention to time itself, which reduces the density of experience per standard temporal unit. Second, the erosion of episodic memory lowers the density of experience in almost all remembered intervals, making for the almost universal feeling that "time flies." Time is perceived to be roughly

synchronized with clocks and calendars when the density of experience per standard temporal unit is moderate. Here, a combination of temporal socialization and routine social experience enables us to translate the flow of subjective experience into standard temporal units, and vice versa.

The foregoing theory assumes that variation in the perception of time is determined by one's circumstances. More recently, it has been theorized that temporal experience is conditioned by self-determination via "time work"—that is, calculated effort by individuals and groups to control, manipulate, and customize their experience of time or that of others. By means of folk theories and practices, we make time seem to pass more quickly or slowly than it would have otherwise (duration). We decide how often certain things should happen (frequency). We arrange our conduct in a particular order (sequence). We choose when to engage in various activities (timing). We set time aside for the people and pursuits that matter in our lives (allocation). And we take time from others, notably our employers (the theft of time). From this perspective, multiple dimensions of temporal experience are produced by our intervention or forbearance.

Transcendental Arguments

Transcendental arguments constitute an important type of argumentation strategy in post-Kantian philosophy. While they have mostly been employed in general epistemology, often in attempts to overcome skepticism about the external world or other minds, they are also relevant to philosophical explorations of the social sciences. This entry first sketches the structure of transcendental arguments and then provides examples of their use in the philosophy of science in general and the philosophy of the social sciences in particular.

As it will turn out, it is in some cases debatable whether a given philosophical argument or piece of reflection should be classified as "transcendental" or not. The current debate over transcendental arguments is an indication of the difficulties in strictly separating transcendental philosophies from nontranscendental ones. There may be no single essential criterion that distinguishes transcendental arguments from nontranscendental argumentation. The context is decisive.

The History and Structure of Transcendental Arguments

Although Immanuel Kant himself only rarely used the term *transcendental argument,* this type of argument is largely based on his *Critique of Pure Reason* (1781/1998). After Kant, philosophers of quite different persuasions—such as Edmund Husserl, Charles S. Peirce, and Ludwig Wittgenstein—have engaged in transcendental inquiries, though it is often controversial how exactly a certain argument available in their works should be understood. In contemporary philosophy, a new debate over the nature of transcendental arguments, which is to some extent still going on, was launched by P. F. Strawson and Barry Stroud in the 1950 and 1960s.

Generally, a transcendental argument seeks to demonstrate that something is a *necessary condition* for the *possibility* of something whose actuality is taken for granted or considered indubitable. The historical paradigm case is Kant's project of demonstrating the necessary applicability of the forms of intuition (space and time) and the pure concepts of the understanding, or the categories (e.g., causality), to all objects of humanly possible experience. Kant tried to show that certain sensible and intellectual conditions must obtain if there is any cognitive experience of a structured, nonchaotic reality. As we undeniably do have such experience, the argument concludes that the relevant conditions obtain, for instance, that all experienceable objects and events are spatiotemporal.

A transcendental argument can be schematically presented as follows:

1. If A is possible, then C.
2. A is possible (because actual).
3. Therefore, C.

As such, this schema does not differ from an ordinary *modus ponens* inference. There is, of course, an aspect of *necessity* involved here: Necessarily, if A is possible, the condition C obtains. But it is unclear whether this is anything else but the logical and/or conceptual necessity of any deductively valid argument. Clearly, necessity cannot be attached to the obtaining of C itself, because this is contingent. According to Kant himself, it is contingent that there *is* any experience; a fortiori, it is contingent that its conditions obtain, if they do. The relevant kind of necessity in a transcendental argument is *presuppositional: If* there is (or can be) experience, *then* its conditions must obtain. Typically, this presuppositional necessity is taken to be a powerful weapon against the skeptic: Even the skeptic cannot coherently doubt that there is experience; by allowing that, the skeptic must allow that experience, and its objects have a certain conceptual (categorial) structure.

Mere argument form does not provide us with the "essence" of transcendental arguments. It may be suggested that transcendental arguments—and, more generally, transcendental philosophy as philosophy employing such arguments—have a "family resemblance" character. There can be quite different uses of transcendental arguments depending on the *contexts of inquiry* in which they are set. For example, Kant's employment of transcendental reasoning is connected with his *transcendental idealism,* according to which the spatiotemporal world structured by the categories is not the world of "things in themselves" but a humanly constructed phenomenal world. (However, in the Kantian tradition, the transcendental must *not* be confused with the *transcendent:* Whereas transcendental philosophy examines the conditions and limits of experience, the transcendent—e.g., the things in themselves—lies beyond those limits. Transcendental philosophy or transcendental arguments need not deal with anything transcendent.)

In contrast to Kant's idealism, in the modern epistemological debate, Stroud argued in "Transcendental Arguments" that it remains unclear whether transcendental arguments can overcome skepticism without presupposing idealism. His criticism was directed at Strawson's use of transcendental arguments in *Individuals*. Despite their disagreement about the success of these arguments, Strawson and Stroud agreed that they should be disconnected from transcendental idealism. Others, including Kant scholars like Henry Allison, have suggested that such a connection is vital to whatever success those arguments have.

While many philosophers insist that transcendental arguments, to be interesting, should be inherently antiskeptical, others acknowledge more moderate types of transcendental argument, aiming at clarifications of our conceptual commitments instead of any knocking down of skepticism. Few philosophers maintain that transcendental arguments can reach conclusions about reality as it is, independently of the conditions of experience. Whether this means

that those arguments fall short of what they should achieve or whether this is, rather, something to be expected depends on one's overall philosophical commitments, especially regarding realism and idealism.

Transcendental Arguments in the Philosophy of Science

Philosophers of science have only rarely explicitly employed transcendental arguments, but most key positions in 20th-century philosophy of science rely on Kantian assumptions. The logical empiricists, such as Rudolf Carnap, presupposed a version of the distinction between the empirical and the transcendental in distinguishing between existence questions "internal" and "external" to linguistic frameworks. Carnap's suggestion that external questions concerning the choice of a linguistic framework are practical questions not to be decided theoretically but in terms of the fruitfulness of the framework contributed to setting transcendental philosophy (of science) on a more pragmatic path.

Thomas Kuhn's famous theory of scientific paradigms, presented in *The Structure of Scientific Revolutions,* is, again, not an explicitly transcendental position; indeed, given Kuhn's historicism, it appears to be contrary to transcendental endeavors, but Kuhn may be interpreted as claiming that, at a normal-scientific stage, a paradigm is a necessary condition for the possibility of there being scientific entities or truths about them. Scientific representations of the world would be impossible without socially shared frameworks of ontological and methodological commitments (paradigms); such representations are possible because actual; hence, science is (mostly or perhaps essentially) an activity taking place within paradigms. An additional Kuhnian insight, based on extensive empirical documentation, is that paradigms change historically. The contexts making scientific representations possible are thus not fixed once and for all. The variable C in the transcendental argument schema is, then, truly variable.

Although transcendental arguments seem to have their "timeless" deductive form, they can be operative within historically and pragmatically relativized contexts. The use of transcendental arguments need not, then, be based on ahistorical and essentialist conceptions of philosophy. This is why they can be useful also in contemporary practice–oriented philosophy of (social) science. Moreover, as transcendental arguments seem to lack any unifying essence, it may be more useful to describe philosophical approaches, methodologies, or traditions—instead of isolated arguments—as transcendental.

Transcendental Arguments in the Philosophy of the Social Sciences

The obvious place to look for transcendental arguments in the philosophy of the social sciences (broadly understood) is *hermeneutics,* which seeks to establish conditions for the possibility of meaning and/or communication. Discussions of the necessary presuppositions of communicability and intelligibility can be found in very different philosophies of meaning and understanding, including Martin Heidegger's and Hans-Georg Gadamer's hermeneutics examining understanding as a mode of being in the world, Karl-Otto Apel's and Jürgen Habermas's discourse ethics and theory of communicative action, and Donald Davidson's theory of triangulation. These and other thinkers have offered a variety of "repositionings" of the idea of the transcendental.

Just like the paradigm case of *epistemic* transcendental arguments is Kant's theory of the categories as necessary conditions for the possibility of experience—itself modified and reconceptualized in various ways both in the analytic epistemological discussions following Strawson and Stroud and in the post–logical-empiricist and post-Kuhnian developments in the philosophy of science; the paradigm case of *semantic* transcendental arguments focusing on meaning and understanding is, presumably, Ludwig Wittgenstein's *private-language argument,* presented in *Philosophical Investigations*. Wittgenstein himself never attached this label to his attempt to demonstrate that there can be no such thing as a private language—in the strict sense of a language that only the speaker or user herself could understand—and scholars have debated not only on what the private-language argument exactly seeks to show and possibly succeeds, or fails, in showing but also on whether there is such an argument in the *Investigations,* and even whether there are any traditional philosophical arguments or theses to be found in Wittgenstein at all.

The private-language argument can be seen as straightforwardly transcendental (though the scholarly controversies on this issue must be skipped here): It is, according to Wittgenstein, a necessary condition

for the possibility of meaning (or meaningful communication or meaningful use of language) that meanings are public. Meaningful communication (or use of language) is actual, hence possible; therefore, meanings are public. Thus, necessarily, insofar as there is any communication of meanings or any normatively constrained language use at all, meanings cannot be private to the speaker. Language need not be essentially social, as we may imagine Robinson Crusoe using a solitary language in isolation, but it must be public in the sense that its meanings are in principle open to others. It must also be normatively structured. Otherwise, it is no language at all.

Arguments of this kind, referring to the possibility of meaning and communication, are highly relevant in the philosophy of the social sciences. Following Wittgenstein, Peter Winch challenged "positivistic" social sciences by arguing that social practices—or what Wittgenstein called "forms of life"—should not be causally explained but should be internally understood by learning to understand their rules, just as we learn to play a "language-game" by learning to follow its rules. While many philosophers maintain that Winch went too far in embracing *relativism,* the view that social practices (or cultures, traditions, perspectives, etc.) are only intelligible and rationally discussable in their own terms, "from within"—a view that seems to make any critical dialogue across practices impossible—the transcendental character of Winch's and other Wittgensteinians' arguments can be appreciated without drawing their extreme conclusions. To engage in causally explanatory social science, one must understand the phenomena to be explained, and transcendental arguments and inquiries may play a significant role in clarifying the conceptual networks underlying those phenomena, as well as our conceptual commitments and "pre-understandings."

Transcendental arguments are, thus, also connected with the *Erklären* versus *Verstehen* ("explanation vs. understanding") debate over the methodology of the social sciences, a debate that may have lost its urgency since the 1960s and 1970s but may still characterize important divergences among social-scientific approaches. There is no consensus about the philosophical relevance of transcendental arguments, or even about their nature, but they continue to attract not only scholars interpreting Kant or Wittgenstein but also those systematically working on issues in knowledge and meaning.

Transcendental Pragmatics

This entry introduces Karl-Otto Apel's philosophical thought, which has been of interest to the philosophy of the social sciences. It explains the central feature of Apel's theory of the community of communication, and the nature of pragmatic transcendental conditions (hence a priori) necessary for meaningful discourse, and ends by indicating its

implications also for ethics. Rather than philosophy as a theorizing *in abtracto,* Apel's theory places the philosophical quest for truth and other such philosophical aims at the center of an already existing linguistic community within which theorizing is always already set—thus emphasizing the nonsolipsistic foundations of critical philosophical exercise.

Introduction

"Transcendental pragmatics" is the name given by the German philosopher Karl-Otto Apel (b. 1922, Düsseldorf, Germany) to his philosophical program of a linguistic transformation of transcendental philosophy. Inspired by Martin Heidegger, Hans-George Gadamer, Ludwig Wittgenstein, and above all Charles Sanders Peirce, Apel fused what he called "transcendental hermeneutics" with "transcendental semiotics" in order to articulate the project of critical reflection on the conditions of possibility of valid intersubjective communication.

Apel first developed this philosophical program in a series of essays written during the late 1950s and 1960s. The essays were collected in a two-volume work titled *Transformation der Philosophie,* published in 1973, which was only partly translated into English in 1980. The basic claim is that anyone who seeks truth—whether as philosophers, scientists, or humanists—has always already entered an argumentative discourse that presupposes a series of conditions of possibility. More specifically and succinctly, anyone who makes any claim to truth does so as a member of a community of communication.

The A Priori of the Community of Communication

Using Wittgenstein's argument against the impossibility of a "private language," which claims that no individual is able to have a private, or solely mental, language that he or she alone can speak, Apel arrives at the insight that there is no individual who is not always already a member of a community of communication. Humans are linguistic beings, but only as members of a specific linguistic community, who thus find themselves immersed in historical worlds whose pre-understandings, or ways of giving meaning, condition how they understand the world, others, and themselves. Yet although our community of communication is always a community of a specific natural and historical language, Apel argues that we are not therefore caught in the grip of an inescapable relativism. All communication, regardless of the language in which it is undertaken, presupposes that we aim to reach an agreement about something with someone. All languages have a propositional-performative structure, or dual structure. When we speak, we make claims about the world, a state of affairs, or something, in order to come to an agreement or understanding with someone else.

This dual structure of all languages means that whenever we engage in some argumentative discourse we presuppose four validity claims: (1) a claim to communicable meaning or sense, (2) a claim to truth, (3) a claim to veracity or truthfulness, and (4) a claim of rightness or correctness. When we engage in any kind of communication or discourse, we inescapably and inevitably presuppose that we are making sense, or that we are being intelligible; that we also mean what we claim, or rather that what we claim is something we believe; that what we claim is a truth claim that can be verified; and, finally, that when we claim some truth about a state of affairs or fact in the world, we do so to someone with whom we have thus established a right relation as an equal partner in a discourse.

Performative Self-Contradiction and Validity Claims

That all discourse presupposes these validity claims is far more intuitive than it may appear prima facie. Some counterexamples demonstrate the "transcendental" character of these presuppositions—that is, that without them all discourse, all meaningful argumentation, becomes impossible or meaningless. One counterexample could be as follows: I claim *x,* but I don't believe what I am claiming; *or* I claim *x,* but I am doing something in a nonsensical way or a way that only I can understand (via some secret code that I alone can crack); *or* I claim *x,* but there is no way anyone can verify it; *or* I claim *x,* but you are either too stupid or, because of your race or gender or religion, incapable of understanding or verifying it. To deny or pretend that any of these validity claims can be bracketed, neutralized, or suspended leads to a performative self-contradiction: that is, I am denying what I am doing. Reflecting on what conditions of meaningful communication cannot be denied or refuted without incurring a performative self-contradiction reveals what conditions of possibility of valid thought or meaningful discourse are

"uncircumventable" (*nichthintergehbar*). The performative self-contradiction becomes the litmus test that reveals to us the *pragmatic transcendental* conditions of possibility of discourse *tout court*. These conditions are *pragmatic* because they are indispensable to all and every act of communication. With every speech act we enunciate, we are simultaneously saying and doing. The conditions of possibility of meaningful communication are transcendental and pragmatic in the sense that they are a priori; they enable and condition meaningfulness, but they are always already operative in the very performance of every speech act.

Ultimate Foundation, Self-Recuperative Principle, and Discourse Ethics

Apel's philosophical project, however, is not simply a linguistic transformation of transcendental philosophy that aims to preserve the Kantian project of transcendental reflection on the conditions of possibility of valid cognition, but now as a transcendental-pragmatic reflection on the conditions of meaningful discourse, it is also a comprehensive philosophical proposal with several pillars. These pillars also reveal how Apel's project is different from Jürgen Habermas's "universal or formal pragmatics," with which it shares some features. Transcendental pragmatic aims to be a synthesis of both transcendental hermeneutics and transcendental semiotics. The hermeneutical investigation into the conditions of valid understanding, which is not simply about understanding differently but understanding better, is fused with Peircian semiotics (from the American pragmatist Charles Sanders Peirce), whose basic insight is that all cognition, and discourse, is mediated by indexes, icons, and symbols. All understanding takes place in and through semiosis.

Apel positions his transcendental pragmatics as a "first philosophy," *prima philosophia,* which supersedes the prior paradigms of first philosophy, namely, ontological metaphysics (from Aristotle through Aquinas), and transcendental philosophy of consciousness (from René Descartes to Edmund Husserl). As a *prima philosophia,* transcendental pragmatics offers a non-metaphysical and nonsolipsistic ultimate foundation (*Letztbegründung*) that reveals the conditions of possibility of all critique and reflection, thus refuting all relativism, hyperbolic methodical doubt, and incommensurability of hermeneutical horizons. Most interestingly, Apel's philosophical project also offers a normative reconstruction of philosophy from the standpoint of the semiosis of all cognition and understanding as a reconstruction of the ways in which different paradigms have failed to properly address the semantic, syntactical, and pragmatic dimensions of sign use. Apel argues, furthermore, that his project includes the elaboration of what he called the "self-recuperative principle" (*Selbsteinholungsprinzip*), which holds that human history, and thus the human and natural sciences, can be reconstructed from the quasi-teleological standpoint of a better understanding that can give an account of itself in a normative and noncontingent way. All understanding and critical discourse presuppose progress, one that can be elucidated by reflection on what enables our present ability to come to a valid intersubjective agreement. Finally, transcendental pragmatics also elucidates the foundations of a discourse ethics or normative morality, which in turn entails an *ethics of responsibility.* Transcendental pragmatic reflection on the uncircumventable conditions of possibility of valid intersubjective communication reveals the always already implicit recognition of some basic moral norms: isonomia and reciprocal recourse to dialogue in order to come to an agreement about what principles should guide our ethical action.

Transhumanism and Human Enhancement

Human enhancement encompasses efforts to extend human health, longevity, and cognitive abilities beyond their current biological limits. *Transhumanism* is the Enlightenment-inspired doctrine that science can accomplish human enhancement and that individuals should be able to use technologies that allow them to live longer, healthier, and more enabled lives. The emergence of a global, self-consciously transhumanist movement in the late 20th century has been accompanied by growing diversity within transhumanism and a growing number of bioconservative critics from the traditional Left and Right.

Proto-Transhumanism and Enlightenment Bio-Utopianism

The aspiration to transcend human limitations is found in the earliest recorded human cultures. The Epic of Gilgamesh, for instance, is the story of a man searching for immortality. Shamanic and religious traditions attempted to use supernatural means to heal and achieve superhuman powers and immortality. But the European humanist and Enlightenment traditions established a new direction for these aspirations, combining faith in reason and individual self-governance with utopian expectations of a free and bountiful technological future. For Enlightenment materialists like Julien de La Mettrie, human beings are not confined to their bodies and brains by divine will but by chance and have the power to become something better. The Marquis de Condorcet, Benjamin Franklin, and William Godwin proposed that eventually human beings would be able to conquer death, and Denis Diderot suggested that humanity might evolve into a great variety of *post-human* species.

Enlightenment thought also began to interrogate premodern ideas about human uniqueness based on divine creation and ensoulment and proposed that rational and moral subjectivity were the basis of moral and political standing. If rational and moral faculties were not supernatural and could be found in animals, as proposed by David Hume, for instance, then radically evolved humans, animals, and even machines might be rational, emotional, and moral subjects. Denis Diderot proposed in *D'Almbert's Dream* that brains might be taken apart and reconstituted later, that intelligent animals and animal–human hybrids might be possible, and that sophisticated machines might have minds.

Many of the debates among contemporary transhumanists, and between them and their secular critics, can be seen as legacies of the contradictions between different strains of Enlightenment thought.

Nineteenth- and Early-Twentieth-Century Transhumanism

The improvement of the human condition through social reform took precedence over the *bio-utopian* imagination in the 19th century, until the emergence of eugenics. The eugenicists believed that the future of humanity could be improved by discouraging childbearing in groups with bad heritable traits ("idiots," criminals, the poor in general) and encouraging reproduction by those with better traits. Some have argued that transhumanism is a modern form of *eugenicism,* albeit a liberal one that proposes genetic betterment through individual germinal choice and gene therapy rather than mandated sterilization, abortion, and murder.

Transhumanists, on the other hand, identify with bio-utopians like the British Marxist geneticist J. B. S. Haldane, who rejected the pseudoscience and authoritarianism of eugenics and proposed instead, in his 1923 seminal essay *Daedalus, or a Science and the Future,* that people would be able to choose their own genetic traits in the future. Haldane's friend and fellow-geneticist Julian Huxley in 1927 coined the term *transhumanism* to encompass the belief that humanity could, scientifically and spiritually, transcend itself.

Speculative fiction also began to explore *biofuturism*. The Fabian socialist H. G. Wells alternated between the dystopian biofuture of *The Time Machine* and the optimistic utopianism of *Men Like Gods* (1923) and *The Open Conspiracy* (1928). Olaf Stapledon inspired a generation of writers with the breadth of post-human options presented in his 1930 *Last and First Men* and 1937 *Star Maker.* Julian's brother Aldous Huxley wrote *Brave New World* in 1932, partly as a critique of the bio-utopian ideas in their British social circle.

In 1926, the Irish Marxist and scientist J. D. Bernal contributed another strain to contemporary transhumanism with his essay *The World, the Flesh and the Devil.* Bernal proposed that humans would eventually colonize space in genetically modified *cyborg* bodies with brains linked to machines.

After the defeat of fascism and the widespread rejection of anything associated with eugenics, combined with the growth of nuclear anxiety and ecological awareness and the emergence of antirationalism and pastoralism in the counterculture, bio-utopianism nearly disappeared in the 1950s.

Counterculture Meets High Technology

In the 1960s, however, numerous trends began to reignite the bio-utopian imagination. One was the emergence of an antiaging subculture, the most radical exponents of which were the cryonicists. In his 1962 *The Prospect of Immortality* and 1972 *Man Into Superman,* cryonics pioneer Robert Ettinger proposed that the human body could be radically redesigned to be immortal, to fly, to swim like a fish, to photosynthesize, and to eventually become a galaxy-spanning brain. Techno-optimistic futurists, developing out of corporate and national security consulting, began discussing the ramifications of trends like artificial reproductive technologies and brain–machine interfaces. For instance, the New York City–based futurist "FM-2030" (born Fereidoun M. Esfandiary in Iran) began discussing our period of history as "transhuman," transitional to the post-human, and promoted putatively transhuman lifestyles and value systems in his 1970 *Optimism One* and 1973 *Upwingers: A Futurist Manifesto*. The rapidly growing science fiction subculture began to produce optimistic visions of a post-human future in works by writers such as Cordwainer Smith, Robert Heinlein, and Frederick Pohl. A small group of feminists, such as Shulamith Firestone and Marge Piercy, proposed that artificial wombs would liberate women from patriarchy. Responding to rapid advances in medicine, bioethicists such as Joseph Fletcher began to defend the benefits of genetic and cognitive enhancement technologies.

These trends converged in Southern California in the late 1980s around a group of futurist thinkers led by the philosopher Max More (born Max O'Connor). More founded the *Extropy Institute* and its journal, which quickly spread to an international virtual community though e-mail and the Internet. The Extropians defined transhumanism as a class of philosophies that seek to guide us toward a post-human condition, of which extropianism was the flavor aligned with anarcho-capitalism. The Extropians were especially enthusiastic about the prospect that in future nanotechnology, molecule-scaled machines would enable indefinite longevity and the uploading of consciousness to nanomachine bodies.

In the late 1990s, European transhumanists began to coalesce around the more politically inclusive *World Transhumanist Association* (WTA), founded by the Oxford philosopher Nick Bostrom and British utilitarian thinker David Pearce. In the 2000s, the WTA grew quickly, with chapters and allied groups in dozens of countries. In 2009, the WTA rebranded itself as *Humanity+*.

Transhumanist Subcultures

As the transhumanist subculture has grown, many subgroups have emerged. One division has been between the antistatist libertarians and the left-leaning transhumanists, or "technoprogressives." The Institute for Ethics and Emerging Technologies, founded in 2005 by Nick Bostrom and James Hughes, is the principal organization of techno-progressive-leaning intellectuals. These camps fall out over whether government-funded research and health and safety regulations are necessary for the development of emerging technologies and whether problems of equitable access should be addressed through the provision of universal health care.

Although most transhumanists are secular, and a sizeable group is militantly atheist, there are also many who hold a variety of spiritual views from the idiosyncratic to the orthodox. One of the largest transhumanist groups is the Mormon Transhumanist Association, for instance, which sees transhumanism as the fulfillment of Mormon prophecy.

In recent years, the millennialist subculture within transhumanism, *singularitarianism,* has also grown rapidly. The concept of "singularity" was proposed by the mathematician and science fiction author Vernor Vinge in the early 1990s as the point at which greater-than-human machine intelligence begins rapidly improving itself, effectively ending human-directed history. Most Singularitarians believe this point will occur in the 21st century. Some, such as the inventor and futurist Ray Kurzweil, believe that this

"intelligence explosion" will enable radical longevity, cure social problems like hunger and climate change, and create a new, superconnected post-human civilization. Others believe that a "Terminator-like" scenario of runaway robotics is more likely to be deflected only by determined efforts to ensure "AI friendliness." Most Singularitarians are skeptical that the transhumanist program of human enhancement and augmentation could allow human beings to stay in control of machine intelligence, given the limitations of organic brains compared with the exponential improvements in computing power.

Bioconservatives and Academic Post-Humanism

As transhumanism has grown, so also have a set of explicitly anti-transhumanist or "bioconservative" groups. These groups are motivated by a wide variety of criticisms of transhumanism, from ideas about human exceptionalism and the natural order to concerns about the safety of new technologies, and equality and quality of life in a transhuman society. Religious conservatives have started organizations like the Center for Bioethics and Human Dignity to argue against transhumanism as a form of spiritual heresy. Groups on the Left, such as the Center for Genetics and Society, argue that transhumanism is a stalking horse for racism, corporate control, and neo-eugenics. Left-leaning bioethicists George Annas and Lori Andrews mounted campaigns to make human genetic enhancement an international "crime against humanity."

The most visible critics of transhumanism have been Francis Fukuyama, whose 2002 *Our Posthuman Future* called for global regulation of transhuman technology, and the bioethicist Leon Kass, who led the U.S. President's Council on Bioethics when it published the anti-enhancement volume *Beyond Therapy* in 2003. Fukuyama's complaint focused on the erosion of a shared human identity that supposedly undergirds the political order, while Kass launched a Neo-Aristotelian critique of the effects of life extension and enhancement on human dignity and virtue. Also in 2003, the environmentalist Bill McKibben published his anti-transhumanist book *Enough,* and the German social theorist Jürgen Habermas published his bioconservative tract *The Future of Human Nature*. In 2010, the New Zealand philosopher Nicholas Agar published *Humanity's End,* the most sophisticated critique of transhumanist ideas to date.

As bioethicists polarized over cognitive enhancement in the past decade, many liberals have sided with transhumanism, for example, Greg Stock, Gregory Pence, Allen Buchanan, Art Caplan, John Harris, and Julian Savulescu. Some have gone one step further than the transhumanists to argue for a moral *obligation* for certain kinds of enhancements (e.g., especially when the "natural lottery" has disadvantaged some by birth, who need to be enhanced if the liberal principle of equal opportunities for all is to be taken seriously in practice).

A diverse group of cultural theorists have also been gathered under the banner of post-humanism, from the "cyborgologists" Donna Haraway and Chris Hables Gray, to theorists of the eroding virtualized self, like Katherine Hayles and Robert Pepperell, to postmodern critics of Enlightenment humanism, like Cary Wolfe. Some of these writers share with transhumanism a focus on cyborgs and the augmented body in reality and fiction, but they range from ambivalent to hostile to transhumanism's normative claims.

Trust, Epistemic

Knowledge is a common good. Relying on others in acquiring knowledge is part of our ordinary cognitive life. The floating of other people's words in our minds is the price we pay for thinking. This doesn't concern ordinary beliefs only: Collaborative work in contemporary science is such that scientists must trust each other in order to achieve a relevant epistemic result. Trust is thus a fundamental ingredient not only of our social life but also of our epistemic practices.

The study of epistemic trust in philosophy and in social science encompasses a wide range of questions about the role of trust in knowledge, the division of cognitive labor in society, collaborative work in science, and deference to the authority of experts. This entry reviews the enhanced role given to epistemic trust in recent accounts of epistemology, ethics, and the social sciences.

The Received View: The Autonomous Knower

Traditionally, epistemology has banned from actual knowledge beliefs acquired by trusting others. One of the strongest requirements for the acquisition of knowledge is the *autonomy* of the subject. The overall project of classical epistemology, from Plato to contemporary rationalist approaches, is a normative enterprise aiming at establishing criteria, rules, and principles as a guarantee to preserve the autonomy and freedom of thought necessary to the acquisition of knowledge. Authority, received opinions, and common knowledge are considered in this tradition as the major sources of false beliefs. To strengthen the cognitive autonomy of the rational thinker, philosophers of all times have listed rules of "epistemic conduct" that guarantee freedom of thought. Rene Descartes's classic treatise on method, *Rules for the Direction of Natural Intelligence,* is dedicated to explaining how people should think in order to attain true ideas and bases its model of the autonomous knower on self-reflection or self-contained meditation. In the empiricist tradition, John Locke, in his *Essay Concerning Human Understanding,* insists on the risk of being "infected" by other people's opinions and lists a series of obligations on one's own mental conduct to avoid contamination by ill-formed beliefs.

Challenging the Traditional View

Yet the massive reliance on others that permeates our cognitive life calls for an epistemic treatment. This has become a central issue in contemporary debates in philosophy of knowledge and *social epistemology.* A number of approaches have been put forward to account for the epistemic reliability of the division of cognitive labor so typical in contemporary, information-dense societies. The received image taken from the traditional epistemology of the solitary scientist, the autonomous knower who has absolute control of the sources of his or her beliefs, is a remote ideal, a limit case that doesn't correspond to the reality of our epistemic practices. One could even argue that it is not even an ideal: A distribution of epistemic competencies makes a society more efficient and rational than does a concentration of knowledge within a tiny group of experts.

Trust in Social Sciences and Moral Philosophy

Trust is a central notion of social science. It is considered as the "glue" of our society, the mechanism that is at the basis of social relations, of transfer of power to political authority, and of cooperation. Various approaches in the social sciences have tried to account for the notion of trust. In the *rational choice* tradition, trust is seen as a cognitive capacity. The sociologist Diego Gambetta (1988) defines it as

> a level of subjective probability with which an agent assesses that another agent or group of agents will perform a particular action, both *before* he can monitor such action (or independently of his capacity ever to be able to monitor it) *and* in a context in which it affects *his own* action. (p. 218)

The political theorist Russell Hardin defines trust as a form of *encapsulated interest,* that is, a belief that it is in the interest of the trusted to attend to the trustor's interests in the relevant matter. These are *evidential* approaches to trust that see it as knowledge or belief for which we can find a rational justification in terms of the capacity we have to read and assess the commitments of others. Other approaches, which one may call *motivational,* see trust not only as a cognitive competence, that is, based on the degree of our beliefs about the future actions of the trusted, but also as involving a motivational, nonrepresentational dimension that may depend on our deep moral, emotional, or cultural precommitments.

These approaches have been developed mainly in sociology and moral philosophy. The philosopher Annette Baier defines trust as an accepted vulnerability to another's possible but not expected ill will toward one and explores the varieties of moral, emotional, and cultural grounds on which we accept this vulnerability.

Trust in Epistemology

One of the main tasks of the investigation of epistemic trust is to understand which concept of trust applies in the case of knowledge acquisition. Is trust in other people's beliefs a cognitive capacity to assess the probability of their reliability? Is it an accepted vulnerability based on forms of precommitments or deference to authority? In which cases are we *justified* in trusting what other people say? These questions evoke another important contemporary debate in social epistemology, that is, the status of *testimonial knowledge* and the *epistemology of testimony.* Reductionist approaches to testimony state that justification of testimony is always reducible to more basic forms of knowledge acquisition, such as perception and inference. Nonreductionist approaches claim that we have an a priori justification in trusting other people's beliefs, in the absence of any rational *defeaters* of that belief, that is, any stronger evidence that the testimony we receive is false.

The main criticism of the application of rational-choice approaches to trust in the case of epistemology revolves around the fact that, in the case of knowledge acquisition, we should be able to assess not only the willingness of our informants to be trustworthy but also their competence. A 5-year-old child can be trustworthy but lacking the appropriate competence to be a reliable informant. Also, in most cases of belief acquisition by trusting others, we do not have the means to estimate the subjective probability of the informant to be right. A patient who trusts her doctor and a child who trusts her parents are not able to calculate the odds at stake. Motivational approaches to trust seem to deal better with this problem, by providing reasons to trust that go beyond pure assessment of the evidence available. But they also bear problems if applied to the epistemic case, because they seem unable to avoid the risk of credulity and irrationality that accompanies prima facie any a priori trust in others as a source of knowledge. To understand what motivates us to trust others in acquiring knowledge, we should be clear about the precommitments that sustain our cognitive relations in society.

Trust, Social

The notion of social trust as a topic of analysis and investigation is important in philosophy and in the social sciences, as it plays a crucial role in social life and especially in cooperative activities. The whole sphere of sociality rests on people being together. Without trust, people would have to rely on rules and sanctions alone. Understanding what social trust is exactly is the starting point for understanding what it takes to be trusted by, and to trust, others.

This entry focuses on an analysis of social trust that distinguishes two main types of trust from each other: *social normative* (or genuine) trust and *predictive* trust.

A rule of thumb is that when trust is betrayed the trustor had genuine trust—her trust was justified, but the trustee did not respect her rights, although he had led her to believe so. They had a relationship of mutual respect for specific rights. However, when the trustor is mistaken in her trust for the reason that her predictions were poor, she is to blame. She had predictive trust, based on some beliefs about the trustee. In genuine trust, the betrayed trustor rightfully blames the trustee, unless the trustor was mistaken about there being a mutual understanding about respect for certain rights. In predictive trust, the disappointed trustor makes the wrong predictions and has herself to blame. Of course, she could accuse the trustee of deception if he deliberately gave her the false impression. *Misplaced trust* is an ambiguous term as it can mean betrayed justified genuine trust, mistaken unjustified genuine trust, or mistaken predictive trust.

A Conceptual Analysis of Social Trust

Social trust is trust between people or groups that can function as agents. Trust is an attitude (and/or feeling) that people have when they feel at peace and have an accepting attitude about being dependent on another person for an action. The trustee should be aware of the dependence and have a choice to either accommodate the trustor or let him down. The trustor may have no other option than to trust, but he may still have genuine trust in the other person. In everyday language, to "trust someone for buying the tickets" may mean to have social normative (genuine) trust or predictive trust in her, or it may mean to (decide to) depend/rely on her, based on trust or prediction. In everyday speech, the distinction between the meanings of words often becomes blurred. To depend/rely on someone for something or to decide to do so based on a prediction of her future favorable behavior or on trust of that person should be distinguished from trusting in the sense of having an attitude or feeling of trust. "Entrusting someone with buying the tickets and after that depending/relying on her" does not, but it may entail trust. The person is made aware of what is expected of her and that people depend on her. Entrusting involves a decision, just like depending and relying usually do.

The notion of trust can be divided into two kinds depending on which of the two main kinds of mental states it is related to, respectively. These will be called (1) *social normative* (genuine) trust, based on a belief of a relationship of mutual respect for rights, and (2) *predictive* trust, based on a belief of having sufficient reasons for trusting. Genuine trust may be betrayed by the trustee, while predictive trust cannot be betrayed—it is the trustor who made the wrong prediction, leading her into having a trusting attitude and perhaps into the state of relying on another person or deciding to rely on him. In the context of economics, this latter kind of "trust" is further stretched into a mere prediction. The trustor calculates the probability for an action to take place, "decides to trust," and has various degrees of trust. The trustee might not even be aware that someone is counting on his action. In predictive trust, the attitude of trust is taken without a decision, and the trustor either trusts or not as a consequence of her calculations.

The following example suits both genuine and predictive trust. When John finds himself relying on Mary or decides to rely on her in acting on a matter of his concern, without fear of being disappointed, he may be said to trust Mary and rely on her vis-à-vis the action. He believes that Mary is aware of his dependence and that she has a choice to let him down. John may have no options but still trusts her. Alternatively, he may just trust her for potentially acting on the matter and still decide not to rely on her but choose to act himself. Predictive trust is

an attitude that John arrives at after believing that Mary can and will perform the action in a way that furthers John's welfare. He thus has an accepting attitude of being dependent on Mary and has a positive feeling about it. This takes place in a context where John wants Mary to perform the action; he believes she knows about this and that his want is relevant to her—she is free to and will take it into account in her acting. John's predictive trust is based on his reason-based beliefs, and if Mary does not deliver, John blames himself for his mistaken beliefs.

Social normative or genuine trust not only presupposes that the trustor is at peace with being dependent on the trustee, including all the beliefs of predictive trust, but it also involves the trustor's belief of a mutually acknowledged right to be accommodated in a specific case. In the above example, John's belief in such an acknowledged right is not the reason for his expectation to be accommodated by Mary, but this is the reason why he expects this *of* Mary, and this is why he feels betrayed in his trust if Mary does not perform the action. More specifically, the belief in upholding a right goes as follows: John believes that Mary and he have a relationship of mutual respect for certain rights, a belief that is based on his having certain rights and her having certain (other) rights that are respected. If the present expected action is not among the actions that he has a right to expect, he is not justified in having genuine trust in Mary. When John's genuine trust is justified, and he is not mistaken about what his respected rights are, Mary betrays his trust if she does not accommodate him. The trustor's belief of the relationship of mutual respect for rights is not just another reason for predictive trust. It is why he trusts (a causal reason)—the backbone of genuine trust.

When people have predictive trust in each other, they just count on each other to behave in the desired way, having good reasons to expect this. For example, Mary trusts that John will buy her a necklace, because she believes he is in love. She trusts the priest to give her wallet back, because she believes he is honest. When people have reasons to believe that they have rights, but they lack the belief that these are acknowledged in a relationship of mutual respect for rights, they may do no more than count on the belief that the trustee will act in accordance with those rights, on the basis of his moral character or some expected sanctions. Mary has predictive trust in John concerning his nonviolent behavior, by believing that he follows the law. Later, she has genuine trust in him vis-à-vis this matter, when she believes that they have a relationship of mutual respect for certain rights, including the right to be treated without violence.

Genuine trust is like a gift that has to be accepted by the trustee. It is an honor to be offered someone's trust, but as the gift of trust involves a demand on the trustee, he has to accept this demand. If Mary trusts John to come home early, she may have predictive trust in him, based on good reasons. For her to have genuine trust in John, she must believe that they have a relationship of mutual respect for rights. Only if it is her right (and she rightfully believes that he has accepted this), can she blame him for betrayal if he comes late. If trust does not involve the option of betrayal, it is not genuine trust. Of course, Mary may be wrong in her beliefs (based on her subjective experiences) about their mutual understanding of their charter of rights. In that case, she has misplaced genuine trust in the sense of unjustified genuine trust. Only justified genuine trust may be betrayed.

Genuine trust is not restricted to personal relationships. Two businessmen may have predictive trust in each other that will develop into genuine trust through time. When people respect each other's rights for instrumental reasons, one could call it *thin* genuine trust. In *thick* genuine trust, a person's rights are respected for intrinsic reasons: He ought to have what is his right to have. Basic trust is a child's default position when cared for. Some adults preserve their basic trust for people to a larger extent than others. They may fare poorly in bad company, but on the other hand, a trusting attitude invites people to be fair. General trust in a person is trust in his or her fairness concerning a wide range of matters—that is, rightful demands will be accommodated. People may have general predictive trust in a member of the clergy, based on his position, and general genuine trust in a friend, based on a relationship of mutual respect for a wide range of rights.

The relationship of mutual respect for rights in the case of genuine trust could in extreme cases be a relationship of one-sided respect for rights, such as in a situation where one party is in no position to accommodate the other party. For example, a severely handicapped wife cannot be expected to respect in practice her husband's rights in any way. Outside such extreme examples, mutuality is needed

for stability of the trust relationship. One could even argue that the golden rule would be a central principle for the charter of rights in a relationship of mutual respect for rights in social normative trust.

Trust has been studied as a commitment, a relationship, an attitude, an emotion, or a mixed case, for example, a belief with an affective component. Predictive reliance on and prediction of a person's behavior allow for depending on the side effects of his action. Trusting requires a context where the trustee is believed to be aware of the trustor's wish to be (potentially) dependent on the trustee's action and to be free to choose to take the trustor's wish into account and free to let him down. The belief of a person's trustworthiness is a result of predictive trust or genuine trust or a judgment preceding predictive trust. In the context of prediction, it is the result of an evaluation before the decision to depend on the person. Trusting involves risks, but only when seen from a third-person point of view. When a person trusts, he may be aware of the third-person point of view, but he does not deem it risky, or else he would not trust. This holds for both predictive trust and social normative (genuine) trust—the two main kinds of trust that one does not decide to have but one just "falls into," like falling in love. Risk calculations belong to predictions, and so do degrees of "trust." People may decide to depend/rely on others on the basis of their predictions.

Truth, Philosophical Theories of

There is probably in philosophy no other notion that enjoys the privilege of being both so simple and so entangled. On the one hand, truth is, as René Descartes said, "so transcendentally clear that it is impossible to ignore it." On the other hand, as soon as we try to spell out the nature of the property or relation in which truth consists, we encounter difficulties, taking us to the highest reaches of metaphysics—those of the nature of knowledge, of the mind dependence or independence of reality, and of language and its relation to the world. This has led many thinkers to adopt Pontius Pilate's stance when he asked, shrugging his shoulders, "What is truth?" But Pilate was wrong. There is something important to say about truth.

In this entry, classical and more modern theories and notions of truth are critically reviewed. It is also pointed out that truth has a special normative role.

Classical Definitions of Truth

Can truth be defined? Most classical philosophers distinguish real definitions, which define the essence of a thing, from nominal definitions, which characterize adequately its concept. Aristotle's definition of truth seems to provide both: "To say of what is that it is not, or of what is not that it is, is false, while to say of what is that it is, and of what is not that it is not, is true"? (*Metaphysics*, Γ 7, 1011b 26–27). The tradition has taken it as a statement of what has come to be known as a *correspondence theory of truth,* according to which truth is a relation of correspondence between our judgments and reality.

Aristotle, however, does not say much about what this relation of correspondence might be, so it is tempting to interpret him rather as giving us only an explanation of the meaning of the word *true*. Similarly, when St. Thomas Aquinas says that truth is the *adaequatio* between *res* and *intellectus* (i.e., "reality" and "mind"), he does not tell us how to define the agreement in question.

For Immanuel Kant, truth as correspondence is only the "nominal" definition of truth, and he gives an argument against any attempt at giving a real definition of truth as correspondence: "I can only compare my judgments with an object by making a judgment about the object, so my judgment is correct only if it is confirmed by itself" (cited in Kunne, 2003, pp. 126–127). Although the argument is flawed (it conflates giving a definition of truth with giving a criterion of truth), it has had some success, and it has inspired Gottlob Frege's argument against the correspondence theory: If truth could be defined, a definition of it would have to say that *it is true* that such and such a property is ascribable to truth, hence would presuppose what is in question.

This objection also plagues many definitions of truth as correspondence to facts or states of affairs. If a proposition *P* is true if and only if it corresponds to the facts, what fact other than *the fact that P* itself can be a candidate for the corresponding entity? Thus, if it is true that *Rome is north of Naples,* it seems to be made true by the fact that Rome is north of Naples and also by the fact that Naples is south of Rome, but furthermore, it seems, also by the fact that Rome is to the north of the largest city within 20 miles of Ischia and such that London is in England. Clearly, since these descriptions have the same extension (i.e., refer to the same things: cities), they designate the same fact. So either we are bound to take *the fact that P* as trivially equivalent to *P*—in which case adding that the latter corresponds to the former is trivial—or we have to accept that each particular fact corresponds to potentially *all* the facts. This argument, known at the "slingshot," threatens all definitions of truth as correspondence to facts.

One natural reaction to the idea that there is nothing more in the notion of fact than that of a true proposition is to try to define truth as an epistemological notion. The *coherence theory of truth* says that a judgment is true if and only if it coheres with a system of other judgments. Coherence, however, can be defined in many ways—as a logical relation or as an explanatory one. Moreover, any addition of a belief to (or subtraction from) a coherent set of beliefs can destroy its coherence. To idealize by supposing that there is a maximally coherent set of all coherent sets quickly leads to versions of absolute idealism.

The second kind of epistemological theory is *verificationism*. It says that a judgment is true if and only if it can be warranted or justified, and so it identifies truth with our knowledge of truth. Most versions of verificationism grant that truth cannot be defined through actual verification: It is quite easy to imagine statements that are warranted but untrue. So most epistemic views of truth side for some version of idealized verification, according to which truth has to be in some sense ideally knowable. But at least some versions of this view lead to the "knowability paradox": Since all truths are knowable and since no one can know that a proposition is both true and not known to be true, it cannot be true that a proposition is both true and not known to be true, hence all truths are known, which is a *reductio* of verificationism.

Pragmatism can be also considered as a version of ideal verificationism. In its simple version, it says, with William James, that "truth is the expedient in our thinking" and that a true statement is one that is useful. Since this is easily refutable (many truths are useless, and many useful judgments are false), we are invited to idealize again and to consider truths in the long run, or at the end of inquiry. But such a state is hard to figure out.

Deflationism

Many philosophers have been tempted to conclude from the difficulties of formulating a satisfactory philosophical theory of truth that there is none to be had. Do we actually need to define truth? Our ordinary concept seems to consist of a set of trivialities: A true statement is true to the facts; truth is not the same thing as justification; truth is objective, is timeless, and has no degrees; and a statement "*P*" is true if and only if *P*. The latter platitude has been called the principle of "disquotation": It allows us, from *"P" is true,* to remove the quotes and the predicate *true* to get the equivalent assertion of *P*. What more is there when one says that it is true that snow is white than the assertion that snow is

white? On this view, *true* is just a logical word, like *and* or *not:* Truth has no essence and is not a deep metaphysical notion. *Deflationism* or minimalism is the doctrine according to which there is nothing more to say about truth than these trivialities. Alfred Tarski gave, in this spirit, a semantic theory for formal languages in which truth is defined, for a given language, in a metalanguage in which one can derive equivalences of the form *P* is true if and only if *P.* Tarski proved that truth cannot be defined *within* a language but has to be defined in another language, and there is no limit to the hierarchy of languages.

Deflationism, however, is hardly tenable. First, if it says that truth is a predicate of sentences, it is implausible, since truth is a predicate of propositions, or of thought contents. We can certainly say that a sentence like "$E = mc^2$" is true even when we do not understand what it means, but we can hardly say that we have asserted a truth if we do not know what truth it is. Second, truth is more than a mere device of disquotation. It is also a norm of assertion (if one asserts that *P,* then *P* is supposed to be true) and a norm of belief (one ought to believe only what is true). If we disregard this normative dimension, we obviously miss something of the point of the concept of truth. Third, the deflationist concept of truth cannot capture the objectivity that is involved in truth. If truth is reduced to assertion, any kind of assertion will aim at truth and any kind of discourse to which the notion of truth can be applied will be equally susceptible to being true, independent of the reasons that one has to assert. Truth seems to apply to a number of distinct domains: There are mathematical truths, physical truths, moral truths, legal truths, historical truths, sociological truths, possibly metaphysical and religious truths, but also fictional truths, poetical truths, and comic truths, and so on. If truth is but a device of assertion, shall we say that it applies equally to all these domains? But certainly we do not want to say that statements in fictional narratives, for instance, are just as true as mathematical ones or that truth aptness is the same for physics or for ordinary objects, such as tables and cars, and for ethics or literature. The deflationist theory seems too hospitable. If we are ready to accept that there are ethical truths, it is not clear that we want to say that they are true in the same sense as the truths of physics. This minimalist conception of truth actually deprives the concept of truth of any bite. More than that, if truth is just the expression of one's opinion, when one asserts that *P,* then what prevents us from saying that there are as many truths as opinions, hence falling into complete relativism?

Realism Versus Relativism

We face a dilemma. On the one hand, we want to say that truth is a concept or a property that is robust enough to include a set of features associated with a realistic position: True judgments must correspond to an independent reality, which in some sense causes them rather than the reverse, on which there can be intersubjective agreement, and they must be stable and noncontextual. On the other hand, we want to allow that truth can be less objective in some domains, without losing its central properties. If we take the first horn, we face the problem of having to define the appropriate notions of correspondence, fact, and objectivity, which is not an easy matter; and we risk a kind of truth chauvinism, which will restrict the application of truth only to very few domains (are we even sure that the realist concept applies fully in physics?). If we choose the second horn, we risk ending up with a too welcoming, but excessively shallow, notion of truth.

One way out of this dilemma is to defend a kind of *functionalism* about truth, in analogy with the corresponding doctrine in the philosophy of mind. Just as the mental state of pain can be defined by its causal role and realized in various ways depending on the organisms that instantiate it (e.g., in different neuronal configurations in mammals, reptiles, or cephalopods), we can say that truth is defined by its role as characterized by its formal properties and the various truisms associated with it, although these properties are realized differently in various domains. Thus, truth might not be correspondence in certain domains, such as ethics or literature; or it could be ideal warrant in some other domains, such as mathematics, or a different kind of property in the domain of fiction. We could thus allow a form of truth pluralism, together with an acceptance of a core of truth properties applicable in different ways to distinct domains. But the common functional core of truth properties must not be too formal, for we risk being led back to the deflationist view. We need also to be able to admit that truth does *not*

apply in certain domains, or that if it applies, it is sufficiently robust. Take the case of comic truth. You say that Buster Keaton is funny, and I say he isn't. Comic truth is highly relative. So is it truth at all? Suppose, however, that, along with a kind of classicism in aesthetics, we accept that there are some minimal canons of the comic. We could thus accept what David Hume calls a common standard of taste, and some consensus on what is funny, although we would deny that we can reach agreement as in, say, history. We would have to say that the notion of truth is very etiolated in this domain, or perhaps that it does not apply at all. The core properties of truth must involve at least some claims about the possibility for truth to determine some kind of *knowledge* of independent facts, and not merely rational beliefs, in a realist sense of this notion: This entails that some truths might not be known. Such a concept probably excludes the comic or the fictional from the realm of truth aptness.

For the same reasons, there cannot be relative truths. Indeed many, if not most, truths are contextual, in the sense that they have to be evaluated relative to given situations, times, places, speakers, and so on. If I say that I am hungry, the truth of my statement is relative to me, to the present moment, and so on. But once these parameters are fixed, the statement is perfectly evaluable for truth. Cultural relativism is the view that our judgments are relative to various frameworks—to a language, to a conceptual scheme, to a community, or to various historical circumstances. But can the idea that the schemes or frameworks be incommensurable be made to work? According to a well-known argument by Donald Davidson, this is impossible if we use the concept of truth in the ordinary sense.

Can there be nevertheless some faultless disagreements in some domains, such as in matters of taste or in ethics? If I say that that murder is wrong and if you say that it is not, can we say that my statement is true for me and yours true for you, hence that we do not contradict each other? The situation is better described as one in which I *believe* that murder is wrong and you *believe* that it is not, which is an ordinary disagreement. That certain statements can be assessed only relative to a circumstance of assessment is undeniable, but does it follow that there can be a concept of "True for x"? This is dubious, since it would entail that a statement could be both true and correct for x but not true and correct for y. But the norm of correctness for truth would disappear if it were made relative to a perspective.

The Value of Truth

Truth is a norm for our assertions and our beliefs: We aim at having true beliefs, and if we discover that one of our beliefs is false, we have to reject it. Does it follow that we ought to believe all truths, including those that are of no interest for us? If we believe that P, and if Q logically follows from P, but Q is absurd, are we under the obligation to believe Q? Normative requirements, like the norm of truth or the principles of logic are general; they do not entail that we should believe all truths and infer all consequences without attending to the reasons for our beliefs. The same holds about the value that is attached to truth. Truth is the aim of scientific inquiry, and most of the transfer of information within a society aims at propagating true beliefs.

Democracy could thus not exist, and not only if the basic rights of freedom of opinion and of speech were not granted, and thereby the capacity to spread information and to evaluate it were blocked. Nevertheless, this social and political primacy of truth has been contested on at least three fronts. Thinkers like John Rawls or Jürgen Habermas have argued that a politically liberal society cannot rest on the notion of truth, since it would entail that some political arrangements are true whereas others are not, and they have argued that weaker notions such as rational consensus are better. Sceptics or relativists about truth, from Friedrich Nietzsche to Michel Foucault, and more recently Richard Rorty, have argued that invoking the notion of truth in politics hides an attempt to confiscate power in the name of a spooky ideal, and they have proposed to replace truth by notions such as solidarity or wisdom. And a number of writers in science studies, too, have argued that truth and objectivity are but the masks under which political power hides itself.

It is not clear, however, that attempts to replace truth by other, more politically useful notions can actually dispense with the concept of truth. If democracy is not to fall into what John Stuart Mill called the tyranny of opinion, one needs an objective concept of truth, whereby it is possible to give reasons in favor of the truth of certain views. The fact that history and the contemporary observation

of the media culture shows that people *claim* their views to be true but aim at manipulating opinion does nothing to show that truth itself is a fiction in the service of political power. On the contrary, without the capacity to say that "two plus two equals four," we might end up in a world not so different from the one of Orwell's *Nineteen Eighty-Four.*

UNCONSCIOUS

In ordinary language, "unconscious" is often used to characterize the condition of having no awareness, as when one is in a coma, or in a deep, dreamless sleep. In contrast, psychologists use the term *unconscious* to refer to a characteristic of certain mental states. A mental state is unconscious if and only if (a) one is in that state and (b) one is not aware that one is in that state. There is widespread agreement among social and behavioral scientists that a great deal of our mental life is unconscious and that any adequate explanation of human behavior must include the unconscious within its purview. However, there are fundamental disagreements about the nature of unconscious mental states and their relation to consciousness.

Historical Background

Although notions of unconscious mental processes have a pedigree extending back to the ancient world, the unconscious was not seriously taken up by science until the 19th century. To understand what precipitated this development, it is necessary to consider its historical background.

The 17th-century French philosopher René Descartes argued that consciousness is a *defining characteristic* of the mental; nothing can be mental unless one is conscious of it. The notion that mentality is coextensive with consciousness was immensely influential and was widely accepted by philosophers and scientists during the ensuing three centuries. This conception of the mind came under increasing pressure during the latter half of the 19th century, when the newly minted sciences of the mind (neurology, psychology, and psychiatry) began to accumulate observations that were difficult to reconcile with the Cartesian paradigm. For example, experiments using hypnotism demonstrated that behavior can be caused by mental states of which one is unaware. Subjects can be given a post-hypnotic suggestion to perform some action in response to a trigger after they have emerged from the hypnotic state, *without being aware of why they are doing this*. Observations of this kind—as well as of phenomena such as anosognosia (a neurological disorder characterized by unawareness of an obvious disability)—and the discovery of the role of nonconscious inferences in visual perception, all militated against the view that the human mind is transparent to itself.

Researchers struggled to find ways to reconcile these phenomena with the Cartesian conception of the mind. One strategy, sometimes called *dissociationism,* was to deny that so-called unconscious mental states were really unconscious. Advocates of this approach were influenced by studies of what is nowadays called "multiple-personality disorder" (or "dissociative identity disorder"), a form of mental illness in which two or more distinct, alternating personalities (or "selves") inhabit the mind of the sufferer. Dissociationists proposed that one or more dissociated secondary consciousnesses can exist alongside a person's primary consciousness. According to the dissociationists, ostensibly unconscious mental states are states of a split-off secondary consciousness to which one's primary

consciousness does not have access. A different explanatory strategy, sometimes called *dispositionalism,* was to deny that unconscious states are really mental. To understand it, one needs to understand what dispositions are. Dispositions are latent tendencies: A thing has the disposition to *F* if it tends to *F* under certain circumstances. The property of fragility is a good example of a disposition. To say that an object is fragile is to say that it has the disposition to shatter easily. One of the important features of dispositions is that they can fail to give rise to the states that they are dispositions for (a fragile wine glass may never shatter, because it is never exposed to conditions under which the disposition to shatter would be realized). The dispositionalists' view of unconscious mental states was that specific states of the central nervous system dispose one to have specific conscious mental states. The idea is that for any mental state *M,* there is some neural state *N* that is the disposition for *M* and without which *M* could not occur. However, just like the wine glass, it is possible for a brain to be in *N* without being in *M*. Dispositionalists held that being in such neural states can affect behavior in ways that are similar to the effects of the corresponding mental states. Because of this, it is tempting—although erroneous—to think of them as unconscious *mental* states.

Both dissociationists and dispositionalists struggled to make sense of recalcitrant facts while remaining loyal to the Cartesian presumption that all mental states are conscious. Sigmund Freud's conception of the unconscious is philosophically significant precisely because he jettisoned the Cartesian presumption in favor of the view that cognition is essentially unconscious.

Freud

For many people, the notion of the unconscious is inextricably linked to the work of Sigmund Freud (1856–1939). Freud was one of the first students of human nature to provide a sophisticated theory of the unconscious aspects of mental life. His work has had an immense impact on the social and behavioral sciences, although the extent of this influence is often unrecognized and unacknowledged. Trained as a clinical neurologist, Freud was familiar with discussions about the unconscious that were unfolding in the scientific literature during the closing decades of the 19th century. Although early in his career he embraced the view that all mental states are conscious, he abandoned this position in 1895 in favor of the view that our psychological life is mainly unconscious.

Freud's theory of the unconscious resists easy summary, in part because of its complexity and in part because he reconfigured it several times during his lengthy career. To explain it, it is helpful to begin with his account of consciousness. Freud adhered to what is nowadays known as a *restrictivist* theory of consciousness—that is, he believed that all conscious mental states have a sensory or "qualitative" character. He argued that even very abstract thoughts have a qualitative component, because they are disclosed to consciousness in the form of inner speech. When you entertain a conscious thought—for instance, the thought that there is a highest prime number—what goes on in your mind resembles the experience of *hearing your own utterance* of the sentence "There is a highest prime number." Of course, you do not literally hear this sentence, but you have an experience that is something like hearing it. Freud explained this by hypothesizing that cognitive states are unconscious and become conscious only by activating what he called "motor speech representations" (the neurological basis for speech) that express their content. These outgoing impulses are too weak to produce vocalizations, but they generate feedback to the brain that gives rise to the quasi-auditory sensations of conscious thought. So cognition is an unconscious process. As Freud often put it, deliberately using a Kantian idiom, the mental is unconscious *an sich* ("in itself"). *All* of our thoughts occur outside of awareness. What we call conscious cognitions are really just conscious *representations* of unconscious cognitive states.

If consciousness plays no essential role in cognition, then it is possible that there are unconscious mental states that never become conscious. Freud argued that this is the case and held that it can occur in two ways. Many of our cognitive states do not become conscious because their becoming conscious would make no contribution to our lives. These states are unconscious in consequence of our cognitive architecture. Other states are actively barred from entering consciousness—they are, in Freud's terminology, "censored" or "repressed." Repressed thoughts are thoughts that are not represented (or, alternatively,

misrepresented) in inner speech. Freud believed that repression is emotionally driven: Thoughts are excluded from consciousness in virtue of their capacity to produce severe psychological conflict.

It is often said that Freud claimed that we repress emotions and sexual impulses. In fact, he specifically repudiated the idea that emotions and impulses can as such be repressed. In Freud's theory, it is only thoughts—that is, propositionally structured cognitive representations—that are capable of being repressed. We can speak loosely of repressed affective and appetitive states, but we must bear in mind that it is the thoughts associated with those states that can be repressed, rather than the states themselves. Freud thought that the repression of such thoughts has a significant impact on behavior, because thoughts excluded from consciousness cannot function as reasons for one's actions. So repressing the cognitive component of an emotion or desire effectively blocks its direct expression as a motive for action (although not its indirect, nonrational expression).

During the final decade of his life, Freud was especially concerned with the interplay between individual psychology and cultural life. He argued that participating in the cooperative enterprise of civilization requires us to repress (in the loose sense described above) certain desires that are hostile to the social order. Culture demands repression and enforces it through child-rearing practices that shape psychological development in socially congenial ways. Conversely, repression also feeds culture by diverting our primitive, antisocial desires into socially acceptable, symbolic outlets (sublimations). Freud held that cultural practices and institutions, such as art, religion, and even science, are ultimately motivated by, and depend on, repressed psychological forces. The explanatory relation between repression and culture is reciprocal: Repression cannot be properly understood unless one takes culture into account, and culture cannot be properly understood unless one takes repression into account.

Post-Freudian Developments

Although psychoanalytic theory had an immense impact on conceptions of human nature, it came to be regarded as a scientific failure. Psychoanalytic claims about how the mind works were, although intuitively appealing, empirically unsupported and experimentally intractable. As the 20th century progressed, psychology became an increasingly rigorous scientific discipline and had little use for the speculative claims of Freudian theory.

For much of the century, psychology was dominated by versions of behaviorism. Although behaviorism provided a powerful theory of how learning shapes behavior, it was also wedded to a scientific ideology that eschewed any talk about inner mental processes. The behaviorist monopoly was eventually broken during the 1960s by what became known as the "cognitive revolution." Inspired by the rise of computer science, cognitive scientists began to focus on the subpersonal information-processing routines that underpin human behavior: information-processing routines that are structurally unconscious. Because of the Freudian connotations of the term *unconscious,* psychologists at first tended to refer to these processes as "automatic" or "nonconscious." However, in 1987, the psychologist John Kihlstrom, also a contributor to this encyclopedia, wrote an influential paper in which he argued that much of the research on cognitive science is concerned with what he called the "cognitive unconscious," borrowing a term coined by Jean Piaget. Although Kihlstrom described the Freudian unconscious as a version of the cognitive unconscious, psychologists have tended to use the term *cognitive unconscious* to differentiate their perspective from the Freudian one. Research into the cognitive unconscious has given rise to an immense scientific literature and a plethora of innovative experimental procedures. Although the existence of unconscious mental processing is no longer controversial in psychology, there is still debate about how sophisticated unconscious cognition can be—that is, whether the unconscious is "smart" or "dumb." Investigations into the subliminal perception stimuli, memory, learning (especially language acquisition), emotion, and motivation have tended to support the hypothesis that quite complex cognitive processes can, and often do, occur outside of awareness.

Unconscious Social Behavior

Psychological explanations attribute social behavior to the individual's mental states—the thoughts, feelings, and desires that cause the individual to act in a particular way toward others. While the cognitive revolution in social psychology appeared to emphasize the role of conscious cognition in social interaction, a recent trend has been to underscore the role of *unconscious* cognitive processes automatically evoked by stimulus inputs and executed outside phenomenal awareness and voluntary control. However, claims that social behavior is dominated by unconscious processes, such that "free will" plays little or no role in human experience, thought, and action, go beyond the presently available evidence.

The earliest psychological theories of social behavior, put forward in the 1920s and 1930s, were couched in a version of stimulus–response behaviorism that made no reference to consciousness. This attitude carried over into the "golden age" of experimental social psychology, in the 1950s and 1960s, which emphasized social influence and the power of the situation to influence the individual's experience, thought, and action. However, the cognitive revolution in experimental psychology gave rise to an alternative cognitive perspective, which emphasized people's *perception* of the situation, their goals, their expectations concerning the consequences of their actions, and so on. Although it was rarely stated quite so clearly, the implication of the cognitive perspective in social psychology—like the cognitive perspective in psychology generally—was that the percepts, memories, and thoughts that mediated social behavior were consciously accessible to the actor, guiding his conscious choices and actions.

Beginning in the 1970s, however, cognitive psychology reawakened an interest in unconscious mental life with the distinction between *automatic* and *controlled* processing. Controlled processing is conscious and deliberate; it consumes cognitive resources and involves serial processing. Automatic processes, by contrast, are inevitably evoked by the appearance of particular environmental stimuli; once evoked, they are incorrigibly executed, in a "ballistic" fashion; they consume few or no cognitive resources; and they do not interfere with each other or with controlled processes, thus permitting some degree of parallel processing. Automatic processes are reflex-like in some respects, but they are not necessarily innate: In principle, any process, no matter how complex, can be automatized if it is practiced diligently enough. Whether they are innate or acquired, automatic processes are unconscious in the strict sense of the term; they operate outside conscious awareness and are independent of conscious control.

The automatic/controlled distinction was quickly imported into social psychology, with a number of prominent investigators arguing that much of social behavior occurs automatically in response to certain cues, without mediation by conscious, deliberate thought. Within cognitive psychology, there is a general consensus that every task has both automatic and controlled components, and considerable effort has been devoted to measuring their differential

contributions to performance. In social psychology, however, a view has developed that social cognition and behavior are overwhelmingly governed by automatic processes—with one theorist invoking classic "Ivory Soap" advertisements to assert that behavior is 99.44% automatic and another asserting that that free will is so severely compromised by automaticity that, *pace* Descartes, we are automatons after all.

Automaticity has been dubbed "the new unconscious"—the "old" unconscious being the "monsters from the Id" (a phrase from the 1956 science fiction film *Forbidden Planet*), envisioned by Sigmund Freud and other proponents of classical psychoanalysis. But the basic idea was anticipated by William McDougall's "hormic psychology," which argued that social behavior was motivated by a set of basic instincts that operated unconsciously, as well as by the "behavior viewpoint" of Floyd Allport, that social behavior reflected unconditioned or conditioned responses to social stimuli. The embrace of automaticity does not exactly revive Skinnerian behaviorism, however, because the new theorists adopt the central dogma of the cognitive revolution—that cognitive, emotional, and motivational states and processes intervene between the environmental stimulus and the organismal response. But when the intervening states and processes are automatically evoked by environmental stimuli, the embrace of automaticity looks more and more like behaviorism with a cognitive face.

In fact, nothing in the literature justifies the assertion that automatic processes dominate social cognition and behavior. Most of the published research constitutes demonstration experiments that merely show that automaticity plays *some* role in social interaction. But many of these experiments involve a very loose operationalization of automaticity, relying on fewer than the four canonical features listed above. The few comparative experiments published to date reveal much more of a balance between the automatic and controlled components of processing—except in special circumstances, such as very narrow response windows, where controlled processing simply cannot come into play. Nothing in the literature supports the idea that social behavior is wholly, or even largely, driven by automatic processes—much less, as some have concluded, that conscious will is an illusion and introspection only gets in the way of adaptive behavior.

Acceptance of the concept of automaticity has helped legitimize the concept of unconscious mental life, but it does not exhaust the possible unconscious determinants of social behavior. In the conventional view, automatic processes operate on conscious mental contents—percepts, memories, thoughts, and the like—to generate other conscious mental contents. We are aware of *what* we think, even if we are not aware of *why* or *how* we think it. Beginning with the study of implicit memory in amnesic patients, however, it has become clear that mental states—percepts, memories, the knowledge acquired through learning—can influence ongoing experience, thought, and action in the absence of phenomenal awareness. Indeed, the "Implicit Association Test" has been promoted as a means of assessing unconscious attitudes and beliefs that can result in prejudice and aggression directed toward social out-groups. Although the idea of unconscious beliefs, attitudes, and goals remains controversial, widespread acceptance of implicit memory, perception, and learning in the cognitive domain implies that the notion of implicit emotion and motivation should not be dismissed out of hand. Because the lack of conscious awareness precludes conscious control almost by definition, any effects of unconscious thoughts, feelings, and desires must be mediated by automatic processes.

UTOPIANISM

Utopianism is a term used across the humanities and the social sciences to refer to dreams of a better life or to orientations that transcend what is currently possible or realistic. The term developed in the context of European accounts of utopia.

Meaning

Utopia means "no place" (from *topos,* Greek for "place" and the privative prefix *un-*), especially an ideal place that is no place—that is, no actualized or real place—although it sometimes extends to spaces in which we can be different. Some, such as Leszek Kołakowski, want to define utopia narrowly as referring only to beliefs that a definitive and unsurpassable condition is attainable that can be arrived at by human efforts. Others associate utopia with dreams of a better life quite generally, and so with the human capacity to envisage alternative possibilities. On this broader view, utopias allow thinking beyond the present; they also manifest human desire and offer critiques of existing states of affairs.

Types

Utopias are of many different types. They include literary texts; accounts of ideal societies, especially societies based on social harmony; social designs of allegedly better arrangements for practical life; social and economic outlooks; works of political and social theory; and intentional communities. There are technoscientific utopias, green utopias, gender utopias, geographic utopias, electronic and digital utopias, and so forth. Utopias may be realistic or imaginary; eutopic, heterotopian, or dystopian; on the left or the right; and authoritarian or libertarian. They may be based on an allegedly perfect human nature, or they may be about how imperfect human nature can be changed or managed. There may also be utopias of space and time. Distinctions are also possible with utopias made by human beings and those not so made. Utopia also has a history, and the manifestations of utopianism vary over time; they include some forms of millenarianism as well as ideal lands such as Arcadia and Cockaigne.

The Study of Utopianism

The study of utopianism, an area that has developed as a serious area of inquiry in recent years, illustrates the need for *a closer relationship between philosophy and the social sciences.* The standard charges that utopias are unrealistic, impractical, and potentially dangerous are overstated and only partially supported by detailed studies of intentional communities such as religious orders, communes, and kibbutzim. Some utopias are realistic and/or have practical elements. Clearly, utopias that are elements of political movements can be dangerous, as attempts to realize utopian designs in practice may be in any area. Nonetheless, the deeper significance of utopia and utopianism is not restricted to the sociopolitical but extends to the metaphysical and natural-scientific as well. Older work on utopia tends to neglect both and confuses utopianism in general with European utopianism, with its focus on nonexistent ideal societies and the pursuit of social harmony and happiness. While it is now widely recognized that utopian thinking may be necessary in a range of circumstances for human beings, there is little contemporary philosophical or natural-scientific work on why this should be so.

Social Theory

This situation partly reflects the tendency for different disciplines to understand utopia and utopianism differently. Sociologists, following Karl Mannheim, who famously contrasted ideology and utopia, associate utopia with the emergence of modern society in Western Europe and with models of social harmony. They sometimes forget that utopianism has flourished in many parts of the world and before the modern period, especially in Asia. In cultural sociology, utopia is used to describe the nonplaces of the consumerism generated by capitalism. In politics, utopianism is associated with the problems of perfectionist politics and communism.

Following the collapse of communism and the attacks by Isaiah Berlin and Leszek Kołakowski implying that utopia is based on ethical monism and leads to repression and violence, utopianism has fallen out of fashion, at least at the level of a political strategy.

On the other hand, although many writers refer to a decline or even an end of utopia, neoliberalism

has flourished, despite its utopian elements, even though those advocating such utopianism have often denounced utopia as the left-wing illusion that it is possible to achieve goals such as equality and social justice. There has also been a retreat from the redemptive utopianism associated with German Jewish thinkers such as Walter Benjamin, Herbert Marcuse, and Theodor Adorno, a development partly explained, as the American Marxist Frederic Jameson notes, by changes in capitalism. In law, utopianism tends to be practical and about designing better institutions, organizations, and regulative regimes. The distinguished Brazilian legal theorist Roberto M. Unger advocates a utopianism of this sort. Given the contemporary need to devise new global institutions, utopianism as a form of practical political philosophy and a technique of invention probably has a future more than most political commentators suggest.

Philosophy

In philosophy, utopianism is associated with technical issues in metaphysics and logic, including theories of possibility and possible worlds. Philosophers are more inclined than social scientists to distinguish the *ideal,* or what is normatively maximal, from what is *without a place*—and both from what is *only imagined*. Utopian philosophy and the philosophy of utopianism, which is often a subset of it, has been relatively neglected by scholars of utopianism at the technical level. The most important utopian philosopher is the German Jewish philosopher Ernst Bloch (1875–1977). Bloch reinterprets utopia as a feature of reality itself and as having a place in the now of the moment. In his masterpiece *The Principle of Hope* (three volumes), he argues that utopian surplus can be found throughout human consciousness, in daydreams and in cultural materials from all over the world, and also in nature. Bloch's work has been noted by scholars of utopia, but his philosophical contributions, including his utopian metaphysics, have been largely overlooked. French discussions of philosophy and utopianism (by Louis Marin and Michele Le Doeuff), on the other hand, have been taken up to some extent.

In the longer term, modern European utopianism is likely to be eclipsed by global utopianism, which takes the philosophy of possibility and nonexistence seriously. Students of utopia have too often ignored religious utopianism; even in religious studies utopia has been understudied, even though religious utopias are found worldwide and are often strikingly successful over many centuries. This is now changing with the development of postsecular thought, and many contemporary scholars interested in utopia are attempting to rethink the relationship between the secular and the religious. Once again, serious attention is only now being paid to the ontological implications of the tendency of the human imagination to project counterfactual states of affairs and to the biology that makes it possible for them to do so.

Value Neutrality in Science

The claim of the value neutrality of science is that *scientific* knowledge neither supports nor undermines any value judgment and that accepting a scientific theory in accordance with proper epistemic criteria is compatible with holding any viable value outlook. The claim is consistent with science being "value relevant": Scientific knowledge may inform the means to bring about goals that are judged valuable, and priorities of research may be set by the goal of producing such knowledge. Since Max Weber's influential writings in the early 20th century, defending the sound scientific status of the social sciences has often included arguments that the social sciences are, or ought to be, value neutral. This entry will first introduce the philosophical background of the value neutrality of science; then, after four criticisms of its applicability to the social sciences are sketched, its viability as an ideal will be briefly entertained.

Philosophical Background

The claim that science is value neutral follows from three proposals: first, the alleged dichotomy of fact and value, the proposal that factual statements and value judgments are distinct and separable, having no relations of logical entailment with one another; second, that science deals only with matters of fact; and, third, that scientific knowledge could support or undermine value judgments only if the latter were logically entailed by the former. The dichotomy of fact and value often is grounded in David Hume's famous argument that "ought" cannot be entailed by "is." It has been reinforced by the common views that value judgments express subjective preferences or emotional responses and (in the natural sciences) that scientific theories represent the underlying structures of phenomena, the processes and interactions of their components, and the laws that govern them, dissociated from their connection with human experiences, lives, values, and social/cultural forms—so that the language of scientific theory is "mathematical" or "technical" and so does not contain the categories needed to make value judgments. While attempts have been made—for example, in economics and behaviorist psychology—to deploy only "technical" categories, in the social sciences generally, this has not been a serious option.

Many criticisms made of the value neutrality of the social sciences begin with questioning the third proposal above. They do not question that scientific knowledge can have no logical entailments in the realm of values. Rather, they maintain that scientific knowledge gained in the social sciences can sometimes support or undermine value judgments in virtue of the relations that exist between factual statements and value judgments in certain contexts, which make it unintelligible to accept the factual statement and to deny a specified value judgment—unless explanation that makes sense of denying the value judgment is provided. In these contexts, the value judgments are not logically entailed by the relevant factual statements (or accepted theoretical explanations) but follow from them, other things being equal, thereby providing support for—that is, a reason to make—the value judgments. The first

three criticisms sketched below are of this kind; in them, the source of departure from neutrality is provided by these nonentailment relations. The fourth criticism locates the source differently, when—unlike most versions of the first three—it challenges part of the first proposal by questioning whether the criteria used in evaluating scientific knowledge are free from compromises with particular ethical/social values.

Criticisms

Social-Scientific Understanding "Secretes" Value Commitments

The adoption of a *theoretical framework* (Charles Taylor's term) is motivated by a conception of human wants, needs, and purposes, or reinforced by holding a particular value outlook that influences the kinds of categories used in efforts to gain understanding of phenomena and contributes to selecting the phenomena for which understanding is to be sought in inquiry. These categories are not only limited to "technical" ones but also include terms (sometimes called "thick ethical terms") that (unlike "thin ethical terms," e.g., *good* and *bad*) may be used simultaneously in descriptive and evaluative modes—so that value judgments follow, other things being equal, from empirically confirmed claims. Consider, for example, the following statement: "The drug companies are being driven more by financial ambition and marketing considerations than by scientific and public health objectives, and that is the root of their current problems." Clearly, this claim is subject to empirical test. However, it would be unintelligible, other things being equal, to accept that it is well confirmed and not to make the value judgment that the drug companies are acting badly—*driven more by financial ambition* is one of the thick ethical terms deployed in making the claim. This is an example of how social-scientific understanding *secretes* (Taylor's term) value commitments. The empirically confirmed claim does not logically entail the value judgment. There is no logical contradiction involved in accepting the claim and denying the appraisal. Other things might not be equal! But it is not intelligible to accept the claim and deny the value judgment, unless one provides evidence that other things are not equal (e.g., by providing evidence that, in current circumstances, responding to marketing considerations is the only way to get funding to support public health programs).

"Explanatory Critique" in the Social Sciences

Research in the social sciences may lead to the confirmation or disconfirmation of a proposition such as "Democracy is not viable outside the institutions of capital and the market." It may also lead to the confirmation of statements about who believes the proposition, about how widely the belief is shared, and, if it is widely believed, about the causes of its being so. This makes possible what Roy Bhaskar calls "explanatory critique." If research were to disconfirm the proposition, and also to confirm that it is widely believed (though false) and that its being widely believed is partly explained in terms of mechanisms integral to prevailing social structures, then—other things being equal—a negative value judgment of the social structures follows, and also—other things being equal—a positive value judgment of projects aiming to replace them with alternative structures. Again, other things might not be equal—for example, evidence might be available that the alternative structures would probably be the source of greater harm. Explanatory critique, according to Bhaskar, reflects an "emancipatory impulse" in the social sciences; the social sciences have the capacity to uncover "false consciousness" and its sources, and from such results follows, other things being equal, positive appraisal of projects aiming for emancipation from the grip of ideology. Unlike the first criticism, explanatory critique does not depend on any role played by "thick ethical terms."

Social Science Results May Undermine Presuppositions of Value Outlooks

Rejecting the view that value judgments express subjective preferences or emotional responses, some philosophers maintain that holding values presupposes—or follows, other things being equal, from—claims that are open to empirical investigation. Hugh Lacey illustrates this when he maintains that holding values of technological progress—for example, the value of technoscientific innovations introduced for the sake of economic growth—presupposes claims such as "Technoscientific innovation provides benefits that contribute toward the well-being of human beings generally"; "There are technoscientific solutions to most human problems, including those occasioned by technoscientific innovations themselves"; and "There are no serious alternative proposals available today to the pursuit of economic growth

based on technoscientific innovation." These claims may be investigated in the social sciences, and if they were disconfirmed, it would leave the values of technological progress without a sound basis, unless a new set of presuppositions were devised to replace the disconfirmed ones. Equally, their confirmation would strengthen commitment to the values. Here again, other things being equal, empirically confirmed claims imply making certain value judgments.

Criteria of Appraisal of Scientific Understanding Include Value Commitments

Unlike the first three, the fourth criticism—often associated with feminist philosophers of science—disputes that the criteria used in evaluating scientific knowledge are free from value commitments and that they can be clearly distinguished and separated from ethical/social values. This criticism draws, in part, on case studies that show that, as a matter of fact, there are scientific theories (not only in the social sciences) that have been accepted on the basis of criteria that depend on particular ethical/social values. Then, inevitably the theories—for example, about alleged genetically based differences in the mathematical abilities of males and females—contribute to supporting certain values and undermining others and to providing backing for projects that embody these values and, normally, not others. Criticism from such case studies cannot be conclusive, however, for it is open to the rejoinder that claims accepted on the basis of such value-laden criteria are not really instances of scientific knowledge. Some actually accepted theories may not be properly accepted, that is, on the basis of criteria that are not implicated in value commitments; actually accepted theories may not accord with neutrality, but that does not mean that scientific knowledge does not accord with it. To meet this rejoinder, the criticism may be completed by making this more far-reaching claim: It is not just that some theories are actually accepted partly on the basis of value-laden criteria but that empirical data combined with the proposed purely cognitive criteria always underdetermine what theories should be accepted, and so the role of ethical/social value-laden criteria cannot be avoided, even in principle.

General agreement has not been reached on the soundness of these and other criticisms of the neutrality of the social sciences and, thus, on the merits of the claim of the value neutrality of science.

Concluding Remarks

The idea that scientific knowledge neither supports nor undermines any value judgment has had a strong appeal throughout the modern scientific tradition, and despite the abundance of criticism, that appeal remains. Part of the appeal comes from what has been thought to be a consequence of neutrality, namely, that science may be considered to be part of the common patrimony of humanity; in principle, items of scientific knowledge may be used, more or less evenhandedly, by the adherents of any viable value outlook to inform their practical projects, even if in actual fact some items of scientific knowledge have special relevance for privileged outlooks. However, it follows from the criticisms that not all items of scientific knowledge may be used, in principle, to serve any viable value outlook. Nevertheless, the criticisms do not rule out that each viable value outlook might be strengthened by some items from the totality of scientific knowledge and that the totality (though not each individual item) of scientific knowledge may serve viable value outlooks evenhandedly—provided that science (including the social sciences) as a whole, as a worldwide practice, permits space for conducting research under a sufficient variety of theoretical frameworks, to ensure that the values "secreted" in the frameworks adopted in research are not limited to a few specially privileged ones. Then, even if the criticisms are sustained, the proposal that "scientific knowledge as a whole, the totality of scientific knowledge and properly accepted theories, serves evenhandedly all viable value outlooks," which retains much of the appeal of the idea of the neutrality of science, might still be defended as a viable ideal.

VERIFICATIONISM

Verificationism holds that a meaningful statement or a legitimate belief is one that is verifiable by experience. It has its roots in the empiricism of David Hume (1711–1776) and the positivism of August Comte (1798–1857), and it branches out into classical American pragmatism and logical positivism. It is often thought to be a kind of scientism that rules out, as spurious or meaningless, metaphysics, theology, ethics, and other "soft" areas of inquiry.

But while verificationism might be the enemy of some kinds of metaphysics and theology, matters are less straightforward with respect to social and moral philosophy. Verificationists have always been alert to the consequences for non–bench-based areas of inquiry. Hume had called for a science of human nature or, as the subtitle of his *A Treatise of Human Nature* has it, *An Attempt to Introduce the Experimental Method of Reasoning into Moral Subjects*. Comte's *Cours de Philosophie Positive* argued that if we are to prevent the disintegration of society, we must extend the method of science to social and moral thought. Indeed, he is the founder of the discipline of sociology.

When the early American pragmatists—Chauncey Wright, William James, and C. S. Peirce—picked up these verificationist ideas, they too took "science" to be very broad based, including not just the physical and biological sciences but also political economy, economics, and political science. The pragmatist version of verificationism argues that experience goes beyond what our five senses deliver, that we have experience in mathematical contexts, that we might experience value, and that all inquiry must and can be thought of as being a part of a seamless whole.

Verificationism these days is usually taken to refer to the core doctrine of logical positivism—the position that arose in the mid-1920s in Vienna and Berlin and that was imported to America and England at the outset of the World War II. Their aim was to unify all inquiry under the umbrella of science. The "verifiability principle" did most of the work. It was a semantic doctrine, holding that all meaningful sentences are reducible, via formal deductive logic, to statements that are empirically verifiable. Domains of inquiry can achieve clarity and progress by having their theories symbolized in the ideal and clear language of logic and cashed out in observation.

For instance, Rudolf Carnap's version of the verifiability criterion had it that deductive axiomatic theories are given empirical meaning by definitions that hook up the primitive terms in the formal language with observables in the world. He tried to show how we could give precise definitions of all scientific terms, definitions that bottomed out in a primitive language—the "thing-language" or the language of physics.

Philosophy is to get with the program, put its theories in scientific language, and render itself clear. Most of the age-old questions and their purported answers will be shown to be fruitless and meaningless, as they are not reducible to observation statements. They are not empirically verifiable, and so they are *pseudopropositions*. Statements about essences, the Absolute, the thing-in-itself, and so on are quite literally meaningless.

Ethics is in almost as precarious a state. It is either to be reimagined or imperiled. Statements about what is right or wrong are (a) statements about what people actually approve of, not what they ought to approve of—that is, ethics is an empirical science; (b) statements that express emotions or feelings; or (c) meaningless statements. As an example of the second view, we find some of the logical empiricists advocating the "Boo-Hurrah" theory of ethics, in which to say that an act is odious is to say "Boo-hiss!" to it and to say that an act is good is to say "Hurrah!"

Many of the logical positivists, however, opted for one or other version of (c): Ethics and other non–bench-based subjects are not within the bounds of science and hence are spurious. Others, Otto Neurath, for instance, argued for (a), that the social and human world is within the domain of empirical science.

The verifiability principle came under sustained pressure. It faced some formidable objections and was constantly undergoing revision and liberalization in light of them. One set of objections centers around the strength of the verifiability required. If a meaningful statement is one that can conclusively be shown to be true or false, then all kinds of discourses are in trouble. For instance, statements about the past, the future, and the mental states of others are not conclusively verifiable by observation and thus are swept away as meaningless on the strong-verifiability criterion.

Even the statement "blue, here, now," when presented with a patch of blue, is not conclusively verifiable. The perceiver might, for instance, be hallucinating or suddenly be color blind. Indeed, much of science seems to fail the test. For instance, hypotheses about unobservable entities, scientific laws, and dispositional hypotheses seem not to meet the bar. A scientific law is a universal generalization that ranges over an infinite domain, and hence, no finite number of positive instances will conclusively verify it. Statements containing dispositional terms such as *soluble* or *temperature* are analyzable only by counterfactual or subjunctive conditionals: "Were *x* to be placed in water, then it would dissolve" or "Were a thermometer to be in contact with *x,* it would register *y* degrees." Neither kind of statement is subject to conclusive verification.

Many moves were made in an attempt to overcome these challenges. The verifiability principle underwent liberalizations such as not requiring conclusive verifiability, not taking verifiability to be the entirety of meaningfulness, extending deductive logic with inductive logic, and so on. Each move took the verifiability principle farther away from the goals of straightforwardness, clarity, rigor, precision, and certainty, which drove the reductionist program of analyzing meaningful sentences via logic and observational predicates.

As a result, no one wants to be called a verificationist these days. Nonetheless, plenty of positions of the more moderate pragmatist stripe remain, and these positions may carry with them real insights for social and moral philosophy.

Vico's *Scienza Nuova*

Giambattista Vico (1668–1744) was born in Naples and lived there throughout his life. He was professor of Latin Eloquence at the University of Naples from 1699 to 1741 and was named Royal Historiographer by Charles of Bourbon in 1734. His major work, *Scienza nuova* (*New Science*) has the full title of *Principles of New Science of Giambattista Vico Concerning the Common Nature of the Nations* (1730/1744). In it, Vico puts forth a genetic account of what he terms the "great city of the human race," the basis for the generally held view that he is the founder of the philosophy of history. This genetic approach to the comprehension of human society is based on a conception of natural law that Vico opposes to 17th-century natural law theory, especially that of Hugo Grotius, Thomas Hobbes, Samuel Pufendorf, and John Selden.

These thinkers have a nondevelopmental conception of society, in which society originates or can be regarded as originating through a covenant formed among peoples such that they are transformed, as Hobbes describes it, from a state of war of all against all, in which life is "nasty, brutish, and short," into a state of governance. Vico calls the view of natural law held by such thinkers as "the natural law of the philosophers." Natural law or natural right in this sense is an ideal posited in thought to which systems of law are to respond and against which they can be judged.

Against this ideal sense of natural law, Vico opposes a conception of "universal law" based on the *ius gentium,* or "law of the peoples or nations," in Roman law. *Ius gentium* in Roman law is that

part of Roman law that is common to all other systems of law and is distinct from *ius civile,* or "positive law," law as enacted by a particular authority within a particular society and varying from society to society. *Ius gentium* is that part of law that is actually held in common by all nations and that makes law, law in each system of laws.

Vico reconceives *ius gentium* from a static principle common to all nations to a dynamic principle that he calls "ideal eternal history" and that refers to a pattern of development common to all nations. All nations develop in terms of a course of three ages: (1) an age in which society is formed in terms of gods; (2) an age of heroes, in which society is dominated by heroic figures who embody the virtues necessary for human custom; and (3) an age of humans, in which society is governed by written law and rationalistic thought. Gods and heroes are formed by what Vico calls imaginative universals, not the abstract universals of reason. With the loss of the agency of gods and heroes, the secular mentality of the third age dissolves into a rational madness that Vico calls "the barbarism of reflection." The nation returns to the necessities that govern primitive life, and a recourse of the three ages can ensue. Vico's reading of Western history regards the age of gods and heroes to have occurred before Homer and the age of humans to commence with the arrival of Greek science and philosophy, ending in the fall of Rome. The recourse begins in a return to religion, developing into the heroic society of the high Middle Ages that culminates with Dante, followed by the inception of Renaissance philosophy and culture that extends into Vico's own time and ours.

Vico claims that because humans make history, they can in turn make a science of history. This claim is based on Vico's principle that "the true is the made." We can make a science of the world of nations because the true and the made are convertible. Thus, there can be a science (*scienza*) of history, but there can be only a consciousness (*coscienza*) of nature. Since natural objects are not made by us, "natural science" can produce only a kind of exact awareness, not a complete knowledge or truth of them.

In his philosophy of history, Vico separates sacred history from the history of the gentile nations. The gentile nations arise from the offspring of the sons of Noah after the world dries out from the universal flood. Only the gentile nations are governed by the ages of the ideal eternal history. The offspring of the sons of Noah become giants, many of whom are transformed into the fathers of the first families by responding to the new experience of lightning and thunder as the great forest of the world dries out. They imitate the sound of thunder and utter the first word—*Jove*—and begin to take the auspices of Jove's action in the sky. Others who do not have this response remain feral but later seek the protection of the first families and become *famuli,* or "persons in servitude," to them. In this way, social classes are originally formed that later generate the classes of nobles and plebeians.

Each nation rises, matures, and falls within history. No nation, in Vico's view, ever masters history. Yet all in the known world of nations can be studied by beginning with its origin and narrating its development. This narrative sense of historical and social science depends on what Vico calls "a new critical art," which is accomplished by a philological-philosophical method in which an empirical knowledge of the customs, languages, laws, and deeds of a people is joined with the philosophical analysis of the universal elements of human experience.

Virtual Environments and Social Interaction

The entry discusses philosophical issues raised by the emerging advanced technologies creating virtual environments in which a kind of "social" interaction between people may be said to take place. This also raises issues for social science as well as ethics.

Virtual environments have given rise to considerable philosophical speculation from the time the relevant technology first appeared: Is it possible to distinguish between the real and the virtual? What is the relation between real persons and online characters (or avatars)? Can interactions in virtual spaces lead to new ways for people to interact, perhaps even forming whole new societies?

On closer inspection, these questions depend on how virtual environments are defined. One definition that can be said to reflect a consensus among researchers in the field revolves around the notion of *presence,* the idea that people who use virtual reality technology experience being in another place or space. If it is added that this experience must be sensory (rather than, say, the imagined experience of another place that a novel or movie might provide) and that the user must also be able to interact with or navigate within the space, then this definition delimits virtual environments in the way researchers have come to use the term and also in a way that clearly sets them apart from other technologies and experiences.

This definition is not limited to "high-tech" types of virtual environments, such as those experienced by donning a head-mounted display or standing in a Cave-type display and flying around with a 3D joystick, which are also known as *immersive environments*. Rather, it includes environments like *Second Life* or popular online games like *World of Warcraft,* where thousands of avatars can interact and play with each other. The latter are also places or spaces that people experience in terms of *presence* and that they can interact with and navigate through—though in the case of games, they are engaged in highly structured role-play (which arguably diminishes the sense of presence). In any event, it is important to distinguish between virtual environments for single users and those where avatar representations can work and play together—which have become known as shared or multiuser or collaborative virtual environments. When people experience the latter or when they engage in social interaction, the term *copresence* is used.

While the technology exists for virtual touch, smell, and taste (three of the five senses), in practice most virtual environments are limited to visual and aural environments (the two other senses), though these environments also include a kind of pseudo-touch whereby objects can be manipulated (a house can be built or a ball thrown—though they are weightless!). Thus, the interaction with the environment is mainly via seeing it, hearing it, and navigating through it and manipulating objects. This also applies in multiuser environments to interacting with others' avatars. Once this is recognized, again, many of the philosophical conundrums (can people be hurt in virtual environments?) quickly disappear (in a purely visual and aural environment, not physically!).

Similarly, can avatars be used to explore multiple personalities? Yes, although this often takes the form of an exploration of visual representations of the self and how people represent themselves to other avatars. Of course, people can come to identify with one or more of these visual representations, but as in real-world encounters, it is hard to "stage" oneself in a role that does not truly present who one is. In this respect, much also depends on the type of technology used. Consider, for example, the difference in possibilities for self-representation in text-based virtual environments (many environments like Second Life have been and still are mainly text based), as against environments where voice communication is used (Second Life has also enabled communication via voice, though this is still not very common): The possibilities for misrepresenting oneself are far more restricted in an environment with voice.

Virtual environments—and especially multiuser ones—have become popular means of socializing and pursuing leisure and various other activities (e.g., education) in online spaces. They have also become useful laboratories for doing social science research. This is because they allow all interactions to be captured digitally and analyzed and provide an environment whose parameters can be altered at will and that does not have the same risks as physical environments. Examples here include environments for simulating fire escapes or for shy people to introduce themselves to others, or environments in which people can adopt different kinds of appearance to see how this affects their encounters with others. Many interesting and useful insights about social interaction have been produced using virtual environments in this way.

Yet these research possibilities also present some new conundrums in terms of the *ethics* of research: How far can researchers go in exposing research subjects to harm, even if the harm experienced is mainly psychological? Environments that are patently not real are experienced as such, which makes some experiments in these environments problematic. Another issue is raised by the fact that some environments are rich with data—but almost like a "big brother" society under surveillance. Here, we can think of Second Life or online games, which, although they are public, allow researchers

to watch and analyze behaviors in detail and in a perfectly panoptic way. Arguably, while this may be legal, it may also be intrusive—or worse—from the viewpoint of research ethics.

This entry has confined itself to a tightly defined idea of virtual environments and discussed only a few related issues and prospects for the social sciences. If a broader view is taken whereby *virtual* is taken to mean any online phenomena, then the net could be cast much wider too in terms of the social implications. What about the virtual relationships people have via social networking sites such as Facebook? Or the addiction to gambling online? Or the followings that celebrities have on Twitter? In this wider picture, much of the knowledge and information we access, the relationships we maintain, and the way we entertain are moving into the digital realm. This is a much broader sense of *virtual,* and yet the narrower notion of virtual environments discussed here can shed much light on these more general social issues—since interaction with immersive virtual spaces can be seen as an extreme version of less immersive and more quotidian experiences via the Internet and the Web.

Virtue Epistemology

Virtue epistemology is a distinctive approach to understanding the evaluative and metaphysical dimensions of cognition. Although the field is marked by considerable diversity and disagreement, there is broad agreement on at least two fundamental principles. On the one hand, virtue epistemologists agree that cognition is *normative*. Cognitive science has much to teach us about how we perceive, remember, reason, inquire, and so on, but unfortunately, there is no easy path from these extremely valuable empirical insights to conclusions about how we *ought* to cognize or what counts as *good* cognition. This is not to say that empirical facts about cognition are irrelevant to the normative questions but only that important questions remain once all the science is in. On the other hand, virtue epistemologists agree that the ultimate source of epistemic normativity, and hence the central focus of epistemological inquiry, are cognitive agents and communities, along with the fundamental powers, traits, and habits that constitute their intellect. This contrasts with the mainstream approach in the analytic philosophy of the later 20th century, which focuses on individual beliefs and inferences instead of individuals and their cognitive character. Traits that promote good cognition or intellectual flourishing are called, following a tradition extending back to Aristotle, *intellectual* or *cognitive* or *epistemic virtues,* hence the name "virtue epistemology."

Virtue epistemologists try to answer long-standing philosophical questions about cognition by focusing on how an agent's intellectual powers, habits, and abilities ("dispositions" for short) enter into the conduct of inquiry and formation of belief. A crucial resource here is the notion of an outcome *manifesting* a disposition, which is an especially intimate relationship between the outcome and the disposition. For example, one important philosophical question about cognition is "When is a belief based on perceptual experience?" A virtue epistemologist might answer, "When the perceptual experience causes the subject to form the belief, and the fact that it does so manifests the subject's disposition to trust his senses." Another question—perhaps the most important question in this area—is "What is knowledge?" A virtue epistemologist would answer, "Knowledge is true belief manifesting epistemic virtue." Another important question is "Why is knowledge more valuable than true belief?" A popular answer among virtue epistemologists is "Because you do not necessarily deserve credit for believing the truth, as might happen if you luckily guessed the correct answer to a question; by contrast, you know something only if you deserve credit for arriving at the truth, through

the exercise of your epistemic virtues, which makes knowledge better than mere true belief."

What counts as an epistemic virtue? A standard answer is that one central and important class of virtues includes the subject's truth-conducively reliable doxastic dispositions. That is, they are dispositions that make the subject good at detecting and endorsing the truth, so that he or she usually gets it right when he or she exercises those dispositions. A further set of important and, from a philosophical perspective, poorly understood dispositions concerns the metacognitive task of suspending judgment on a question. It is not obvious that the quality of these dispositions can be measured simply in terms of how reliably they produce true beliefs, since suspending judgment occurs only if one *refrains* from forming a belief. So when ought one to suspend judgment? Most, if not all, of our cognitive dispositions have innate biological and social bases, so the abstract account of epistemic virtue put forward by the virtue epistemologist must be properly supplemented through insights from the biological, cognitive, and social sciences.

The nature and scope of epistemic virtues is an area of potentially fertile interdisciplinary work among philosophers and scientists. For example, some virtue epistemologists, often called "virtue responsibilists," accept a more demanding conception of epistemic virtue than the minimal reliabilist conception of virtue mentioned above. Responsibilists define epistemic virtues as praiseworthy and refined character traits with a distinctive motivational profile, such as conscientiousness and open-mindedness, which underwrite robust, broad-based dispositions to inquire well across a wide range of circumstances. These epistemic traits share the same profile as the ethical traits featured in the Aristotelian tradition of virtue ethics, such as generosity, justice, and compassion. But a rich body of work in social psychology has led many psychologists and philosophers alike to question the existence of such traits. For instance, in one set of experiments involving seminarians at Princeton Seminary, the strongest predictor of whether a seminarian would stop to help a stricken person was how much time the seminarian thought he had to arrive at a lecture on time, not on how compassionate he was. In another set of experiments, whether the subject offered help to a distressed passerby was strongly influenced by whether the subject had recently found a dime in a payphone, not by how compassionate she was. These and other equally surprising results are often taken to suggest that we dramatically overemphasize the prevalence of individual traits in determining behavior and correspondingly underemphasize the impact of situational factors. If this is correct, then it does not bode well for the responsibilist conception of epistemic virtue. Does the hypothesis that we have refined epistemic virtues fare any better than the hypothesis that we have refined ethical virtues? This is an issue ripe for further experimental work, which would have important philosophical consequences.

The cultivation of epistemic virtues is another area of fruitful overlap between virtue epistemology and the sciences. Just as there is no doubt that a human's biological endowment heavily influences his or her cognitive character, there is equally little doubt that his or her socialization has a similar effect. For example, consider how much humans rely on testimony. Competently consuming testimony involves a battery of skills and presuppositions. There is strong evidence that a speaker's social status, gender, and ethnicity affect how his or her testimony is regarded. Unless we are disposed to be appropriately sensitive to features relevant to the quality of testimony, and appropriately insensitive to irrelevant features, we run the risk of incompetently or unfairly consuming testimony. Scientific research is essential to help us understand our habits and predispositions, both vicious and virtuous, in this regard.

Weber and Social Science: Methodological Precepts

Max Weber's views on social-scientific methodology are rather multifaceted and complex. Efforts by scholars to present them entail the risk of oversimplification or of emphasizing certain aspects of his thought while neglecting others. This entry tries to avoid such distortions by discussing Weber's methodological precepts with attention both to the influences on his work and to the influences his work has exerted on others.

Introduction

Weber's views on social-scientific method elude easy characterization. He has been construed as an antipositivist by scholars pointing to his famous notion of *Verstehen,* while, at the same time, he has also been taken to be a kind of positivist mainly because of his adherence to a strict distinction between "is" and "ought"—that is, facts versus values in social-scientific reasoning. Both these characterizations are exaggerated, since Weber's *Verstehen* method for understanding social action must be seen as what it really is, namely, a rational process—not one based on empathy—while his view on the fact/value distinction is less blunt than it appears in his popular "twin lectures" of 1917 and 1919. Moreover, in his methodological works, value freedom as an ideal for scientific research is qualified as value relation, thus bridging the gulf between "is" and "ought."

According to Paul Honigsheim, Weber's biographer, Weber hated the sharpening of methodological knives if there was nothing on the table to be carved. Nevertheless, his methodology is more often extracted from his methodological essays rather than from its applications. Weber was not a "card-carrying" philosopher, and he himself admitted that he was not philosophically minded. Yet he was never a sociologist by profession either, except for a part-time assignment during the last year of his life as professor of political economy in Munich. His first teaching position was in commercial law. Insofar as methodological issues were concerned, he relied on others—for example, his Heidelberg colleague, the Neo-Kantian philosopher Heinrich Rickert. Weber's references to Rickert are quite explicit. The relationship between the two thinkers, however, is problematic. The use of Rickert might have been a matter of convenience and does not give us the full picture of the influences on Weber's thought. Systematizing Weber along Rickertian lines would neglect the explicit reservations in Weber's views on Rickert's terminology, such as in the so-called Nervi fragment, a small note from Max to Marianne Weber from 1903 (extensively discussed by Bruun).

Weber is best seen as a synthesizer who borrows from others: For example, the concept of ideal type is taken over from Georg Jellinek, though it gets transformed. To Weber, concepts are human constructs—in contrast to the Hegelian tradition. Weber's Neo-Kantian nominalist concept formation procedure allows for an intersubjective selection from a vast and chaotic reality, based on postulated

points of departure. Intersubjectivity is a precondition for cumulativity in the process of knowledge production. For the historical school, by contrast, abstraction from reality presented a major problem they could not account for in their methodological controversy with Austrian marginalist economics. However, Weber does not exhaust the topic of how concepts are actually formed.

Perspectivism is sometimes a term used to catch the essence of Weber's methodology, in which value hierarchies are rationalized from a postulated point of departure ("interest"), so the resulting policy recommendations can be scrutinized regarding their logical consistency.

In *Gesammelte Aufsätze zur Religionssoziologie* (*GARS;* see Further Readings), at least in the section Intermediate Reflections, Weber expresses explicitly a methodological creed coherent with several other texts and, in fact, deals with the notion of ideal type as well as with what can be seen as the unique Western scientific creed. However, Weber's methodology is not only to be found in his explicit methodological texts. It can also be found in its applications. Already in the 1890s, Weber applies the methodology he later develops. *Freiburger Antrittsrede* (The National State and Economic Policy, 1895/1994) is a good example when explaining the logic of the agrarian policy east of the Elbe and why German settlers are replaced by Polish migrant workers. It is pioneering policy science—rationalizing value hierarchies for the purposes of an instrumental decision making.

There is no single Weberian school of devoted followers; instead, we have competing interpretations. Weber's most famous methodological tool, the so-called ideal type, has been—in very different ways—a starting point for the three main methodological paradigms in social science, namely, Parsonsian macrosociological functionalism, Schützean hermeneutics, and Lazarsfeld's empirical survey tradition (we shall return to these later). The ideal type is a heuristic tool separating hypothesis from theory. There are several ideal types of social entities or social phenomena. The one regarding bureaucracy is perhaps the most famous, closely followed in importance by the historical types of Protestant ethic and the spirit of capitalism. The bureaucracy ideal type, however, is not an *ideal* ideal type, since it is a general type rather than a historical individual, such as the ones we find in *GARS*. One encounters bureaucracy in many historical locations, from ancient Egypt to the Soviet Union. However, the growth of modern bureaucracy is part of an irreversible rationalization process, which is at the core of Weber's philosophy of history.

Weber's Methodology

Weber's methodology could be encapsulated in the formula "three controversies, two traditions, and one predicament."

a. The *predicament* refers to the post-Enlightenment dilemma of an anxiety of choice—in other words what Weber's neighbor Ernst Troeltsch labeled the "polytheism of values." Weber's methodology in social science corresponds to a Kierkegaardian-Nietzschean predicament in philosophy. The criticism voiced would go like this: By postulating a top value, we can rationalize value hierarchies in the service of instrumental social policy. There is no scientific way to judge between competing ultimate values, such as liberty or equality.
b. The historical school, dominant at the time, was unable to account for the principles of selection behind their identification of central forces in history. Historicism was ever present in Germany at that time, and it was idiographic rather than nomothetic.

The *two traditions*—in addition to the prevailing historicism just mentioned—were Neo-Kantianism (in Weber's case, the Neo-Kantianism of Rickert's southwest or "Baden" school) and Austrian political economy (i.e., Carl Menger's marginalism). Both of them left their imprint on Weber's "value–aspect–choice methodology," in which interests or perspectives played the central role in explaining how social-scientific research and the choice of themes could be governed by the interests or perspectives of the researchers involved.

The *three controversies* were as follows. Weber's ideal type, is an attempt to help the historicists in the Schmoller camp (the younger historical school) out of their cornered position in the famous *Methodenstreit,* the central controversy forming the background to Weber's methodology. The other two controversies were the *demarcation or specificity debate* and the *objectivity debate*. Let us discuss these in turn.

1. The *Methodenstreit* (controversy over method) between Gustav Schmoller and Carl Menger peaked in the 1880s. The central issue was how

to establish laws. This placed the historicists in a vulnerable position, since their natural inclination to the contrary was to be ever more idiographic, in the spirit of Leopold von Ranke. So by wishing to be idiographic, they were handicapped in terms of laying down the laws of history. Throughout the 19th century, history (seen as idiographic) versus theory (seen as nomothetic) was the main divide, and it still is today. Weber launched his ideal-type method in response to the *Methodenstreit*.

2. The *demarcation debate* or *specificity controversy* had to do with a discussion carried out within the antipositivist–historicist camp regarding the grounds on which the specificity of cultural or historical "science" (i.e., the social sciences) could be argued. The aim was to carve out a safe realm for the human or social sciences that could not be easily invaded by the ideal of unified science. In this way, the social sciences were to be demarcated from the natural sciences by the use of a certain criterion: Were the two kinds of science different in terms of content or the methodology employed? In the specificity debate, Weber actually sides with Wilhelm Dilthey, the father of hermeneutic understanding, in that the *object* (and not the method) is the main difference between positivist natural-scientific explanation and the "moral" sciences. But Weber chose to do so by applying and developing Rickert's method, with its lucid concept formation, by explicit value premises, as Gunnar Myrdal later would call them. Yet it is rather a myth that Weber is a close follower of Dilthey. Weber refers to Dilthey 14 times; however, almost all of them are in the first Roscher and Knies essay (1903), the first in a series of methodological essays from 1903 to 1907. Weber never uses the term *hermeneutics*. His ideal types of rational action are formulated so that "even a Chinese would understand."
3. The *controversy over objectivity:* Around the turn of the 20th century, the problem of intersubjective confirmation and objectivity was addressed full-front in social science, although philosophers such as David Hume and Jeremy Bentham had paved the way a long time before.

The objectivity debate, regarding testable and intersubjective truth, still goes on, although it peaked within the German Social Policy Association in 1913. The interpretations of Weber's position on offer are debatable, but very few would deny that he is an anti–natural law advocate, something made explicit in the early paragraphs of *Economy and Society.* In trying to understand his position on objectivity, we must keep in mind that in Weberian anti-metaphysics there are no firm starting points and no transcendental truths. Instead, a point of view has to be postulated as a starting point or goal value posited for policy recommendations. Going back to what was mentioned earlier, this ultimate value cannot be proved by means of science. Whether such starting points might be found by other means is a somewhat open question in Weber's case. There is, moreover, a long debate about Weber's own ultimate value, whether it was the contemporary cultural values of liberalism or nationalism. However, in "Suffrage and Democracy" one gets the sense that culture itself, more precisely German culture, is the ultimate value.

In the famous "Objectivity" essay of 1904, Weber's notion of ideal type is formulated in a negative way, as a list of what it is *not*. He uses the term *einseitige Steigerung* (one-sided accentuation), indicating that concept and reality are not isomorphic. *Steigerung* has often been supposed to be central for the understanding of the ideal type as heuristics. It is, however, only used once in Weber's collected methodological writings. It is further often assumed that Weber's ideal type is a method of empathy; this is an exaggeration. Weber's interpretive *Verstehen* is of a rational kind, and Carl Menger's rational actor model served as a prototype or model for him. Weber's *Verstehen* has nothing to do with psychology, neither in the sense of a "basic law of psychophysics" nor in a hermeneutic empathetic sense. This can be seen in the use of the card game Skat as an example in his methodological essays, in which understanding is an act of rational interpretation followed by ad hoc explanations of anomalies.

Additional Influences

The account offered so far does not exhaust all the influences on Weber's methodology.

a. John Stuart Mill's canons of comparative research were very likely an additional tacit influence on Weber's comparative sociology of religion. Weber, in a letter to the medieval historian Georg von Below, explains why he needs to underpin his Calvinist thesis laid out in *The Protestant Ethic and the Spirit of Capitalism*

by a study of all other rational religions. For a German scholar, British influences could be a rather sensitive issue at the time, despite *Geisteswissenschaften* being a translation of Mill's "moral science."

b. Weber also refers to Marx's analysis of the logic of the capitalist mode of production as an ideal type. Weber's historical materialist influences are present in *The Social Causes of the Decline of Ancient Civilization* (1896), in contrast to his Calvinist thesis.

c. Yet another less visible influence is Georg Simmel. They knew each other well and took each other for granted, without much need for explicit references. Weber's copy of Simmel's book—kept in the Weber archives in Munich—on Nietzsche and Schopenhauer is full of Max Weber's annotations in the margins.

Weber's Influence on Contemporary Social Thought

Weber's methodology has been extremely influential, serving as a starting point for several extensions. Below, we shall present the three prominent cases we introduced earlier: (1) Talcott Parsons's macrosociological functionalist system, (2) Paul Lazarsfeld's survey tradition, and (3) Alfred Schütz's phenomenology.

But first some different examples. (a) A noteworthy exception where no influence can be seen is that of the Chicago school, despite both its historical and its thematic affinities with Weber's thought. (b) Another case is the Frankfurt school, which appears to be a synthesis of Weber and Marx. Jürgen Habermas wrote a whole book on Weber, which, however, has played a rather minor role in modern Weberology. (c) On a different front, as far as rational choice theory goes, there is again not much of an influence. Employing Weber as a rational choice pioneer has its limits, since his research deals mainly with unintended consequences in need of idiographic clarification. (d) On the other hand, Weber's so-called scientific value relativism has been particularly influential in Scandinavia, with its strong anti-metaphysics inclination. It was initiated by Axel Hägerström's "value nihilism" and then carried on within Scandinavian legal realism by scholars such as Gunnar Myrdal and Alf Ross.

Parsons's misrepresentation of Weber is rather obvious; already in the headline of his translation of *Wirtschaft und Gesellschaft* (*WuG; Economy and Society,* Part 1), Parsons used the label *theory,* although Weber explicitly states that it is *not* a theory. However, Parsons might well have saved Weber's sociological legacy for posterity by producing a macrosociology out of his taxonomy in *Economy and Society*—a successful wishful extension that became a cornerstone of sociology.

Lazarsfeld also displays a paradigmatically biased reaction to the ideal type, denouncing it rather as an inhibiting mishap and negative test case suffused by the German "*Verstehen* language." Lazarsfeld instead lists a number of surveys carried out by Weber as pioneering, such as those in his investigations in industrial sociology from 1908, his survey of the design of opinion polls, his survey of the press, and so on.

Schütz does not neglect the problem of intersubjectivity, one of Weber's most crucial concerns. Schutz wrestles with transcultural empathy and is stuck with a lack of rational evidence, something that Weber provides with the rational actor model.

That three dominant and competing paradigms are built from the same cornerstone is a problem insofar as they all claim to be interpretations of Weber. It illustrates an inherent problem with approaches to classic texts that read them as if they were valid in present times. Classic texts should be left in their contexts and are better understood there.

Concluding Remarks

Max Weber can be seen as an antisociologist within sociology. He is part of a longer tradition of secularization and calculability going back to as far as Niccoló Machiavelli, with Thomas Hobbes and Jeremy Bentham as midway stations. Despite his enormous influence, he is not a genuine innovative classic introducing a wholly new paradigm or a "rupture" in the Kuhnian sense. He is rather a mediator.

It is also fair to say that Weber's writing a century ago is no up-to-date guide in methodology. He is nevertheless still with us, since the main methodological and philosophical divides surveyed above have remained the same for the past two centuries. He thus occupies a prominent strategic place in intellectual history. His legacy is rich yet split into many currents.

If you build at a crossroad, you get many followers.

Weber's *Verstehende* Approach

A *Verstehende* ("understanding," from the German *verstehen,* "to understand") approach emphasizes that any systematic empirical study of culture and society must begin and end with the examination of their meaning as experienced in the lives of human beings. Similarly, human behavior must be understood as *meaningful action*. In Max Weber's (1864–1920) case, the approach found expression in three main areas: (1) in accounts of motivation, most famously in the Protestant work ethic; (2) in reflections on the inner logic of life spheres, such as religion or the economy; and (3) in Weber's ideal types of bureaucracy or individual rational action. Underlying all the examples of his approach was the persistent demand that the social scientist should account for the course of human affairs by relating it to the intentions, beliefs, and actions of individuals.

The Person and His Time

The German intellectual context of Weber's work involved intense disputes around the application of natural-scientific methodology in fields as diverse as experimental psychology, economics, and sociology. Darwinian science and an aggressive Nietszchean secularism challenged Christian beliefs and the Kantian philosophical grounding of ethics, while Marxism denied the separation of theory and practice in its confrontation with existing political structures.

Weber came from a family connected with the textile industry and national politics. He became a lawyer and social researcher before becoming a professor of economics and finance in 1896. His fierce polemics gained him national recognition in both academic and public policy debates, asserting both the intellectual independence of academic social science and the relevance of its methods and findings to political life.

In a context of rising nationalism, Weber combined liberal individualism with patriotism and a commitment to scientific objectivity. He recognized fully the contradictions that arose between them. Even while asserting that the individual was the basic unit, the atom of social science research, he acknowledged the deep internal conflicts experienced by the modern individual and in his own life. Indeed, for him, conflict was a primary aspect of modernity, unresolvable except by retreat into old faiths that he could no longer share (his mother had been a devout Protestant Christian). His vast legacy of correspondence with friends and colleagues, as well as his published work, are the most compelling evidence, unrivalled in its extent, of the intimate connections between personal agonies, political outlook, and intellectual contributions to knowledge.

Themes

Weber left no systematic account of his *Verstehende* approach. Considering the many and varied ways it was exemplified in his work, we can group his concern for *Verstehen* under three main headings: (1) individual motivation, (2) life spheres, and (3) ideal types.

Individual Motivation

In the first place, individuals are bundles of needs, drives, passions, and beliefs. Weber did not consider himself a psychologist, although at one point he conducted a survey of psychological factors in factory workers' output. But it was always the framing of these in social relations and the way they were translated into meaningful patterns of action that was his primary focus. The most celebrated example of this theme occurred in his 1904–1905 study of the motivations behind early capitalism, *The Protestant Ethic and the Spirit of Capitalism*. We arrive at an understanding of the individual's response to the idea of predestination not from its logic but by appreciating the anxiety about salvation it promoted and the way this was allayed by hard work. In what Weber called "the paradox of consequences," a new work ethic gave an extra impetus to capitalistic behavior in this world, even though the hopes of the believer were centered on the next.

This nexus of beliefs, behavior, and economic conditions was a theme he repeated in extensive comparative studies of religion. In India and China, he found religious and ethical doctrines reinforcing enduring systems of social relations, whereas in ancient Israel, he found a persistent thread of religious rationalism demanding that everyday life should be subject to divine law and encouraging involvement in a project to save the whole people.

Very often Weber's accounts of religion have been interpreted as a direct refutation of Marxist materialism, though he rejected replacing a one-sided determinism with another that was equally one-sided. His *Protestant Ethic* essay was followed by one showing how in the United States people might join a church to gain business opportunities. He was an advocate of a multicausal interpretation of social life where ideas worked more often in indirect ways, though, drawing on the image of switching points on a railway track, he also argued they could move the underlying course of history in one direction rather than another.

Life Spheres: Coherence and Conflict

In his reflections on the underlying course of history, we can find a second theme in his *Verstehende* approach. As a German lawyer, he was familiar with the state administration and bureaucracy as a rational system of rules depending on the objectivity and sense of duty of trained officials. Later, he saw the rationality of bureaucracy as an aspect of a comprehensive process of rationalization in every sphere of life: in capitalist finance, in forms of production, and in science above all, but also in sexual behavior, where he was fully aware of trends in psychoanalysis, and in religion, where from time immemorial theologians had sought to develop ritual and dogma to justify the ways of God to human beings. However, the quest for meaning in life, which he tended to see as a universal desire under conditions of the rationalization of every life sphere, meant a growing cleavage between the search for personal fulfillment and the demands of an increasingly machine-like world, an "iron cage."

For Weber, a *life sphere* was a complex of meanings—a set of activities, ideas, and beliefs connected with each other through logic, mutual implication, and necessary association. Examples of life spheres were religion, economics, sexuality, and the media. He never attempted a systematic account of life spheres, but in their inner coherence, they had power over people and, driven to ultimate conclusions, they came into conflict with each other. The classic case was conflict between the demands for a strong state and a free market, the theme of Weber's controversial inaugural professorial lecture.

Advancing rationalization meant increasing conflict between different life spheres. Weber was the exact antithesis of a celebrator of progress and the advance of reason. Human beings pursued ideas to their logical conclusions and suffered the consequences. If they believed in complete sexual freedom, they would suffer the consequences in their personal relationships. His *Verstehende* approach conveyed a tragic view of human existence, caught between the remorseless advance of rational intelligibility in institutional life and a deepening sense of personal conflict.

Rationality and Ideal Types

Weber never addressed the nature of rationality directly, even though his work is pervaded by the terminology of rationality and he wrote at length on its influence in human affairs. He did, however, argue that in the shape of the rational ideal type, it was an indispensable instrument for social research and historical explanation. This third aspect of his *Verstehende* approach involves his most explicit concern for scientific methodology and bears his signature more than any other of his contributions to knowledge.

An ideal type is a complex of meanings that the historian or social and cultural researcher summarizes, identifying its most salient features to distinguish it from other such complexes and present it in a more clear-cut and coherent way than might ever be found in reality. It is a rational construction by the analyst rather than an existing entity. Reality and the ideal type must not be confused—not that Weber appears to have had any doubts about reality. For him, reality was what the social and cultural sciences dealt with, but the problem was that there was no way to represent reality in its fullness and it was necessary to have clear concepts to illuminate areas of investigation. Weber considered the idea of bureaucracy as an ideal type. The image of a perfectly functioning hierarchy of offices, dutiful officials, and complete records existed nowhere in reality, not even in his beloved Germany, but it served as a template against which existing state administrations could be compared.

Most famous of all his ideal types was homo economicus—economic man—the premise of classical economics, which imagined a rational actor finding the means to pursue objectives with the least possible cost, and therefore maximizing personal satisfaction, and then asking what the aggregate outcome would be in a market situation where everyone behaved in that way. Weber, as an economist who was also a historian, deemed that this kind of conduct was never fully realized in actual life but real situations approximated to it sufficiently because people strove to achieve this degree of rationality, and the resulting economic analysis was therefore a very powerful tool for understanding how real markets worked. This kind of economic theory clinched for him the worth of ideal-type analysis.

Rational action of an individual actor supplied the social scientist with the most understandable data on which to base explanations of the course of social events. When Weber sought to catalog the most elementary concepts necessary for a rigorous discipline of sociology, he identified two kinds of rationality within a fourfold classification of action. The first was a rationality of ends and means and the second, a rationality of conduct that realized values. Additionally, he recognized two types of nonrational action—the expression of emotion and the observation of tradition. These four basic types of action were the ultimate constituent elements in all his subsequent definitions of complex types of social relations, including authority, representation, organization, and the state.

Individualism in Method and in Life

Weber's typology of action exemplified a ruling dictum in his *Verstehende* approach to history and the scientific study of human affairs. All explanation had in principle to be brought back to the actions of individuals. This applied to even his most famous concept, *charismatic authority,* possessed by figures as different as, for example, the Dalai Lama and Napoleon.

It depended ultimately on individual followers acting on a belief in their extraordinary powers. Weber was correspondingly dismissive of sociologists or political scientists who sought to ground their academic discipline on collective concepts like society or the nation and denounced those who used the academic lectern to preach patriotism in their name.

Weber was both a fervent adherent to the German national cause and a dedicated believer in the rigors and discipline of scientific research. Intellectually, his position was later called *methodological individualism*. In his personal life, his individualism took the form of heroic struggle with inner demons rather than the free expression of individuality, despite the widespread popular cult of personality. The asceticism of his religious upbringing stayed with him long after he had left its beliefs behind. Weber exemplified in his life the modernity that was the focus of his work. The demand to find meaning through rationality, the quest for understanding human life on this earth when traditional answers had been rejected, was for him the fate of the modern person. The scientist took that quest to new levels and incurred the additional grief of knowing that it could never reach its goal.

Welfare Economics

Welfare economics is a subfield of economics; it shares many concepts with microeconomics, but it is more concerned with *improving* the welfare of economic agents than with explaining how markets operate. Welfare economics has been somewhat marginalized within the context of contemporary economics. Some authors, notably Anthony B. Atkinson, have argued that welfare economics has ceased to exist for all practical purposes. But its concepts and methods, sometimes under different guises and in revised forms, continue to be used in many settings that fall under the rubric of "normative economics." The application of economic reasoning to the problem of identifying and rectifying unfair or otherwise undesirable economic and social situations is a research project that is very much alive. It encompasses approaches that have evolved to improve on some of the dilemmas that welfare economics has stumbled on. The original concern of welfare economics with improving the welfare of economic agents (typically measured in terms of preferences over utilities, e.g., utilities derived from different levels of income, consumption, etc.) has to some extent been replaced by a concern for ways of improving their well-being defined in broader terms. This entry looks at the origins and evolution of welfare economics before concluding with a reflection on the challenges that lie ahead.

From the "Old" to the "New" Welfare Economics

Welfare economics asks, "How can societal welfare be improved?" This is not a purely hypothetical question. There are many circumstances where markets seem to fail to allocate resources adequately, such as when "negative externalities" cause some people to unfairly carry part of the costs of activities profitably undertaken by others (e.g., industrial pollution). In the mathematical language of economists, it can be expressed as follows: Maximize the function

$$W = W(w_1, w_2, \ldots, w_n),$$

subject to some feasibility constraints, in a society composed of n individuals (the welfare status of a representative individual i being represented by w_i). As long as the function remains purely generic, as stated here, the problem remains merely hypothetical. However, the pioneers of the

discipline, notably Alfred Marshall (1842–1924), F. Y. Edgeworth (1845–1926), and Arthur Pigou (1877–1959), assumed that welfare could be measured in terms of the utilities assigned by the economic agents to allocations of available resources in the economy. Because they treated utilities as cardinal measures, and therefore addable, the previous equation then becomes

$$W_x = u_1(x) + u_2(x) + \ldots + u_n(x),$$

where u_i stands for the utility assigned to the allocation x by the representative individual i. To use a familiar metaphor, let x_1 stand for a particular division of the pie that we want to compare with other ways of cutting it, say, x_2. If $W_{x_2} > W_{x_1}$ then x_2 should be preferred to x_1. Thus, the hypothetical problem mentioned above now becomes the practical one of finding the particular allocation of resources (let us call it x^*) that maximizes this fully specified function. The philosophical background of this approach is clearly utilitarian. Although Bentham was aware of the methodological difficulties attendant on summing up disparate utilities, the Pigovian welfare function evokes Bentham's maxim: "the greatest happiness for the greatest number of people."

This model did not remain dominant for very long. In light of criticisms leveled at it by Lionel Robbins in the 1930s, it became accepted that cardinal measures of utility cannot be objectively assessed. (This argument was later revised by positing that the only valid data are "revealed preferences," i.e., the observed choices made by individuals on the basis of inaccessible and noncomparable psychological dispositions.) The alternative is to use only ordinal ranking; the "New Welfare Economics" was established on this epistemological foundation. The touchstone of this approach is the concept of Pareto efficiency. An economic outcome *A* is more efficient in a Paretian sense than an outcome *B* if at least one agent is better off in *A* and no one is worse off; a Pareto optimum is a situation in which no one can be made better off without making at least one other agent worse off. Although informationally poor, this concept owes its success to the fact that it can be shown that the competitive market equilibrium happens to be a Pareto optimum. (This is known as the first "fundamental theorem of welfare economics.") There is, however, nothing intrinsically desirable, let alone just, about Paretian efficiency, except perhaps that it can be considered to be a rather robust protection against envy. To allow for transfers that could compensate the "losers" for the gains achieved by their more advantaged counterparts, several options were proposed (e.g., the Kaldor-Hicks compensation criteria). These suffer, however, from two drawbacks. One is of an ethical nature: The transfers envisioned by Nicholas Kaldor (1908–1986) or John Hicks (1904–1989) are purely hypothetical—in other words, welfare economics says nothing about the *actual* achievement of a fair redistribution. The second weakness is methodological; it can be shown that the criteria proposed by Kaldor or Hicks lead to intransitive results—transfers can lead to a vicious circle where one moves from situation *A* to situation *B* and then to situation *C,* only to come back to *A*.

A more promising development was proposed in 1938 by Abram Bergson, and later further developed by Paul Samuelson in the form of the Bergson-Samuelson social welfare function. *If* policymakers can assume that some particular end is socially desirable (there are, of course, many such ends, including Benthamite utilitarianism), then it is possible to build a social welfare function based only on ordinal rankings. At least in principle, such a function should be instrumental in identifying the optimal allocation of resources given the end chosen and given a "production–possibility frontier."

Impossibility Theorems or the Achilles's Heel of Welfare Economics?

In the early 1950s, Kenneth Arrow proposed a theorem that dashed the hope of ever finding an appropriate social welfare function. Most people would agree that in a democracy the electoral process is the only way to identify the criteria defining such a function. What Arrow demonstrated was that there is no paradox-free method of aggregating individual preferences into a social choice that expresses a collective preference for some particular way of allocating societal resources. If one assumes that any democratic procedure must meet a few minimum conditions, such as (a) "unlimited domain"—that is, all alternatives are allowed; (b) Pareto optimality—in other words, if every individual prefers *a* to *b,* then the social choice is also *a;* and (c) "independence of irrelevant alternatives"—that is, if *a* is preferred to *b* when there is a choice between *a, b,* and *c, a* should still be preferred to *b* when a fourth alternative, *d,* is added to the mix; thus, when there are more than two agents who must choose among three or more alternatives, only a "dictator" (i.e., someone whose

preferences prevail over those of everyone else) can break potential intransitive cycles (see above). But, evidently, the presence of a "dictator" is inadmissible in a democratic polity. Soon after Arrow proposed his theorem, several other comparable impossibility theorems were formulated.

The simplest response is to relax some of Arrow's initial conditions. For example, it can be shown that when all the alternatives can be aligned on a single axis (e.g., a left-to-right ideological spectrum), then cycling is no longer an issue. Behavioral welfare economics is another response. It allows for "irrational" preferences when such preferences can be shown to be empirically observed. But more radical, albeit more controversial, revisions of the research program of welfare economics are now under way.

Beyond Welfarism

A "welfarist" perspective assumes that the ranking of preferences over individual utilities are the building blocks of any welfare economics model. In recent years, several theorists have sought to move beyond this limitation by taking into account not only a wide range of dimensions of well-being, such as health or education, but also normative considerations having to do with the exercise of individual rights, such as the capacity to freely choose how one wishes to live. When such sources of information become available, interpersonal comparisons are no longer ruled out. The point is not that such measures are not themselves also partly subjective but rather that, contrary to utilities, they are not incommensurable —that is, intersubjective agreement on the dimensions of well-being is feasible. Reasoned debates can produce consensual agreement about states of the world that are more or less desirable (e.g., famine is to be avoided); democratic procedures other than voting open up, and Arrow's disturbing conclusion no longer appears so formidable. Many economists are still hesitant to move in that direction, but as the saying goes, "The train has already left the station." Nonwelfarism is likely to become the framework within which the future of welfare economics will be decided. Happiness economics encompasses various empirical approaches to the measurement and analysis of well-being. A more theoretically sophisticated path has been opened up by Amartya Sen's "capabilities approach." Sen distinguishes between "functionings" and "capabilities": The former enter into the definition of actual well-being, while the latter are a vector of functionings that a particular individual under specific circumstances has access to. For Sen, the goal of social policy is to equalize capabilities by making it possible for all to aspire to the functionings that they ought to be entitled to achieve as human beings deserving decent lives.

New Dilemmas

Nonwelfarism, however, raises some serious questions. While utilitarianism has no place for rights, nonwelfarist approaches risk falling into the trap of paternalism by arbitrarily selecting which rights or values, including the priority granted to freedom and self-realization, ought to be pursued. Moreover, the implementation of such schemes could challenge the political legitimacy and exceed the fiscal capacity and administrative resources of governments.

We-Mode, Tuomela's Theory of

The *we-mode* theory originated in Raimo Tuomela's work and provides a philosophical and conceptual account of human social action and institutional reality. The theory accounts for phenomena such as collective activity, cooperation, and coordination in group contexts, as well as the mode of existence of institutional and corporate entities. The we-mode theory puts forth an ontologically individualistic (or *interrelationistic*) but conceptually collectivistic theory of *collective intentionality* that accounts for the irreducibility and apparent purposiveness of joint action and other collective intentional phenomena, such as collectively accepted institutional beliefs and collective emotions. The we-mode theory also relates to issues in social ontology concerning the mode of existence of social entities by providing a functional account of groups as social systems, abstractly formulated task-right systems with impersonal roles or positions that may be filled by any qualified members. The we-mode theory is accordingly conceptually equipped to account for the unity of institutions and organizations such as trade unions and business corporations, as well as institutional practices such as economic exchange and agreement making. The paradigms of we-mode thinking and acting are nevertheless to be found in simple joint actions where the participants intentionally cooperate as a group, as when singing a duet or painting a house together. This entry discusses the main conceptual features of Tuomela's we-mode theoretical framework and contrasts it with the *progroup I-mode,* ending with a brief discussion of recent developments within the we-mode theory and prospects for further research.

The We-Mode Theory

The we-mode theory may be seen as providing a revisionary conceptual framework of agency, which complements the more individualistic frameworks that are currently prominent in social science. The we-mode theory approaches social reality from an intuitive macrosocial or top-down perspective, where groups are considered the primary agents and individual members are viewed as position holders within those groups rather than as autonomous individuals who reason from their private points of view. The members of we-mode groups are assumed to give up part of their natural authority to act to the group and to be collectively committed to the group's activities. They are naturally disposed to perform their duties as group members and to conform to the directives, which are conferred on them by their collective decisions or by their leaders, depending on whether we are dealing with democratically or hierarchically organized groups, respectively. The most central authoritative element within the group is what Tuomela calls its *ethos,* which consists of constitutive contents such as goals and beliefs that have been collectively accepted by the members *for the group*. The collective construction of the ethos grants to groups a kind of intentional autonomy over and above its members, since collective acceptance is based on implicit or explicit agreement making, including compromises and interaction effects that cannot be reduced to the members' intentional psychologies. The group is irreducible to its members also for the further reason that it may survive partial or complete change of members, provided that the new members accept membership and are prepared to go along with the group's activities.

The we-mode framework is in itself ambivalent between an instrumentalist and a realist interpretation of group agency, but there are reasons to take it as a genuine explanatory theory rather than as a mere conceptual framework for intentional interpretation. The central motivating idea behind the we-mode framework is that groups often appear to behave in a purposive and goal-directed manner, thus warranting their treatment as agents at least in an instrumental sense. The we-mode theory is nevertheless in the last instance vindicated by its consequences rather than by its intuitive plausibility, and the onus is accordingly on showing that the behavioral predictions and explanations that are generated within the we-mode approach differ from the ones that are generated within the I-mode. The theory must of course grant that groups are not the same kinds of agents as individual agents, since they lack the corporeal and qualitative characteristics of ordinary human individuals. They may still be treated functionally as agents, which are real and active causal forces in the social world. This is all consistent with individuals or (in the last instance) their neural states and behavioral dispositions being the fundamental causal motors in the social world.

Thus, we may say that the intentional agent in the we-mode approach is the group but the ontological agent is the individual.

The we-mode framework is based on an intuitive analogy between individual and collective agents, which may be elucidated in terms of the three criterial features of the we-mode: *group reasons, collective commitment,* and the *collectivity condition.* These constitutive features of the we-mode framework are argued to be interdependent but irreducible to one another and to the standard individualist framework of agency. The we-mode framework is thus irreducible to the individualist (I-mode) framework of agency in a manner that is not entirely unlike the way in which the individualist framework of intentional interpretation has been argued to be irreducible to the vocabulary of the physical and biological sciences. The difference between the two cases is that in the latter we are dealing with reduction between two different conceptual schemes (viz., the conceptual framework of the physical and biological sciences against the conceptual framework of intentional interpretation), whereas in the former we are dealing with reduction between two different applications of essentially one and the same conceptual scheme (viz., groups vs. individuals as intentional agents).

The analogy view regards groups as agents that may act instrumentally in light of the motivating reasons that are provided by the collectively accepted beliefs, desires, and intentions that are contained in its ethos. These reasons are normally thought to provide the members with reason-based directives, which are *preemptive* (viz., exclusionary with regard to competing individualistic I-mode reasons) and *presumptive* (viz., sufficient in the absence of stronger countervailing reasons to the contrary). The notion of group reasons may be further elucidated by drawing a distinction between (a) the *group agent's reasons* relative to its ethos and (b) the group-based reasons (or *group reasons*) of its members. The group agent's reasons are provided by the collectively accepted contents in its ethos, whereas the group reasons of its members are the proximate reasons that they act for when they are performing their duties as group members. The distinction is especially relevant in the case of hierarchically organized groups, where only a proper subset of the members have insight into the group's constitutive goals but other members are prepared to go along with the group's activities and follow the directives that are conferred on them by the leaders. The group members' reasons may also be seen to involve elements that are not involved on the level of the group agent's reasons, because the members are normatively and group-socially obligated to one another to perform their parts as group members. The we-mode theory accordingly posits a kind of normative emergence when we move from the group agent's reasons to the group reasons of its members, according to the most recent formulations of the theory by Tuomela.

The satisfaction of an intention requires commitment to bringing about the content of the intention, and the group members may thus be required to be collectively committed to their joint intention, according to the analogy view. The notion of commitment entails a disposition to think and act in an appropriate manner in order to bring about or maintain the content of the intention, namely, to see to it that the content of the intention is realized. This may require performing relevant practical inferences in addition to performing the right bodily actions, and collective commitment in particular requires the agents to take the group into account in their practical reasoning and deliberation (e.g., "We will perform *X*"; "Our performing *X* requires that I do *Y*"; "Hence, I will do *Y*"). The members of a we-mode group are group-socially committed to one another to perform their parts in a manner that incurs properly normative rights and obligations between them, as remarked in the discussion of group reasons above. The members may be expected to step in and help one another if needed and to perform whatever is required for the satisfaction of the collective goal, even though that may require performing more than their distributive share (in the limiting case, the entire collective action may be performed by a single member, while the rest of the group monitors the situation and is ready to step in if needed). This results in more solidarity and stability being present in the we-mode collective agency than in the I-mode, where the members are required to deliberate separately when the division of tasks changes.

The satisfaction conditions for the group's intention are fixed by the content of the intention and by the *collectivity condition,* according to which the collective intention is satisfied simultaneously and interdependently for all individual members of the group on conceptually necessary grounds. Tuomela, in his

Philosophy of Sociality, allows there to be weaker *progroup I-mode* counterparts to the central notions of collective commitment, group reasons, and the collectivity condition, where the modal component does not hold true. Thus, a collection of individuals may each separately intend to realize the same outcome by means of their coordinated behaviors, but here the simultaneous satisfaction of their intentions is a contingent and situation-specific matter. They do not intend to act together as an irreducible social whole, that is, as a group or as a body (metaphorically speaking), and therefore they are not bound together in the strong we-mode manner. There thus exist both we-mode and progroup I-mode collective intentionality, and both are required for providing a complete account of social life. The we-mode may be seen to provide the fundamental common ground of human society, but even we-mode social institutions tolerate an important amount of activity in the I-mode: One need only think about what would happen to social institutions such as the economy if people suddenly stopped using money (a we-mode activity or constitutive institutional rule), although the economic sphere is usually thought to consist primarily of egocentric activity.

The We-Mode and the Progroup I-Mode

The main conceptual difference between the we-mode and the (progroup) I-mode is that in the we-mode the conceptual and justificatory direction is top down—from the group level to the member level—whereas in the I-mode, the conceptual and justificatory direction is bottom up—from the member level to the group level. The macrosocial perspective that the we-mode framework incorporates may accordingly be unpacked in terms of a distinction between three levels of explanation and the asymmetrical relations of reduction or explication between them: (1) the macro level of social institutions and collective social reality, including group agents' intentions and their reasons for them; (2) the interpersonal meso level of joint intentions and actions, including group members' collective commitment to their joint actions and group-social normativity between them; and (3) the personal level of (I-mode or we-mode) mental states and attitudes, including the members' part-performance intentions and their coordinative social reasons for performing their shares. The we-mode accounts for (3) in terms of (2) and (1), whereas the I-mode accounts for (1) and (2) in terms of (3). The central opposition in the I-mode/we-mode theory is accordingly not between individual and collective agency but between *private* and *collective* agency—that is, agency that is based (in a conceptual sense) on an individual agent's private mental states and attitudes against agency that is based in part on the group's actions and attitudes. Thus, both I-mode and we-mode mental states are *personal* states in the sense that they are attributed to individuals, but we-mode states are essentially public and group dependent, whereas I-mode states are private and atomistic.

The conceptual relations between the group level, the interpersonal jointness level, and the individual agent level are accounted for in partly circular terms when we are operating within the we-mode framework. The central member-level counterpart of the group's intention is the personal *we-intention,* which may upon analysis be seen to presuppose the existence of a joint intention between the members. Technically, a we-intention may in the present context be understood as a *reason-based we-attitude,* where the others' thinking and acting thus and so is a partial motivating or presuppositional reason for one's own thinking and acting thus and so. Thus, when the members we-intend to perform a joint action (*X*) together, each member intends to perform his part of *X as his part of X,* in part because of the social reason that the others intend to perform their parts of *X*. The circularity of the account results from the fact that the *X* term seemingly cannot be analyzed without reference to the joint intention itself should the entire joint action and not only its parts be intentionally performed. This kind of circularity is nevertheless functionally innocuous because the members may operate on a cognitively nondemanding and pre-analytic notion of joint intention. The group intention, the joint intention, and the we-intentions of the participants taken together may be viewed as equivalent under ideal conditions when each participant is functioning as a full group member; by relaxing this condition, we arrive at quasi we-mode groups, where some of the members function in the I-mode. The modest circularity of we-intentions is not only tolerable but may even be regarded as a vindication of the conceptual irreducibility of the we-mode framework, since it is a characteristic of irreducible concepts that they cannot be accounted for without circularity arising.

The collective attitudes of the group are accounted for within the we-mode approach in terms of the members' reflexive and performative *collective acceptance* of attitudes for the group. Collective acceptance is *performative* in the sense that it creates attitudes for the group on an analogy with declarative speech acts, which have the power to create institutional facts by representing them as true (e.g., "I hereby pronounce you husband and wife"). Collective acceptance is *reflexive* in the sense that it involves reference to itself within its representational content (e.g., "We hereby collectively accept that squirrel pelt counts as money in virtue of our collectively accepting that squirrel pelt counts as money in the group"). The conceptual irreducibility of the we-mode may accordingly be partially brought out in terms of the need for the group members to have a thick reflexive concept of "we" that is operative in the collective construction of attitudes for the group. This strong "togetherness" notion of "we" may be pulled apart by philosophical analysis from the weak aggregative notion of "we" that I-mode social groups are based on, although ordinary language does not make such a distinction. The difference between the two is crucial for understanding human sociality, if the mainly functional arguments that have been put forth in support of the I-mode/we-mode distinction are tenable. The present entry has concentrated on the main conceptual features of the we-mode framework, and the reader is referred to the original works by Tuomela for a closer survey of his arguments in favor of the we-mode.

Recent Developments in the We-Mode Theory

There have been two important foci of research in recent years within the we-mode approach: (1) group-internal normativity and the authoritative nature of group reasons and (2) the relation between the we-mode framework and team reasoning in game theory. The following discussion concentrates on the relation between team reasoning and the we-mode approach, since recent research on group-internal normativity was already discussed above in the context of group reasons and group-social commitment. Within the I-mode/we-mode theory, individuals who function in the I-mode think and act on the basis of their own beliefs and preferences, whereas in the we-mode, they think and act in terms of their collectively accepted attitudes and may therefore be characterized as being engaged in *we-reasoning*. To elaborate, whereas in the I-mode the primary practical question is "What should I do?", in the we-mode the primary practical questions are "What should our group do?" and "What should I do as a group member?" As has been noted by economists and game theorists, framing a decision problem in terms of *team thinking* may help agents achieve collectively rational outcomes in coordination problems such as the Hi-Lo and in social dilemma situations such as the Prisoner's Dilemma. Relating their notion of we-reasoning to the game-theoretic notion of team reasoning, the following claims have been put forth by Hakli, Miller, and Tuomela: (a) operating in the we-mode may lead to different action recommendations from the progroup I-mode, and it may prevent dilemma situations from arising because the agents frame the situation as a collective-decision problem; (b) we-reasoning (in the we-mode) can decrease the amount of Nash equilibria in decision problems, but it cannot increase them, and it may thereby increase the likelihood of collectively rational solutions and lead to greater collective order and stability than (progroup) I-mode reasoning; and (c) we-reasoning (in the we-mode) economizes the members' cognitive activities since they may proceed on the assumption that the others will perform their parts and are thus not required to be aware of the others' specific mental states to the same extent as in the (progroup) I-mode. Nevertheless, there remain substantial problems about relating the impoverished conceptual framework of game theory to the richer action-theoretic concepts that are employed in philosophy of action and within the we-mode approach.

World-Systems Analysis

This entry introduces the influential social-scientific systemic approach known as *world-systems analysis* and reviews its methodological precepts, showing their philosophical import.

World-systems analysis emerged from the context of Dependency Theory, in response to modernization theory, which suggested that failure to develop was the fault of nations themselves, not of systemic forces. Modernization theory argued that development would succeed if the less developed simply acquiesced in economic and political programs favored by and allegedly followed in the West. Dependency scholars suggested that development and underdevelopment were two sides of the same coin, acting to develop a core and underdevelop a periphery. When critical scholars turned to broaden their study of core and peripheral social structures and trace their historical origins and relations, world-systems analysis emerged.

Philosophical and Methodological Precepts

World-systems *analysis* is not a theory but an approach that includes several philosophical and methodological positions, being (a) systemic (world economies, not nation-states and/or firms, are the appropriate unit of analysis), (b) materialist (focused on economic processes, especially capital accumulation), (c) transdisciplinary (emphasizing holistic coherence by transcending traditional academic disciplines), (d) historical (deploying historical method as intrinsic and extending research back 500 years or more), and (e) methodologically open (and nondeterministic).

Let us view these methodological positions in some detail:

a. *System:* World-systems analysis escapes the limitations of state centrism. During the Romantic Period, the history of most Western nations was recast into a statecentric mold. History was rewritten to portray states as self-contained units of development. Influenced by the "total-history" approach and the perspective of the *longue durée* pioneered by Fernand Braudel in the 1940s, world-systems analysis rejected the state as the primary unit of analysis, in favor of new concepts. Dependency theory and world-systems analysis agree that the whole is greater than the sum of its parts and that no part (e.g., nation-state) can be adequately understood in isolation from its position, role, and function in the whole—in other words, the world-system and its historical structure and processes.

b. *Economic materialism:* A materialist perspective informs world-systems analysis by a focus on capital accumulation as a force animating individuals, families, firms, states, and systems. Material wealth derived from the production of commodities for exchange on the world market was redeployed to reshape social structures and ensure future accumulation. World-systems analysis contends that the origins of capitalism emerged in the European world economy in the "long 16th century" (1450–1600). This period of "transition to capitalism" is understood as a modal shift from a system where territorial power yielded economic wealth to one where capitalist wealth yielded (geo)political power. Once consolidated, this new "logic" constituted the central dynamic of the "modern world-system," understood to be distinct from that of any earlier period. In a break with this interpretation, a group of scholars led by Andre Gunder Frank and Barry K. Gills challenged the idea that the critical structuring element of the world system emerged with the transition to capitalism within Europe, and highlighted

continuities in structure and process before and after the alleged transition to capitalism. This continuity included nearly all the critical elements attributed to the modern capitalist world-system. A major disagreement emerged. The new world system approach (note the lack of the hyphen) emphasizes the thesis that the world system, and its main structure and processes, existed well before 1500 and the rise of European hegemony. This perspective attracted a multidisciplinary circle of scholars in prehistory, world history, anthropology, sociology, geography, political science, and international relations.

c. *Holism/transdisciplinarity:* Both of the world(-)systems approaches outlined above accept the proposition that holistic analysis of social phenomena is preferred. Development cannot be adequately apprehended without full attention to history, politics, sociology, or anthropology. As part of world(-)systems analysis, scholars considered the separation of the social sciences and the consequent compartmentalization and fragmentation of knowledge, which, however, has generated the impetus to reintegrate insights into a new coherent structure.

d. *History:* World(-)systems analysis is a historical method that attempts to trace the origins of capitalism and capture its dynamics in world history. To do so, some advocate a profound differentiation between precapitalist and capitalist social systems, and for some the "long 16th century" remains the pivotal transitional period in world history. The chronology and periodization of the critical junctures of the world(-)system have never been agreed on. Some scholars suggest that capitalist practices were in place by the 14th or 15th century, while others push similar dynamics back into the 12th and 13th centuries and eastward into the Orient. A more radical interpretation pushes the advent of capitalist processes back to the classical period, or even deep into prehistory. Another tendency of world(-)systems analysis adopts the comparative method to look at social systems, including the study of very different forms and scales of world-systems and world economies, especially in microsystems and hinterlands.

e. *Methodological openness:* World(-)systems analysis adopts a nondeterministic mode, one that emphasizes cyclical conceptions of time and historical processes while not privileging linear conceptions of social change. Not all processes recur, but world(-)systems analysis sees great importance in the repetition of systemic cycles and patterns, such as economic and political rise and decline, the concentration and de-concentration of wealth and power, and cycles or transitions of hegemony. Chaotic processes may give rise to various cycles and trends, but they remain indeterminate in the long term. There is little agreement, however, on what might come next. Following Karl Marx, some argue that the contradictions inherent in the capitalist world economy will eventually lead to its final breakdown and transformation, perhaps into a form of socialism, but the essential elements of any subsequent social systems cannot be predicted. Other predictions suggest a long-term shift in the center of gravity of the world system back toward Asia, and China in particular. There is an emphasis on the utility of world(-)systems analysis to understanding the contemporary global crisis as a global center shift and a hegemonic transition, as well as a civilizational crisis.
