Usability Testing: An Evaluation Process for Internet Communications

Preface

The Internet Encyclopedia is the first comprehensive examination of the core topics in the Internet field. *The Internet Encyclopedia*, a three-volume reference work with 205 chapters and more than 2,600 pages, provides comprehensive coverage of the Internet as a business tool, IT platform, and communications and commerce medium. The audience includes the libraries of two-year and four-year colleges and universities with MIS, IT, IS, data processing, computer science, and business departments; public and private libraries; and corporate libraries throughout the world. It is the only comprehensive source for reference material for educators and practitioners in the Internet field.

Education, libraries, health, medical, biotechnology, military, law enforcement, accounting, law, justice, manufacturing, financial services, insurance, communications, transportation, aerospace, energy, and utilities are among the fields and industries expected to become increasingly dependent upon the Internet and Web technologies. Companies in these areas are actively researching the many issues surrounding the design, utilization, and implementation of these technologies.

This definitive three-volume encyclopedia offers coverage of both established and cutting-edge theories and developments of the Internet as a technical tool and business/communications medium. The encyclopedia contains chapters from global experts in academia and industry. It offers the following unique features:

1) Each chapter follows a format which includes title and author, chapter outline, introduction, body, conclusion, glossary, cross references, and references. This unique format enables the readers to pick and choose among various sections of a chapter. It also creates consistency throughout the entire series.
2) The encyclopedia has been written by more than 240 experts and reviewed by more than 840 academics and practitioners chosen from around the world. This diverse collection of expertise has created the most definitive coverage of established and cutting edge theories and applications in this fast-growing field.
3) Each chapter has been rigorously peer reviewed. This review process assures the accuracy and completeness of each topic.
4) Each chapter provides extensive online and offline references for additional readings. This will enable readers to further enrich their understanding of a given topic.
5) More than 1,000 illustrations and tables throughout the series highlight complex topics and assist further understanding.
6) Each chapter provides extensive cross references. This helps the readers identify other chapters within the encyclopedia related to a particular topic, which provides a one-stop knowledge base for a given topic.
7) More than 2,500 glossary items define new terms and buzzwords throughout the series, which assists readers in understanding concepts and applications.
8) The encyclopedia includes a complete table of contents and index sections for easy access to various parts of the series.
9) The series emphasizes both technical and managerial issues. This approach provides researchers, educators, students, and practitioners with a balanced understanding of the topics and the necessary background to deal with problems related to Internet-based systems design, implementation, utilization, and management.
10) The series has been designed based on the current core course materials in several leading universities around the world and current practices in leading computer- and Internet-related corporations. This format should appeal to a diverse group of educators, practitioners, and researchers in the Internet field.

We chose to concentrate on fields and supporting technologies that have widespread applications in the academic and business worlds. To develop this encyclopedia, we carefully reviewed current academic research in the Internet field at leading universities and research institutions around the world. Management information systems, decision support systems (DSS), supply chain management, electronic commence, network design and management, and computer information systems (CIS) curricula recommended by the Association of Information Technology Professionals (AITP) and the Association for Computing Management (ACM) were carefully investigated. We also researched the current practices in the Internet field used by leading IT corporations. Our work enabled us to define the boundaries and contents of this project.

TOPIC CATEGORIES

Based on our research we identified 11 major topic areas for the encyclopedia:

- Foundation;
- Infrastructure;
- Legal, social, organizational, international, and taxation issues;
- Security issues and measures;
- Web design and programming;
- Design, implementation, and management;
- Electronic commerce;
- Marketing and advertising on the Web;

- Supply chain management;
- Wireless Internet and e-commerce; and
- Applications.

Although these 11 categories of topics are interrelated, each addresses one major dimension of the Internet-related fields. The chapters in each category are also interrelated and complementary, enabling readers to compare, contrast, and draw conclusions that might not otherwise be possible.

Although the entries have been arranged alphabetically, the light they shed knows no bounds. The encyclopedia provides unmatched coverage of fundamental topics and issues for successful design, implementation, and utilization of Internet-based systems. Its chapters can serve as material for a wide spectrum of courses, such as the following:

- Web technology fundamentals;
- E-commerce;
- Security issues and measures for computers, networks, and online transactions;
- Legal, social, organizational, and taxation issues raised by the Internet and Web technology;
- Wireless Internet and e-commerce;
- Supply chain management;
- Web design and programming;
- Marketing and advertising on the Web; and
- The Internet and electronic commerce applications.

Successful design, implementation, and utilization of Internet-based systems require a thorough knowledge of several technologies, theories, and supporting disciplines. Internet and Web technologies researchers and practitioners have had to consult many resources to find answers. Some of these sources concentrate on technologies and infrastructures, some on social and legal issues, and some on applications of Internet-based systems. This encyclopedia provides all of this relevant information in a comprehensive three-volume set with a lively format.

Each volume incorporates core Internet topics, practical applications, and coverage of the emerging issues in the Internet and Web technologies field. Written by scholars and practitioners from around the world, the chapters fall into the 11 major subject areas mentioned previously.

Foundation

Chapters in this group examine a broad range of topics. Theories and concepts that have a direct or indirect effect on the understanding, role, and the impact of the Internet in public and private organizations are presented. They also highlight some of the current issues in the Internet field. These articles explore historical issues and basic concepts as well as economic and value chain concepts. They address fundamentals of Web-based systems as well as Web search issues and technologies. As a group they provide a solid foundation for the study of the Internet and Web-based systems.

Infrastructure

Chapters in this group explore the hardware, software, operating systems, standards, protocols, network systems, and technologies used for design and implementation of the Internet and Web-based systems. Thorough discussions of TCP/IP, compression technologies, and various types of networks systems including LANs, MANS, and WANs are presented.

Legal, Social, Organizational, International, and Taxation Issues

These chapters look at important issues (positive and negative) in the Internet field. The coverage includes copyright, patent and trademark laws, privacy and ethical issues, and various types of cyberthreats from hackers and computer criminals. They also investigate international and taxation issues, organizational issues, and social issues of the Internet and Web-based systems.

Security Issues and Measures

Chapters in this group provide a comprehensive discussion of security issues, threats, and measures for computers, network systems, and online transactions. These chapters collectively identify major vulnerabilities and then provide suggestions and solutions that could significantly enhance the security of computer networks and online transactions.

Web Design and Programming

The chapters in this group review major programming languages, concepts, and techniques used for designing programs, Web sites, and virtual storefronts in the e-commerce environment. They also discuss tools and techniques for Web content management.

Design, Implementation, and Management

The chapters in this group address a host of issues, concepts, theories and techniques that are used for design, implementation, and management of the Internet and Web-based systems. These chapters address conceptual issues, fundamentals, and cost benefits and returns on investment for Internet and e-business projects. They also present project management and control tools and techniques for the management of Internet and Web-based systems.

Electronic Commerce

These chapters present a thorough discussion of electronic commerce fundamentals, taxonomies, and applications. They also discuss supporting technologies and applications of e-commerce inclining intranets, extranets, online auctions, and Web services. These chapters clearly demonstrate the successful applications of the Internet and Web technologies in private and public sectors.

Marketing and Advertising on the Web

The chapters in this group explore concepts, theories, and technologies used for effective marketing and advertising

on the Web. These chapters examine both qualitative and quantitative techniques. They also investigate the emerging technologies for mass personalization and customization in the Web environment.

Supply Chain Management

The chapters in this group discuss the fundamentals concepts and theories of value chain and supply chain management. The chapters examine the major role that the Internet and Web technologies play in an efficient and effective supply chain management program.

Wireless Internet and E-commerce

These chapters look at the fundamental concepts and technologies of wireless networks and wireless computing as they relate to the Internet and e-commerce operations. They also discuss mobile commerce and wireless marketing as two of the growing fields within the e-commerce environment.

Applications

The Internet and Web-based systems are everywhere. In most cases they have improved the efficiency and effectiveness of managers and decision makers. Chapters in this group highlight applications of the Internet in several fields, such as accounting, manufacturing, education, and human resources management, and their unique applications in a broad section of the service industries including law, law enforcement, medical delivery, health insurance and managed care, library management, nonprofit organizations, banking, online communities, dispute resolution, news services, public relations, publishing, religion, politics, and real estate. Although these disciplines are different in scope, they all utilize the Internet to improve productivity and in many cases to increase customer service in a dynamic business environment.

Specialists have written the collection for experienced and not-so-experienced readers. It is to these contributors that I am especially grateful. This remarkable collection of scholars and practitioners has distilled their knowledge into a fascinating and enlightening one-stop knowledge base in Internet-based systems that "talk" to readers. This has been a massive effort but one of the most rewarding experiences I have ever undertaken. So many people have played a role that it is difficult to know where to begin.

I should like to thank the members of the editorial board for participating in the project and for their expert advice on the selection of topics, recommendations for authors, and review of the materials. Many thanks to the more than 840 reviewers who devoted their times by proving advice to me and the authors on improving the coverage, accuracy, and comprehensiveness of these materials.

I thank my senior editor at John Wiley & Sons, Matthew Holt, who initiated the idea of the encyclopedia back in spring of 2001. Through a dozen drafts and many reviews, the project got off the ground and then was managed flawlessly by Matthew and his professional team. Matthew and his team made many recommendations for keeping the project focused and maintaining its lively coverage. Tamara Hummel, our superb editorial coordinator, exchanged several hundred e-mail messages with me and many of our authors to keep the project on schedule. I am grateful to all her support. When it came to the production phase, the superb Wiley production team took over. Particularly I want to thank Deborah DeBlasi, our senior production editor at John Wiley & Sons, and Nancy J. Hulan, our project manager at TechBooks. I am grateful to all their hard work.

Last, but not least, I want to thank my wonderful wife Nooshin and my two lovely children Mohsen and Morvareed for being so patient during this venture. They provided a pleasant environment that expedited the completion of this project. Nooshin was also a great help in designing and maintaining the author and reviewer databases. Her efforts are greatly appreciated. Also, my two sisters Azam and Akram provided moral support throughout my life. To this family, any expression of thanks is insufficient.

Guide to the Internet Encyclopedia

The Internet Encyclopedia is a comprehensive summary of the relatively new and very important field of the Internet. This reference work consists of three separate volumes and 205 chapters on various aspects of this field. Each chapter in the encyclopedia provides a comprehensive overview of the selected topic intended to inform a board spectrum of readers ranging from computer professionals and academicians to students to the general business community.

In order that you, the reader, will derive the greatest possible benefit from *The Internet Encyclopedia,* we have provided this Guide. It explains how the information within the encyclopedia can be located.

ORGANIZATION

The Internet Encyclopedia is organized to provide maximum ease of use for its readers. All of the chapters are arranged in alphabetical sequence by title. Chapters titles that begin with the letters A to F are in Volume 1, chapter titles from G to O are in Volume 2, and chapter titles from P to Z are in Volume 3. So that they can be easily located, chapter titles generally begin with the key word or phrase indicating the topic, with any descriptive terms following. For example, "Virtual Reality on the Internet: Collaborative Virtual Reality" is the chapter title rather than "Collaborative Virtual Reality."

Table of Contents

A complete table of contents for the entire encyclopedia appears in the front of each volume. This list of titles represents topics that have been carefully selected by the editor-in-chief, Dr. Hossein Bidgoli, and his colleagues on the Editorial Board.

Following this list of chapters by title is a second complete list, in which the chapters are grouped according to subject area. The encyclopedia provides coverage of 11 specific subject areas, such as E-commerce and Supply Chain Management. Please see the Preface for a more detailed description of these subject areas.

Index

The Subject Index is located at the end of Volume 3. This index is the most convenient way to locate a desired topic within the encyclopedia. The subjects in the index are listed alphabetically and indicate the volume and page number where information on this topic can be found.

Chapters

Each chapter in *The Internet Encyclopedia* begins on a new page, so that the reader may quickly locate it. The author's name and affiliation are displayed at the beginning of the article.

All chapters in the encyclopedia are organized according to a standard format, as follows:

- Title and author,
- Outline,
- Introduction,
- Body,
- Conclusion,
- Glossary,
- Cross References, and
- References.

Outline

Each chapter begins with an outline indicating the content to come. This outline provides a brief overview of the chapter so that the reader can get a sense of the information contained there without having to leaf through the pages. It also serves to highlight important subtopics that will be discussed within the chapter. For example, the chapter "Computer Literacy" includes sections entitled Defining a Computer, Categories of Computers According to Their Power, and Classes of Data Processing Systems. The outline is intended as an overview and thus lists only the major headings of the chapter. In addition, lower-level headings will be found within the chapter.

Introduction

The text of each chapter begins with an introductory section that defines the topic under discussion and summarizes the content. By reading this section the readers get a general idea about the content of a specific chapter.

Body

The body of each chapter discusses the items that were listed in the outline section.

Conclusion

The conclusion section provides a summary of the materials discussed in each chapter. This section imparts to the readers the most important issues and concepts discussed within each chapter.

Glossary

The glossary contains terms that are important to an understanding of the chapter and that may be unfamiliar to the reader. Each term is defined in the context of the particular chapter in which it is used. Thus the same term may be defined in two or more chapters with the detail of the definition varying slightly from one to another. The encyclopedia includes approximately 2,500 glossary terms.

For example, the article "Computer Literacy" includes the following glossary entries:

Computer A machine that accepts data as input, processes the data without human interference using a set of stored instructions, and outputs information. Instructions are step-by-step directions given to a computer for performing specific tasks.

Computer generations Different classes of computer technology identified by a distinct architecture and technology; the first generation was vacuum tubes, the second transistors, the third integrated circuits, the fourth very-large-scale integration, and the fifth gallium arsenide and parallel processing.

Cross References

All the chapters in the encyclopedia have cross references to other chapters. These appear at the end of the chapter, following the text and preceding the references. The cross references indicate related chapters which can be consulted for further information on the same topic. The encyclopedia contains more than 2,000 cross references in all. For example, the chapter "Java" has the following cross references:

JavaBeans and Software Architecture; Software Design and Implementation in the Web Environment.

References

The reference section appears as the last element in a chapter. It lists recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research papers that are important to an understanding of the topic are also listed. The references in this encyclopedia are for the benefit of the reader, to provide direction for further research on the given topic. Thus they typically consist of one to two dozen entries. They are not intended to represent a complete listing of all materials consulted by the author in preparing the chapter. In addition, some chapters contain a Further Reading section, which includes additional sources readers may wish to consult.

Passwords

Jeremy Rasmussen, *Sypris Electronics, LLC*

INTRODUCTION

The ancient folk tale of Ali Baba and the forty thieves mentions the use of a password. In this story, Ali Baba finds that the phrase "Open Sesame" magically opens the entrance to a cave where the thieves have hidden their treasure. Similarly, modern computer systems use passwords to authenticate users and allow them entrance to system resources and data shares on an automated basis. The use of passwords in computer systems likely can be traced to the earliest timesharing and dial-up networks. Passwords were probably not used before then in purely batch systems.

The security provided by a password system depends on the passwords being kept secret at all times. Thus, a password is vulnerable to compromise whenever it is used, stored, or even known. In a password-based authentication mechanism implemented on a computer system, passwords are vulnerable to compromise due to five essential aspects of the password system:

Passwords must be initially assigned to users when they are enrolled on the system;
Users' passwords must be changed periodically;
The system must maintain a "password database";
Users must remember their passwords; and
Users must enter their passwords into the system at authentication time.

Because of these factors, a number of protection schemes have been developed for maintaining password security. These include implementing policies and mechanisms to ensure "strong" passwords, encrypting the password database, and simplifying the sign-on and password synchronization processes. Even so, a number of sophisticated cracking tools are available today that threaten password security. For that reason, it is often advised that passwords be combined with some other form of security to achieve strong authentication.

TYPES OF IDENTIFICATION/ AUTHENTICATION

Access control is the security service that deals with granting or denying permission for subjects (e.g., users or programs) to use objects (e.g., other programs or files) on a given computer system. Access control can be accomplished through either hardware or software features, operating procedures, management procedures, or a combination of these. Access control mechanisms are classified by their ability to verify the authenticity of a user. The three basic verification methods are as follows:

What you have (examples: smart card or token);
What you are (examples: biometric fingerprint [see Figure 1] or iris pattern); and
What you know (examples: PIN or password).

Of all verification methods, passwords are probably weakest, yet they are still the most widely used method in systems today. In order to guarantee strong

Figure 1: A biometric fingerprint scanner.

authentication, a system ought to combine two or more of these factors. For example, in order to access an ATM, one must have a bank card and know his or her personal identification number (PIN).

HISTORY OF PASSWORDS IN MODERN COMPUTING

Conjecture as to which system was the first to incorporate passwords has been bandied about by several computing pioneers on the Cyberspace History List-Server (CYHIST). However, there has not been any concrete evidence as yet to support one system or another as the progenitor. The consensus opinion favors the Compatible Time Sharing System (CTSS) developed at the Massachusetts Institute of Technology (MIT) Computation Center beginning in 1961. As part of Project MAC (Multiple Access Computer) under the direction of Professor Fernando J. "Corby" Corbató, the system was implemented on an IBM 7094 and reportedly began using passwords by 1963. According to researcher Norman Hardy, who worked on the project, the security of passwords immediately became an issue as well: "I can vouch for some version of CTSS having passwords. It was in the second edition of the CTSS manual, I think, that illustrated the login command. It had Corby's user name and password. It worked—and he changed it the same day."

Passwords were widely in use by the early 1970s as the "hacker" culture began to develop, possibly in tacit opposition to the ARPANET. Now, with the explosion of the Internet, the use of passwords and the quantity of confidential data that those passwords protect have grown exponentially. But just as the 40 thieves' password protection system was breached (the cave could not differentiate between Ali Baba's voice and those of the thieves), computer password systems have also been plagued by a number of vulnerabilities. Although strong password authentication has remained a "hard" problem in cryptography despite advances in both symmetric (secret-key) and asymmetric (public-key) cryptosystems, the history of password authentication is replete with examples of weak, easily compromised systems. In general, "weak" authentication systems are characterized by protocols that either leak the password directly over the network or leak sufficient information while performing authentication to allow intruders to deduce or guess at the password.

Green Book: The Need for Accountability

In 1983, the U.S. Department of Defense Computer Security Center (CSC) published the venerable tome *Trusted Computer System Evaluation Criteria,* also known as the Orange Book. This publication defined the assurance requirements for security protection of computer systems that were to be used in processing classified or other sensitive information. One major requirement imposed by the Orange Book was accountability: "Individual accountability is the key to securing and controlling any system that processes information on behalf of individuals or groups of individuals" (Latham, 1985).

The Orange Book clarified accountability as follows:

Individual user identification: Without this, there is no way to distinguish the actions of one user on a system from those of another.

Authentication: Without this, user identification has no credibility. And without a credible identity, no security policies can be properly invoked because there is no assurance that proper authorizations can be made.

The CSC went on to publish the *Password Management Guideline* (also known as the Green Book) in 1985 "to assist in providing that much needed credibility of user identity by presenting a set of good practices related to the design, implementation and use of password-based user authentication mechanisms." The Green Book outlined a number of steps that system security administrators should take to ensure password security on the system and suggests that, whenever possible, they be automated. These include the following 10 rules (Brotzman, 1985):

System security administrators should change the passwords for all standard user IDs before allowing the general user population to access the system.

A new user should always appear to the system as having an "expired password" which will require the user to change the password by the usual procedure before receiving authorization to access the system.

Each user ID should be assigned to only one person. No two people should ever have the same user ID at the same time, or even at different times. It should be considered a security violation when two or more people know the password for a user ID.

Users need to be aware of their responsibility to keep passwords private and to report changes in their user status, suspected security violations, etc. Users should also be required to sign a statement to acknowledge understanding of these responsibilities.

Passwords should be changed on a periodic basis to counter the possibility of undetected password compromise.

Users should memorize their passwords and not write them on any medium. If passwords must be written, they should be protected in a manner that is consistent with the damage that could be caused by their compromise.

Stored passwords should be protected by access controls provided by the system, by password encryption, or by both.

Passwords should be encrypted immediately after entry, and the memory containing the plaintext password should be erased immediately after encryption.

Only the encrypted password should be used in comparisons. There is no need to be able to decrypt passwords. Comparisons can be made by encrypting the password entered at login and comparing the encrypted form with the encrypted password stored in the password database.

The system should not echo passwords that users type in, or at least should mask the entered password (e.g., with asterisks).

PASSWORD SECURITY—BACKGROUND

Information Theory

Cryptography is a powerful mechanism for securing data and keeping them confidential. The idea is that the original message is scrambled via an algorithm (or cipher), and only those with the correct key can unlock the scrambled message and get back the plaintext contents. In general, the strength of a cryptographic algorithm is based on the length and quality of its keys. Passwords are a similar problem. Based on their length and quality, they should be more difficult to attack either by dictionary, by hybrid, or by brute-force attacks. However, the quality of a password, just as the quality of a cryptographic key, is based on entropy. Entropy is a measure of disorder.

An example of entropy

Say a user is filling out a form on a Web page (see Figure 2). The form has a space for "Sex," and leaves six characters for entering either "female" or "male" before encrypting the form entry and sending it to the server. If each character is a byte (i.e., 8 bits), then $6 \times 8 = 48$ bits will be sent for this response. Is this how much information is actually contained in the field, though?

Clearly, there is only one bit of data represented by the entry—a binary value—either male or female. That means that there is only one bit of entropy (or uncertainty) and there are 47 bits of redundancy in the field. This redundancy could be used by a cryptanalyst (someone who analyzes cryptosystems) to help crack the key.

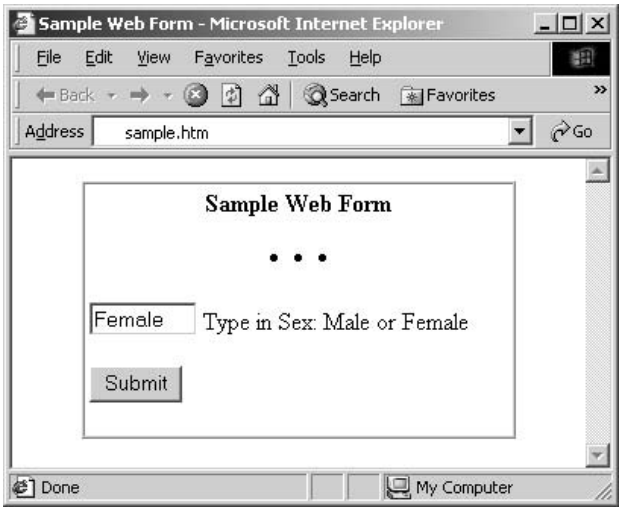

Figure 2: Sample Web page entry form.

Fundamental work by Claude Shannon during the 1940s illustrated this concept, that is, that the amount of information in a message is not necessarily a function of the length of a message (or the number of symbols used in the message) (Sloane & Wyner, 1993). Instead, the amount of information in a message is determined by how many different possible messages there are and how frequently each message is used.

The same concepts apply to password security. A longer password is not necessarily a better password. Rather, a password that is difficult to guess (i.e., one that has high entropy) is best. This usually comes from a combination of factors (see "Guidelines for selecting a good password"). The probability that any single attempt at guessing a password will be successful is one of the most critical factors in a password system. This probability depends on the size of the password space and the statistical distribution within that space of passwords that are actually used.

Over the past several decades, Moore's Law has made it possible to brute-force password spaces of larger and larger entropy. In addition, there is a limit to the entropy that the average user can remember. A user cannot typically remember a 32-character password, but that is what is required to have the equivalent strength of a 128-bit key. Recently, password cracking tools have advanced to the point of being able to crack nearly anything a system could reasonably expect a user to memorize (see "Password Length and Human Memory").

Cryptographic Protection of Passwords

Early on, the most basic and least secure method of authentication was to store passwords in plaintext (i.e., unencrypted) in a database on the server. During authentication, the client would send his or her password to the server, and the server would compare this against the stored value. Obviously, however, if the password file were accessible to unauthorized users, the security of the system could be easily compromised.

In later systems, developers discovered that a server did not have to store a user's password in plaintext form in order to perform password authentication. Instead, the user's password could be transformed through a one-way function, such as a hashing function, into a random-looking sequence of bytes. Such a function would be difficult to invert. In other words, given a password, it would be easy to compute its hash, but given a hash, it would be computationally infeasible to compute the password from it (see "Hashing"). Authentication would consist merely of performing the hash function over the client's password and comparing it to the stored value. The password database itself could be made accessible to all users without fear of an intruder being able to steal passwords from it.

Hashing

A hash function is an algorithm that takes a variable-length string as the input and produces a fixed-length value (hash) as the output. The challenge for a hashing algorithm is to make this process irreversible; that is, finding

Table 1 Output from the MD5 Test Suite

a string that produces a given hash value should be very difficult. It should also be difficult to find two arbitrary strings that produce the same hash value. Also called a message digest or fingerprint, several one-way hash functions are in common use today. Among these are Secure Hashing Algorithm-1 (SHA-1) and Message Digest-5 (MD-5). The latter was invented by Ron Rivest for RSA Security, Inc. and produces a 128-bit hash value. See Table 1 for an example of output generated by MD5. SHA-1 was developed by the U.S. National Institute of Standards and Technology (NIST) and the National Security Agency (NSA) and produces 160-bit hash values. SHA-1 is generally considered more secure than MD5 due to its longer hash value.

Microsoft Windows NT uses one-way hash functions to store password information in the Security Account Manager (SAM). There are no Windows32 Applications Programming Interface (API) function calls to retrieve user passwords because the system does not store them. It stores only hash values. However, even a hash-encrypted password in a database is not entirely secure. A cracking tool can compile a list of, say, the one million most commonly used passwords and compute hash functions from all of them. Then the tool can obtain the system account database and compare the hashed passwords in the database with its own list to see what matches. This is called a "dictionary attack" (see "Password Cracking Tools").

To make dictionary attacks more difficult, often a salt is used. A salt is a random string that is concatenated with a password before it is operated on by the hashing function. The salt value is then stored in the user database, together with the result of the hash function. Using a salt makes dictionary attacks more difficult, as a cracker would have to compute the hashes for all possible salt values.

A simple example of a salt would be to add the time of day; for example, if a user logs in at noon using the password "pass," the string that would be encrypted might be "1p2a0s0s." By adding this randomness to the password, the hash will actually be different every time the user logs in (unless it is at noon every day). Whether a salt is used and what the salt actually is depends upon the operating system and the encryption algorithm being used. On a FreeBSD system, for example, there is a function called crypt that uses the DES, MD5, or Blowfish algorithms to hash passwords and can also use three forms of salts.

According to Cambridge University professor of computing Roger Needham, the Cambridge Multiple Access System (CMAS), which was an integrated online–offline terminal or regular input-driven system, may have been among the earliest to implement such one-way functions. It first went online in 1967 and incorporated password protection. According to Needham: "In 1966, we conceived the use of one-way functions to protect the password file, and this was an implemented feature from day one" (R. Needham, personal communication, April 11, 2002).

One-way hashing is still being used today, although it does not address another weakness—in a networked environment, it is difficult to transmit the password securely to the server for verification without its being captured and reused, perhaps in a replay attack. To avoid revealing passwords directly over an untrusted network, computer scientists have developed challenge–response systems. At their simplest, the server sends the user some sort of challenge, which would typically be a random string of characters called a nonce. The user then computes a response, usually some function based on both the challenge and the password. This way, even if the intruder captured a valid challenge–response pair, it would not help him or her gain access to the system, because future challenges would be different and require different responses.

These challenge-and-response systems are referred to as one-time password (OTP) systems. Bellcore's S/KEY is one such system in which a one-time password is calculated by combining a seed with a secret password known only to the user and then applying a secure hashing algorithm a number of times equal to the sequence number. Each time the user is authenticated, the sequence number expected by the system is decremented, thus eliminating the possibility of an attacker trying a replay attack using the same password again. One-time passwords were more prevalent before secure shell (SSH) and secure sockets layer (SSL) systems came into widespread use.

PASSWORD CRACKING TOOLS

Password-Cracking Approaches

As mentioned earlier, passwords are typically stored as values hashed with SHA-1 or MD5, which are one-way functions. In other words, this entire encyclopedia could be hashed and represented as eight bytes of gibberish. There would be no way to use these eight bytes of data to obtain the original text. However, password crackers know that people do not use whole encyclopedias as their passwords. The vast majority of passwords are 4 to

12 characters. Passwords are also, in general, not just random strings of symbols. Because users need to remember them, passwords are usually words or phrases of significance to the user. This is an opportunity for the attacker to reduce the search space.

An attacker might steal a password file–or sniff the wire and capture the user ID/password hash pairs during logon–and then run a password-cracking tool on it. Because it is impossible to decrypt a hash back to a password, these programs will try a dictionary approach first. The program guesses a password—say, the word "Dilbert." The program then hashes "Dilbert" and compares the hash to one of the hashed entries in the password file. If it matches, then that password hash represents the password "Dilbert." If the hash does not match, the program takes another guess. Depending on the tool, a password cracker will try all the words in a dictionary, all the names in a phone book, and so on. Again, the attacker does not need to know the original password–just a password that hashes to the same value.

This is analogous to the "birthday paradox," which basically says, "If you get 25 people together in a room, the odds are better than 50/50 that two of them will have the same birthday." How does this work? Imagine a person meeting another on the street and asking him his birthday. The chances of the two having the same birthday are only 1/365 (0.27%). Even if one person asks 25 people, the probability is still low. But with 25 people in a room together, each of the 25 is asking the other 24 about their birthdays. Each person only has a small (less than 5%) chance of success, but trying it 25 times increases the probability significantly.

In a room of 25 people, there are 300 possible pairs (25*24/2). Each pair has a probability of success of $1/365 = 0.27\%$, and a probability of failure of $1 - 0.27\% = 99.726\%$. Calculating the probability of failure: $99.726\%^{300} = 44\%$. The probability of success is then $100\% - 44\% = 56\%$. So a birthday match will actually be found five out of nine times. In a room with 42 people, the odds of finding a birthday match rise to 9 out of 10. Thus, the birthday paradox is that it is much easier to find two values that match than it is to find a match to some particular value.

If a wave of dictionary guesses fails to produce any passwords for the attacker, the cracking program will next try a hybrid approach of different combinations—-such as forward and backward spellings of dictionary words, additional numbers and special characters, or sequences of characters. The goal here again is to reduce the cracker's search space by trying "likely" combinations of known words.

Only after exhausting both of these avenues will the cracking program start in on an exhaustive or brute-force attack on the entire password space. And, of course, it remembers the passwords it has already tried and will not have to recheck these either during the brute-force search.

Approaches to Retrieving Passwords

Most password-cracking programs will first attempt to retrieve password hashes to begin their cracking processes. A sophisticated attacker will not try to guess passwords by entering them through the standard user interface because the time to do so is prohibitive, and most systems can be configured to lock a user out after too many wrong guesses.

On Microsoft Windows systems, it typically requires the "Administrator" privilege to read the password hashes from the database in which they are stored. This is usually somewhere in the system registry. In order to access them, a cracking tool will attempt to dump the password hashes from the Windows registry on the local machine or over the network if the remote machine allows network registry access. The latter requires a target Windows machine name or IP address.

Another method is to access the password hashes directly from the file system. On Microsoft Windows systems, this is the SAM. Because Windows locks the SAM file where the password hashes are stored in the file system with an encryption mechanism known as SYSKEY, it is impossible to read them from this file while the system is running. However, sometimes there is a backup of this file on tape, on an emergency repair disk (ERD), or in the repair directory of the system's hard drive. Alternately, a user may boot from a floppy disk running another operating system such as MS-DOS and be able to read password hashes directly from the file system. This is why security administrators should never neglect physical security of systems. If an attacker can physically access a machine, he or she can bypass the built-in file system security mechanisms (see Recovering Windows NT Passwords).

Todd Sabin has released a free utility called PWDUMP2 that can dump the password hashes on a local machine if the SAM has been encrypted with the SYSKEY utility that was introduced in Windows NT Service Pack 3. Once a user downloads the utility, he or she can follow the instructions on the Web page to retrieve the password hashes, load the hashes into a tool such as L0phtCrack, and begin cracking them.

Password Sniffing

Instead of capturing the system user file (SAM on Windows or /etc/passwd or /etc/shadow on Unix/Linux), another way of collecting user IDs and passwords is through sniffing network traffic. Sniffing uses some sort of software or hardware wiretap device to eavesdrop on network communications, usually by capturing and deciphering communications packets. According to Peiter "Mudge" Zatko, who initially wrote L0phtCrack: "Sniffing is slang for placing a network card into promiscuous mode so that it actually looks at all of the traffic coming along the line and not just the packets that are addressed to it. By doing this one can catch passwords, login names, confidential information, etc" (Zatko, 1999b).

L0phtCrack offers an "SMB Packet Capture" function to capture encrypted hashes transmitted over a Windows network segment. On a switched network, a cracker will only be able to sniff sessions originating from the local machine or connecting to that machine. As server message block (SMB) session authentication messages are captured by the tool, they are displayed in the SMB Packet Capture window. The display shows the source and destination IP addresses, the user name, the SMB challenge, the encrypted LAN manager hash, and the encrypted NT LAN manager hash, if any. To crack these hashes,

the tool saves the session and then works on the captured file.

Recovering Windows NT Passwords

Or, why physical security is still important. Norwegian software developer Petter Nordahl-Hagen has built a resource ("The Offline NT Password Editor") for recovering Windows passwords on workstations. His approach bypasses the NTFS file permissions of Windows NT, 2000, and XP by using a Linux boot disk that allows one to reset the Administrator password on a system by replacing the hash stored in the SAM with a user-selected hash. His program has even been shown to work on Windows 2000 systems with SYSKEY enabled. An MS-DOS version also exists, as does a version that boots from CD-ROM instead of floppy disk.

Thus, physical access to the workstation can mean instant compromise, unless, perhaps the system BIOS settings are also password-protected and do not allow a user to boot from floppy or CD-ROM (however, several attacks against BIOS settings have also been published).

Types of Password-Cracking Tools

Password-cracking tools can be divided into two categories—those that attempt to retrieve system-level login passwords and those that attack the password protection mechanisms of specific applications. The first type includes programs such as L0phtcrack, Cain & Abel, and John the Ripper. Some sites for obtaining password-cracking tools for various platforms, operating systems, and applications are included in the Further Reading section at the end of this chapter.

The Russian company ElcomSoft has a developed a range of programs that can crack passwords on Microsoft Office encrypted files, WinZip or PKZip archived files, or Adobe Acrobat (PDF) files. The U.S. federal government charged ElcomSoft with violating the Digital Millennium Copyright Act of 1998 for selling a program that allowed people to disable encryption software from Adobe Systems that is used to protect electronic books. The case drew attention after ElcomSoft programmer Dmitry Sklyarov was arrested at the DefCon 2001 convention in July, 2001 (US. ElcomSoft & Sklyarov FAQ, n.d.).

PASSWORD SECURITY ISSUES AND EFFECTIVE MANAGEMENT

Enforcing Password Guidelines

The FBI and the Systems Administration and Networking Security (SANS) Institute released a document summarizing the "Twenty Most Critical Internet Security Vulnerabilities." The majority of successful attacks on computer systems via the Internet can be traced to exploitation of security flaws on this list. One of items on this list is "accounts with no passwords or weak passwords." In general, these accounts should be removed or assigned stronger passwords. In addition, accounts with built-in or default passwords that have never been reconfigured create vulnerability because they usually have the same password across installations of the software. Attackers will look for these accounts, having found the commonly known passwords published on hacking Web sites or some other public forum. Therefore, any default or built-in accounts also need to be identified and removed from the system or else reconfigured with stronger passwords.

The list of common vulnerabilities and exposures (CVE) maintained by the MITRE Corporation (http://www.cve.mitre.org) provides a taxonomy for more than 2000 well-known attacker exploits. Among these, nearly 100 have to do with password insecurities, and another 250 having to do with passwords are "candidates" currently under review for inclusion in the list. The following provides a few samples:

Some Sample Password Vulnerabilities in the CVE List

CVE-1999–0366: "In some cases, Service Pack 4 for Windows NT 4.0 can allow access to network shares using a blank password, through a problem with a null NT hash value."

CVE-2001–0465: "TurboTax saves passwords in a temporary file when a user imports investment tax information from a financial institution, which could allow local users to obtain sensitive information."

CVE-2000–1187: "Buffer overflow in the HTML parser for Netscape 4.75 and earlier allows remote attackers to execute arbitrary commands via a long password value in a form field."

CVE-1999–1104: "Windows 95 uses weak encryption for the password list (.pwl) file used when password caching is enabled, which allows local users to gain privileges by decrypting the passwords."

CVE-2000–0981: "MySQL Database Engine uses a weak authentication method which leaks information that could be used by a remote attacker to recover the password."

CVE-2000–0267: "Cisco Catalyst 5.4.x allows a user to gain access to the 'enable' mode without a password."

CVE-1999–1298: "Sysinstall in FreeBSD 2.2.1 and earlier, when configuring anonymous FTP, creates the ftp user without a password and with/bin/date as the shell, which could allow attackers to gain access to certain system resources."

CVE-1999–1316: "Passfilt.dll in Windows NT SP2 allows users to create a password that contains the user's name, which could make it easier for an attacker to guess" (Common Vulnerabilities, n.d.).

SANS suggests that to determine if one's system is vulnerable to such attacks, one needs to be cognizant of all the user accounts on the system. First, the system security administrator must inventory the accounts on the system and create a master list. This list should include even intermediate systems, such as routers and gateways, as well as any Internet-connected printers and print controllers. Second, the administrator should develop procedures for adding authorized accounts to the list and for removing accounts when they are no longer in use. The master list should be validated on a regular basis. In addition, the administrator should run some password strength-checking tool against the accounts to look for weak or nonexistent passwords. A sample of these tools is noted in the Further Reading section at the end of this chapter.

Many organizations supplement password control programs with procedural or administrative controls that ensure that passwords are changed regularly and that old passwords are not reused. If password aging is used, the system should give users a warning and the opportunity to change their passwords before they expire. In addition, administrators should set account lockout policies, which lock out a user after a number of unsuccessful login attempts, and cause him or her to have his password reset.

Microsoft Windows 2000 and Windows XP include built-in password constraint options in the "Group Policy" settings. An administrator can configure the network so that user passwords must have a minimum length, a minimum and maximum age, and other constraints. It is important to require a minimum age on a password.

The following outlines the minimal criteria for selecting "strong" passwords.

Guidelines for Selecting a Good Password

The goal is to select something easily remembered but not easily guessed.

Length

Windows systems: seven characters or longer

Unix, Linux systems: eight characters or longer

Composition

Mixture of alphabetic, numeric, and special characters (e.g., #, @, or !)

Mixture of upper and lower case characters

No words found in a dictionary

No personal information about the user (e.g., any part of the user's name, a family member's name, or the user;s date of birth, Social Security number, phone number, license plate number, etc.)

No information that is easily obtained about the user, especially any part of the user ID

No commonly used proper names such as local sports teams or celebrities

No patterns such as 12345, sssss, or qwerty

Try misspelling or abbreviating a word that has some meaning to the user (Example: "How to select a good password?" becomes "H2sagP?")

Password Aging and Reuse

To limit the usefulness of passwords that might have been compromised, it is suggested practice to change them regularly. Many systems force users to change their passwords when they log in for the first time, and again if they have not changed their passwords for an extended period (say, 90 days). In addition, users should not reuse old passwords. Some systems support this by recording the old passwords, ensuring that users cannot change their passwords back to previously used values, and ensuring that the users' new passwords are significantly different from their previous passwords. Such systems usually have a finite memory, say the past 10 passwords, and users can circumvent the password filtering controls by changing a password 10 times in a row until it is the same as the previously used password.

It is recommended that, at a predetermined period of time prior to the expiration of a password's lifetime, the user ID it is associated with be notified by the system as having an "expired" password. A user who logs in with an ID having an expired password should be required to change the password for that user ID before further access to the system is permitted. If a password is not changed before the end of its maximum lifetime, it is recommended that the user ID it is associated with be identified by the system as "locked." No login should be permitted to a locked user ID, but the system administrator should be able to unlock the user ID by changing the password for that user ID. After a password has been changed, the lifetime period for the password should be reset to the maximum value established by the system.

Social Engineering

With all the advances in technology, the oldest way to attack a password-based security system is still the easiest: coercion, bribery, or trickery against the users of the system. Social engineering is an attack against people, rather than machines. It is an outsider's use of psychological tricks on legitimate users of a computer system, usually to gain the information (e.g., user IDs and passwords) needed to access a system. The notorious "hacker" Kevin Mitnick, who was convicted on charges of computer and wire fraud and spent 59 months in federal prison, told a Congressional panel that he rarely used technology to gain information and used social engineering almost exclusively (Federation of American Scientists, n.d.).

According to a study by British psychologists, people often base their passwords on something obvious and easily guessed by a social engineer. Around 50% of computer users base them on the name of a family member, a partner, or a pet. Another 30% use a pop idol or sporting hero. Another 10% of users pick passwords that reflect some kind of fantasy, often containing some sexual reference. The study showed that only 10% use cryptic combinations that follow all the rules of "tough" passwords (Brown, 2002).

The best countermeasures to social engineering attacks are education and awareness. Users should be instructed never to tell anyone their passwords. Doing so destroys accountability, and a system administrator should never need to know it either. Also, users should never write down their passwords. A clever social engineer will find it if it is "hidden" under a mouse pad or inside a desk drawer.

Some Examples of Social Engineering Attacks

"Appeal to Authority" Attack. This is impersonating an authority figure or else identifying a key individual as a supposed acquaintance, in order to demand information. For example: A secretary receives a phone call from someone claiming to be the "IT Manager." He requests her user ID and password, or gives her a value to set her password to immediately because "there has been a server crash in the computer center and we need to reset everyone's account." Once she has complied, he now has access to a valid user ID and password to access the system.

"Fake Web Site" Attack. The same password should not be used for multiple applications. Once a frequently used

password is compromised, all of the user's accounts will be compromised. A good social engineering attack might be to put up an attractive Web site with titillating content, requiring users to register a username and password in order to access the "free" information. The attacker would record all passwords (even incorrect ones, which a user might have mistakenly entered thinking of another account), and then use those to attack the other systems frequented by the user. The Web site could even solicit information from the users about their accounts—for example, what online brokerage, banking, and e-mail accounts they used. Web site operators can always keep a log of IP addresses used to access the site and could go back to attack the originating system directly.

"Dumpster Diving" Attack. Many serious compromises are still caused by contractors and third parties throwing away draft instruction manuals, development notes, etc., with user IDs and passwords in them. Social engineers may employ "dumpster diving," that is, digging through paper printouts in the trash looking for such significant information to gain system access.

Single Sign-On and Password Synchronization

One issue that has irritated users in large secure environments is the burgeoning number of passwords they have to remember to access various applications. A user might need one password to log onto his or her workstation, another to access the network, and yet another for a particular server. Ideally, a user should be able to sign on once, with a single password, and be able to access all the other systems on which he or she has authorization.

Some have called this notion of single sign-on the "Holy Grail" of computer security. The goal is admirable—to create a common enterprise security infrastructure to replace a heterogeneous one. And it is currently being attempted by several vendors through technologies such as the Open Group's Distributed Computing Environment (DCE), MIT's Kerberos, Microsoft's ActiveDirectory, and Public-Key Infrastructure (PKI)-based systems. However, few, if any, enterprises have actually achieved their goal. Unfortunately, the task of changing all existing applications to use a common security infrastructure is very difficult, and this has further been hampered by a lack of consensus on a common security infrastructure. As a result, the disparate proprietary and standards-based solutions cannot be applied to every system. In addition, there is a risk of a single point of failure. Should one user's password be compromised, it is not just his local system that can be breached but the entire enterprise.

Password synchronization is another means of trying to help users maintain the passwords that they use to log onto disparate systems. In this scheme, when users periodically change their passwords, the new password is applied to every account the user has, rather than just one. The main objective of password synchronization is to help users remember a single, strong password. Password synchronization purports to improve security because synchronized passwords are subjected to a strong password policy, and users who remember their passwords are less likely to write them down.

To mitigate the risk of a single system compromise being leveraged by an intruder into a network-wide attack:

Very insecure systems should not participate in a password synchronization system,

Synchronized passwords should be changed regularly, and

Users should be required to select strong (hard to guess) passwords when synchronization is introduced.

Unix/Linux-Specific Password Issues

Traditionally on Unix and Linux platforms, user information, including passwords, is kept in a system file called /etc/passwd. The password for each user is stored as a hash value. Despite the password being encoded with a one-way hash function and a salt as described earlier, a password cracker could still compromise system security if he or she obtained access to the /etc/passwd file and used a successful dictionary attack. This vulnerability can be mitigated by simply moving the passwords in the /etc/passwd file to another file, usually named /etc/shadow, and making this file readable only by those who have administrator or "root" access to the system.

In addition, Unix or Linux administrators should examine the password file (as well as the shadow password file when applicable) on a regular basis for potential account-level security problems. In particular, it should be examined for the following:

Accounts without passwords.

UIDs of 0 for accounts other than root (which are also superuser accounts).

GIDs of 0 for accounts other than root. Generally, users don't have group 0 as their primary group.

Other types of invalid or improperly formatted entries.

User names and group names in Unix and Linux are mapped into numeric forms (UIDs and GIDs, respectively). All file ownership and processes use these numerical names for access control and identity determination throughout the operating system kernel and drivers.

Under many Unix and Linux implementations (via a shadow package), the command `pwck` will perform some simple syntax checking on the password file and can identify some security problems with it. `pwck` will report invalid usernames, UIDs and GIDs, null or nonexistent home directories, invalid shells, and entries with the wrong number of fields (often indicating extra or missing colons and other typos).

Microsoft-Specific Password Issues

Windows uses two password functions—a stronger one designed for Windows NT, 2000, and XP systems, and a weaker one, the LAN Manager hash, designed for backward compatibility with older Windows 9X networking login protocols. The latter is case-insensitive and does not allow passwords to be much stronger than seven characters, even though they may be much longer. These passwords are extremely vulnerable to cracking. On a standard desktop PC, for example, L0phtCrack can try

every short alphanumeric password in a few minutes and every possible keyboard password (except for special ALT-characters) within a few days. Some security administrators have dealt with this problem by requiring stronger and stronger passwords; however, this comes at a cost (see An Argument for Simplified Passwords).

In addition to implementing policies that require users to choose strong passwords, the CERT Coordination Center provides guidelines for securing passwords on Windows systems (CERT, 2002):

Using SYSKEY enables the private password data stored in the registry to be encrypted using a 128-bit cryptographic key. This is a unique key for each system.

By default, the administrator account is never locked out; so it is generally a target for brute force logon attempts of intruders. It is possible to rename the account in User Manager, but it may be desirable to lock out the administrator account after a set number of failed attempts over the network. The NT Resource Kit provides an application called `passprop.exe` that enables Administrator account lockout except for interactive logons on a domain controller.

Another alternative that avoids all accounts belonging to the Administrator group being locked over the network is to create a local account that belongs to the Administrator group, but is not allowed to log on over the network. This account may then be used at the console to unlock the other accounts.

The Guest account should be disabled. If this account is enabled, anonymous connections can be made to NT computers.

The Emergency Repair Disk should be secured, as it contains a copy of the entire SAM database. If a malicious user has access to the disk, he or she may be able to launch a crack attack against it.

Password-Cracking Times

Let us start with a typical password of six characters. When this password is entered into a system's authentication mechanism, the system hashes it and stores the hashed value. The hash, a fixed-sized string derived from some arbitrarily long string of text, is generated by a formula in such a way that it is extremely unlikely that other texts will produce the same hash value—unlikely, but not impossible. Because passwords are not arbitrarily long—they are generally 4 to 12 characters—this reduces the search space for finding a matching hash. In other words, an attacker's password-cracking program does not need to calculate every possible combination of six-character passwords. It only needs to find a hash of a six-character ASCII-printable password that matches the hash stored in the password file or sniffed off the network.

Because an attacker cannot try to guess passwords at a high rate through the standard user interface (as mentioned earlier, the time to enter them is prohibitive, and most systems can be configured to lock the user out after too many wrong attempts), one may assume that the attacker will get them either by capturing the system password file or by sniffing (monitoring communications) on a network segment. Each character in a password is a byte. One does not typically need to consider characters with a leading zero in the highest-order bit, because printable ASCII characters are in codes 32 through 126. ASCII codes 0–31 and 127 are unprintable characters, and 128–255 are special ALT-characters that are not generally used for passwords. This leaves 95 printable ASCII characters.

If there are 95 possible choices for each of the six password characters, this makes the password space $95^6 = 735,091,890,625$ combinations. Modern computers are capable of making more than 10 billion calculations per second. It has been conjectured that agencies such as the NSA have password-cracking machines (or several machines working in parallel) that could hash and check passwords at a rate of 1 billion per second. How fast could an attacker check every possible combination of six-character passwords? 735,091,890,625/1,000,000,000 = about 12 minutes (see Table 2).

What if the system forces everyone to use a seven-character password? Then it would take the attacker 19 hours to brute-force every possible password. Many Windows networks fall under this category. Due to the LAN Manager issue, passwords on these systems cannot be much stronger than seven characters. Thus, it can be assumed that any password sent on a Windows system using LAN Manager can be cracked within a day. What if the system enforces eight-character passwords? Then it would take 77 days to brute-force them all. If a system's standard policy is to require users to change passwords every 90 days, this may not be sufficient.

PASSWORD LENGTH AND HUMAN MEMORY

Choosing a longer password does not help much on systems with limitations such as the LAN Manager hash issue. It also does not help if a password is susceptible to a dictionary or hybrid attack. It only works if the password appears to be a random string of symbols, but that can be difficult to remember. A classic study by psychologist George Miller showed that humans work best with the magic number 7 (plus or minus 2). So it stands to reason that once a password exceeds nine characters, the user is going to have a hard time remembering it (Miller, 1956).

Here is one idea for remembering a longer password. Security professionals generally advise people never to write down their passwords. But the user could write down half of it—the part that looks like random letters and numbers—and keep it in a wallet or desk drawer. The other part could be memorized—perhaps it could be a misspelled dictionary word or the initials for an acquaintance, or something similarly memorable. When concatenated together, the resulting password could be much longer than nine characters, and therefore presumably stronger.

Some researchers have asserted that the brain remembers images more easily than letters or numbers. Thus, some new schemes use sequences of graphical symbols for passwords. For example, a system called PassFace, developed by RealUser, replaces the letters and numbers in passwords with sequences or groups of human faces. It

is one of several applications that rely on graphical images for the purpose of authentication. Another company, Passlogix, has a system in which users can mix drinks in a virtual saloon or concoct chemical compounds using an onscreen periodic table of elements as a way to log onto computer networks.

AN ARGUMENT FOR SIMPLIFIED PASSWORDS

Employing all of the guidelines for a strong password (length, mix of upper and lower case, numbers, punctuation, no dictionary words, no personal information, etc.) as outlined in this chapter may not be necessary after all.

This is because, according to security expert and TruSecure Chief Technology Officer Peter Tippett, statistics show that strong password policies only work for smaller organizations (Tippett, 2001). Suppose a 1,000-user organization has implemented such a strong password policy. On average, only half of the users will actually use passwords that satisfy the policy. Perhaps if the organization frequently reminds its users of the policy, and implements special software that will not allow users to have "weak" passwords, this figure can be raised to 90%. It is rare that such software can be deployed on all devices that use passwords for authentication; thus there are always some loopholes. Even with 90% compliance, this still leaves 100 easily guessed User/ID password pairs. Is 100 better than 500? No, because either way, an attacker can gain access. When it comes to strong passwords, anything less than 100% compliance allows an attacker entré to the system.

Second, with modern processing power, even strong passwords are no match for current password crackers. The combination of 2.5-gigahertz clock speed desktop computers and constantly improving hash dictionaries and algorithms means that, even if 100% of the 1,000 users had passwords that met the policy, a password cracker might still be able to defeat them. Although some user ID/password pairs may take days or weeks to crack, approximately 150 of the 1000, or 15%, can usually be bruteforced in a few hours.

In addition, strong passwords are expensive to maintain. Organizations spend a great deal of money supporting strong passwords. One of the highest costs of maintaining IT help desks is related to resetting forgotten user passwords. Typically, the stronger the password (i.e., the more random), the harder it is to remember. The harder it is to remember, the more help desk calls result. Help desk calls require staffing, and staffing costs money. According to estimates from such technology analysts as the Gartner Group and MetaGroup, the cost to businesses for resetting passwords is between $50 and $300 per computer user each year (Salkever, 2001).

So, for most organizations, the following might be a better idea than implementing strong password policy: Simply recognize that 95% of users could use simple (but not basic) passwords—that is, good enough to keep a casual attacker (not a sophisticated password cracker) from guessing them within five attempts while sitting at a keyboard. This could be four or five characters (no names or initials), and changed perhaps once a year. In practical terms, this type of password is equivalent to the current "strong" passwords. The benefit is that it is much easier and cheaper to maintain.

Under this scenario, a system could still reserve stronger passwords for the 5% of system administrators who wield extensive control over many accounts or devices. In addition, a system should make the password file very difficult to steal. Security administrators should

also introduce measures to mitigate sniffing, such as network segmentation and desktop automated inventory for sniffers and other tools. Finally, for strongest security, a system could encrypt all network traffic with IPSec on every desktop and server.

Dr. Tippett states: "If the Promised Land is robust authentication, you can't get there with passwords alone, no matter how 'strong' they are. If you want to cut costs and solve problems, think clearly about the vulnerability, threat and cost of each risk, as well as the costs of the purported mitigation. Then find a way to make mitigation cheaper with more of a security impact" (Tippett, 2001).

CONCLUSION

Passwords have been widely used in computing systems since the 1960s; password security issues have followed closely behind. Now, the increased and very real threat of cybercrime necessitates higher security for many networks that previously seemed safe. Guaranteeing accountability on networks—i.e., uniquely identifying and authenticating users' identities—is a fundamental need for modern e-commerce. Strengthening password security should be major goal in an organization's overall security framework. Basic precautions (policies, procedures, filtering mechanisms, encryption) can help reduce risks from password weaknesses. However, lack of user buy-in and the rapid growth of sophisticated cracking tools may make any measure taken short-lived. Additional measures, such as biometrics, certificates, tokens, smart cards, and other means can be very effective for strengthening authentication, but the tradeoff is additional financial burden and overhead. It is not always an easy task to convince management of inherent return on these technologies, relative to other system priorities. In these instances, organizations must secure their passwords accordingly and do the best they can with available resources.

GLOSSARY

Access control The process of limiting access to system information or resources to authorized users.

Accountability The property of systems security that enables activities on a system to be traced to individuals who can then be held responsible for their actions.

ARPANET The network first constructed by the Advanced Research Projects Agency of the U.S. Department of Defense (ARPA), which eventually developed into the Internet.

Biometrics Technologies for measuring and analyzing living human characteristics, such as fingerprints, especially for authentication purposes. Biometrics are seen as a replacement for or augmentation of password security.

Birthday paradox The concept that it is easier to find two unspecified values that match than it is to find a match to some particular value. For example, in a room of 25 people, if one person tried to find another person with the same birthday, there would be little chance of a match. However, there is a very good chance that some pair of people in the room will have the same birthday.

Brute force A method of breaking decryption by trying every possible key. The feasibility of a brute-force attack depends on the key length of the cipher and on the amount of computational power available to the attacker. In password cracking, tools typically use brute force to crack password hashes after attempting dictionary and hybrid attacks to try every remaining possible combination of characters.

CERT Computer Emergency Response Team. An organization that provides Internet security expertise to the public. CERT is located at the Software Engineering Institute, a federally funded research and development center operated by Carnegie Mellon University. Its work includes handling computer security incidents and vulnerabilities and publishing security alerts.

Cipher A cryptographic algorithm that encodes units of plaintext into encrypted text (or *ciphertext*) through various methods of diffusion and substitution.

Ciphertext An encrypted file or message. After plaintext has undergone encryption to disguise its contents, it becomes ciphertext.

Crack, cracking Traditionally, using illicit (unauthorized) actions to break into a computer system for malicious purposes. More recently, either the art or science of trying to guess passwords, or copying commercial software illegally by breaking its copy protection.

CTSS Compatible Time Sharing System. An IBM 7094 timesharing operating system created at MIT Project MAC and first demonstrated in 1961. May have been the first system to use passwords.

Dictionary attack A password cracking technique in which the cracker creates or obtains a list of words, names, etc., derives hashes from the words in the list, and compares the hashes with those captured from a system user database or by sniffing.

Entropy In information theory, a measure of uncertainty or randomness. The work of Claude Shannon defines it in bits per symbol.

Green Book The 1985 U.S. DoD CSC-STD-002–85 publication *Password Management Guideline*, which defines good practices for safe handling of passwords in a computer system.

Hybrid attack A password-cracking technique that usually takes place after a dictionary attack. In this attack, a tool will typically iterate through its word list again using adding certain combinations of a few characters to the beginning and end of each word prior to hashing. This attempt gleans any passwords that a user has created by simply appending random characters to a common word.

Kerberos A network authentication protocol developed at MIT to provide strong authentication for client/server applications using secret-key cryptography. It keeps passwords from being sent in the clear during network communications and requires users to obtain "tickets" to use network services.

MAC Message authentication code, a small block of data derived by using a cryptographic algorithm and secret key that provide a cryptographic checksum for the input data. MACs based on cryptographic hash functions are known as HMACs.

Moore's Law An observation named for Intel cofounder Gordon Moore that the number of transistors per square inch of an integrated circuit has doubled every year since integrated circuits were invented. This "law" has also variously been applied to processor speed, memory size, etc.

Nonce A random number that is used once in a challenge–response handshake and then discarded. The one-time use ensures that an attacker cannot inject messages from a previous exchange and appear to be a legitimate user (see Replay Attack).

One-way hash A fixed-sized string derived from some arbitrarily long string of text, generated by a formula in such a way that it is extremely unlikely that other texts will produce the same hash value.

One-time password Also called OTP. A system that requires authentication that is secure against passive attacks based on replaying captured reusable passwords. In the modern sense, OTP evolved from Bellcore's S/KEY and is described in RFC 1938.

Orange Book 1983 U.S. DoD 5200.28-STD publication, *Trusted Computer System Evaluation Criteria*, which defined the assurance requirements for security protection of computer systems processing classified or other sensitive information. Superseded by the Common Criteria.

Password synchronization A scheme to ensure that a known password is propagated to other target applications. If a user's password changes for one application, it also changes for the other applications that the user is allowed to log onto.

Plaintext A message or file to be encrypted. After it is encrypted, it becomes *ciphertext*.

Promiscuous mode A manner of running a network device (especially a monitoring device or sniffer) in such a way that it is able to intercept and read every network packet, regardless of its destination address. Contrast with nonpromiscuous mode, in which a device only accepts and reads packets that are addressed to it.

Replay attack An attack in which a valid data transmission is captured and retransmitted in an attempt to circumvent an authentication protocol.

Salt A random string that is concatenated with a password before it is operated on by a one-way hashing function. It can prevent collisions by uniquely identifying a user's password, even if another user has the same password. It also makes hash-matching attack strategies more difficult because it prevents an attacker from testing known dictionary words across an entire system.

SAM Security Account Manager. On Windows systems, the secure portion of the system registry that stores user account information, including a hash of the user account password. The SAM is restricted via access control measures to administrators only and may be further protected using SYSKEY.

Shadow password file In the Unix or Linux, a system file in which encrypted user passwords are stored so they are inaccessible to unauthorized users.

Single sign-on A mechanism whereby a single action of user authentication and authorization can permit a user to access all computers and systems on which that user has access permission, without the need to enter multiple passwords.

Sniffing The processes of monitoring communications on a network segment via a wire-tap device (either software or hardware). Typically, a sniffer also has some sort of "protocol analyzer" which allows it to decode the computer traffic on which it's eavesdropping and make sense of it.

Social engineering An outside hacker's use of psychological tricks on legitimate users of a computer system, in order to gain the information (e.g., user IDs and passwords) needed to gain access to a system.

SSH Secure Shell. An application that allows users to login to another computer over a network and execute remote commands (as in rlogin and rsh) and move files (as in ftp). It provides strong authentication and secure communications over unsecured channels.

SSL Secure Sockets Layer. A network session layer protocol developed by Netscape Communications Corp. to provide security and privacy over the Internet. It supports server and client authentication, primarily for HTTP communications. SSL is able to negotiate encryption keys as well as authenticate the server to the client before data is exchanged.

SYSKEY On Windows systems, a tool that provides encryption of account password hash information to prevent administrators from intentionally or unintentionally accessing these hashes using system registry programming interfaces.

Patent Law

Gerald Bluhm, *Tyco Fire & Security*

INTRODUCTION

This chapter introduces the fundamental concepts of patent law, both in the United States and internationally, with some focus on software and Internet-related issues. Patents have been described as monopolies for limited terms, in exchange for inventors disclosing how their inventions are made or used. With the promise of such monopolies, inventors are encouraged to invent and thus reap the rewards made possible by the rights accorded. Competitors must either obtain a license to make or use a patented invention or discover new ways that circumvent a patented invention as defined by the patent claims.

Some have rejected the use of the word "monopoly" to describe patents. Regardless of whether one uses the word "monopoly," certain rights are granted to the owner of a patent: the right to *exclude* others from making, using, selling, or offering to sell the invention in the United States, importing the invention into the United States, or importing into the United States something made by a patented process. What may not be obvious is that a patent does not grant its owner the right to make, use, sell, offer to sell, or import the patented invention. In fact, many patented inventions are improvements made on existing (and patented) work, and if made, used or sold, they would constitute infringement of the earlier patent.

U.S. PATENT LAW

Constitutional Basis

The U.S. Constitution grants to Congress the power "To promote the Progress of . . . useful Arts, by securing for limited Times to . . . Inventors the exclusive Right to their respective . . . Discoveries" (U.S. Constitution Article I, Section 8, Clause 8). In accordance with this power, Congress has over time enacted several patent statutes. In particular, in 1952, the present patent law, codified under Title 35 of the United States Code (abbreviated as "35 U.S.C.," available on the Web at http://uscode.house.gov/title_35.htm), was enacted, although it has been amended many times over the years.

How Does an Inventor Get a Patent?

The U.S. Patent and Trademark Office

Under the U.S. Department of Commerce, the U.S. Patent and Trademark Office (USPTO; http://www.uspto.gov) processes patent applications and ultimately issues or grants patents. During the processing of an application (a process known as *patent prosecution*), the application is examined by an examiner who is familiar with the specific technology field of the invention described in the application. Typically, the examiner will object to the application because he or she feels that, when compared with prior art (existing knowledge possessed or information accessible by those in the subject technology field), there is nothing novel or unobvious about the invention. Patent prosecution typically involves communications back and forth between the examiner and the inventor (or the inventor's patent attorney or agent) in which the inventor or attorney clarifies for the examiner how the invention is in fact novel and unobvious over the prior art.

Inventors can represent themselves before the USPTO. Alternatively, an inventor (or the assignee to whom the inventor assigns ownership of an invention) may employ an attorney or agent registered with the USPTO. Both patent attorneys and patent agents have technical backgrounds in some science or engineering field and have taken and passed a registration examination administered by the USPTO. In addition, patent attorneys have completed law school and are admitted to practice law in at least one jurisdiction, whereas patent agents are not attorneys.

What Is Patentable?

An inventor may obtain a patent for "any new and useful process, machine, manufacture, or composition of matter, or any new and useful improvement thereof" (35 U.S.C. §101). In a landmark U.S. Supreme Court case in which whether a live, human-made microorganism could be patented was at issue, the Supreme Court unequivocally stated that "anything under the sun that is made by man" is patentable (*Diamond v. Chakrabarty,* 1980).

What is not patentable? Generally speaking, laws of nature, physical phenomena and abstract ideas, per se, are not patentable. For example,

> a new mineral discovered in the earth or a new plant found in the wild is not patentable.... Likewise, Einstein could not patent his celebrated law that $E = mc^2$; nor could Newton have patented the law of gravity. (*Diamond v. Chakrabarty*, 1980)

Of course, a practical application of some physical phenomena may be patentable. For example, although a new plant found in the wild is not patentable, its medicinal use may be patentable. In *Diamond v. Chakrabarty* (1980), the Supreme Court clearly stated that even living things, in this case microorganisms produced by genetic engineering, are patentable. In fact, all that matters is whether the living matter is the result of human intervention.

In particular, Internet-related inventions are patentable and can be protected with method claims, apparatus claims, so-called Beauregard claims, embedded signal claims, and so on, all of which are discussed later in the chapter. Many Internet-related inventions are protected by "business method" patents.

Business Methods

Prior to the *State Street Bank and Trust Co. v. Signature Financial Group, Inc.* (1998) decision by the Court of Appeals for the Federal Circuit (CAFC) in 1998, there was some uncertainty as to whether methods of doing business were patentable. Although the invention claimed was technically a "machine" that implemented business methods, *State Street* (available at Georgetown University's Web site at http://www.ll.georgetown.edu/federal/judicial/fed/opinions/97opinions/97-1327.html) is cited for confirming that indeed business methods themselves are patentable.

In that decision, Signature was the assignee (owner) of U.S. Patent No. 5,193,056. The claimed invention is a system in which mutual funds pool their assets into an investment portfolio to take advantage of economies of scale in administering investments. State Street Bank had been negotiating a license with Signature Financial. When negotiations broke down, State Street Bank sought a declaratory judgment that the patent was invalid because it described a business method. The court, however, determined that indeed business methods are patentable subject matter.

When is a method a business method? It is not always clear if a particular method is strictly a business method. For example, Amazon.com received a patent (U.S. Patent No. 5,960,411) for its 1-click invention. Although the invention has been labeled a method of doing business by some, Amazon has asserted that its 1-click patent is not a business method patent.

The USPTO has established a classification system, with more than 400 classes, which are further divided into subclasses. Every application is assigned to a class and subclass according to the technology of the invention. In general, methods that fall into the USPTO's Class 705 ("Data processing: financial, business practice, management, or cost/price determination") are considered to be business methods. Refer to http://www.uspto.gov/web/offices/ac/ido/oeip/taf/def/705.htm for a list of Class 705 categories. For example, some of the first few subcategories of Class 705 include health care management; insurance; reservation, check-in, or booking display for reserved space; staff scheduling or task assignment; market analysis, demand forecasting, or surveying; and so on. For those inventions that are considered to be business methods, some special rules apply during prosecution of a business method patent application and with respect to infringement. Whereas most patent applications are subjected to examination by a single examiner, the USPTO subjects business method applications to one or more extra reviews. This extra review was added in part as a response to numerous complaints, made in the popular press and elsewhere, that many patents were being issued on inventions that were "clearly" not patentable.

Furthermore, accused infringers of issued business method patents have at their disposal an extra defense against the accusation that infringers of other types of patents do not have. For example, for most patents, if Party A receives a patent for an invention, and Party B has been practicing the invention before issuance of the patent, Party B must stop its practice or obtain a license once the patent issues. After *State Street*, however, Congress added §273 to Title 35 of the U.S. Code as part of the American Inventor's Protection Act of 1999, providing for "intervening rights" to protect parties that may not have applied for a business method patent based on the misconception that such patents were unobtainable. The details of §273 are beyond the scope of this article, but basically it provides, in certain situations, a defense to an infringement claim for a party that was using the patented business method before the patent issued.

Requirements of an Invention

Three basic requirements must be met before one can obtain a patent for an invention: the invention must be novel, it must not be obvious in view of the current state of the art (and with respect to a person knowledgeable or "of ordinary skill" in the art), and it must be useful.

Novelty is statutorily provided for in 35 U.S.C. §102, which describes several conditions in which a patent may not be obtained: 35 U.S.C. §102 states that a patent cannot be obtained if the invention was known or used by others in the United States prior to the patent applicant's invention (this could happen, for example, when two people separately invent the same invention, each unaware of the other's activity or accomplishment) or if the invention has been patented or described in a printed publication anywhere in the world. "Printed publications" may include any information that is freely accessible via the Web, even though a Web page is not technically printed in hard copy.

Even inventors' own writings can be held against them. Inventors have 1 year to file a patent application in the United States if the inventions were patented or described in a printed publication anywhere in the world or if the inventions were in public use or on sale in the U.S.

The prohibition against obviousness is statutorily provided for in 35 U.S.C. §103(a), which states in essence

that even if the invention is not exactly the same as that described in a patent or publication or that is in use or on sale, if the difference is obvious, a patent cannot be obtained. Examiners often provide rejections based on their sense that it would be obvious to combine two or more published patents or other publications that complement each other. Of course, such a combination must be obvious to a person having ordinary skill in the art, and it must have been obvious at the time the invention was made. (Often, by the time a patent issues 2 or 3 years after the patent application was filed, or even when the application was filed, it may seem to be obvious in light of the prior art. However, the critical time to examine obviousness is when the invention was made. As many court decisions show, it is not always an easy thing to cast away current knowledge and place oneself back to the time the invention was made to determine whether it was obvious.) Thus, assertions as to whether an invention is obvious or not in view of the cited art can be highly subjective.

U.S.C. §101 requires that an invention be useful. At least three categories of subject matter have been identified by the Supreme Court that are not, by themselves, patentable: laws of nature, natural phenomena, and abstract ideas. The invention must be useful, concrete, and tangible. For example, the CAFC in *State Street Bank* said that mathematical algorithms by themselves are unpatentable because "they are merely abstract ideas constituting disembodied concepts or truths that are not 'useful.'"

Generally speaking, the requirement that an invention be "useful" is an extremely low bar to patentability. Nonetheless, an invention can fail the usefulness test if an applicant fails to explain adequately why the invention is useful or if an assertion of utility is not credible. For example, the invention considered in *Newman v. Quigg* (1989) was considered to be a perpetual motion machine and thus found to be inoperative (as going against the laws of thermodynamics). It therefore did meet the usefulness standard.

In addition to these requirements, a specification is required in the patent application that includes a written description and at least one claim. The written description must describe the invention and teach enough about it in sufficient detail so as to enable "one skilled in the art" to make or use the invention. The written description must also describe the "best mode" (i.e., the best way to carry out the invention) known to the inventor, although there is no requirement to point out a specific embodiment of the invention as the best mode. (The first paragraph of 35 U.S.C. §112 discusses the requirements of the written description.) The specification must conclude with at least one claim that is the legal statement defining the invention. Courts looks to the claims when determining whether an accused party is infringing a patent. Claims are discussed in more detail later in the chapter. Finally, 35 U.S.C. §113 sets forth the particular requirements for drawings, which must be supplied as necessary to provide an understanding of the invention.

Patent Prosecution

The process of obtaining a patent, from filing of a patent application to responding to office actions from the USPTO, to paying the issue fee, is referred to as *patent prosecution*. The first step in the patent prosecution process, other than invention itself, is often the conducting of a "prior art" search. There is no obligation on the part of an applicant to do a search (although there is an obligation to report known material information to the PTO). Nonetheless, performing a search is often a good idea. If search results show that the invention is not novel, a long and costly (and possibly doomed) prosecution process can be avoided. Even if the invention still appears to be novel after such a search, oftentimes the search helps the person who ultimately drafts the patent application to focus on those parts that are truly novel, by exposing those aspects that are well known or that have been described in printed publications.

A search for U.S. and European patents and published patent applications can be performed, for example, using respectively the USPTO's online search facility and the European Patent Office (EPO) online search facility (see http://ep.espacenet.com). Most patent offices in other countries have their own Web sites that can be searched. A list of these Web sites can be found at the USPTO's and the EPO's Web sites.

In addition, many useful documents and news items may be found on the Web using standard Web searching facilities. Although these are excellent sources, more extensive (and expensive) searches may be conducted using proprietary databases that may contain articles from hundreds or thousands of trade journals, professional publications, newspapers, magazines, and so on.

The next step is preparing or drafting the patent application. As noted earlier, a patent attorney or agent often does this, although inventors can represent themselves before the PTO. The application is then filed with the PTO. Once received by the PTO, an application is assigned an application number and eventually assigned to an art group, consisting of examiners who are familiar with the particular field to which the application/invention pertains.

Eventually the application is assigned to a specific examiner in the art group, who reviews the application in view of both the results of his or her own prior art search and any material information submitted by the applicant. Typically, the examiner objects to one or more aspects of the application, and in an *Office Action*, rejects one or more of the claims based on the prior art. Or the examiner may object to unclear language in the specification or an informality in the submitted drawings. An Office Action is mailed to the applicant (or his attorney), and the applicant must reply within a certain time frame or the application will be considered abandoned.

The applicant can reply to the Office Action in several ways. For example, the applicant can point out the differences between the invention and the prior art cited by the examiner in the Office Action, stressing that the invention is not taught or even suggested by a knowledge of the prior art. In the reply to the Office Action, the applicant can cancel claims, amend claims for clarity, narrow claims to overcome the examiner's rejections, or even broaden claims. New claims may also be added (at least in response to a first Office Action). Corrections to the specification or drawings may also be made, but in any case,

the applicant is never allowed to introduce new matter into the application.

The examiner often makes a subsequent Office Action "final." Certain rules apply when the applicant replies to a final Office Action—for example, new claims cannot normally be added, and only certain amendments of a limited nature are permitted—but a "final" Office Action is not as final as it sounds.

If some claims are allowed in an Office Action, an applicant can, in his or her reply, cancel the rejected claims, permitting a patent to issue with the allowed claims. A new application, called a "continuation" can then be filed with the rejected claims. (Note that this continuation application must be filed while the parent application is pending, that is, before the parent issues as a patent with the allowed claims).

Alternatively, if no claims are allowed, the applicant, in response to a Final Office Action, may file a *Request for Continued Examination*. For the equivalent cost of filing a new application, the applicant is allowed to continue prosecution without the finality of the final office action. In older cases, filed before May 29, 2000, the applicant may, while the first application is pending, file a continuation-type application, called a *Continued Prosecution Application* and allow the first application to become abandoned.

During the course of prosecution, it may be desirable to file a new set of claims while allowing the original application to proceed. For example, the applicant may determine that aspects of the original application not previously claimed may be worth pursuing and may file the same specification with a different set of claims, claiming priority to the first application. This second application is also known as a continuation application. It has its own filing date, but because it claims priority to the first application, it will expire (under the current statute) 20 years from the application date of the first application (or the date of the earliest application in the priority chain). If new matter is added to the specification of a continuation, for example, an improvement or a new configuration, the new application is called a continuation-in-part (CIP). A patent issuing on a CIP application, like other utility patents, expires 20 years from the first application to which the CIP claims priority.

In some cases, an examiner may decide that the claims of an application really describe two or more inventions, each requiring its own prior art search. In this case, the examiner may issue a *restriction requirement* in which the examiner divides the various claims into different groups, each pertaining to a different invention. The applicant is then required to elect one of the groups and to cancel or amend the remaining claims. The canceled claims can be filed (while the original application is still pending) in one or more applications known as "divisional" applications. As with continuations, each divisional application has its own filing date, but each must claim priority to the parent and therefore has a term of 20 years from the filing date of the parent (or the earliest filed application in the priority chain).

Eventually, the applicant hopes, each application (including parent, continuations, CIPs, divisionals) is allowed. For a given allowed patent application, the applicant pays an issue fee, and soon thereafter the patent issues and is then in force. Although the term of a patent is 20 years from the priority date, "maintenance" fees must be paid at specific intervals from the date of issue or the patent expires. Specifically, these intervals are 3 years and 6 months, 7 years and 6 months, and 11 years and 6 months. A 6-month grace period is available for a surcharge.

Appealing an Examiner's Decision

If the applicant is unsatisfied with the examiner's conclusions as to unpatentability, the applicant can appeal to the Board of Patent Appeals and Interferences within the Patent and Trademark Office. Each appeal is heard by at least three members of the board. An applicant who is unhappy with the board's decision may further appeal to the U.S. Court of Appeals for the Federal Circuit (CAFC). The CAFC makes a decision based only on the record from the appeal to the board. Alternatively, an unhappy applicant may file a civil suit against the director of the USPTO in the U.S. District Court for the District of Columbia. Unlike appeals to the CAFC, new evidence may be presented in addition to the record from the appeal to the board.

Publication and Provisional Rights

Applications filed on or after November 29, 2000, are published roughly 18 months from the priority date, unless the applicant specifically requests nonpublication, certifying at the same time that the invention has not been and will not be the subject of an application filed in another country. Early publication can be requested. Applications filed prior to November 29, 2000, but still pending as of that date are not typically published, but publication may be requested.

If a published application eventually issues as a patent, with claims that are "substantially identical" to those published in the application publication, the owner of the patent may be entitled to a reasonable royalty, from the time of the publication date up to the issue date, from someone who makes, uses, offers for sale, or sells the claimed invention in the United States or who imports the claimed invention into the United States and who has actual notice of the published patent application. The rights to these royalties are known as *provisional rights*.

Patent Term—How Long Does a Patent Last?

Patent protection begins on the day a patent issues. Because of a change in law in 1994 to conform to the Uruguay Round of the General Agreement on Tariffs and Trade (GATT), when a patent expires depends on when the application was filed. Prior to the change in law, the term of a U.S. utility patent was 17 years from the issue date. Now, however, any U.S. utility patents issuing from an application filed on or after June 8, 1995, are valid for 20 years from the priority date, that is, the date of the earliest application to which the application claims priority (the earliest filing date in a chain of continuation and divisional applications). Utility patents which were still in force on June 8, 1995, or applications filed prior to that date but still pending, receive the best of both worlds (with regard to patent term): either 17 years from the issue date or 20 years from the priority date, whichever is later.

Various adjustments and extensions may be available under certain conditions. A discussion of these conditions is beyond the scope of this chapter, however. The patent terms discussed here pertain to U.S. utility and plant patents. U.S. design patents expire after 14 years from the issue date.

How to Read a Patent

A patent is organized into several sections. These include a cover sheet, drawings, a specification and claims. The specification includes a background, a summary, a brief description of the drawings, and a detailed description. The cover sheet includes bibliographical information, a short abstract that briefly describes the invention, and usually a copy of one of the drawings considered to be representative of the invention. Drawings must be provided where necessary for understanding the invention. The background section describes prior art, or the state of the art prior to the patented invention. The summary provides a short synopsis of the invention and often is a regurgitation of the claims in plainer language than the claims. A brief description of the drawings typically follows. Next comes a written description (often labeled as a detailed description) of one or more embodiments of the invention. As previously mentioned, the written description must enable any person skilled in the art to make and use the invention. The description must also set forth the "best mode" contemplated by the inventor, although this best mode need not be pointed out as such. Finally, a set of claims is provided which point out and distinctly claim the protected subject matter. Each claim is written as a single sentence and typically consists of a preamble, a transitional phrase, and a set of limitations. For example, Claim 1 of U.S. Patent No. 6,004,596 ("Sealed crustless sandwich") appears as follows:

> I claim:
>
> 1. A sealed crustless sandwich, comprising:
>
> a first bread layer having a first perimeter surface coplanar to a contact surface;
>
> at least one filling of an edible food juxtaposed to said contact surface;
>
> a second bread layer juxtaposed to said at least one filling opposite of said first bread layer, wherein said second bread layer includes a second perimeter surface similar to said first perimeter surface;
>
> a crimped edge directly between said first perimeter surface and said second perimeter surface for sealing said at least one filling between said first bread layer and said second bread layer;
>
> wherein a crust portion of said first bread layer and said second bread layer has been removed.

The *preamble* is the phrase: "A sealed crustless sandwich." The *transitional phrase* is "comprising." These are followed by five limitations: "a first bread layer," "at least one filling," "a second bread layer," "a crimped edge," and the condition "wherein a crust portion . . . has been removed." For this claim to be infringed, an unauthorized party must make, use, sell, or offer to sell or import into the United States a sandwich product that satisfies every one of these limitations. It is irrelevant that a crustless sandwich may have other components not described in the claim, for example, a cherry on top. As long as some food product meets every one of the limitations listed in Claim 1, that product is said to infringe Claim 1. On the other hand, if a sandwich is lacking some element, such as the crimped edge, it cannot literally infringe (but see the subsequent discussion regarding the doctrine of equivalents).

A first claim is typically written broadly to cover a wide range of variations. Narrower claims often follow that include the limitations of the broad claim, plus additional limitations that limit the scope of the invention recited by these narrower claims. Narrower claims are often written as dependent claims.

For example, Claim 1 above is an independent claim. Claim 2 in the same patent reads:

> 2. The sealed crustless sandwich of claim 1, wherein said crimped edge includes a plurality of spaced apart depressions for increasing a bond of said crimped edge.

Claim 2 is called a "dependent" claim because it *depends from* Claim 1, that is, it includes all of the five limitations of Claim 1, plus the further limitation that the crimped edge include "spaced apart depressions." For a sandwich to infringe this claim, it must meet all of the limitations of Claim 1 *and* Claim 2. One reason for providing additional narrower claims is that often, during litigation of a patent suit, some claims may be found to be invalid. Even though a claim may be invalidated in a court of law (for example, if a publication is presented that predates the patent's priority date and that teaches or suggests one or more of the claims), a narrower claim with additional limitations may still be valid, even if it depends from the invalidated claim.

Another reason for providing additional narrower claims is the so-called doctrine of claim differentiation, under which "two claims of a patent are presumptively of different scope" (*Kraft Foods, Inc. v. Int'l Trading Co.*, 2000). According to this doctrine, if a dependent claim includes a narrowing definition of some limitation of a base claim, then the base claim is presumed to encompass not only the narrow definition, but other embodiments as well. For example, Claim 2 may help to support the proposition that Claim 1 covers crustless sandwiches that do not have depressions that are spaced apart as well as crustless sandwiches that have other kinds of bonding mechanisms.

First-time readers of claims are often puzzled by the seemingly bizarre language and grammar used in claims. Sometimes this language results from the statutory requirement that claims particularly point out and distinctly claim the subject matter that the inventor or applicant regards as his or her invention. Thus, use of a definite article

such as "the" is typically not allowed unless it refers to something already defined in the claim (i.e., there is an "antecedent basis" for the thing to which the claim refers). For this reason, one often sees "a number of (things)" where in normal usage, one would say "the number of (things)."

In addition, use of the word "or" is generally frowned upon because it leaves options open and is therefore not considered to distinctly claim an invention. Thus, one often sees in claims language such as "at least one of [Choice A], [Choice B], *and* [Choice C]," or "any of [Choice A], [Choice B], *and* [Choice C]" where in normal speech, one might say "[Choice A], [Choice B], *or* [Choice C]." Similarly, instead of reciting "one or more of," Claims will more often recite "a plurality of" or "at least one of," leading to even more confusing language later in the claims, such as "the at least one of." Although such language may at first be confusing, an understanding of why these terms are used may help in reading and interpreting a claim.

Another aspect of claiming that can be confusing to the layperson is that often almost the exact same language is recited in two different claims. For example, a patent typically will have a method claim and an apparatus (or system) claim that use parallel language. Remember, however, that the right to exclude may be different between a method and an apparatus or composition of matter.

A limitation in an apparatus claim may also be expressed as a means or step for performing a specified function without the recital of any specific structure. While such a limitation is not always triggered by "means for" (also called "means-plus-function") language, and may even be triggered in the absence of such language, such claims are often added to a patent. A "means for" limitation is construed to cover the corresponding structure, material, or acts described in the specification and their equivalents (see 35 U.S.C. §112, sixth paragraph).

In addition to the more or less standard apparatus, method, and "means-for" claims, computer- and software-related inventions are often additionally recited in so-called Beauregard claims and signal claims. As the USPTO states, a computer program is merely a set of instructions, capable of being executed, but is not itself a process [see section 2106(a) of the Manual of Patent Examining Procedure]. To be patentable, a computer-readable medium, or an "article of manufacture" comprising a computer-readable or useable medium, is claimed, having therein a computer program that performs some steps of a process. These types of claims have been called Beauregard claims after the inventor of one of the first patent applications to use such claims (see Beauregard, n.d.).

Another type of claim one might encounter is the so-called propagated signal claim. Such a claim might appear as follows:

> 1. A computer data signal embodied in a carrier wave for [doing something], the computer data signal comprising:
>
> program code for [performing a first action];
>
> program code for [performing a second action];
>
> etc.

Such claims are thought to protect against the unlicensed transmission of a computer program over a network such as the Internet or through modems. Of special concern with claims directed to client–server applications is the fact that a single party may not be performing or using all of the limitations of a claim. In other words, if a claim recites actions taken by both the server and the client and two independent parties control the server and client, then neither party can be an infringer. Therefore, it may be desirable in a patent to have one set of claims directed to the overall invention, another set of claims directed to actions taken at the server (possibly in response to messages received from a client), and yet another set of claims directed to actions taken at a client (possibly in response to messages received from a server).

Protecting Patent Rights

What Rights Are Conferred on a Patentee?

A patent confers specific "exclusive" rights on the owner of a patent. That is, the owner of a patent is granted the right to exclude other parties from various acts, including making, using, offering to sell, or selling the patented invention (as set forth in the claims) within the United States or importing the patented invention into the United States. Where a process is patented (as opposed to an apparatus or composition of matter), the patentee is similarly granted the right to exclude others from using, offering to sell, or selling in the United States or importing into the United States any product made by the claimed process. Note that a patent does not give an owner the right to practice the invention recited in the patent; another (broader) patent may exclude the owner from practicing the invention. These rights begin when the patent is granted, that is, when the patent issues and last until the patent expires. See the Patent Term section for an explanation of how the term of a patent is calculated.

What Is Infringement?

When someone performs one of the restricted acts regarding patented material or a patented method without permission of the patent owner, the patent is said to be "infringed." There are three types of infringement: direct infringement, active inducement to infringe, and contributory infringement. Direct infringement occurs when someone literally performs one of the restricted acts, that is, makes, uses, sells the invention (as set forth in at least one claim of the patent), or offers it for sale in the United States or imports it into the United States. Note that this does not require knowledge by the infringer that the invention is prohibited, nor does it require that the infringer intentionally perform the act. All that is required for direct infringement is the act.

Active inducement to infringe occurs when somebody induces another to infringe. If there is no direct infringement, there cannot be active inducement to infringe, no matter how hard someone tries to induce infringement. (Of course, there could be other legal issues in this case.) Contributory infringement occurs when a component of a patented invention is sold or offered for sale in the United States, or imported into the United States, by a party who is aware that the component is especially made

or adapted for an infringing use. As with active inducement to infringe, there cannot be any contributory infringement unless there is direct infringement by some party. Note that because use must occur within the United States, in an Internet-related patent, there may be no infringement when either a server or a client outside the United States performs some of the elements of a patent claim.

Doctrine of Equivalents and *Festo*

To infringe a patent, a device must have all of the pieces recited in at least one claim. If the device matches the claim's limitations exactly, it is said to "literally" infringe the patent claim. For method patents, if a process matches all of the steps recited by at least one claim, the method is literally infringed. Even if the accused device or process does not match the claims exactly, the judicially created doctrine of equivalents provides that a device that does not literally infringe may still infringe if the differences are "insubstantial." Arguments made by an applicant to overcome an examiner's rejection during prosecution of a patent application may limit the breadth of equivalents. This principle is known as *prosecution estoppel*. In the past, application of prosecution estoppel was somewhat flexible, depending on many variables. More recently, in a 1999 decision, the CAFC, in *Festo Corporation v. Shoketsu Kinzoku Kogyo Kabushiki Co., Ltd.*, drastically limited the scope of the doctrine of equivalents, such that any change to a claim limitation made for patentability acts as a complete bar to the application of the doctrine, as to that limitation.

Even more recently, however, in May 2002, the U.S. Supreme Court overturned the CAFC's complete bar. Instead, the Supreme Court has held that when a claim is narrowed, equivalence may be barred, but the patentee can overcome this bar by showing that "at the time of the amendment one skilled in the art could not reasonably be expected to have drafted a claim that would have literally encompassed the alleged equivalent" (*Festo*, 535 U.S. (2002), slip opinion available at http://www.supremecourtus.gov/opinions/01pdf/00–1543.pdf).

What Are the Remedies?

When the owner of a patent believes another party is infringing, the owner typically seeks one of two things: to have the accused party cease from engaging in the infringing acts or to license the invention to the accused party in order to collect royalties. An owner typically files a lawsuit seeking one or more remedies if the owner does not wish to license the invention or if license negotiations break down or to "persuade" the accused party to obtain a license. The patent owner can seek an injunction against the accused party in which the court can order a cessation of the infringing act. A court can also award monetary damages to compensate the owner for the infringement. These damages can include a reasonable royalty for the use of the invention, as well as interest and other costs on which the court may decide. A court may increase these monetary damages up to three times. In exceptional cases, a court may award attorney fees. (This can be for either party, whichever prevails.)

Defending Against an Accusation of Infringement

Several defenses are available to a party being accused of infringement. This is beyond the scope of this chapter, but a list of possible defenses includes noninfringement, absence of liability, unenforceability, and invalidity of the patent based on numerous reasons. Issuance of a patent by the USPTO creates a presumption of validity of the patent. Nonetheless, a court may rule, based on the patent itself, the prosecution history of the patent application, or new evidence, that the patent is not valid. Generally speaking, damages cannot be obtained for infringements that occurred earlier than 6 years before the filing of the suit. Independent of the statutory time frame, an infringement suit may be barred by *laches,* for example, if the patent owner deliberately delayed bringing the suit for an unreasonable time, knowing that the delay will work to the detriment of the accused infringer. Recently, the CAFC confirmed the existence of *prosecution laches,* in which an unreasonable delay during prosecution of the application, together with harm to the other party caused by the delay, can result in unenforceability of a patent *Symbol Technologies, Inc. et al. v. Lemelson Medical, Education & Research Foundation, Limited Partnership,* 2002).

Court Jurisdiction in Patent Cases

Because patent law is federal law (as opposed to state law), federal courts have jurisdiction over all patent-related cases. Furthermore, although there are many federal courts of appeal, Congress, in seeking to establish a single interpretation of the patent laws, established the Court of Appeals for the Federal Circuit to hear all patent-related appeals (but see below, re *Holmes Group, Inc.*).

Typically, a three-judge panel hears and decides an appealed case. On occasion, that decision may be appealed. One of the parties may ask for an *en banc* rehearing in which all or most of the judges from the CAFC rehear the case. If a party is still not satisfied with the final ruling, they may appeal to the U.S. Supreme Court. Few patent cases are ever heard by the Supreme Court, however, typically one or two a year, if that.

One case that was heard by the Supreme Court recently was *Holmes Group, Inc. v. Vornado Air Circulation Systems, Inc.* (2002), (slip opinion at http://www.supremecourtus.gov/opinions/01pdf/01–408.pdf). In this case, Holmes filed a complaint seeking a declaratory judgment that their products did not infringe Vornado's *trade dress*. Trade dress is another form of protection that does not involve patents. Although the original complaint did not involve patents, Vornado filed a counterclaim alleging patent infringement.

On appeal (after an appeal to and decision by the CAFC), the Supreme Court ruled that the CAFC does not have jurisdiction over a case that involves questions of patent law in which the party bringing the suit did not, in its complaint, assert any patent law issues. Thus, although the CAFC was created in part to form a uniform interpretation of patent law across the country, where the original complaint does not assert any patent law issues, the CAFC does not have jurisdiction, even where patent issues are later asserted in a counterclaim.

Reasons for Obtaining a Patent

There are many reasons a party may wish to obtain patent protection, and the brief discussion presented here is not intended to be all-inclusive. One reason for obtaining a patent is to protect one's intellectual property. Thus, the holder of the patent may be able to prevent competition by preventing others from taking advantage of the invention. Others may decide not to compete at all in the particular area, or may decide to spend significant amounts of time and money developing processes or products that do not infringe. Alternatively, if both sides are willing, the patent holder may license part or all of the patent to another party for a fixed fee, a royalty, or some combination of the two. A license is basically an agreement between a licensor (patent holder) and licensee that the licensor will not sue the licensee for what would otherwise constitute infringement of some or all of the patent claims.

Another reason for obtaining a patent is more defensive. For example, Company B may be reluctant to sue Company A for infringement of Company B's patent, if Company B thinks that Company A may countersue for infringement of Company A's patents. Often, such a situation may result in cross-licensing between the two parties, in which each agrees not to sue the other for infringement of all or part of each other's patents.

Yet another reason for obtaining a patent, especially for start-up companies, is for attracting investment. Investors like to know that there is some value in whatever they are investing in, and the existence of one or more patents (or even pending patent applications) may be an indication of a company's viability.

Types of Patents

In the United States, there are several types of patents: utility patents, plant patents, and design patents. Utility patents are the patents that most people typically think of when they think of patents. Utility patents may be obtained for "any new and *useful* process, machine, manufacture, or composition of matter, or any new and useful improvement thereof" (35 U.S.C. §101). The Plant Patent Act of 1930, now codified as 35 U.S.C. §161, allows "plant patents" for plants that are asexually reproduced. Tubers, such as potatoes, are excluded (i.e., they are not patentable). To be patentable, a plant must have been found in an uncultivated state (e.g., *not* in a garden). A plant patent includes the right to exclude others from asexually reproducing the plant; using, offering for sale, or selling the plant (or parts of the plant) in the United States; or importing the plant into the United States if it was asexually reproduced (see 35 U.S.C. §§161–164).

Despite the availability of plant patents, utility patents may also be obtained for both sexually and asexually reproduced plants (see *J.E.M. AG Supply Inc, dba Farm Advantage, Inc., et al. v. Pioneer Hi-Bred International, Inc.*, 2001; slip op at www.supremecourtus.gov/opinions/01pdf/99–1996.pdf). The requirements for obtaining a plant patent are more relaxed than the requirements for obtaining a utility patent, however.

Design patents may be obtained for new, original, and ornamental designs for manufactured articles. A design patent protects the way an article looks, as depicted in the drawings. Design patents have a term of 14 years from the issue date. Design patents may be obtained for computer-generated icons, including full-screen displays and individual icons. The USPTO's Manual of Patent Examining Procedure (MPEP), section 1504.01(a) provides "Guidelines for Examination of Design Patent Applications for Computer-generated Icons." (See U.S. Design Patent D453,769 for an example of a design patent for a computer-generated icon.) According to the MPEP (section 1504.01(a).1.A), to satisfy the manufactured article requirement, such an icon must be claimed as "a computer-generated icon shown on a computer screen, monitor, other display panel, or a portion thereof" or with similar language. The icon must also be fundamentally ornamental rather than functional. Fonts may also be patented with design patents. (For an example, see U.S. Design Patent D454,582.)

Provisional Applications

A provisional application is a patent application and must have a written description and drawings sufficient to teach the invention to one skilled in the art. A provisional application is never examined, however, and no claims are required. It is relatively inexpensive to file and provides a priority date for any application filed within a year claiming the benefit of the provisional application, as to the matter disclosed in the provisional application. Note, however, that a provisional application is automatically abandoned 1 year from its filing date. Provisional applications do not issue. A nonprovisional application must be filed within a year to receive the benefit of the filing date. Although a provisional application establishes a priority date, the 20-year term of an issued patent claiming the benefit of the provisional application begins on the filing date of the first nonprovisional application in the priority chain.

NON-U.S. PATENTS

General Information

Patents are, of course, available in other countries as well as in the United States. For example, one may apply for and obtain a patent in almost any country in the world. One may file a first application almost anywhere in the world, follow up with applications in other countries within 1 year of filing the first application, and obtain the first application's filing date as a priority date. Besides filing in individual countries, there are several regional areas in which applications can be made. These include the European Patent Convention (EPC; http://www.epo.org); the African Intellectual Property Organization (OAPI; http://www.oapi.wipo.net), the members of which are French-speaking African countries; the African Regional Industrial Property Organization (ARIPO; http://www.aripo.wipo.net), the members of which are English-speaking African countries; and the Eurasian Patent Organization (EAPO), the members of which include former republics of the Union of Soviet Socialist Republics (http://www.eapo.org).

For protection in European countries that are EPC members, an application is filed at the European Patent Office (EPO) in Munich, Germany, designating some or

all EPC member countries. Only one application needs to be filed and prosecuted to obtain coverage for any or all of the member countries. The application can be filed and prosecuted in English up to the point of issuance. A separate national patent issues for each selected country, and each patent is subject to the patent laws of the country in which it issues. A separate European Community Patent may become available in the next few years, wherein an application filed under this regime would issue as a single community-wide patent, subject ot a single jurisdiction with regard to various legal claims.

Yet another alternative is to file an application according to the Patent Cooperation Treaty (PCT; see http://www.wipo.int/pct/en). A PCT application serves as an application in each country designated in the application. The process begins when an applicant from a member country files a PCT application in a designated receiving office (such as the U.S. Patent and Trademark Office). This begins the "international stage." The application is published 18 months after the priority date. A search is performed and the search results are returned to the applicant. At the request of the applicant, a preliminary examination may be performed. This is similar to patent prosecution in the United States, although the applicant typically has just one chance to respond to a Written Opinion and to amend the claims. Thirty months (31 months for some countries) from the priority date, or 20 months in some countries if the preliminary examination has not been requested, the application must enter the *national stage* in those countries or regions in which protection is sought. Prosecution of the application then continues independently in each country or region until grant.

Filing patent applications in multiple jurisdictions can be expensive. To keep costs down, applicants typically file only in those jurisdictions where the invention is likely to be used most frequently and where meaningful enforcement can be achieved. A PCT application enables an applicant, for a relatively low cost, to delay for up to 30 months (31 months in some cases) both the designation of particular countries or regional jurisdictions and the costs of entering in those countries and regions.

Although beyond the scope of this chapter, there are foreign filing licensing requirements that must be considered before filing foreign or international (i.e., PCT) applications.

Differences Between the United States and Other Countries

Although many of the procedures and rights are similar, some differences between the United States and other nations exist. For one, in the United States (and Canada and Australia), an application may be filed up to 1 year after a publication that describes the invention. In most, if not all, other countries, such a disclosure prior to the filing of an application is an absolute bar to obtaining a patent. Another difference is that in the United States, when two inventors claim to have independently invented the invention, the patent is awarded to the first to invent (with some caveats). Of course, the precise instance of invention may be difficult to discern and to prove, leading to a complicated procedure known as interference proceedings. The rest of the world follows a "first-to-file" policy, in which a patent for an invention is awarded to the first applicant to file, regardless of who invented first.

Another difference is the term of a patent. Although patents issuing on U.S. applications filed after June 8, 1995, have a term of up to 20 years from the priority date, which is the same as foreign patents, as mentioned previously, earlier patents have a term of 17 years from issuance, and there are still many patents with this term in force.

Computer programs are also handled differently. In the United States, a computer program is patentable if it produces a "useful, concrete, and tangible result" (*State Street*,1998). In many foreign countries, however, software per se is explicitly barred from being patentable.

Another notable difference is that in the United States, the applicants must be the inventors (although they can assign their rights), whereas in other countries, the applicant may be either the inventor or the assignee. Also, in the United States, examination of a patent application by an examiner is automatic. In many other countries (e.g., Japan and South Korea), examination must be requested within some time period from the filing date. For example, in Japan, the examination must be requested within 3 years for a patent application filed on or after October 1, 2001. For applications filed prior to that date, the request must be within 7 years.

CONCLUSION

A patent does not give the owner the right to practice the invention, that is, the right to make, use, sell or offer for sale the invention in the United States, to import the invention into the United States, or to import into the United States something made by a patented process, but rather gives the inventor the right to exclude others from doing these things. That is, in return for disclosing the invention, the patentee is granted a limited term (typically 20 years from filing) in which the competition cannot use the patented device or method. The competition therefore must research and develop noninfringing alternatives, a process that could be costly, timely, and, in some cases, futile, giving the patentee a substantial advantage over the competition. Alternatively, the patentee may choose to license the patented technology and collect a royalty. For these and other reaons discussed above, patents are valuable assets for any business, large or small.

GLOSSARY

Claim The part of a patent which distinctly calls out the inventive subject matter that is protected by the patent.

Dependent claim A patent claim that incorporates by reference the limitations of another patent claim. Such a claim typically begins with language such as "The device of Claim X, further comprising" in which the limitations of Claim X are incorporated by reference.

Doctrine of claim differentiation A doctrine under which two claims of a patent are presumptively of different scope, so that if a dependent claim includes a narrowing definition of some limitation of a base claim, then the base claim is presumed to not only encompass the narrow definition, but other embodiments as well.

Doctrine of equivalents A doctrine by which, even if a device or process does not exactly match the claims of a patent, the device may still infringe the patent if the differences are insubstantial.

Element Although "element" and "limitation" are sometimes used interchangeably, the term "element" is used more frequently by the courts to refer to aspects of an alleged infringing device or method. In an infringement case, the elements of the alleged infringing device or method are compared with the claim limitations of the patent allegedly being infringed. Note, however, that 35 U.S.C. §112 refers to both an "element in a claim" (sixth paragraph) and "limitations of [a] claim" (fourth and fifth paragraphs).

Independent claim A patent claim that does not incorporate any other patent claim by reference.

Laches An equitable principle whereby a party is estopped (not allowed) from bringing a lawsuit after an unreasonable or unexplained delay which has a detrimental effect on the party being sued.

Limitation Part of a claim that defines a particular aspect of the invention. Every claim has at least one limitation, and most claims have two or more limitations.

Means plus function A particular claim limitation may be written in "means plus function" language, wherein the claim is a means or a step for performing a specified function, without reciting particular structure, material or acts, which are thus construed to be those described in the specification (and equivalents). "Means plus function" claim elements are specifically authorized by 35 U.S.C. §112, sixth paragraph.

Nonobvious One of the basic requirements in obtaining a patent is that the invention be nonobvious to one of ordinary skill in the particular art concerned, in view of the known (prior) art.

Novelty One of the basic requirements in obtaining a patent is that the invention be novel. Legally, this means that the invention must not be barred by any of the conditions stated in 35 U.S.C. §102.

Patent A grant for a fixed term that gives the holder certain rights to exclude others from practicing the patented invention as claimed. Title 35 of the United States Code provides the patent law statutes.

Patent Cooperation Treaty (PCT) A treaty under which an applicant of a member country can file a single patent application that may designate one, many, or all of the member countries. A PCT patent application is an application. The PCT does not grant patents.

Prior art The accumulated knowledge of those skilled in the particular art concerned, which can bar issuance of a patent if the claims are not novel or nonobvious in view of the prior art. Prior art that can bar issuance of a patent in the United States is defined in 35 U.S.C. §102.

Prosecution The process of obtaining a patent, from the filing of an application to the issuance of the patent (or abandonment of the application).

Prosecution laches An equitable principle in which unreasonable delay during prosecution of a patent application, together with harm to another party caused by the delay, can result in unenforceability of the issued patent.

Provisional application A patent application designated as such that is never examined but serves to provide a priority date.

Provisional rights The rights of a patent owner to a reasonable royalty for an infringing device or method, covering the period between publication of a patent application and the granting of the patent with substantially identical claims as those in the published application.

U.S. Patent and Trademark Office (USPTO) The U.S. agency authorized to grant and issue patents and to facilitate the registration of trademarks.

Peer-to-Peer Systems

L. Jean Camp, *Harvard University*

CLIENTS, SERVERS, PEERS

Peer-to-peer systems (P2P) are the result of the merger of two distinct computing traditions: the scientific and the corporate. Understanding the two paths that merged to form P2P illuminates the place of P2P in the larger world of computing. Thus peer-to-peer computing when placed in historical context is both innovative and consistent with historical patterns. This larger framework assists in clarifying the characteristics of P2P systems and identifying the issues that all such systems must address by design. Recall that the core innovation of P2P is that the systems enable Wintel (Windows/Intel) desktop computers to function as full participants on the Internet, and the fundamental design requirement is coordination.

Computers began as centralized, hulking, magnificent creations. Each computer was unique and stood alone. Computers moved into the economy (beyond military uses) primarily through the marketing and design of IBM. When a mainframe was purchased from IBM it came complete. The operating systems, the programming, and (depending on the purchase size) sometimes even a technician came with the machine. Initially mainframe computers were as rare as supercomputers are today. Machines were so expensive that the users were trained to fit the machine, rather than the software being designed for the ease of the user. The machine was the center of the administrative process as well as a center of computation. The company came to the machine.

Technical innovation (the front-end processor and redesigned IBM machines) made it possible to reach multiple mainframes from many locations. Front-end processors allowed many terminals to easily attach to a single machine. Thus the first step was taken in bringing access to the user in the corporate realm. Processing power could be widely accessed through local area networks (LAN). Yet the access was through terminals with little processing power and no local storage. The processor and access remained under the administrative control of a single entity. While physical access was possible at a distance, users were still expected to learn arcane commands while working with terse and temperamental interfaces.

In parallel with the adoption of computing in the corporate world, computing and communications were spreading through the scientific and technical domains. The ARPANET (the precursor to the Internet) was first implemented in order to share concentrated processing power in scientific pursuits. Thus the LAN was developing in the corporate realm while the wide area network (WAN) was developing in the world of science.

Before the diffusion of desktop machines, there were so-called microcomputers on the desktops in laboratories across the nation. These microcomputers were far more powerful than concurrent desktop machines. (Currently microcomputers and desktop computers have converged because of the increase in affordable processing power.) Here again the user learned to communicate based on the capacities of the machine. These users tended to embrace complexity; thus they altered, leveraged, and expanded the computers.

Because microcomputers evolved in the academic, scientific, and technical realm the users were assumed to be capable managers. Administration of the machines was the responsibility of the individual users. Software developed to address the problems of sharing files and resources assumed active management by end users. The early UNIX world was characterized by a machine being both a provider and a consumer of services, both overseen with a technically savvy owner/manager.

The Internet came from the realm of the UNIX world, which evolved independently of the desktop realm. Comparing the trajectories of e-mail in the two realms is illustrative. On the desktop, e-mail evolved in proprietary environments where the ability to send mail was limited to those in the same administrative domain. Mail could be centrally stored and was accessed by those with access rights provided by a central administrative body. In contrast, in UNIX environments, the diffusion of e-mail was enabled by each machine having its own mail server. For example, addresses might be michelle@smith.research.science.edu in one environment as opposed to john_brown@vericorp.web in the other. (Of course early corporate mail services did not use domain names, but this fiction simplifies the example.) In the first

case Michelle has a mail server on her own UNIX box; in the second John Brown has a mail client on his machine that connects to the shared mail server being run for Vericorp. Of course, now the distinct approaches to e-mail have converged. Today users have servers that provide their mail, and access mail from a variety of devices (as with early corporate environments). E-mail can be sent across administrative domains (as with early scientific environments). Yet the paths to this common endpoint were very different with respect to user autonomy and assumptions about machine abilities.

The Internet and UNIX worlds evolved with a set of services assuming all computers were contributing resources as well as using them. In contrast, the Wintel world developed services where each user had corresponding clients to reach networked services, with the assumption that connections were within a company. Corporate services are and were provided by specialized powerful PCs called (aptly) servers. Distinct servers offer distinct services with one service per machine or multiple services running from a single server. In terms of networking, most PCs either used simple clients, acted as servers, or connected to no other machines.

Despite the continuation of institutional barriers that prevented early adoption of cross-corporate WANs, the revolutionary impact of the desktop included fundamentally altering the administration, control, and use of computing power. Standalone computers offered each user significant processing ability and local storage space. Once the computer was purchased, the allocation of disk space and processing power were under the practical discretion of the individual owner. Besides the predictable results, for example the creation of games for the personal computer, this required a change in the administration of computers. It became necessary to coordinate software upgrades, computing policies, and security policies across an entire organization instead of implementing the policies in a single machine. The difficulty in enforcing security policies and reaping the advantages of distributed computing continues, as the failures of virus protection software and proliferation of vulnerabilities illustrates.

Computing on the desktop provides processing to all users, offers flexibility in terms of upgrading processing power, reduces the cost of processing power, and enables geographically distributed processing to reduce communications requirements. Local processing made spreadsheets, "desktop" publishing, and customized presentations feasible. The desktop computer offered sufficient power that software could increasingly be made to fit the users, rather than requiring users to speak the language of the machines.

There were costs to decentralization. The nexus of control diffused from a single administered center to across the organization. The autonomy of desktop users increases the difficulty of sharing and cooperation. As processing power at the endpoints became increasing affordable, institutions were forced to make increasing investments in managing the resulting complexity and autonomy of users.

Sharing files and processing power is intrinsically more difficult in a distributed environment. When all disk space is on a single machine, files can be shared simply by altering the access restrictions. File sharing on distributed computers so often requires taking a physical copy by hand from one to another that there is a phrase for this action: sneakernet. File sharing is currently so primitive that it is common to e-mail files as attachments between authors, even within a single administrative domain. Thus currently the most commonly used file-sharing technology remains unchanged from the include statements dating from the sendmail on the UNIX boxes of the 1980s.

The creation of the desktop is an amazing feat, but excluding those few places that have completely integrated their file systems (such as Carnegie Mellon which uses the Andrew File System) it became more difficult to share files, and nearly impossible to share processing power. As processing and disk space become increasingly affordable, cooperation and administration became increasingly difficult.

One mechanism to control the complexity of administration and coordination across distributed desktops is a client–server architecture. Clients are distributed to every desktop machine. A specific machine is designated as a server. Usually the server has more processing power and higher connectivity than the client machines. Clients are multipurpose, according to the needs of a specific individual or set of users. Servers have either one or few purposes; for example, there are mail servers, Web servers, and file servers. While these functions may be combined on a single machine, such a machine will not run single-user applications such as spreadsheet or presentation software. Servers provide specific resources or services to clients on machines. Clients are multipurpose machines that make specific requests to single-purpose servers. Servers allow for files and processing to be shared in a network of desktop machines by reintroducing some measure of concentration. Recall that peers both request and provide services. Peer machines are multipurpose machines that may also be running multiple clients and local processes. For example, a machine running Kazaa is also likely to run a Web browser, a mail client, and a MP3 player. Because P2P software includes elements of a client and a server, it is sometimes called a *servlet*.

Peer-to-peer technology expands file- and power-sharing capacities. Without P2P, the vast increase in processing and storage power on the less-predictable and more widely distributed network cannot be utilized. Although the turn of the century sees P2P as a radical mechanism used by young people to share illegal copies, the fundamental technologies of knowledge sharing as embedded in P2P are badly needed within government and corporate domains.

The essence of P2P systems is the coordination of those with fewer, uncertain resources. Enabling any party to contribute means removing requirements for bandwidth and domain name consistency. The relaxation of these requirements for contributors increases the pool of possible contributors by order of magnitude. In previous systems sharing was enabled by the certainty provided by the technical expertise of the user (in science) or administrative support and control (in the corporation). P2P software makes end-user cooperation feasible for all by simplification of the user interface.

PCs have gained power dramatically, yet most of that power remains unused. While any state-of-the-art PC purchased in the past five years has the power to be a Web server, few have the software installed. Despite the affordable migration to the desktop, there remained a critical need to provide coordinated repositories of services and information.

P2P networking offers the affordability, flexibility, and efficiency of shared storage and processing offered by centralized computing in a distributed environment. In order to effectively leverage the strengths of distributed coordination P2P systems must address reliability, security, search, navigation, and load balancing.

P2P systems enable the sharing of distributed disk space and processing power in a desktop environment. P2P brings desktop Wintel machines into the Internet as full participants.

Peer-to-peer systems are not the only trend in the network. Although some advocate an increasingly stupid network and others an increasingly intelligent network, what is likely is an increasingly heterogeneous network.

FUNCTIONS OF P2P SYSTEMS

There are three fundamental resources on the network: processing power, storage capacity, and communications capacity. Peer-to-peer systems function to share processing power and storage capacity. Different systems address communications capacity in different ways, but each attempts to connect a request and a resource in the most efficient manner possible.

There are systems that allow end users to share files and file and groupware processing power. Yet none of these systems are as effective as peer to peer systems. However, all of these systems solve the same problems as P2P systems do: naming, coordination, and trust.

Mass Storage

As the sheer amount of digitized information increases, the need for distributed storage and search increases as well. Some P2P systems enable sharing of material on distributed machines. These systems include Kazaa, Publius, Free Haven, and Gnutella. (Limewire and Morpheus are Gnutella clients.)

The Web enables publication and sharing of disk space. The design goal of the Web was to enable sharing of documents across platforms and machines within the high-energy physics community. When accessing a Web page a user requests material on the server. The Web enables sharing, but does not implement searching and depends on DNS for naming. As originally designed the Web was a P2P technology. The creation of the browser at the University of Illinois Urbana–Champaign opened the Web to millions by providing an easy-to-use graphical interface. Yet the dependence of the Web on the DNS prevents the majority of users from publishing on the Web. Note the distinction between the name space, the structure, and the server as constraints.

The design of the hypertext transport protocol (HTTP) does not prevent publication by an average user. The server software is not particularly complex. In fact, the server software is built into Macintosh OS X. The constraints from the DNS prevent widespread publication on the Web. Despite the limits on the namespace, the Web is the most powerful mechanism used today for sharing content. The Web allows users to share files of arbitrary types using arbitrary protocols. Napster enabled the sharing of music. Morpheus enables the sharing of files without constraining the size. Yet neither of these allows the introduction of a new protocol in the manner of HTTP.

The Web was built in response to the failures of distributed file systems. Distributed files systems include the network file system and the Andrew file system, and are related to groupware. Lotus Notes is an example of popular groupware. Each of these systems shares the same critical failure—institutional investment and administrative coordination are required.

Massively Parallel Computing

In addition to sharing storage P2P systems can also share processing power. Examples of systems that share processing power are Kazaa and SETI@home.

There are mechanisms other than P2P systems to share processing power. Such systems run only on UNIX variants, depend on domain names, are client–server, or are designed for use only within a single administrative domain. Metacomputing and clustering are two approaches to sharing processing power. Despite the difference in platform, organization, and security, the naming and organization questions are similar in clusters and peering systems.

Clustering systems are a more modern development. Clustering software enables discrete machines to run as a single machine. Beowulf came from NASA in 1993 (Wulf et al., 1995). The first Beowulf Cluster had 16 nodes (or computers) and the Intel 80486 platform. (Arguably this was more than a money-saving innovation as it was a pivotal moment in the fundamental paradigmatic change in the approach to supercomputing reflected in P2P.) DAISy (Distributed Array of Inexpensive Systems) from Sandia was an early provider of a similar functionality. Yet these systems are descended from the UNIX branch of the network tree. Each of these systems are built to harness the power of systems running Linux, as opposed to running on systems loaded with the Windows operating system. (Linux systems are built to be peers, as each distribution includes, for example, a Web server and browser software as well as e-mail servers and clients.)

Clustering systems include naming and distribution mechanisms. Recall Beowulf, an architecture enabling a supercomputer to be built out of a cluster of Linux machines. In Beowulf, the machines are not intended to be desktop machines. Rather the purpose of the machines is to run the software distributed by the Beowulf tree in as fast a manner as possible. Beowulf is not a single servlet. Beowulf requires many elements, including message-passing software and cluster management software, and is used for software designed for parallel systems. Beowulf enables the same result as that provided by a P2P processor-sharing system: the ability to construct a supercomputer for a fraction of the price. Yet Beowulf assumes the clusters are built of single-purpose machines within a single administrative domain.

EXAMPLES OF P2P SYSTEMS

In this section the general principles described above are discussed with respect to each system. For each system design goals and organization (including centralization) are discussed. Mechanisms of trust and accountability in each system are described.

Given the existence of a central server there are some categorizations that place SETI@home and Napster outside the set of P2P systems. They are included here for two reasons. First for theoretical reasons, both of these systems are P2P in that they have their own name spaces and utilize heterogeneous systems across administrative domains in cooperative resource sharing (Oram, 2001). Second, any definition that is so constrained as to reject the two systems that essentially began the P2P revolution may be theoretically interesting but are clearly flawed.

P2P systems are characterized by utilization of desktop machines that lack domain names, experience intermittent connectivity, have variable connection speeds when connected, and possibly have variable connection points (for laptops, or users with backup ISPs).

Napster

Napster began as a protocol, evolved to a Web site, became a business with an advertising-driven value of millions, and is now a wholly owned subsidy of Bertelsmann entertainment. Yet the initial design goal was neither to challenge copyright law nor to create a business; the original goal was to enable fans to swap music in an organized manner. Before Napster there were many Web sites, ftp sites, and chat areas devoted to locating and exchanging music files in the MPEG3 format; Napster, however, simplified the location and sharing processes. The goal of Napster was to allow anyone to offer files to others. Thus the clients were servers, and therefore Napster became the first widely known P2P system.

Before Napster, sharing music required a server. This required a domain name and specialized file transfer software or streaming software. The Napster client also allowed users to become servers, and thus peers. The central Napster site coordinated the peers by providing a basic string-matching search and the file location. As peers connected to Napster to search, the peers also identified the set of songs available for download.

After Napster the client software was installed on the peer machine and contacted http://www.napster.com, Napster the protocol then assigned a name to the machine. As the peer began to collect files it might connect from different domains and different IP addresses. Yet whether the machine was connected at home or at work Napster could recognize the machine by its Napster moniker.

Thus Napster solved the search problem by centralization and the problem of naming by assignment of names distinct from domain names.

When a peer sought to find a file, the peer first searched the list of machines likely to have the file at the central Napster archive. Then the requesting peer selected the most desirable providing peer, based on location, reputation, or some other dimension. The connection for obtaining the file was made from the requesting peer to the providing peer, with no further interaction with the central server. After the initial connection the peer downloaded the connection from the chosen source. The chosen source by default also provided a listing of other songs selected by that source.

Accountability issues in Napster are fairly simple. Napster provided a single source for the client; therefore downloading the peer-to-peer software needed to join the network was not an issue of trust. Of course, the Napster Web site itself must be secure. Napster had been subject to attacks by people uploading garbage files but not by people upload malicious files.

In terms of trust, each user downloaded from another peer who was part of the same fan community. Grateful Dead fans share music as do followers of the Dave Matthews Band. Each group of fans shared music within their communities. It is reasonable to assert that Napster was a set of musical communities, as opposed to a single community of users.

Kazaa

Kazaa is a P2P system optimized for downloads of large files. Unlike the hobbyist or scientific basis of many P2P systems, the widely installed Kazaa software has always been a business first. Kazaa is downloaded by users presumable for the access to music and, in particular, large video files on remote machines. Kazaa was created by a team of Dutch programmers and then sold to Sharman Networks. In 2002 Kazaa was downloaded by more than 120 million users. Kazaa has always sold advertising, charging to access the customers' attention span. Kazaa has decentralized search and file distribution.

Kazaa also installs up to four types of additional software in order to enhance its revenue stream. First, and most importantly for Kazaa, the software installs an ad server. Kazaa's business model depends on advertiser revenue. Kazaa installs media servers to enable high-quality graphics in its advertising.

Second, Kazaa installs software to use processing resources on the users' machines. Sharman Networks has teamed with Brilliant Networks to develop software that enables processing power to be shared. With a centralized command the Brilliant Software owners can utilize the processing power of all Kazaa users. As of the close of 2002, the system is not being used to resell processing power. Company statements suggest it is being used to allow machines to serve ads to others (Borland, 2002).

Third, Kazaa installs media servers that allows complex video advertisements.

Fourth, Kazaa alters affiliate programs. Many companies get a percentage of purchases. Affiliate programs are used by businesses, not-for-profits, and individuals. Kazaa intercepts affiliate messages and alters the flow of revenue to Kazaa.

In some versions, Kazaa includes a shop-bot, which compares prices while the user shops using a browser. The shop-bot identifies sites with better prices when the user seeks an identifiable good.

Kazaa also offers New.net—an alternative domain name root. By enabling an alternative root New.net allows

users to choose domains names other than the original top-level domain names and allows domain name registrants to maintain their own privacy. (The governing body of the original top-level domain names increasingly requires identifying information whenever a domain name is purchased. Anonymous domain names, and thus anonymous speech, are increasingly disallowed in the top-level domains controlled by ICANN.)

In terms of trust the user must trust Kazaa and trust other users.

In order to encourage users to cooperate Kazaa has a *participation level*. According to a competitor (K-lite) the participation level measures the ratio of downloads to uploads. Depending on this ratio the speed of downloads is altered. A user who offers popular content is allowed higher access speeds than users who download but do not upload.

According to Kazaa the participation level only matters if there is competition for a file. If two or more users seek to access a file then the user with the higher participation level has priority. According to K-lite there are controls on download speeds for all access attempts.

Besides offering uploads, another way to increase a participation level is to increase the detail of metadata available about a file. Integrity is a measure of the quality of the descriptors of the data. Metadata describes the content, including identifying infected or bogus files by rating them as "D." "Integrity level" is another trust mechanism implemented with Kazaa. This means that the descriptors may be good regardless of the quality of the data. Other descriptions include content and technical quality.

Kazaa implements mechanisms to enables users to trust each other and trust the content downloaded. Kazaa does not implement technical mechanisms to encourage the user to trust Kazaa itself. Kazaa offers stated privacy policies for all the downloaded software. However, the difference between the descriptions of participation level at Kazaa and K-lite suggests that there is distrust. In addition, the prominent declaration on Kazaa's site that there is no spyware in October 2002 in Kazaa suggests that there is indeed concern. This declaration directly contradicts media reports and the description of competitors describing the installation of spyware by Kazaa. (See Lemos, 2002.)

Search for Intelligent Life in the Universe

SETI@home distributes radio signals from the deep space telescope to home users so that they might assist in the search for intelligent life. The Arecibo telescope sweeps the sky collecting 35 Gbyte of data per day.

To take part in this search, each user first downloads the software for home machine use. After the download the user contacts the SETI@home central server to register as a user and obtain data for analysis. Constantly connected PCs and rarely connected machines can both participate.

There are other projects that search for intelligent life via electromagnetic signals. Other programs are limited by the available computing power. SETI@home allows users to change the nature of the search, enabling examination of data for the weakest signals.

SETI@home is indeed centralized. There are two core elements of the project—the space telescope at Arecibo and the peer-to-peer analysis system. Each user is allocated data and implements analysis using the SETI software. After the analysis the user also receives credit for having contributed to the project.

SETI tackles the problem of dynamic naming by giving each machine a time to connect, and a place to connect. The current IP address of the peer participant is recorded in the coordinating database.

SETI@home is P2P because it utilizes the processing power of many desktops, and uses its own naming scheme in order to do so. The amount of data examined by SETI@home is stunning, and far exceeds the processing capacity of any system when the analysis is done on dedicated machines. SETI is running 25% faster in terms of floating point operations per second at 0.4% of the cost of the supercomputer at Sandia National Laboratories. (The cost ratio is 0.0004.) SETI@home has been downloaded to more than 100 countries. In July 2002 there were updates to the SETI software in Bulgarian, Farsi, and Hebrew.

The software performs Fourier transforms—a transformation of frequency data into time data. The reason time data are interesting is that a long constant signal is not expected to be part of the background noise created by the various forces of the universe. Finding a signal that is interesting in the time domain is indicative of intelligent life.

The client software can be downloaded only from SETI@home in order to make certain that the scientific integrity of code is maintained. If different assumptions or granularity are used in different Fourier analyses, the results cannot be reliably compared with other results using original assumptions. Thus even apparently helpful changes to the code may not, in fact, be an improvement.

SETI@home provides trustworthy processing by sending out data to different machines. This addresses both machine failures and malicious attacks. SETI@home has already seen individuals altering data to create false positives. SETI@home sends data to at least two distinct machines, randomly chosen, and compares the results. Note that this cuts the effective processing rate in half, yielding a cost/processing ratio of 0.002 as opposed to a 0.004. However, the cost per processing operation remains three orders of magnitude lower for SETI@home than for a supercomputer.

SETI@home has also had to digitally sign results to ensure that participants do not send in results multiple times for credit within the SETI@home accounting system. (Since there is no material reward for having a high rating the existence of cheating of this type came as a surprise to the organizers.) SETI@home can provide a monotonically increasing reputation because the reputation is the reward for participation. In addition to having contributions listed from an individual or a group, SETI@home lists those who find any promising anomalies by name.

Gnutella

Gnutella was developed as an explicit response to the legal problems of Napster (von Lohmann, 2001). The developers of Gnutella believed that the actions labeled as theft by the owners of copyrights were in fact sharing.

Philosophical and economic arguments (qualitative and quantitative) that Napster encouraged the purchase of compact discs have been made, e.g., Pahfl (2001). Some argue that the sharing of songs on Napster was more advertisement than substitute for a purchased work. The creators of Gnutella had observed the expansion of rights of trademark holders and the ability of censors to use copyright law to prevent critical speech. (The Church of Scientology has had particular success in this legal strategy.)

Based on concepts of fair use and ideological commitments to sharing, Gnutella enables sharing of various types of files. Gnutella allows users to share their disk space for storage and search by integrating the search into the client.

Gnutella searches works on the basis of local broadcasts. Each peer is connected to *n* other peers in a search pattern, and so on down the line. If a peer receives a query that it can answer, it responds affirmatively. If the peer does not have the requested content then the receiving peer resends the query to its immediate peers. Because Gnutella is built in this modular fashion, shutting down a single peer will not prevent sharing. Gnutella applications can exist in a large networked tree or as independent cells.

The broadcast model of searching is considered to be a weakness with respect to the ability to scale (Ritter, 2002). However, Gnutella's search technique allows local cells to survive without broader connections and implements a very through search. Gnutella enables scaling through segmenting the network. Gnutella creates a small world network, where there is a network of closely connected nodes and few connections between the networks. The design is based on the six-degrees-of-separation concept (familiar to some as the Kevin Bacon game).

In Gnutella the searches are made anonymous, yet downloads are not. Thus there is the assumption that the server contacted by a requester will not log the request. Yet this assumption has not held up in practice. Gnutella requires that requestors trust providers. The trust assumption has been used to entrap criminals. In particular, some users work to defeat the use of Gnutella to trade child pornography. By using a tool to generate fake file names combining explicit words and young ages and logging the file, it is fairly simple to post deceptively named files and create a "Wall of Shame," publicly showing the IP address of those who request the files. In this case the lack of anonymity enabled social accountability. Of course, the same techniques can be used to bait those interested in files about Chinese Democracy or open source software; yet in 2000 there was no record of the practice. The example of the Wall of Shame illustrates the complexity of the issue of accountability in distributed anonymous systems.

Limewire and Morpheus

Limewire and Morpheus are implementations of the Gnutella protocol. Currently Limewire is the most popular as a Macintosh servlet while Morpheus dominates the Wintel world. Morpheus is also available for the Macintosh platform. Limewire is written in Java and is available for all platforms. (As of October 2002, Limewire is available for 12 platforms.) The source of Limewire is available, theoretically preventing some of the revenue-capturing methods of Kazaa. (Of course, Limewire could make the same arrangement with New.net, as described below.)

Limewire offers a version without advertisements for $9.50 and with advertisements for free. (Note that Opera uses the same strategy.) The version with ads installs ClickTillUWin.com—a bit of adware that pops windows up as long as the program is active.

Limewire has developed a two-tier network. There are coordinating peers (called ultrapeers) who assist in searching and organizing downloads. These are used to optimize the system for all users. The standard peers connect to one or two ultrapeers. The ultrapeers do not host the files, but rather organize downloads. Each ultrapeer is associated with a subnet, and the ultrapeers are themselves tightly connected.

In order to increase the speed of downloads and distribute the load on peer-providing files Limewire uses swarming transfers. Swarm downloading entails downloading different elements of files available on multiple low-bandwidth connections to obtain the equivalent service of a single broadband connection. Swarming prevents concentration of downloads from a single server as well. Essentially swarm downloading provides decentralized load balancing.

Limewire implements accountability by allowing a source to obtain information about the number of files shared by a requester. If a peer requesting a file does not offer many files to others, the peer receiving the request may automatically refuse to share any files with the requester.

Morpheus similarly offers source code availability. Morpheus bundles its code with adware, as with Limeware. Morpheus also installs software to resell disk space and CPU cycles. Early on Morpheus redirected affiliation programs to Morpheus; however, this appears to have ended in later versions.

Mojo Nation

Mojo Nation implements a shared P2P system to enable reliable publishing at minimal cost. Mojo Nation solves the problem of availability and uses microcurrency to address the problem of persistence. Mojo Nation is designed to prevent free riding. Mojo Nation implements a micropayment system and a reputation system using a pseudocurrency called Mojo. Mojo is not convertible.

Mojo Nation software combines the following functions: search, download, search relay, and publishing content. Search relay is used to support the searches of other users.

The Mojo Nation is designed to provide reliability. Mojo Nation provides reliability by using a swarm download. Any participant in Mojo Nation is pseudonymous. Mojo identities are public keys (RSA) generated by the user's own computer. The pseudonym can then be moved with the machine, and is associated with its own Mojo balance.

Mojo Nation is not optimized for a particular type of file. Swarm downloading enables downloads of large files, while small files present no particular problem. Examples of large files include video, while MP3 files are smaller and more easily managed.

Mojo is designed neither to enable (as with Publius) nor to disable (as with Free Haven [Sniffen, 2000]) file deletion. Files may be published individually or as an explicit collection. Publication of collections enables the creation of user lists and collaborative filtering, as with Napster and Amazon.

Mojo peers can search for content, download content, support others' searches, offer content, or relay search information. The relay function enables users who are behind firewalls or otherwise blocked to continue to use Mojo Nation.

Searching and downloading cost Mojo while supporting others' searches and providing content earns Mojo. Each downloaded peer software package begins with some Mojo, so pseudo-spoofing assaults on the system are possible. Pseudo-spoofing is the creation of many accounts in order to built the account or reputation of some single account.

Distributed.net

Distributed.net is a volunteer cooperative association of individuals interested in supporting distributed computing for scientific and social gain. Distributed.net is a not-for-profit that addresses computational challenges for the public good.

One distributed.net interest is testing security mechanisms for the Internet. In particular much of the security on the Internet is based on public key encryption. The basis for public key encryption is that there exists mathematical functions that are one way with a trap door. A one-way function is one that is easy to do but hard to undo. Physical examples of one-way functions abound: words cannot be unsaid, a broken egg cannot be repaired, and a thousand tacks cannot easily be placed back in a tube. A trap door is a mathematical secret (the cryptographic key) that makes the one-way function possible to undo. While there is no trap door for eggs, replacing tacks can be made simple with a dustpan and well-matched funnel.

Distributed.net also works to examine the strength of algorithms where both users share one key. In these algorithms the information-hiding system is attacked by trying every possible key. By giving many users different keys to guess, any message can be attacked more effectively.

Distributed.net tests the difficulty of breaking the security of a most widely used encryption algorithm. The difficulty of this feat is of interest to militaries, businesses, and privacy advocates because all three groups share an interest in protecting information.

Distributed.net is an increasingly large and valuable shared resource. Distributed.net seeks computational challenges for scientific advancement. Future possible challenges include working on DNA coding or examining public health data for possible correlations of disease outbreaks or symptoms.

P2P IN BUSINESS

Corporate P2P systems seek to solve two primary problems—real-time collaboration and knowledge management.

For many users real-time collaboration currently is not feasible, especially if the collaboration crosses administrative domains. The problems of corporate networks are the problems of sharing information across domains, and (with increasingly mobile devices) identifying trusted devices and users. For many users, collaboration is implemented via attaching documents to unencrypted mail and hoping that no one is watching. While P2P is decried as being designed for theft, in fact the creation of scalable namespaces and trust networks integrated with collaborative tools is valuable for every group from families to enterprises.

Peer-to-peer systems in the corporate environment must solve the same problems as noncommercial P2P systems: disparate machines, distant locations, participants with widely different capacities, and a lack of single namespace that covers all machines. Yet in a business domain there is a central authority or chain of command that determines (and delegates) the relative authority of participants. Therefore reputation systems in P2P systems can be replaced with more formal security systems based on authentication of users. Both classes of systems offer their own namespaces.

Yet even with P2P technology there is a culture of proprietary and the practice of closed code. Therefore the descriptions here necessarily lack the detail provided for the more academic or open networks described above.

Groove

Groove, founded in October 1997, is a commercial application of P2P technology for solving the chronic problem of institutional knowledge management. The core Groove team includes Ray Ozzie, the creator of Lotus Notes. (Notes is a server-based product for sharing data and workspaces.) Groove is also of interest because it has been embraced as a standard by Microsoft. Groove is P2P in that it allows users to share material on their own machines and create a new namespace for users and files to allow this to happen.

Groove shares with Lotus Notes the concepts of accounts, identities, and shared-space membership, and conceptually expands to include presence and contacts. Unlike Lotus Notes, the participants in a Groove workspace need not share administrative access to a single server or even have a Notes client to share content.

In contrast to Lotus, Groove utilizes the capacities of users' desktops as opposed to requiring that users place their shared documents in a remote workspace. When documents are updated on the users' workspace, they are seamlessly shared.

Groove is a package of software that includes instant messaging, e-mail, document sharing, and real-time collaboration, sometimes called shared whiteboards. As Groove is tightly integrated with the Microsoft Office Suite an Office document can be shared within Groove with simultaneous instant messaging without switching between applications or requiring additional namespaces.

Groove is emphatically not a single sign-on project. Groove allows users to create multiple roles: employee, supervisor, mom, work, wife, or PTA president. Each role has its own "identity" and reputation within the sphere of its identity. This also allows users and communities to

create their own namespaces without threatening (by the temptation to leverage) corporate namespaces.

In summary Groove integrates P2P sharing of files, Microsoft Office document revision tools, e-mail, and chat in a single software package. (Given the nature of the software and the integration of other tools Groove cannot be classified as an application or communications software alone.)

Tenix

Tenix has an explicit P2P basis. Tenix offers to bring P2P to the corporate environment by adding a secure namespace and offering the option of storing files in a central location. Tenix uses a public key infrastructure (PKI) to allow corporations to verify users and create powers of delegation.

By using a public key hierarchy Tenix creates a virtual P2P network where users can identify themselves within the cryptographically secure namespace. A review of the PKI section will illustrate that one way to implement public key systems is to create a set of trusted roots. These roots then use cryptographic credentials to allow users in the same PKI to verify themselves. A Tenix identity is a single-user identity, in contrast to Groove where a Groove identity is a role. (For example, Jean Camp is a single identity while Professor Camp and Aunt Jean are distinct professional and family roles.)

Tenix creates supernodes in the same conceptual model as Kazaa.

Group membership, access control, and version information are stored on a central server. Tenix can be installed with an ultrapeer to coordinate naming and resource location. Alternatively coordination can be provided by Tenix so that the organization can choose to outsource and still leverage P2P systems.

Tenix is P2P in that it enables users to share resources, but it can be installed so that the P2P options are not fully utilized and the system a closed server architecture.

CONCLUSION

There are significant research issues with respect to digital networked information, including problems of naming, searching, organizing, and trusting information. Because peer-to-peer systems required downloading and installing code as well as providing others with access to the user's machine, the problem of trust is particularly acute. The vast majority of users of peer-to-peer systems are individuals who lack the expertise to examine code even when the source code can be downloaded and read.

Peer-to-peer systems currently are at the same state as the Web was in 1995. It is seen as an outlaw or marginal technology. As with the Web, open source, and the Internet itself the future of peer to peer is both in the community and in the enterprise.

Peer-to-peer systems solve (with varying degrees of success) the problem of sharing data in a heterogeneous network. Just as no company is now without an intranet using Web technologies, in a decade no large enterprise will be without technology that builds on today's peer-to-peer systems.

Peer-to-peer systems bring the naïve user and the Wintel user onto the Internet as full participants. By vastly simplifying the distribution of files, processing power, and search capacity peer-to-peer systems offer the ability to solve coordination problems of digital connectivity.

Peer-to-peer software is currently a topic of hot debate. The owners of high-value commodity content believe themselves to be losing revenue to the users of peer-to-peer systems. In theory all downloaded music may be lost revenue. An equally strong theoretical argument is that peer-to-peer systems now serve as a mechanism for advertising, like radio play, so that music popular on peer-to-peer networks is music that will be widely purchased.

There are strong lobbying efforts to prohibit peer to peer software. Some ISPs prohibit peer to peer software by technical and policy means.

There is debate within as well as about the peering community. By bundling software for ads, peer-to-peer systems are creating innovative business models or alternatively committing crimes against users. In one case the reselling of processing power by the software creators is seen as an innovative way to support the peer-to-peer network. From the other perspective the peers bring the value to the community and bundled software illegitimately exploits that value. Thus some decry the bundled software installed with P2P code as parasitic or spyware. Installing advertising, software that records user actions, or software that redirects affiliate programs is seen by users as a violation of the implied agreement. (The implied contract is that users share their own content and in return obtain content provided by others.)

Press coverage of peer-to-peer systems today is not unlike press coverage of early wireless users at the turn of the last century, both admiring and concerned about radical masters of frightening technology bent on a revolution. In a decade or so, peer-to-peer systems within the enterprise will be as frightening and revolutionary as radio is today. Yet without breakthroughs in the understanding of trust in the network, peer to peer across administrative domains may founder on the problems of trust and thus become, like Usenet and gopher, footnotes for the historical scholar.

GLOSSARY

Cluster A set of machines whose collective resources appear to the user as a single resource.

Consistency Information or system state shared by multiple parties.

Domain name A mnemonic for locating computers.

Domain name system The technical and political process of assigning, using, and coordinating domain names.

Front-end processor The first IBM front-end processor enabled users to access multiple mainframe computers from a single terminal.

Node A machine (sometimes a set of machines) that has a single specific name.

Metadata Data about data, e.g., location, subject, or value of data.

Persistent Information or state that remains reliably available over time despite changes in the underlying network.

Reliable The maintaining of a system's performance as a whole despite localized flaws or errors; e.g., file recovery despite disk errors, file transmission despite partial network failure; alternatively a system (particularly a storage system) in which all failures are recoverable, so that there is never long-term loss.

Scalable The idea that a system that works within a small domain or for a small number of units will also work for a number of units orders of magnitude larger.

Swarm A download of the same file from multiple sources.

Servlet Software-integrating elements of client and server software.

Top-level domain name The element of the domain name that identifies the class and not the specific network; early examples: edu and org.

Trusted The state of a component if the user is worse off should the component fail, the component allows actions that are otherwise impossible, i.e., it is enabling, and there is no way to obtain the desired improvement without accepting the risk of failure. (Note that reliable systems do not require trust of a specific component.)

UNIX A family of operating system used by minicomputers and servers, and increasingly on desktops; Linux is a part of the UNIX family tree.

Virus A program fragment that attaches to a complete program in order to damage the program, files on the same machine, and/or infect other programs.

INTRODUCTION

From its introduction to the programming community in 1987, Perl has become today one of the most widely known and used programming languages. Designed by Larry Wall, and originally thought of as a natural enhancement for the popular *csh* shell script notation of Unix, Perl was at first primarily used for text manipulation. Its maturity in the early 1990s coincided with the rise of the Web, and it rapidly became the most popular programming language for HTML form processing and other Web development as well.

Perl has been called a "Swiss Army chainsaw" for its plethora of features coupled with its considerable programming power and flexibility. The common phrase among hardened Perl programmers is "there's more than one way to do it." Most programming goals can be achieved in Perl in at least three ways, depending on which language features and techniques the programmer prefers to use. It is not uncommon for an experienced Perl programmer to reach for the manual when reading code written by another programmer. Perl has also been called "duct tape for the Web," emphasizing its utility for producing applications, Web sites, and general program fixes for a wide variety of problems and domains.

In this chapter we give a brief history of Perl, including major events preceding Perl that set the historical stage for it. We provide an overview of the language, including example code to show how its features are used in practice. We discuss Web site programming in Perl using the CGI (Common Gateway Interface) standard and show several database interface methods in Perl. We discuss the community of programmers that has grown up around Perl and conclude with a presentation of several technologies that are logical follow-ons to Perl.

A BRIEF HISTORY OF PERL

Perl grew out of the Unix programming community. Though it did not formally appear until the late 1980s, the technical components and motivations for Perl were developed in the two decades prior to that. Here are the main events in the "genealogy" of Perl:

1969 Unix is created at Bell Labs
1977 awk is invented by Aho, Weinberger, and Kernighan
1978 "sh" shell is developed for Unix
1987 Perl is created
1995 (March) Perl 5.001 released, the most recent major version;
as of this writing, Perl version 5.8.0 is the newest download at http://www.perl.com

The "Unix philosophy" of software construction, at least in the early days of that operating system, was to provide users with a large toolbox of useful "filters"—programs that could do one small task well—and then compose a larger program from the smaller ones. The shell script notations *sh* and *csh* were the means by which composition was done; *sed, awk, tr*, and other programs were some of the more commonly used filters. Perl was developed ostensibly to solve a problem in text processing that *awk* was not good at and has continued to evolve from there.

To summarize Perl completely and succinctly, we probably cannot do much better than this excerpt from the original Unix help file:

> Perl is (an) interpreted language optimized for scanning arbitrary text files, extracting information from those text files, and printing reports based on that information. It's also a good language for many system management tasks. The language is intended to be practical (easy to use, efficient, complete) rather than beautiful (tiny, elegant, minimal). It combines (in the author's opinion, anyway) some of the best features of C, sed, awk, and sh, so people familiar with those

languages should have little difficulty with it. (Language historians will also note some vestiges of csh, Pascal, and even BASIC|PLUS.) Expression syntax corresponds quite closely to C expression syntax. If you have a problem that would ordinarily use sed or awk or sh, but it exceeds their capabilities or must run a little faster, and you don't want to write the silly thing in C, then perl may be for you. There are also translators to turn your sed and awk scripts into perl scripts. OK, enough hype.

Larry Wall is a trained linguist and this interest and expertise shows in Perl. Here he summarizes the nature and intent of his language and his design rationale:

> When they first built the University of California at Irvine campus, they just put the buildings in. They did not put any sidewalks, they just planted grass. The next year, they came back and built the sidewalks where the trails were in the grass. Perl is that kind of a language. It is not designed from first principles. Perl is those sidewalks in the grass. Those trails that were there before were the previous computer languages that Perl has borrowed ideas from. And Perl has unashamedly borrowed ideas from many, many different languages. Those paths can go diagonally. We want shortcuts. Sometimes we want to be able to do the orthogonal thing, so Perl generally allows the orthogonal approach also. But it also allows a certain number of shortcuts, and being able to insert those shortcuts is part of that evolutionary thing.
>
> I don't want to claim that this is the only way to design a computer language, or that everyone is going to actually enjoy a computer language that is designed in this way. Obviously, some people speak other languages. But Perl was an experiment in trying to come up with not a large language—not as large as English—but a medium-sized language, and to try to see if, by adding certain kinds of complexity from natural language, the expressiveness of the language grew faster than the pain of using it. And, by and large, I think that experiment has been successful.
>
> —Larry Wall, in *Dr. Dobbs Journal*, Feb. 1998

In its early versions, Perl was simple and much closer to the scripting notations from which it grew. In later versions, as with many languages, Perl began to accumulate features and facilities as advocates tried to make it more general-purpose and keep it in step with object-oriented language developments.

PERL LANGUAGE OVERVIEW

A discussion of the programming features and facilities of Perl is in order before we present the areas in which Perl can be applied. This will be an overview, not a tutorial, so no attempt is made to provide an exhaustive or in-depth treatment. Components of Perl that are unique or unusual will be emphasized at the expense of features common to many languages.

Perl is an interpreted language, meaning that a control program that understands the semantics of the language and its components (the *interpreter*) executes program components individually as they are encountered in the control flow. Today this usually is done by first translating the source code into an intermediate representation—called *bytecode*—and then interpreting the bytecode. Interpreted execution makes Perl flexible, convenient, and fast for programming, with some penalty paid in execution speed.

Perl programs are often called *scripts* because of its historical development as an extension of the Unix command-level command scripting notations. A Perl script consists of a series of *declarations* and *statements* with interspersed *comments*. A *declaration* gives the interpreter type information and reserves storage for data. Each *statement* is a command that is recognized by the Perl interpreter and executed. Every statement is usually terminated by a semicolon, and in keeping with most modern syntax, white space between words is not significant. A *comment* begins with the # character and can appear anywhere; everything from the # to the end of the line is ignored by the Perl interpreter.

Though the Perl language proper does not have multiline (block) comments, the effect can be achieved using POD (plain old documentation) directives that are ignored by the interpreter. POD directives begin with an "=" and can appear anywhere the interpreter expects a statement to start. They allow various forms of documentation and text markup to be embedded in Perl scripts and are meant to be processed by separate POD tools. A block comment can be made by opening it with a directive such as `"=comment"` and ending it with `"=cut"`. All lines in between are ignored.

Perl is considered by some to have convoluted and confusing syntax; others consider this same syntax to be compact, flexible, and elegant. Though the language has most of the features one would expect in a "full service" programming notation, Perl has become well known for its capabilities in a few areas where it exceeds the capabilities of most other languages. These include

String manipulation
File handling
Regular expressions and pattern matching
Flexible arrays (hashes, or associative arrays)

In the following sections we present the basics of core language, with emphasis on the functions that Perl does especially well.

Basic Data Types and Values

Perl provides three types of data for programmers to manipulate: *scalar, array*, and *hash* (*associative array*). Scalar types are well known to most programmers, as is the array type. The hash is less well known and one of the most powerful aspects of Perl (along with pattern matching, discussed later). Scalar values include *integer, real, string*,

and *boolean*, with the expected operations available for each. Variables do not have to be declared before use; the first character indicates the type.

Scalars

Scalar variables have a leading "$"; for example, these are all valid Perl scalar variables:

```
$n $N $var28 $hello_World $_X_ $_
```

Case matters in Perl, so the first two examples are different variables. The final variable "$_" is special, one of many that the Perl interpreter will use by default in various operations if the programmer does not indicate otherwise. Any particular valid identifier can be used to designate a scalar, an array, *and* a hash. The leading character determines which of the three types the variable has. For example, here the identifier "name" is used to denote three different variables:

```
$name @name %name
```

The first is a scalar; the second is an array; the last is a hash. All three can be used concurrently, as they denote different storage areas. A variable of the type *scalar* can contain any scalar value:

```
$v1 = "good morning";
$v1 = 127;
```

The first assignment places a string value in the variable. The second replaces the string with an integer value. This is different from many strongly typed languages (such as C++ and Java), where types are finely divided into categories such as integer, real, string, and boolean. In Perl these are values, but not types; Perl uses type distinction mainly to separate singular entities (scalar) from collective entities (arrays and hashes).

String values are delimited with either single or double quotes. Single-quoted literals are used exactly as written, whereas double-quoted literals are subject to escape character and variable interpolation before the final value is obtained. For example:

```
$numer = 2;
$st1 = 'one fine $numer day';
$st2 = "$numer fine day \n";
print $st2;
print "$st1\n";
```

The output from this script is

```
2 fine day
one fine $numer day
```

Four interpolations have taken place. In the second line, the `$numer` appears to be a use of a variable, but because the string is in single quotes the characters are included as they appear. In the third line the string literal is in double quotes, so the variable name is replaced with its current value (2) to produce the final string value; the escape sequence "\n" also puts in a *newline* character. The first *print* statement shows the result. The second *print* shows two interpolations as well, as the string being printed is in double quotes. The value in `$st1` is interpolated into the output string and then a *newline* is added to the end. Even though `$st1` has `'$numer'` in its value, this is not recursively interpolated when those characters are put into the output string.

Context

Many of the operators in Perl will work on all three types, with different results being produced depending on the form of the operands. This polymorphism is known in Perl as *context*. There are two major contexts: *scalar* and *list*. Scalar context is further classified as *numeric, string,* or *boolean*. Consider a scalar variable that is assigned an integer value. If the same variable is later used in a string context (meaning operated on by a string function), the integer value is automatically treated as a string of ASCII characters representing the digits of the integer. For example:

```
$v1 = 127;
$v1 = $v1 . ", and more !!";
print $v1, "\n";
$v1 = 127;
print $v1 + " 151 ", "\n";
print $v1 + ", and more !!", "\n";
```

The output from these statements is

```
127, and more !!
278
127
```

The "." operator in the second assignment performs string concatenation, making the expression have string context; the interpreter therefore treats the value of `$v` as an ASCII string of digits, not as an integer. Because integers and strings are both scalars, we can store the resulting string value back into `$v`, which previously held an integer value. The `"+"` in the second *print* is an arithmetic operator, giving that expression numeric context; the interpreter converts the string `"151"` to the obvious integer value for addition. The final *print* is also a numeric context, but there is no obvious valid integer value for the string `," and more !!"` so a zero is used for the addition.

Arrays

Use of array variables in expressions can cause some confusion. In fact, Perl's somewhat convoluted syntax is one of the main complaints against the language. ("It's the magic that counts," quipped Larry Wall on one occasion, when this feature of the syntax was publicly noted.) When an array is manipulated collectively, the leading "@" notation is used:

```
@A = ("hi", "low", 17, 2.14159, "medium");
@A = @B;
print "$B[1] \n";
```

This code fragment outputs "`low`" on one line. The first statement creates an array A by assigning the members of

the list to consecutive array elements; the second line then sets another array B to have all the same values. Finally, it prints the second element from B (array indexes start at 0 in Perl). Arrays contain scalars as elements, so integer, real, boolean, and string values can be stored in the same array. Note also that when individual elements in an array are manipulated, the scalar notation "$" is used; the reasoning is that the element itself is not an array, but a scalar. Using this notation, individual array elements can be given values via assignment.

Array references can be used anywhere a scalar can be, such as in a subscript expression. If an array subscript expression produces a scalar that is not an integer (such as string or real) Perl converts it to some reasonable integer interpretation:

```
$A[0] = 72;
$A[4] = "moderate exercise";
$A[$i] = $B[$j];
print "$A[$A[3]]\n";
```

Here the last line produces "17" on one line. The inner expression evaluates to 2.14159; to use this as a subscript Perl takes the integer part. Thus, it prints `$A[2]`, which is the scalar 17.

Hashes

Hashes (associative arrays) have elements that are indexed by any scalar (usually strings) rather than by integer value:

```
$assoc{"first"} = 37;
$assoc{'second'} = 82;
$assoc{"third"} = "3_rd";
```

Syntactically, subscripts are delimited with curly braces rather than brackets, and string constants used for subscripts can be delimited with single or double quotes. Elements are retrieved from an associative array in similar fashion:

```
$str = "first";
$N = $assoc{$str};
print "$assoc{'second'} - $N \n";
print %assoc, "\n";
```

The output from this segment is

```
82 - 37
first37third3_rdsecond82
```

The last line shows that accessing the entire associative array is possible with the leading "%," and that when printed this way, the output shows up as (index, value) pairs in arbitrary order (determined by the interpreter). Note also in the next to last line that scalar variables can appear inside strings; they are *interpolated*, that is, replaced by their values in the value of the string. Input/output is discussed in more detail later.

Basic Operations

Scalar

Scalar values can be manipulated by the common operators we would expect of a modern programming language. Numbers have arithmetic operations and logical comparisons, autoincrement and decrement (++ and −−), and operator assignments (+ =, − =, ∗ =). Strings have lexical comparison operations, as well as concatenation, truncation, substring extraction and indexing operations. Booleans have the expected logical operators, and the conjunction (&&) and disjunction (||) are evaluated clause by clause and will short-circuit as soon as the final expression value can be determined.

Array

Perl has the expected assignment and referencing operators for arrays; it also provides subrange operators to use part of an array. `$#arr3` will give you the scalar value that is the last index used in array `@arr3`; because Perl indexes arrays from 0, `$#arr3 + 1` will give the array length. Several predefined functions allow a programmer to use arrays as implementations of other data abstractions. For example, *push(@ar7, $elt),* and *pop(@arr7)* will treat the array @arr7 as a stack; *reverse, sort, shift, join, splice,* and *map* are other predefined functions on arrays.

Hash (Associative Array)

Hashes have assignment and multiassignment to create attribute/value pairs and have array referencing via scalar subscripts (usually strings) to retrieve the value associated with an attribute. Most other operations are provided as functions on the array name. For example, *keys (%aa2)* will return a list of the subscript strings for which there are values in the hash *aa2*. Other such operations are *values*, *each*, and *delete*.

Control Flow

Aside from syntactic differences, Perl has much the same *while*, *until*, and *for* loop structures most programming languages have. In keeping with the stated goal of being flexible and not limiting, however, Perl allows several forms of limited jumps within the context of loops that many other languages do not.

If/elsif/else

The traditional if/then/else conditional statement is altered a bit in Perl. There is no then keyword required on the true clause, and following that may be nothing, an else clause, or an elsif clauses. An elsif clause flattens the decision tree that would otherwise be formed by having another if/else as the body of an else clause. Perl lacks a case statement, so the elsif functions in this capacity, as in this example:

```
if ($thresh < 10) {
     # ... the 'then' block of the
        conditional
} elsif ($thresh < 20) {
     # the next block in the decision tree
} elsif ($thresh < 40) {
     # and the next ...
```

```
} else {
     # the final clause catches what falls
        through
}
```

The negation shorthand *unless(exp)* can be used for *if (!exp)* in all contexts where the *if* keyword is valid.

Expressions and Do Blocks

In Perl, statements are viewed as expressions, and executing a statement produces a value for that expression. Every value can also, by convention, be interpreted as a truth value. Any empty string, the number 0, and the string "0" are all treated as "false"; other values are treated as "true" (with a few exceptions). For example, executing the assignment $a = 27$ has the effect of setting the value of variable $a, but it also produces the value 27 as the result of the expression. If this expression were used in a context where a Boolean was needed, then the 27 would be interpreted as "true":

```
$a = $b = 27; # assigns 27 to both
  variables,
              # since the first
                 assignment to $b
                 produces 27 as its value
print "val: ", ($a = $b = 27), "\n";
if ($a = 27) {# assignment to $a...
   illustration only, not good style
    print "it was true \n";
} else {
    print "it was false \n";
}
if ($a = 0) {# another assignment to $a
    print "it was true \n";
} else {
    print "it was false \n";
}
```

This code fragment produces this output:

```
val: 27
It was true
It was false
```

A *do* {*BLOCK*} statement simply executes the code within the statement block and returns the value of the last expression in the block. We can use this feature combined with statement values to produce an alternate form of conditional. The following two statements are equivalent:

```
($thresh < 125) && do {print "it passed
  \n";};
if ($thresh < 125) {print "it passed \n";};
```

In the first form we also make use of the fact that Perl will evaluate the clauses of a logical conjunction one at a time, left to right, and stop if one should evaluate to false. In this case, should the boolean comparison fail, the second clause of the conjunction (the one with the printing) will not be attempted.

Loop Structures

Looping in Perl is done with variants of the *while*, the *do,* and the *for* structures. The *while* structure is equivalent to that of Java, C, or C++. The loop body block executes as long as the controlling expression remains true. The *until(expnB)* structure is functionally equivalent to *while(! expnB)*:

```
while ($d < 37) {$d++; $sum += $d;}
until ($d >= 37) {$d++; $sum += $d;}
```

The *do/while* and *do/until* structures work similarly to the *while* structure, except that the code is executed at least once before the condition is checked.

```
do {$d++; $sum += $d;} while ($d < 37);
do {$d++; $sum += $d;} until ($d >= 37);
```

The *for* structure works similarly to those of C, C++, or Java and is really syntactic sugar for a specific type of *while* statement. More interesting is the *foreach* loop, which is specifically designed for systematic processing of Perl's native data types. The *foreach* structure takes a scalar, a list, and a block and executes the block of code, setting the scalar to each value in the list, one at a time. Thus the *foreach* loop is a form of *iterator*, giving access to every element of some controlling collection. Consider this example:

```
my @collection = ("first", "second",
   "third", "fourth");
foreach $item (@collection) {print
   "$item\n";}
```

This will print out each item in collection on a line by itself. We are permitted to declare the scalar variable directly within the *foreach*, and its scope is the extent of the loop. Perl programmers find the *foreach* loop to be one of the most useful structures in the language.

last Operator

The *last* operator, as well as the *next* operator that follows, applies only to loop control structures. These operators cause execution to jump from where they occur to some other position, defined with respect to the block structure of the encompassing control structure. Thus, they function as limited forms of *goto*. Last causes control to jump from where it occurs to the first statement following the enclosing block. For example:

```
$d = 2;
while ($d++) {
    if ($d >= 37) { last;}
    $sum += $d;
}
# last jumps to here
```

next operator

The *next* operator is similar to *last* except that execution jumps to the end of the block, but remains *inside* the block,

rather than exiting it. Thus, iteration continues normally. For example:

```
while ($d < 37) {
   $d++;
   if (($d%5)==1 ) { next};
   $sum += $d;
   # next jumps to here
}
```

Jumps can be made from inner nested loops to points in outer loops by labeling the loops, and using the appropriate label after the *last* and *next*. We can now combine several of these features to give another way to "fake" the case statement shown previously as a decision tree with *if / elseif /else*:

```
CASE: {
   ($thresh < 10) && do {
      #  the 'then' block of the conditional
      last CASE; }
   ($thresh < 20) && do {
      #  the next block in the
         decision tree
      last CASE; }
   ($thresh < 40) && do {
      #  and the next...
      last CASE; }
   #  the final clause here catches what
     falls through
} # end of CASE block
```

As we mentioned earlier, there is *always* more than one way to do things in Perl.

Subroutines

A subprogram in Perl is often called a function, but we shall use the term subroutine here to distinguish programmer-defined structures from the built-in functions of Perl. A subroutine is invoked within the context of some expression. In early versions of Perl, an ampersand (&) was placed before the subroutine name to denote invocation; current versions allow invocation without it as well. If the subroutine takes arguments, they are placed within parentheses following the name of the subroutine.

```
&aSubProg();
bSubProg();
cSubProg($ar3, $temp5, @ARY);
```

Control is transferred to the code of the subroutine definition, and transfers back either when the end of the subroutine code is reached, or an explicit return()statement is executed in the subroutine body.

The subroutine *definition* is marked by the keyword `sub` followed by the name of the subroutine, without an ampersand prefix. A block of code for the subroutinebody follows, enclosed in curly braces; this is executed when the subroutine is called.

```
sub aSubProg {
   stmt_1;
   stmt_2;
   $a = $b + $c;
}
```

The value returned by a Perl subroutine is the value of the last expression evaluated in the subroutine. In this example, *aSubProg* will return the value `$a` has at the time when the subroutine ends. Functions such as *print* return values of `0` or `1`, indicating failure or success.

Arguments are enclosed in parentheses following the name of the subroutine during invocation; thus, they constitute a *list*. They are available within the subroutine definition block through `@_` the predefined (list) variable:

```
aSubProg ($a, "Literal_string", $b);

sub aSubProg {
   foreach $temp(@_) { print "$temp \n"; }
}
```

Any variables defined within the body of a Perl program are available inside a Perl subroutine as global variables. Consequently, Perl provides an explicit scope operator (*my*) that can be used to limit the visibility of variables and protect globals from inadvertent side effects. Similarly, these locals will not be visible outside the subroutine. Local variables are, by convention, defined at the top of a Perl subroutine:

```
aFunc ($a, $b);
sub aFunc {
   my ($aLocal, $bLocal);
   $aLocal = $_[0]; # @_ is used $_[i] for
     individual arguments
   $bLocal = $_[1];
}
```

`$aLocal` and `$bLocal` will have the same values inside the subroutine as `$a` and `$b` have at the time it is invoked. Changes to either local variable inside the function, however, will not affect the values of `$a` or `$b`.

Built-In Functions and System Operations

Perl offers a rich selection of built-in functions as part of the standard interpreter. These include mathematical operations (such as abs, sin, sqrt, log); list manipulation operations (such as join, reverse, sort); array manipulation operations (such as push, pop, shift); string manipulation operations (such as chop, index, length, substr, pack, reverse); and myriad operating system functions reflecting Perl's Unix birthright.

Because one of the reasons for the creation of Perl was to give Unix programmers more expressive power and convenience, the language provides several mechanisms for invocating operating system services from executing

scripts. The most general method is the system function:

```
$retVal = system("pwd");
```

In this example, the Perl interpreter uses the system command to get the underlying operating system to execute the Unix "pwd" command. The result of the command appears on STDOUT just as it would if it were done from the command line; the return value, in this case, is an indicator of success or failure. Often programmers want to capture the output of a system command for inclusion in the executing script. This is accomplished by enclosing the command in backward single quotes, often called "backticks":

```
$dir = 'pwd';
print "the current directory is $dir \n";
```

Many other operating system (specifically, Unix) manipulations are available in Perl via built-in functions. The *chdir* function allows a Perl script to alter the default directory in which it finds its files while executing; the *opendir, readdir*, and *closedir* functions allow a Perl script to obtain directory listings; *mkdir* and *rmdir* allow a script to create and delete directories; *rename* and *chmod* allow a script to rename a file and change its access permissions. All these capabilities exist because Perl was originally designed to make it easy for system managers to write programs to manipulate the operating system and user file spaces.

Functions *exec, fork, wait*, and *exit* allow scripts to create and manage child processes. Perl provides a means of connecting a running process with a file handle, allowing information to be sent to the process as input using print statements, or allowing the process to generate information to be read as if it were coming from a file. We illustrate these features in the section *Network Programming in Perl*.

Regular Expressions and Pattern Matching

Perhaps the most useful, powerful, and recognizably Perlish aspect of Perl is its pattern-matching facilities and the rich and succinct text manipulations they make possible. Given a pattern and a string in which to search for that pattern, several operators in Perl will determine whether—and if so, where—the pattern occurs. The pattern descriptions themselves are called *regular expressions*. In addition to providing a general mechanism for evaluating regular expressions, Perl provides several operators that perform various manipulations on strings based upon the results of a pattern match.

Regular Expression Syntax

Patterns in Perl are expressed as regular expressions, and they come to the language through its Unix *awk* heritage. Because regular expressions are well understood from many areas of computing, we will not give an involved introduction to them here. Rather, we will simply use Perl examples to give an idea of the text processing power they give the language.

By default, regular expressions are strings that are delimited by slashes, *e.g.*, `/rooster/`. This delimiter can be changed, but we will use it for the examples. By default, the string that will be searched is in the variable `$_`. One can apply the expression to other strings and string variables, as will be explained below.

The simplest form of pattern is a *literal string*. For example:

```
if (/chicken/) {print "chicken found in
   $_\n";}
```

The "/" delimiters appearing alone denote a default application of the match operator. Thus this code fragment searches in the default variable $_ for a match to the literal "chicken," returning true if found. In addition to including literal characters, expressions can contain categories of characters. They can specify specific sequences with arbitrary intervening strings; they can specify matches at the beginning or end; they can specify exact matches, or matches that ignore character case. Examples of these uses include:

```
/.at/              # matches "cat," "bat," but not "at"
/[aeiou]/          # matches a single character from the set of vowels
/[0-9]/            # matches any single numeric digit
/\d/               # digits, a shorthand for the previous pattern
/[0-9a-zA-Z]*/     # matches a string of alphanumeric characters, or length zero or more
/\w/               # words, a shorthand for the previous pattern
/[^0-9]/           # not a digit
/c*mp/             # any number of c's followed by mp
/a+t/              # one or more a's followed by t
/a?t/              # zero or one a followed by t
/a{2,4}t/          # between 2 and 4 a's followed by t
/k{43}/            # exactly 43 occurrence of "k"
/(pi)+(sq)*/       # strings with one or more "pi" pairs followed by zero or more "sq" pairs
/^on/              # match at start: "on the corner" but not "Meet Jon"
/on$/              # match at end: "Meet Jon" but not "on the corner"
/cat/i             # ignore case, matches "cat", "CAT", "Cat", etc.
$A =~/pong/           # does the content of string variable $A contain "pong"?
<STDIN> =~/b.r+/      #  does the next line of input contain this pattern
                      # which matches bar, bnr, bor, brrr, burrrrrr, etc.
```

Pattern matching is *greedy*, meaning that if a pattern can be found at more than one place in the string, the leftmost instance is returned; if there are overlapping leftmost instances, the longest match will be identified.

String Manipulation

Regular expression operators include a regular expression as an argument but instead of just looking for the pattern and returning a truth value, as in the examples above, they perform some action on the string, such as replacing the matched portion with a specified substring (like the well-known "find and replace" commands in word processing programs). The simplest is the "m" operator, the explicit match. In the following example, a string is searched for the substring "now" (ignoring character case); the match operator return value is interpreted as a Boolean for control of the conditional:

```
my($text) = "Now is the time, now seize
   the day";
if ($text =~ m/now/i) {print "yep, got
   it\n";}
if ($text =~ /now/i) {print "yep, got
  it\n";} # equivalent form, no "m"
```

In general, in invoking the match operator the "m" is usually omitted, as illustrated in the third line above. If a pattern is given with no explicit leading operator, the match operator is employed by default. Though we do not extract or use the matching substring in this example, the operator actually matches on the first three characters "Now" because of the ignore case option.

The substitution operator "`s`" looks for the specified pattern and replaces it with the specified string. By default, it does this for only the first occurrence found in the string. Appending a "`g`" to the end of the expression causes global replacement of all occurrences.

```
s/cat/dog/   # replaces first "cat" with
   "dog" in the default variable $_
s/cat/dog/gi # same thing, but applies
   to "CAT", "Cat" everywhere in $_
$A =~ s/cat/dog/ # substitution on the
   string in $A rather than the default $_
```

The *split* function searches for all occurrences of a pattern in a specified string and returns the pieces that were separated by the pattern occurrences as a list. If no string is specified, the operator is applied to `$_`.

```
$aStr = "All category";
@a = split(/cat/, $aStr); # a[1] is "All "
   and a[2] is "egory"
@a = split(/cat/);        # this split
   happens on the string in default $_
```

The *join* function performs the opposite of a split, assembling the strings of a list into a single string with a separator (the first argument) placed between each part:

```
$a = join(":", "cat", "bird", "dog");
  # returns "cat:bird:dog"
$a = join("", "con", "catenate");
   # returns "concatentate"
$a = "con". "catenate"; # $a gets the value
   "concatentate"
@ar = ("now", "is", "the", "time");
$a = join "", @ar;          # $a gets the
   value "nowisthetime"
```

In the second line above, where the separator is no character at all, the effect of the *join* is the same as using Perl's concatentation operator, as shown in the third line. The added power of *join* is that it will operate on all elements of a list without them being explicitly enumerated, as illustrated in the fourth and fifth lines.

Pattern Memory

The portion of the string that matches a pattern can be assigned to a variable for use later in the statement or in subsequent statements. This feature is triggered by placing the portions of a pattern to be *remembered* in parentheses. When used in the same statement or pattern, the matched segment will be available in the variables `\1, \2, \3`, etc. in the order their targets occur. Beyond the scope of the statement, these stored segments are available in the variables `$1, $2, $3,` etc. as well as contextually. Other matching information available in variables include `$&`, the sequence that matched; `$'`, everything in the string up to the match; and `$'`, everything in the string beyond the match.

For example, the following program separates the file name from the directory path in a Unix-style path name. It works by exploiting Perl's greedy matching, along with the pattern memories:

```
my($text) = "/tmp/subsysA/user5/fyle-zzz";
my($directory, $filename) = $text =~ m/
  (.*\/)(.*)$/;
print "D=$directory, F=$filename\n";
```

The pattern finds the last occurrence of "/" in the target string so that the Unix directory can be split out from the file name. The first set of parentheses saves this directory substring, and the second set captures the file name. The assignment after the match on `$text` stores both pattern memories by positional order into the variables `$directory` and `$filename`. Here is another example using the `\1` and `$1` memory notations:

```
$A = "crave cravats";
$A =~ s/c(.*)v(a.)*s/b\1\2e/;
   # \1 is "rave cra" and \2 is "at"
print "$A\n";
print "$1\n";
print "$2\n";
```

The output from this code fragment is

```
brave craate
rave cra
at
```

The substitute operator in the second line performs the match by first finding the longest string of characters between the "c" and "v" and saving it in the `\1` memory. It then finds the longest string of "a" followed by any single character in the rest, and saves that in the `\2` memory. Once matched, the replacement string is formed by concatenating the memories, adding a "b" at the front, and adding an "e" at the end. The last two lines show that the string parts that matched the pattern parts are still available after the match for as long as the variables `$1` and `$2` are not overwritten.

Input/Output and File Handling

File handling is another area where Perl makes life easy for the programmer. The basic file manipulation operators, coupled with array capabilities, make creating internal structures out of text input succinct and efficient. Files are accessed within a Perl program through *filehandles*, which are bound to a specific file through an `open` statement. By convention, Perl filehandle names are written in all uppercase, to differentiate them from keywords and function names. For example:

```
open (INPUT, "index.html");
```

associates the file named "index.html" with the filehandle INPUT. In this case, the file is opened for read access. It may also be opened for write access and for update (appending) by preceding the filename with appropriate symbols:

```
open (INPUT, ">index.html");  # opens for
   write
open (INPUT, ">>index.html"); # opens for
   appending
```

Because Perl will continue operating regardless of whether a file open is successful or not, we need to test the success of an `open` statement. Like other Perl constructs, the `open` statement returns a true or false value. Thus, one common way to test the success of the open and take appropriate action is to combine the lazy evaluation of logical *or* with a `die` clause, which prints a message to STDERR and terminates execution:

```
open (INPUT, "index.html") || die "Error
   opening file index.html ";
```

Files are closed implicitly when a script ends, but they also may be closed explicitly:

```
close (INPUT);
```

Perl provides default access to the keyboard, terminal screen, and error log with predefined filehandles STDIN, STDOUT, and STDERR; these handles will be automatically available whenever a script is executed. Once opened and associated with a filehandle, a file can be read with the diamond operator (<>), which can appear in a variety of constructs. STDIN is most commonly accessed this way. When placed in a scalar context, the diamond operator returns the next line; when place in an array context, it returns the entire file, one line per item in the array. For example:

```
$a = <STDIN>; # returns next line in file
@a = <STDIN>; # returns entire file
```

STDOUT is the default file accessed through a `print` statement. STDERR is the file used by the system to which it writes error messages; it is usually mapped to the terminal display. Here is an example that reads an entire file from STDIN, line-by-line, and echos each line to STDOUT with line numbering:

```
$lnum = 0;
while (<STDIN>) {  # read one line at a time
  until EOF
                  # in this case, the
                    default variable $_
                    receives the line
   chomp;         # remove line-ending
     character (newline here)
                  # again, it operates on $_
                     automatically
   $lnum++;       # auto-increment operator
     on line counter
   print "$lnum: $_\n";  # print the line
     read, using default $_
}
```

This shows one of the many Perl conveniences. In many contexts, if no scalar variable is indicated, an operation will give a value to a variable named '`$_`', the default scalar variable. This is in keeping with Perl's design philosophy of making it very easy to do common tasks. We could also have omitted the filehandle STDIN and simply have written "`while (<>)`"; the diamond operator will operate on STDIN by default if given no filehandle explicitly.

Once a file has been opened for either write or update access, data can be sent to that file through the *print* function. A *print* with no filehandle operates on STDOUT by default. For example:

```
print OUTPUT "$next \n"; # to a file opened
   with handle OUTPUT
print "this statement works on STDOUT
   by default\n";
```

In many circumstances the actions taken by a Perl program should take into account attributes of a file, such as whether or not it currently exists, or whether it has content. A number of tests can be performed on files through *file test* operators. For example, to check for file existence use the *–e* test:

```
if (-e "someFile.txt") {
   open (AFYLE, "someFile.txt") || die "not
     able to open file";
}
```

Using different characters, many other attributes can be tested including if a file is readable, writable, executable, or owned by certain users, if it is text or binary, if it is a directory or symbolic link, or if it is empty, to name a few.

There's More Than One Way To Do It

In concluding this section we again illustrate the famous Perl adage, this time with file *open* statements. Here are several examples of conditional expressions for safely opening files and trapping errors.

```
$aFile = "foo.txt";
if (!open(fh, $aFile)) {die "(a) Can't open
   $aFile: $!";}
open(fh,$aFile) ? " : die "(d) Can't open
   $aFile: $!";
die "(b) Can't open $aFile:
   $!" unless open(fh,$aFile);
open(fh,$aFile) || die "(c) Can't open
   $aFile: $!";
```

The last four lines all do the same thing.

Other Perl Features

Perl has several other features and capabilities that have found their way into the language as it evolved. These later features tend to be capabilities that programmers found useful in other languages and desired to have in Perl. In particular, Perl version 5 introduced *classes, objects,* and *references* (or pointers) into a language that was previously a more traditional Unix scripting notation "on steroids." Because they do not greatly enhance Perl's capabilities in the areas for which it has proven especially superior (text processing, file handling, string matching, OS interactions) we will not go into them in detail. Some programmers even consider these additions to aggravate the already difficult task of reading Perl code. These features are not *unimportant* aspects of the language; they are simply well beyond the original domains of expertise and applicability for which Perl was developed. As such, they represent the natural end to which languages tend to evolve as they gain popularity—something of everything for everyone.

Perl has many more sophisticated capabilities. Access to the interpreter is available to an executing script through the *eval* function, allowing a program to create and then run new code dynamically. Symbol tables can be accessed and manipulated directly with Perl *typeglobs*. Function *closures* can be created (as in many functional languages) allowing subroutines to be packaged dynamically with their data and passed back from a function call as a reference for execution later. *Packages* and *modules* provide encapsulation and namespace control. The later versions of Perl even support concurrent computations with a *thread* model.

We refer the reader to the texts cited in *For More Information* for thorough presentations of all these topics.

PUTTING IT ALL TOGETHER: SAMPLE PROGRAMS

First Example: Text Processing

Here is a Perl script that will take as input a file called "foo.txt" and produce as output a file called "bar.txt"; lines in input will be copied to output, except for the following transformations:

any line with the string "IgNore" in it will *not* go to output
any line with the string "#" in it will have that character and all characters after it, to end of line, removed
any string "*DATE*" will be replaced by the current date in output

One program to do this is as follows:

```
#!/usr/local/bin/perl
$infile = "foo.txt";
$outfile = "bar.txt";
$scrapfile = "baz.txt";
open(INF",<$infile") || die "Can't open
   $infile for reading";
open(OUTF",>$outfile") || die "Can't open
   $outfile for writing";
open(SCRAPS",>$scrapfile") || die "Can't
   open $scrapfile for writing";
chop($date = 'date'); # run system command,
   remove the newline at the end
foreach $line (<INF>) {
   if ($line =~ /IgNore/) {
       print SCRAPS $line;
       next;
   }
   $line =~ s/\*DATE\*/$date/g;
   if ($line =~ /\#/) {
       @parts = split ("#", $line);
       print OUTF "$parts[0]\n";
       print SCRAPS "#". @parts[1..$#parts];
         # range of elements
   } else {
       print OUTF $line;
   }
}
close INF; close OUTF; close SCRAPS;
```

In keeping with the Perl adage that there's more than one way to do things, here is an alternative way to write the *foreach* loop; this one uses the implicit `$_` variable for pattern matching:

```
# this version uses the implicitly defines
  $_ variable
foreach (<INF>) {
   if ( /IgNore/ ) {
       print SCRAPS;
       next;
       }
   s/\*DATE\*/$date/g;
   if ( /\#/ ) {
       @parts = split ("#");
```

```
      print OUTF "$parts[0]\n";
      print SCRAPS "#". @parts[1..$#parts];
        # range of elements
   } else {
      print OUTF;
      }
}
```

And finally, a third version, using boolean and conditional expressions in place of *if–else* statements:

```
# this version uses boolean interpretation
  of expressions as
# substitution for  if clauses in previous
  versions
foreach (<INF>) {
   /IgNore/ && do {print SCRAPS; next};
   s/\*DATE\*/$date/g;
   /#/ ? do {
       @parts = split ("#");
       print OUTF "$parts[0]\n";
       print SCRAPS "#". @parts[1..$#parts];
         # range of elements
   }
   : do {
       print OUTF;
   }
}
```

A Simpler, More Sophisticated Example

Consider this problem: take an input file and produce an output file which is a copy of the input with any duplicate input lines removed. Here is a first solution:

```
#!/usr/local/bin/perl
foreach (<STDIN>) {print unless $seen
  {$_}++;}
```

This is, of course, exactly why so many like Perl so fervently. A task that would take many lines of C code can be done in Perl with a few lines, thanks to the sophisticated text handling facilities built into the language. In this solution, we are reading and writing standard input and output; in Unix we supply specific file names for these streams when the program it is invoked from the command line, like this:

```
second.pl <foo.txt >bar.txt
```

Here is a second solution:

```
#!/usr/local/bin/perl
# this version prints out the unique lines
   in a file, but the order
# is not guaranteed to be the same as they
   appear in the file
foreach (<>) {$unique{$_} = 1;}
print keys(%unique); # values(%unique)
   is the other half
```

And a third solution:

```
#!/usr/local/bin/perl
# this version eliminates duplicate lines
# and prints them out in arbitrary order
# also tells how many time each line was
   seen
# oh, and it sorts the lines in alpha order
foreach (<>) {$unique{$_} += 1;}
foreach (sort keys(%unique)) {
  print "($unique{$_}):$_";
}
```

This last example shows the considerable power and terseness of Perl. In essentially four lines of code, we filter a file to remove duplicate lines, report a count of how many times each unique line appeared in the original input, and print the unique lines sorted in alphabetic order. All the facilities used in this program are part of the standard Perl language definition. It does not depend on any user-supplied routines or libraries.

Directory Information Processing

This example shows more complicated use of pattern memories in text processing. The script reads standard input, which will be piped test from a Linux *dir* command (directory). It writes to standard out, and produces an executable script (in *csh* notation) that copies every file older than 11/01/93 to a directory called `\ancient`. The input looks like this:

```
.            <DIR>        12-18-97 11:14a  .
..           <DIR>        12-18-97 11:14a  ..
INDEX    HTM        3,214  02-06-98  3:12p  index.htm
CONTACT  HTM        7,658  12-24-97  5:13p  contact.htm
PIX          <DIR>        12-18-97 11:14a  pix
FIG12    GIF          898  06-02-97  3:14p  fig12.gif
README   TXT        2,113  12-24-97  5:13p  readme.txt
ACCESS   LOG       12,715  12-24-97  5:24p  ACCESS.LOG
ORDER    EXE       77,339  12-24-97  5:13p  order.exe
         6 file(s)       103,937 bytes
         3 dir(s)     42,378,420 bytes free
```

The Perl solution uses regular expressions, pattern matching, and pattern memories:

```
my $totByte = 0;
while(<>){
   my($line) = $_;
   chomp($line);
   if($line !~ /<DIR>/) { # we don't want to
     process directory lines
       # dates is column 28 and the filename
         is column 44
       if ($line =~ /.{28}(\d\d)-(\d\d)
         -(\d\d).{8}(.+)$/) {
            my($filename) = $4;
            my($yymmdd) = "$3$1$2";
            if($yymmdd lt "931101") {
                print "copy $filename \ \
                  ancient\n";}}
       if ($line =~ /.{12}((\d ||,)
         {14}) \d\d-\d\d-\d\d/) {
```

```
            my($bytecount) = $1;
            $bytecount =~ s/,//; # delete
              commas
            $totByte += $bytecount;
        }
    }
    print STDERR "$totByte bytes are in this
      directory.\n";
}
```

In the first match, the variables `$1`, `$2`, `$3`, and `$4` are the pattern memories corresponding to the parenthesis sets. The first three are reassembled into a *yymmdd* date string which can be compared with the constant "971222." The fourth holds the filename that will be copied to the `\ancient` directory. As a side effect of processing the directory listing, we set up an accumulator and extract a cumulative byte count. This is done with a second match on the same input line, as well as a substitution operation to remove commas from the numbers found.

NETWORK PROGRAMMING IN PERL

The World Wide Web is the most widely known Internet application. Many Web sites provide more than static HTML pages. Instead, they collect and process data or provide some sort of computational service to browsers. For example, several companies operate Web sites that allow a user to enter personal income and expense information, and will then not only compute income tax returns online but also electronically file them with the IRS. There are numerous technical ways to provide this processing horsepower to a Web site (e.g., Microsoft's Active Server Pages, JavaScript, C/C++/C# programs, etc.) but Perl is the most widespread and popular of these options. In this section we look at how Perl scripts can provide communications between Web browsers and servers, and how they can make use of databases for persistent storage. We also discuss some of Perl's capabilities for interprocess communication and network computations.

Web and network programming is not usually done from scratch, but rather by reusing excellent Perl modules written by other programmers to encapsulate details and provide abstractions of the various domain entities and services. We begin with a discussion of the *Comprehensive Perl Archive Network (CPAN)*, the Perl community's repository for these freely shared modules.

Perl Modules and CPAN

CPAN is a large collection of Perl code and documentation that has been donated by developers to the greater Perl programming community. It is accessed on the Web at http://www.cpan.org and contains many modules that have become *de facto* standards for common Perl scripting tasks. In addition to programmer-contributed modules, the source code for the standard Perl distribution can be found there. In the words of Larry Wall in *Programming Perl*, "If it's written in Perl, and it's helpful and free, it's probably on CPAN."

Modules

The *module* is the main mechanism for code reuse in Perl. A module is a package (protected namespace) declared in a file that has "`.pm`" as its filename extension; the package, module, and file have the same name. The author of a module defines which names within it are to be made available to outside Perl programs. This is done through the *Export* module. To incorporate the variables, subroutines, and objects of a module into a program, the *use* statement is employed:

```
use JacksCode; # in which a variable
   $jackrabbit is declared
print "$jackrabbit \n";
print "$JacksCode::jackrabbit \n";
```

In this example, the *use* statement requests access to all names that are exported from the module "JacksCode," which the interpreter will expect to find in a file named "JacksCode.pm" someplace on its search path. If this module declares a variable named "`$jackrabbit`" then the last two lines do the same thing. A variable name imported from a module need no longer be fully qualified with the module name. There are several alternate forms of the *use* statement that give finer-grained control over which of the exported names are imported.

Many of the modules most commonly used by programmers come as part of the standard Perl distribution. CPAN contains dozens of others, including:

CGI, HTML, HTTP, LWP, Apache module families for Web server scripts

POSIX for Unix-programming compatibility

Net::FTP, Net::DNS, Net::TCP, Net::SMTP, Net::IMAP, and many other for dozens of protocols

Math::BigInt, Math::Trig, Math::Polynomial, Statistics and dozens more supporting various forms of mathematical structures and functions

List, Set, Heap, Graph module families giving common abstract data types

Date, Time, Calendar module families

Language::ML, Language::Prolog, C::DynaLib, Python, Java, and other language interfaces

PostScript, Font, PDF, XML, RTF, Tex, SQL module families for documents

PGP, DES, Crypt, Authen module families for encryption and security

As enjoyable as Perl programmers find their craft to be, no one wants to spend time rewriting code someone else has already done well. CPAN is the result of an enthusiastic community effort to leverage success.

Web Server Scripts with CGI

When a Web page contains fill-out forms, or has some other computational behavior required, there are several ways to provide the processing needed on the Web server side of the transaction. One way is via scripts that adhere to the data formatting standards of the CGI Web interface. CGI scripts can be written in any programming language that the server will support. A separate chapter

in this compilation covers the CGI standard in detail, so we concentrate here on the specifics of how Perl allows programmers to take advantage of this standard for Web development.

In any interaction between a Web browser and a Web server, there are data being exchanged. The browser sends information to the server requesting that some action be taken, and the server sends a reply back, usually in the form of an HTML Web page. This interaction often happens by the user filling out the fields of a form in the browser window and clicking on some "submit" button. Submitting the form entails the browser collecting the data from the form fields, encoding it as a string according to the CGI standard, and passing it to the Web server specified in the URL associated with the submit button in the form. This URL contains not only the location of the server that will process the form data, but also the name of the Perl script that should be executed as well on the server side.

Module "CGI"

The data from the browser form is made available to Perl via *environment variables*. In the early days of the Web, site programmers would "roll their own," writing collections of Perl subroutines to decode the incoming CGI-compliant data and process them in various ways. Today, the task is made much easier through the Perl module "CGI," which provides a *de facto* programming standard for these server-side functions. Using the CGI module, a form processing script looks something like this (simplified):

```
use CGI;
$q = CGI::new();
$mid = $q->param("measid");
$uid = $q->param("uid");
$pwd = $q->param("passwd");
print $q->header();
print $q->head($q->title("Company
  Evaluation"));
print $q->body(
   $q->h1("$uid: Submit My Report"),
   $q->hr,
      etc... rest of body elements...
   );
)
```

(The arrow notation (->) is the Perl syntax for dereferencing a reference (chasing a pointer). In this module, and others following, it is used to access the fields and functions of a Perl object.)

As shown here, the CGI module provides functions for retrieving environment variables, creating Web forms as output, and generating HTML tags. This example is selecting data from a Web form containing text fields called "measid," "uid," and "passwd." It is generating an HTTP-compliant return message with the necessary header and an HTML page for the browser to display. Assuming the "uid" here comes in from the form as "Jones," we get:

```
Content-type: text/html;
  charset=ISO-8859--1
<head>
   <title>Company Evaluation</title>
</head>
<body>
   <h1>Jones: Submit My Report</h1>
   <hr>
      etc...
```

The CGI module also assists the Web site developer in solving other problems common with Web scripting. Because the HTTP protocol is stateless, one problem is maintaining session state from one invocation of a script to the next. This is normally done with *cookies,* data a server asks the Web browser to store locally and return on request. However, not all browsers allow cookies, and in those that do the user may turn cookies off for security or privacy reasons. To help with this a script using CGI, when called multiple times, will receive default values for its input fields from the previous invocation of the script.

Web Clients with LWP

Whereas the CGI module supports construction of scripts on the server side of a Web connection, the modules in *LWP (Library for Web access in Perl)* provides support for developing applications on the client side. Most notable among Web clients are the GUI-based browsers, but many other applications acts as clients in HTTP interactions with Web servers. For example, Web crawlers and spiders are non-GUI programs (called "bots" or robots) that continuously search the Web for pages meeting various criteria for cataloging.

The different modules in LWP support different aspects of Web client construction and operation:

HTML for parsing and converting HTML files
HTTP for implementing the requests and responses of the HTTP protocol
LWP core module, for network connections and client/server transactions
URI for parsing and handling URLs
WWW implementing robot program standards
Font for handling Adobe fonts
File for parsing directory listings and related information

A Web interaction starts with a client program establishing a network connection to some server. At the low level this is done via sockets with the TCP/IP protocol. Perl does support socket programming directly (see below), and the module *Net* contains functions to allow a program to follow TCP/IP (as well as many others Internet protocols, such as FTP, DNS, and SMTP). On top of sockets and TCP/IP for basic data transfer, the HTTP protocol dictates the structure and content of messages exchanged between client and server.

Rather than deal with all these technologies individually, the *LWP::UserAgent* module allows the programmer to manage all client-side activities through a single interface. A simple client script would look like this:

```
use LWP::UserAgent; # imports other
  modules too
$client = new LWP::UserAgent();
$acmeReps = new URI::URL('www.acme.com/
  reports/index.html');
$outHead =
   new HTTP::Headers(User-Agent=>'MyBot
     v2.0', Accept=>'text/html');
$outMsg = new HTTP::Request(GET, $acmeReps,
  $outHead);
$inMSg = $client->request($outMsg);
$inMsg->is_success ? {print $inMsg->
  content;} : {print $inMsg->message;}
```

The network connections and message formatting to HTTP protocol requirements is handled transparently by the LWP functions. Here, the client causes a request like this to be sent to the Web server at www.acme.com:

```
GET/reports/index.html HTTP/1.0
User-Agent: MyBot v2.0
Accept: text/html
```

If the requested file is not there, the response from the server will be an error message. If it is there, the response will contain the HTML file for the "bot" to process in some fashion.

Database Use

Many Web sites depend on databases to maintain persistent information—customer data, statistics on site usage, collection of experimental results, medical records. Perl has several ways a CGI script (or any Perl script, Web-based or otherwise) can store and retrieve database records.

Module "DBM"

Perl comes with a module called DBM (database module) that contains functions implementing a built-in database structure. DBM treats an external data store internally as hashes, or key/value pairs. This internal database is intended for simple, fast usage; searching requires as few as three lines of script. The method is convenient for fast retrieval, even from very large databases, when there is a unique key for searching (e.g., ISBN numbers). It is not as useful for complex data or queries:

```
dbmopen (%db, $database, 0400) || die "Can't
  open DB";     #open read only
for ($k=$max; $k< $max+20; $k++){print
  "$k $db{$k}"} #get and print data
dbmclose (%db); #close database
```

In this example, we know the index values are numbers and are unique. The database looks to the Perl script like a hash, so the associative array variable `%db` is used to get the data values from it.

One useful feature Perl provides is DBM filters. These are small data transformation routines, written by a programmer to manage situations where the format of the data fields in a database is not quite compatible with the form needed by a script. Rather than put small data manipulation code chunks scattered throughout the script, or write and call extra functions, DBM filters can be attached directly to the fields of a database; data transformation then takes place automatically as field values are moved into and out of the database. This feature makes the code using the database easier to read and less error prone due to less code replication.

Module "DBI"

For more advanced applications, a relational database is often more desirable than the simple structure of DBM. For this Perl provides the DBI module, or data base interface. DBI is designed to hide the details of specific database systems, allowing the programmer to create scripts that are general. The interface allows expressing SQL queries, executing them against a specific database, and retrieving the results. The DBI module does not contain code specific to any database vendor's product, but it does have references to numerous vendor-specific modules called DBD's (database drivers). A DBD module will contain the detailed code needed to communicate with a specific brand of database system.

Figure 1 illustrates the relationship among the executing script, the DBI, the DBD, and the physical database. When a Perl script invokes a DBI function to execute a query, the query is routed to the appropriate DBD module according to how the DBI database handle was opened (as an Oracle DB, as an Access DB, etc.). The DBD module communicates with the actual files or tables of the physical database system and produces query results. These results are communicated back to the DBI module, which relays them back to the user's Perl script. This layer of indirection gives Perl scripts a generality that makes migration from one physical DB system to another relative painless.

Module "ODBC"

In addition to the DBI module, programmers wishing to write Perl scripts that interface to external databases, such as Access or Oracle, can obtain an ODBC compatibility package as a free download from several third party distributors. This module contains functions that implement the ODBC standard database interface. Perl scripts written to use this standard can then work with any relational database under them, as long as that database has its own ODBC interface. Almost all major relational database vendors provide an ODBC implementation for their products. ODBC provides the same advantages as DBI, but the ODBC standard was designed outside Perl and is available in many other programming languages as well.

Processes and IPC

Although the Web is the major Internet application, it is certainly not the only one, and Perl includes facilities to support general network applications. Although not designed specifically for concurrent or multiprocess computations, Perl does support various forms of processes, interprocess communication (IPC), and concurrency. (Perl having been born of Unix, this section is heavy on Unix process concepts such as pipes and forking.) Processes are

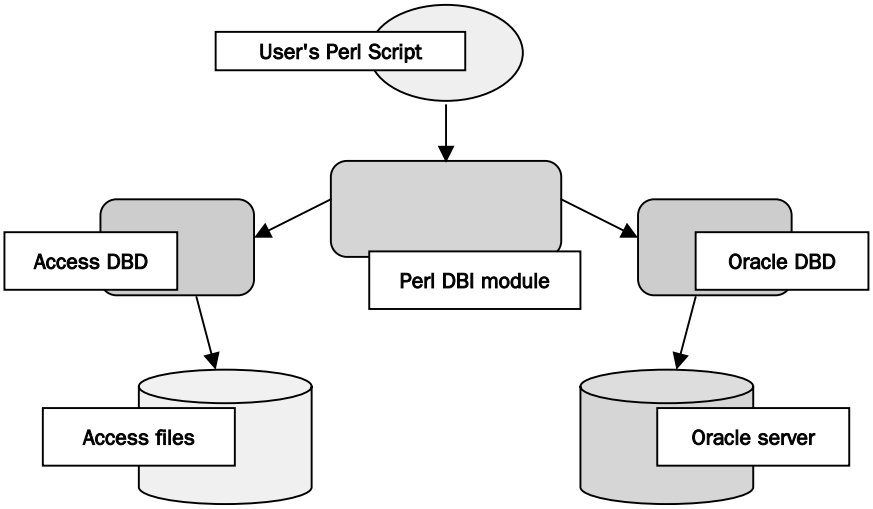

Figure 1: DBI provides an abstract interface for specific database systems.

relatively heavyweight computations each having its own resources and address spaces. Multiple processes may execute on the same machine or on different machines across the Internet. Data exchange among processes is usually done via files, pipes (channels), or lower level sockets.

Simple Unix-style process communications can be established in Perl using file I/O operations. Processes are given filehandles, and communication paths are established with the `open` statement using a pipe symbol "|" on the command the process will execute. To read from a running program, for example, the pipe goes at the end:

```
$pid = open(DATAGEN, "ls -lrt |") || die
  "Couldn't fork: $!\n";
while (<DATAGEN>) {
    print;
}
close(DATAGEN) || die "Couldn't close: $!\n";
```

This program creates a process that executes the Unix "`ls`" command with arguments "`-lrt`" to generate a listing of the current directory. The pipe symbol tells Perl that the *open* is specifying a process command to run instead of a simple file name. To write to a process, the pipe goes at the beginning of the command:

```
$pid = open(DATASINK, "|  myProg args") ||
  die "Couldn't fork: $!\n";
print DATASINK "some data for you\n";
close(DATASINK) || die "Couldn't close:
  $!\n";
```

A script can use *pipe* and *fork* to create two related processes that communicate, with better control than can be had from *open*, *system*, and *backticks*:

```
pipe(INFROM, OUTTO); # opens connected
  filehandles
if (fork) {# both processes share all open
  filehandles
    # run parent code for writing
    close(INFROM);
    # now the writer code...
} else {
    # run child code for reading
    close(OUTTO);
    # now the reader code...
}
```

For more complicated situations, such as reading and writing to the same executing process, the previous methods are not sufficient. There is a special forking form of *open* that can be used. However, using the *IPC::Open2* module is a better approach:

```
use IPC::Open2;
open2(*READFROM, *WRITETO, "myProg arg1
  arg2");
print WRITETO "here's your input\n";
$output = <READFROM>;
    #  etc...
close(WRITETO);
close(READFROM);
```

Here the program "myProg" is executed as a process, using the supplied arguments, and the filehandles READFROM and WRITETO are connected to its standard input and output respectively so the Perl script can exchange data with it.

Module "Socket"

Even finer grained control over processes can be obtained if the programmer is willing to program lower into the operating system. Sockets are the underlying technical mechanism for network programming on the Internet. Perl gives access to this level with built-in functions that operate on sockets. These include

socket to assign a filehandle
bind to associate a socket with a port and address
listen to wait for activity on the server-side connection

accept to allow incoming connection on the server side
connect to establish communications with a server
recv to get data off a socket
send to put data onto a socket
close to end it all

Sockets are given filehandles on creation, so Perl functions that operate on filehandles can be used on sockets as well. Socket functions tend to need hard-coded values related to machine specifics and IP addresses, which limits portability of scripts. The Perl module *Socket* should be used in conjunction with the Perl socket functions to preload machine-specific constants and data into Perl variables.

ON BEYOND PERL

Perl was created when object-oriented (OO) programming concepts were young and less well understood than today. Early versions of Perl, in fact, did not even contain objects or references. As understanding of OO concepts has advanced, Perl has evolved to contain OO features. They work fairly well, but because they were not part of the original design rationale of Perl, many consider them less elegant and cohesive than the original set of language features.

Two more recently developed programming languages—*Python* and *Ruby*—claim Perl in their heritage, but have been designed specifically as OO programming tools. The designers of each wanted to retain the extreme convenience and flexibility of Perl's text handling and string matching, but to incorporate as well other capabilities that go beyond Perl. The results are two notations that are still largely thought of as "scripting" languages, but with more highly integrated object semantics. Following are brief discussions of each with respect to Perl.

Python

Guido van Rossum began work on the design of Python in late 1989. One of his goals for the new language was to cater to infrequent users and not just experienced ones. Infrequent users of a notation can find rich syntax (such as that of Perl) to be more burdensome than helpful. This means that Python is a *compact* language. A programmer can easily keep the entire feature set in mind without frequent references to a manual. C is famously compact in much the same way, but Perl most certainly is not. The Perl design principle of "more than one way to do it" shows up in Perl's wealth of features, notational shortcuts, and style idioms. Van Rossum also wanted a language designed from the beginning to be object-oriented and to have clear module semantics. In Python everything is an object or class including the base data types.

Python has unusual syntax for a modern programming language. Rather than being a free-form notation, in Python white space is important for defining the block structure of a script. Indentation levels serve the same purpose in Python that pairs of "{}" do in Perl, C, and others. Here, the body of the loop and the bodies of the conditional clauses are defined by vertical alignment :

```
while x < y:
    buf = fp.read(blocksize)
    if not buf: break
    conn.send(buf)
x = 3
if x == 4:
   result = x + 2
   print x
else:
   print 'Try again.'
```

Though this initially appears to be a cumbersome throwback, in many ways this makes Python easy to use. Python has a very clean and structured layout and it is very easy to follow what's going on. Perl can frequently look noisy, and new programmers particularly can have difficulty trying to understand the behavior they see from their Perl scripts. Python programmers report that after a short training period, they can produce working code about as fast as they can type, and that they begin to think of Python as *executable pseudocode*.

Python gives programmers good support for modern programming practices such as design of data structures and object-oriented programming. The compactness causes programmers to write readable, maintainable scripts by eliminating much of the cryptic notations in Perl. In Perl's original application domains, Python comes close to but rarely beats Perl for programming flexibility and speed. On the other hand, Python is proving quite usable well beyond Perl's best application domains.

Ruby

Ruby is another language that is advertised as being a natural successor to Perl. It was developed in Japan in 1993 by Yukihiro Matsumoto and began attracting a user community in the United States by the year 2000. In Japan, Ruby has overtaken Python in popularity. Like Python, Ruby is open sourced and so is easy for others to extend, correct, or modify.

Matsumoto was looking to design an object oriented scripting language that did not have the messy "Swiss Army chainsaw" aspects of Perl, but he considered Python to be not object oriented enough. Ruby has retained many of the text manipulation and string matching features of Perl that Python leaves out, but they are elevated to the class level (e.g., regular expressions are classes). Even operators on the base types are methods of the base classes. In addition to classes, Ruby allows metaclass reasoning, allowing scripts to understand and exploit the dynamic structure of objects at runtime. Ruby is best thought of as having modern object semantics, as Python does, but also retaining more of the Perl features and syntax than Python does.

Personalization and Customization Technologies

Sviatoslav Braynov, *State University of New York at Buffalo*

INTRODUCTION

Personalization and customization are considered increasingly important elements of Web applications. The terms usually refer to using information about a user (be it a customer, a Web site visitor, an individual, or a group) to better design products and services tailored to that user. One way to define personalization is by describing how it is implemented and used.

> Personalization is a toolbox of technologies and application features used in the design of an end-user experience. Features classified as personalization are wide-ranging, from simple display of the end-user's name on a Web page, to complex catalog navigation and product customization based on deep models of users' needs and behaviors. (Kramer, Noronha, & Vergo, 2000)

The Personalization Consortium (Personalization Consortium, n.d.), an international advocacy group formed to promote the development and use of personalization technology on the Web, offers the following definition:

> Personalization is the combined use of technology and customer information to tailor electronic commerce interactions between a business and each individual customer.

Personalization usually means gathering and storing information about Web site visitors and analyzing this information in order to deliver the right content in a user-preferred form and layout. Personalization helps to increase customer satisfaction, promote customer loyalty by establishing a one-to-one relationship between a Web site and its visitor, and increase sales by providing products and services tailored to customers' individual needs. The goal of personalization is to better serve the customer by anticipating his needs; it customizes services and products, and establishes a long-term relationship encouraging the customer to return for subsequent visits.

Although both customization and personalization refer to the delivery of information, products, or services tailored to users' needs, the two notions differ in several respects. Customization is usually used to describe the interface attributes that are user-controlled. That is, the user is in control and is able to configure a Web site, a product, or a service according to his or her preferences and requirements. The system is almost passive and provides only a means by which the actual configuration is done. Customization is usually done manually by the user, according to his preferences. An example of customization is My Yahoo (http://my.yahoo.com), shown in Figure 1. In My Yahoo a user can customize content by selecting from various modules (portfolios, company news, weather, currency converter, market summary, etc.) and placing them on a customized Web page, which is updated periodically. In this case, the locus of control lies with the user, who manually selects the modules on the page. In contrast, personalization is automatically performed by a Web site based on the history of previous interactions with the user, on the user's profile, or on the profiles of like-minded users. For example, Amazon.com recommends items to a user and creates personalized Web pages based on the user's navigation and purchase history.

USER PROFILING

Factual and Behavioral Profiles

Personalization requires some information about the user's preferences, needs, goals, and expectations. Information that describes a particular user is called a user profile. Adomavicius and Tuzhilin (1999) consider

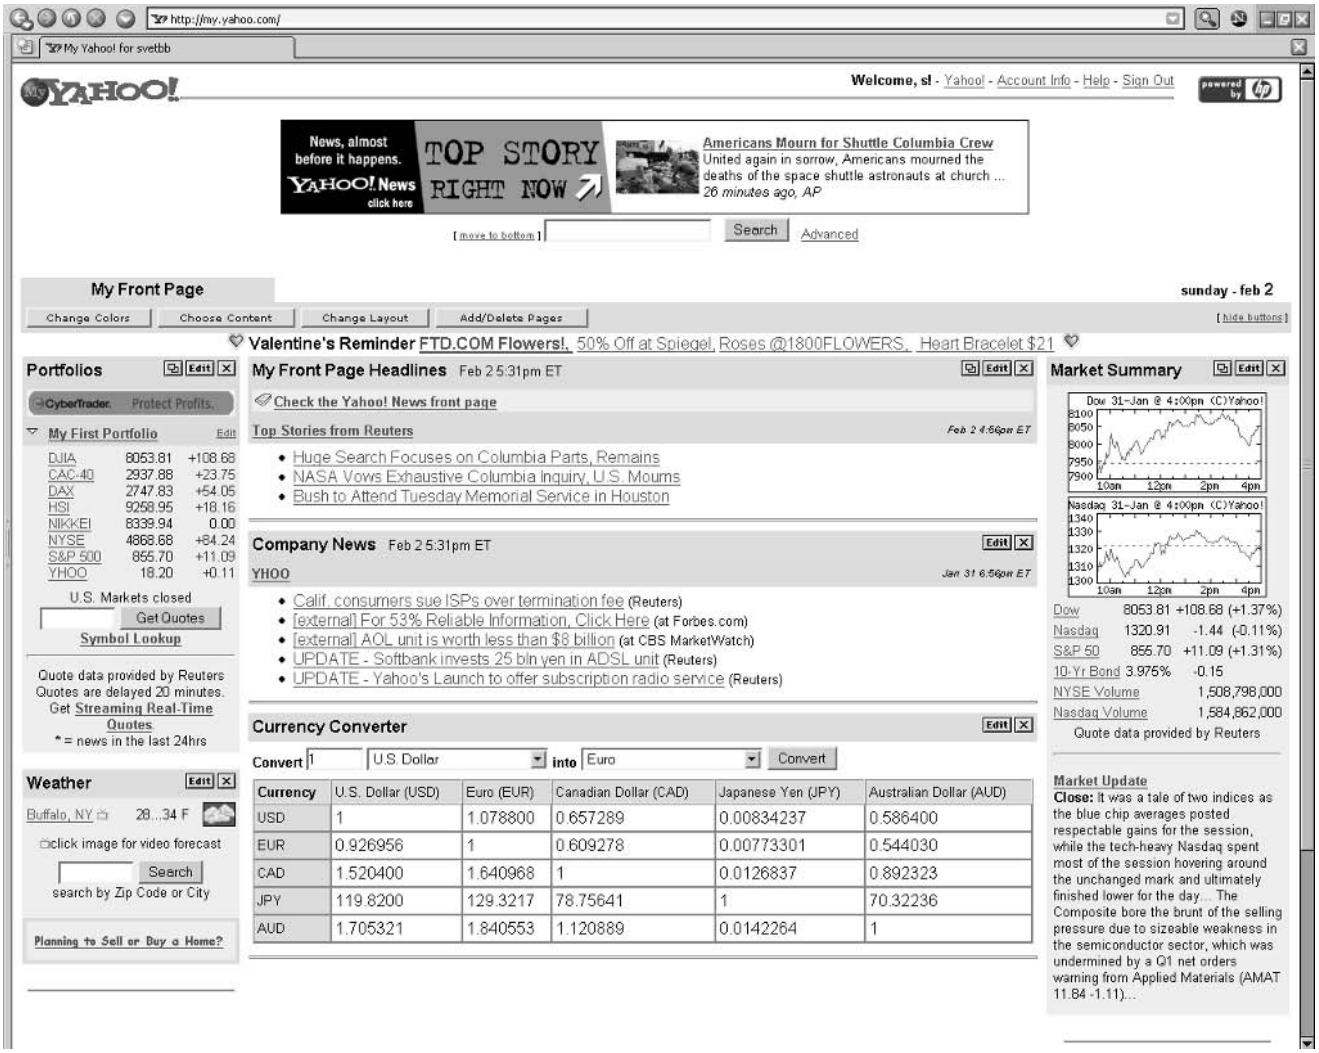

Figure 1: A customized screen of MyYahoo.

two major components of a user profile: behavioral and factual. The factual component contains demographic and transactional information such as age, income, educational level, and favorite brands. Engage Technologies (http:// www.engage.com), for example, sells software that helps companies gather and use factual profiles. The behavioral component contains information about the online activities of the customer. It is usually stored in different forms such as logic-based descriptions, classification rules, and attribute–value pairs. The most common representation of behavioral information is association rules. Here is an example of an association rule: "When shopping on weekends, consumer X usually spends more than $100 on groceries" (Adomavicius & Tuzhilin, 1999). The rules can be defined by a human expert or extracted from transactional data using data mining methods. Broad Vision (http://www.broadvision.com) and Art Technology Group (http://www.atg.com), among others, sell software that helps users build and use rule-based profiles.

The rule-based profile-building process usually consists of two main steps: rule discovery and rule validation. Various data mining algorithms such as Apriori (Agrawal & Srikant, 1994) and FP-Growth (Han, Pei, Yin, & Mao, in press) can be used for rule discovery. A special type of association rules, profile association rules, has been proposed by Agrawal, Sun, and Yu (1998). A profile association rule is one in which the left-hand side consists of customer profile information (age, salary, education, etc.), and the right-hand side of customer behavior information (buying beer, using coupons, etc.). Agrawal et al. (1998) proposed a multidimensional indexing structure and an algorithm for mining profile association rules.

One of the problems with many rule discovery methods is the large number of rules generated, many of which, although statistically acceptable, are spurious, irrelevant, or trivial. Post-analysis is usually used to filter out irrelevant and spurious rules. Several data mining systems perform rule validation by letting a domain expert inspect the rules on a one-by-one basis and reject unacceptable rules. Such an approach is not scalable to large numbers of rules and customer profiles. To solve the problem, Adomavicius and Tuzhilin (2001) proposed collective rule validation. Rules are collected in a single set to which several rule validation operators are applied iteratively. Because many users share identical or similar rules, those can be validated

together. Collective rule validation allows a human expert to reject or accept a large number of rules at once, thereby reducing validation effort.

Explicit Versus Implicit Profiling

Data for user profiling can be collected implicitly or explicitly. Explicit collection usually requires the user's active participation, thereby allowing the user to control the information in his profile. Explicit profiling can take different forms. The user may fill out a form, take part in a survey, fill out a questionnaire, submit personal information at the time of registration, provide a ranking or rating of products, etc. This method has the advantage of letting the customers tell a Web site directly what they need and how they need it.

Implicit profiling does not require the user's input and is usually performed behind the scenes. amazon.com, for example, keeps track of each customer's purchasing history and recommends specific purchases. Implicit profiling usually means tracking and monitoring users' behavior in order to identify browsing or buying patterns in customers' behavior. In many cases, tracking is performed without users' consent and remains transparent to users. Implicit data could be collected on the client or on the server side. Server-side data include automatically generated data in server access logs, referrer logs, agent logs, etc. Client-side data could include cookies, mouse or keyboard tracking, etc. Other sources of customer data are transaction databases, pre-sale and after-sale support data, and demographic information. Such data could be dynamically collected by a Web site or purchased from third parties. In many cases data are stored in different formats in multiple, disparate databases.

Implicit profiling removes the burden associated with providing personal information from the user. Instead of relying on the user's input, the system tries to collect relevant data and infer user-specific information. Although less intrusive, implicit profiling may raise several privacy concerns.

User profiles and their components can be further classified into static and dynamic, and individual and aggregated (group profiles). A profile is static when it changes seldom or never (for example, demographic information). If customer preferences tend to change over time, dynamic profiles can be used. Such profiles are periodically updated to reflect changes in consumer behavior.

OVERVIEW OF FILTERING TECHNOLOGIES

Although necessary, user profile management (creating, updating, and maintaining user profiles) is not sufficient for providing personalized services. Information in user profiles has to be analyzed in order to infer users' needs and preferences. In this section we will briefly explain the most popular personalization techniques: rule-based filtering, collaborative filtering, and content-based filtering. All these techniques are used to predict customers' interests and make recommendations.

Rule-Based Filtering

Association rule mining looks for items that tend to appear together in a given data set. Items could refer to different things in different contexts. They can be products bought by a customer, Web pages visited by a user, etc. To introduce association rules formally, we need the following notation. Let $\mathbf{I}$ denote the set of all items. A transaction $\mathbf{T}$ is defined as a set of items bought together ($\mathbf{T} \subseteq \mathbf{I}$). The set of all transactions is denoted by $\mathbf{D}$. Then, an association rule is defined as an implication between itemsets $\mathbf{A}$ and $\mathbf{B}$, denoted by

$$\mathbf{A} \Rightarrow \mathbf{B},$$

where $\mathbf{A} \subseteq \mathbf{I}$, $\mathbf{B} \subseteq \mathbf{I}$, and $\mathbf{A} \cap \mathbf{B} = \emptyset$. An association rule indicates that the presence of items in $\mathbf{A}$ in a transaction implies the presence of items in $\mathbf{B}$. For example, according to the following association rule, visitors who look at Web pages $\mathbf{X}$ and $\mathbf{Y}$ also look at Web page $\mathbf{Z}$:

look(Visitor, **X**) and look(Visitor, **Y**)
⇒ look (Visitor, **Z**).

Rules can associate items or customers. For example, the following rule associates items,

buys(Customer_1, **X**) and buys(Customer_1, **Y**)
⇒ buys(Customer_1, **Z**),

and the next rule associates customers,

buys(Customer_1, **X**) and buys(Customer_2, **X**)
⇒ buys(Customer_3, **X**).

Rule-based filtering is based on the following idea. If the behavioral pattern of a customer matches the left-hand side of a rule, then the right-hand side can be used for recommendation or prediction.

Two measures are used to indicate the strength of an association rule: *support* and *confidence*. The support of the rule $\mathbf{A} \Rightarrow \mathbf{B}$ is the fraction of the transactions containing both $\mathbf{A}$ and $\mathbf{B}$, i.e., $|\mathbf{A} \cup \mathbf{B}|/|\mathbf{D}|$. The confidence of the rule $\mathbf{A} \Rightarrow \mathbf{B}$ is the fraction of the transactions containing $\mathbf{A}$ which also contain $\mathbf{B}$, i.e., $|\mathbf{A} \cup \mathbf{B}|/|\mathbf{A}|$. Because a large number of association rules can be generated from large transaction databases, weak and nonsignificant associations have to be filtered out. To eliminate spurious associations, minimum support and minimum confidence can be used. That is, all rules that do not meet the minimum support and minimum confidence are eliminated.

An efficient algorithm for association rule mining is frequent pattern growth (FP-growth). The algorithm uses a divide-and-conquer strategy and compresses the database representing frequent items into a frequent-pattern tree (Han et al., in press).

Collaborative Filtering

Collaborative filtering (CF) was one of the earliest recommendation technologies. CF is used to make a recommendation to a user by finding a set of users, called a neighborhood, that have tastes similar to those of the target user.

Products that the neighbors like are then recommended to the target user. In other words, CF is based on the idea that people who agreed on their decisions in the past are likely to agree in the future. The process of CF consists of the following three steps: representing products and their rankings, forming a neighborhood, and generating recommendations.

During the representation stage, a customer–product matrix is created, consisting of ratings given by all customers to all products. The customer–product matrix is usually extremely large and sparse. It is large because most online stores offer large product sets ranging into millions of products. The sparseness results from the fact that each customer has usually purchased or evaluated only a small subset of the products. To reduce the dimensionality of the customer–product matrix, different dimensionality reducing methods can be applied, such as latent semantic indexing and term clustering.

The neighborhood formation stage is based on computing the similarities between customers in order to group like-minded customers into one neighborhood. The similarity between customers is usually measured by either a correlation or a cosine measure. After the proximity between customers is computed, a neighborhood is formed using clustering algorithms.

The final step of CF is to generate the top-*N* recommendations from the neighborhood of customers. Recommendations could be generated using the most-frequent-item technique, which looks into a neighborhood of customers and sorts all products according to their frequency. The *N* most frequently purchased products are returned as a recommendation. In other words, these are the *N* products most frequently purchased by customers with similar tastes or interests. Another recommendation technique is based on association rules. It finds all rules supported by a customer, i.e., the rules that have the customer on their left hand side, and returns the products from the right hand side of the rule.

Content-Based Filtering

Another recommendation technique is content-based recommendation (Balabanovic & Shoham, 1997). Although collaborative filtering identifies customers whose tastes are similar to those of the target customer, content-based recommendation identifies items similar to those the target customer has liked or has purchased in the past. Content-based recommendation has its roots in information retrieval (Baeza-Yates & Ribeiro-Neto, 1999). For example, a text document is recommended based on a comparison between the content of the document and a user profile. The comparison is usually performed using vectors of words and their relative weights. In some cases, the user is asked for feedback after the document has been shown to him. If the user likes the recommendation, the weights of the words extracted from the document are increased. This process is called relevance feedback.

However, content-based recommender systems have several shortcomings. First, content-based recommendation systems cannot perform in domains where there is no content associated with items, or where the content is difficult to analyze. For example, it is very difficult to apply content-based recommendation systems to product catalogs based solely on pictorial information. Second, only a very shallow analysis of very restricted content types is usually performed. To overcome these problems a new hybrid recommendation technique called content-boosted collaborative filtering has been proposed (Melville, Mooney, & Nagarajan, 2002). The technique uses a content-based predictor to enhance existing user data and then provides a recommendation using collaborative filtering.

In general, both content-based and collaborative filtering rely significantly on user input, which may be subjective, inaccurate, and prone to bias. In many domains, users' ratings may not be available or may be difficult to obtain. In addition, user profiles are usually static and may become quickly outdated.

WEB USAGE ANALYSIS FOR PERSONALIZATION

Some problems of collaborative and content-based filtering can be solved by Web usage analysis. Web usage analysis studies how Web sites are used by visitors in general and by each user in particular. Web usage analysis includes statistics such as page access frequency, common traversal paths through a Web site, session length, and top exit pages. Usage information can be stored in user profiles for improving the interaction with visitors. Web usage analysis is usually performed using various data mining techniques such as association rule generation and clustering.

Web Usage Data

Web usage data can be collected at the server side, the client side, or proxy servers or obtained from corporate databases. Most of the data comes from the server log files. Every time a user requests a Web site, the Web server enters a record of the transaction in a log file. Records are written in a format known as the common log file format (CLF), which has been standardized by the World Wide Web Consortium (W3C). The most useful fields of a CLF record are the IP address of the host computer requesting a page, the HTTP request method, the time of the transaction, and the referrer site visited before the current page.

Although server log files are rich in information, data are stored at a very detailed level, which makes them difficult for human beings to understand. In addition, the size of log files may be extremely large, ranging into gigabytes per day. Another problem with server log files is the information loss caused by caching. In order to improve performance most Web browsers cache requested pages on the user's computer. As a result, when a user returns to a previously requested page, the cached page is displayed, leaving no trace in the server log file. Caching could be done at local hosts and proxy servers.

Web usage data can also be collected by means of cookies containing state-related information, such as user ID, passwords, shopping cart, purchase history, customer preferences, etc. According to the W3C cookies are "the data sent by a Web server to a Web client, stored locally by the client and sent back to the server on subsequent

requests." Cookies help keep track of several visits by the same customer in order to build his profile. Some marketing networks, such as DoubleClick, use cookies to track customers across many Web sites.

Users can and often do disable cookies by changing the configuration parameters of their Web browsers. Another way to cope with marketing networks' cookies is by regularly checking the cookie files and deleting them. Some utilities, such as CookieCop, let users automatically accept or reject certain cookies. The program runs as a proxy server and monitors all cookie-related events.

It should be pointed out, however, that rejecting cookies may disable e-commerce transactions. Many retail Web sites, for example, use cookies for shopping-cart implementation, user identification, passwords, etc. Rejecting cookies may also cause problems to companies attempting customization and personalization. In general, there is a tradeoff between privacy and personalization. The more information a user reveals, the more personalized services he obtains.

Other tracking devices, currently producing much controversy, are Web bugs, or clear GIFs. A Web bug is a hidden (or very small) image in a Web page that activates a third-party spying device without being noticed by the Web page visitors. Web bugs are usually used to track users' purchasing and browsing habits.

Mechanisms for User Identification

Server log data contains information about all users visiting a Web site. To associate the data with a particular user, user identification is performed. The simplest form of user identification is user registration, in which the user is usually asked to fill out a questionnaire. Registration has the advantage of being able to collect rich demographic information, which usually does not exist in servers' logs. However, due to privacy concerns, many users choose not to browse sites requiring registration, or may provide false or incomplete information.

Another method for user identification is based on log file analysis. Log-based user identification is performed by partitioning the server log into a set of entries belonging to the same user. Accurate server log partitioning, however, is not always feasible due to rotating IP addresses at ISPs, missing reference due to local or proxy server cashing, anonymizers, etc. For example, many users can be mistakenly classified as a single user if they use a common ISP and have the same IP address. Several heuristics can be used to differentiate users sharing an IP address (Pirolli, Pitkow, & Rao, 1996). One may look for changes in the browser or operating system in the server log file. Because a user is expected to keep the same browser or operating system during his visit to a Web site, a change could mean that another visitor (with a different browser or operating system) uses the same IP address.

Another technique for user identification uses software agents loaded into browsers, which send back data. Due to privacy concerns, however, such agents are very likely to be rejected by users.

The most reliable mechanisms for automatic user identification are based on cookies. Whenever a browser contacts a Web site, it will automatically return all cookies associated with the Web site. Cookie-based user identification is reliable if the user launches each URL request from the same browser.

Another problem with user identification is that Web sites typically deal with both direct and indirect users (Ardissono & Goy, 2001). A customer is an indirect user if he visits a Web site on behalf of someone else. For example, a user may visit a Web store in order to buy a gift for a relative. In this case, the Web store must personalize gift suggestions and recommendations to the preferences of the intended beneficiary (the relative) and not to the preferences of the visitor. To overcome this problem, CDNOW (http://www.cdnow.com) offers a "gift advisor" which differentiates between direct and indirect users.

Session Identification

A user session consists of all activities performed by a user during a single visit to a Web site. Because a user may visit a Web site more than once, a server log may contain multiple sessions for a given user. Automatic session identification can be performed by partitioning log entries belonging to a single user into sequences of entries corresponding to different visits of the same user. Berendt, Mobasher, Spiliopoulou, and Wiltshire (2001) distinguish between time-oriented and navigation-oriented sessionizing. Time-oriented sessionizing is based on timeout. If the duration of a session or the time spent on a particular Web page exceeds some predefined threshold, it is assumed that the user has started a new session.

Navigation-based sessionizing takes into account the links between Web pages, the Web site topology, and the referrer information in a server log. A Web page P_1 is a referrer to another page P_2 if the URL request for P_2 was issued by P_1, i.e., the user came to P_2 by clicking on a link on P_1. A common referrer heuristic is based on the assumption that a user starts a new session whenever he uses a referrer different from or not accessible from previously visited pages. For example, if a user comes to page P_2 with a referrer page P_1 and P_2 is not accessible from P_1 given the Web site topology, then it is reasonable to assume that the user has started a new session. This heuristic, however, fails when the user uses the "Back" button or chooses a recent link kept by the browser.

Clickstream Analysis

Clickstream analysis is a special type of Web usage mining that provides information essential to understanding users' behavior. The concept of clickstream usually refers to a visitor's path through a Web site. It contains the sequence of actions entered as mouse clicks, keystrokes, and server responses as the visitor navigates through a Web site. Clickstream data can be obtained from a Web server log file, commerce server database, or from client-side tracking application.

Most efforts in Web usage analysis are focused on discovering users' access patterns. Understanding users' navigation through a Web site can help provide customized content and structure tailored to their individual needs. Chen, Park, and Yu (1996) proposed an algorithm for mining maximal forward reference, where forward reference is defined as a sequence of pages requested by a user up to

the last page before backtracking occurs. The algorithm first converts server log data into a set of maximal forward references and then determines frequent traversal patterns, i.e., maximal forward references that occur frequently.

Another approach is taken in the Web Utilization Miner (WUM) (Spiliopoulou & Faulstich, 1999). The authors of WUM not only identify sequences of frequently accessed pages but also find less frequent paths having structural or statistical properties of interest. In WUM the path followed by a user is called a trail. Because many users can display similar navigation patterns, users' trails are aggregated into a tree by merging trails sharing a prefix. The aggregate tree can be subsequently used for predicting user's behavior.

Markov models have also been used for modeling users' browsing behavior (Deshpande & Karypis, 2001). Markov models predict the Web page accessed by a user given the sequence of Web pages previously visited. Such models have proved to display high predictive accuracy. On the other hand, they have high state-space complexity, which significantly limits the scope of their applicability.

Mobasher, Dai, Luo, and Nakagawa (2002) proposed an aggregate profiling algorithm based on clustering transactions (PACT). User's transactions are represented as multidimensional space vectors of page views. The vectors are grouped into clusters, each of them representing a set of users with similar navigational patterns. Subsequently, every cluster is associated with a single point (the cluster's centroid) representing an aggregate profile of all users in that cluster. A new user activity is matched against aggregate profiles and items are recommended based on the degree of matching.

INTELLIGENT AGENTS FOR PERSONALIZATION

Intelligent agent technology provides a useful mechanism for personalization and customization. The term intelligent agent has been used in different meaning by different authors. By agent we refer here to a software program acting on behalf of its user and having the following properties (Weiss, 1999):

Autonomy: agents operate without the direct intervention of their user.

Social ability: agents interact with other agents (including humans) via agent-communication language.

Reactivity: agents perceive and adapt to a dynamically changing environment.

Proactiveness: agents do not simply act in response to their environment; they are able to exhibit goal-directed behavior.

Rationality: every agent has a representation of its user's preferences and tries to satisfy them in the best possible way.

Intelligent agents come in different types. *Internet agents* help the user collect, manipulate, and analyze information. Some of them are embedded within an Internet browser and help the user navigate through a Web site. *Interface agents* act like personal assistants collaborating with the user. Interface agents monitor, observe, and learn from the user's actions. Some interface agents can assume the form of a synthetic character; other can model users' emotions or chat with the user, using natural language. *Collaborative agents* act as a team to achieve some common goal. *Mobile agents* can roam the Internet and interact with foreign hosts and other agents on behalf of their users.

In other words, intelligent agents can be viewed as proxies of human users, capable of learning and reasoning about users' preferences. WebWatcher (Joachims, Freitag, & Mitchell, 1997) was one of the first software agents to assist users browsing the Web. It guides users through a Web site by trying to predict the paths they will follow based on the navigation history of previous users of the Web site. WebWatcher believes that a particular hyperlink is likely to be followed by a user if like-minded visitors previously followed it. WebWatcher suggests a link based on current user, user's interest, and a Web page. The user's interest is represented by a set of keywords and a hyperlink is represented by a feature vector. When a new user enters a Web page, WebWatcher compares the current user's interest with the descriptions of the links on the page and suggests the links correlated with the user interest. WebWatcher also uses reinforcement learning to learn how to navigate through a Web site. The learning is based on positive reinforcement WebWatcher receives whenever it chooses a link that fits the user's interests.

Letizia (Lieberman, 1997) is another software agent for client-side personalization. It learns a model of its user by observing his or her behavior. The user model consists of a list of weighted keywords representing the user's interests. Letizia explores the Web ahead of its user and recommends potential links of interest. It records every choice of the user on a Web page and takes the act of viewing a Web page as a positive feedback (evidence of interest). Letizia tries to incrementally learn the user's interest in a page by observing the choices he or she makes. This is an example of unobtrusive personalization, which does not require explicit user interaction: the user is not asked to explicitly rank or evaluate Web pages.

LOCATION-BASED PERSONALIZATION

The information used for personalization may range from a history of past purchases and browsing behavior to explicitly provided user preferences. The rapid growth of wireless networks and mobile commerce provide new opportunities for personalization by offering more user-specific information such as geographic location, date, time, and travel direction. Handheld devices, for example, allow customers to receive personalized content and recommendations on the move, at home, and at work.

One of the most promising technologies is location-based services (LBS), which allows business to identify a user's location and offer context-dependent services. LBS holds the potential to significantly improve CRM, wireless marketing, and emergency services.

In October 2000, Ericsson, Motorola, and Nokia founded the location interoperability forum (LIF) established to provide location-based services. The forum

aims at providing a common device location standard to achieve global interoperability between location-based services regardless of their underlying technologies. At present, there is a wide range of location identification technologies. One method, for example, involves the cell ID number, which identifies a cellular device to a network. Other methods (Deitel, Deitel, Nieto, & Steinbuhler, 2002) are triangulation (used by several satellites in GPS), cell of origin (a cellular phone is located by a nearby tower), angle of arrival (several towers measure the angles from which a cellular phone's signals are received), and observed time difference (the travel time between a cellular phone and multiple towers is measured to determine the phone's location).

Location-based services allow content providers to offer personalized services based on customers' geographic position. Mobile users can receive local weather reports, news, travel reports, traffic information, maps, hotels, restaurant information, etc. For example, Go2 Systems (www.go2online.com) provides a mobile Yellow Pages directory based on users' location. The directory allows users to get directions to various nearby services such as entertainment, real estate, finance, recreation, government, and travel.

One problem with LBS is that the small screen and the limited capabilities of wireless devices can reduce the level of personalization. For example, it is often impractical to use Web-based registration forms or questionnaires for explicit personalization. Billsus, Brunk, Evans, Gladish, and Pazzani (2002) report that only 2–5% of wireless users customize their interfaces, due to technical problems or poor content management. Another problem is complex navigation and the structure of WAP (wireless application protocol) sites. Each WAP site consists of multiple decks, each of them containing one or more cards. Hypertext links can be made between cards in the same or in different decks. As a result, users must make too many selections and move through too many cards in order to achieve their goals. In addition, the limited processing power and slow network access for many mobile devices lead to extended response times.

To improve Web site navigation for wireless devices, Anderson, Domingos, and Weld (2001) proposed a personalization algorithm, MinPath, which automatically suggests useful shortcut links in real time. MinPath finds shortcuts by using a learned model of Web visitor behavior to estimate the savings of shortcut links and to suggest only the few best links. The algorithm takes into account the value a visitor receives from viewing a page and the effort required to reach that page.

PREFERENCE MODELING

User preferences play an important role in user modeling, personalization, and customization. According to the decision-theoretic tradition, human preferences are modeled as a binary relation **R** over a set of possible alternatives such as products and services, information content, layout, and interaction style. A preference relation **R** holds between two alternatives (or choice options) **X** and **Y** (i.e., **R**(**X**, **Y**)) if **X** is more preferred to **Y**. That is, the user will chose **X** when he or she faces a choice between **X** and **Y**. The indifference between **X** and **Y** could be represented as **not**(**R**(**X**,**Y**)) **and not**(**R**(**Y**,**X**)). It has been proved (Fishburn, 1970) that, under certain conditions, a preference relation can be represented by an order-preserving numeric function **U** called a utility function. In other words, alternative **X** is preferred to alternative **Y** if and only if the utility of **X** is greater than the utility of **Y**, (**U**(**X**) > **U**(**Y**)). Knowing a user's utility function allows a system to offer its customers those products, services, or information that maximize the customers' utility. The problem of preference modeling has been approached relatively recently in the computer science community. Usually users' preferences are represented based on ad hoc approaches such as attribute–value pairs and association rules. It is still an open question how to represent user preferences in a computationally tractable way and how to reason with incomplete or inaccurate preferences. In this section we discuss three important preference problems: how to elicit user's preferences, how to reason with conditional preferences, and how to take advantage of users' preferences in personalizing access to databases.

Preference Elicitation

The process of preference elicitation consists of finding a user's preferences for a well-defined set of choices (for example, products). In general, preference elicitation could be performed by interviewing or observing user's behavior. Various methods for preference elicitation have been proposed. Most of them assume that consumer preferences are additive functions over different attributes or decision objectives. That is, a user multiattribute utility function is a weighted sum of single-attribute utility functions,

$$U(x_1, \ldots, x_n) = \sum w_i \, U_i(x_i),$$

where $U(x_1, \ldots, x_n)$ is the user utility function, $U_i(x_i)$ are single-attribute utility functions, and w_i are their weights. The intuition behind this assumption is that it may be natural to think in terms of utility for each attribute and then combine these utilities into an overall multiattribute utility function.

The analytic hierarchy process (AHP) (Saaty, 1980) is a common method for discovering attribute weights w_i. AHP is carried out in two steps. In the first step, an attribute hierarchy is set up. In the second step, the user is asked to compare attributes sharing a parent in the hierarchy. Pairwise attribute comparisons determine the relative importance of each attribute with respect to the attribute on the level immediately above it. The strength of the comparison is measured on a ratio scale. The comparisons are used to build a reciprocal matrix, which is subsequently used to derive the relative weights w_i for the overall utility function.

Another method for preference elicitation is multiattribute conjoint analysis (Luce, 1977). Attribute values are usually discretized and every combination of discrete attribute levels is ranked by the user. The rank is then used as its utility value. The coefficients w_i in the overall utility function are derived using statistical methods such as regression analysis.

Direct approaches to preference elicitation, however, are generally not feasible, due to the exponential number of comparisons and due to the complexity of the questions to be asked. In applications such as recommender systems, product configuration, and adaptive Web stores, users cannot be expected to have the patience to provide detailed preference relations or utility functions. In addition, users cannot always be expected to provide accurate and complete information about their preferences. In general, direct preference elicitation requires a significant level of introspection and imposes a significant cognitive overload on users. Instead of using direct preference elicitation, Chajewska, Getoor, Norman, and Shahar (1998) have used classification to identify a user's utility function. The authors partition users' utility functions into clusters with very similar utility functions in each cluster. Every cluster is characterized by a single reference utility function called prototype. Then for every new user the system finds the cluster to which he is most likely to belong, and uses the prototype utility function for that cluster to predict his preferences.

Reasoning with Conditional Preferences

Most of the research on preference modeling focuses on additive utility functions in which every attribute of the function is independent of other attributes. Such utility functions allow a very elegant representation in the form of a weighted sum of attribute utilities. For example, if a user's preferences for product quality **Q** are independent of his preferences for product brand **B**, then the user's utility could be represented as a weighted sum,

$$\mathbf{U}(\mathbf{Q},\mathbf{B}) = \mathbf{w}_1\mathbf{U}(\mathbf{Q}) + \mathbf{w}_2\mathbf{U}(\mathbf{B})$$

where $\mathbf{U}(\mathbf{Q},\mathbf{B})$ is the overall product utility, $\mathbf{U}(\mathbf{Q})$ is the utility for product quality, and $\mathbf{U}(\mathbf{B})$ is the utility for brand. Additive utility functions are easy to elicit and evaluate. A problem arises, however, if preferences over product attributes are not independent. For example, a preference for brand usually depends on the quality level and vice versa. To overcome this problem, Boutilier, Brafman, Hoos, and Poole (1999) proposed a model of conditional preferences. Preferences are represented as a network called a conditional preference network (CP-network) that specifies the dependence between attributes. In CP-networks a user can specify a conditional preference in the form:

If product quality is medium, then I prefer Brand_1 to Brand_2.

Boutilier et al. (1999) have also formulated and studied the product configuration problem, i.e, what is the best product configuration that satisfies a set of customer preferences. The authors have proposed several algorithms for finding an optimal product configuration for a given set of constraints. In Domshlak, Brafman, & Shimony (2001) CP-networks are used for Web-page personalization. The optimal presentation of a Web page is determined by taking into account the preferences of the Web designer, the layout constraints, and the viewer interaction with the browser. For example, the preferences of the Web page designer are represented by a CP-network and constrained optimization techniques are used to determine the optimal Web page configuration.

Preference-Based Queries

Preference modeling plays an increasingly important role in e-commerce applications where the users face the problem of information overload, i.e., how to choose from among thousands and even millions of products and product descriptions. Preference queries (Chomicki, 2002) have been proposed as a tool to help a user formulate the most appropriate queries and receive the results ranked according to his preferences. Preference queries are based on a preference operator (called winnow) which picks from a given relation the set of the most preferred tuples, according to a given preference formula.

For example, consider the instance of the book relation shown in Figure 2 (Chomicki, 2002). A user's preferences could be formulated as follows: the user prefers a book to another if and only if their ISBNs are the same and the price of the first book is lower. In this case, because the second book is preferred to the first and to the third, and there are no preferences defined between the last two books, the winnow operator will return the second, the fourth, and the fifth book. Chomicki (2002) has studied the properties of the winnow operator and has proposed several algorithms for evaluating preference queries.

APPLICATIONS

This section discusses how personalization techniques can be used to tailor the content, products, and interactions to customers' needs. Some typical personalization applications are explained, such as adaptive Web sites, recommender systems, adaptive Web stores, and customer relationship management.

Adaptive Web Sites

Web sites have been traditionally designed to fit the needs of a generic user. Adaptive Web sites, which customize content and interface to suit individual users or groups of users, provide a more effective way to interact with these users. An adaptive Web site can semiautomatically improve its organization and presentation by learning from

visitors' access patterns (Perkowitz & Etzioni, 2000). An adaptive Web site may automatically create new pages, remove or add new links, highlight or rearrange links, reformat content, etc. In general, Web site adaptiveness could be classified as being either individual- or group-oriented. An individually adaptive Web site consists of a large number of versions—one for each individual user. Group-oriented adaptiveness targets groups of users and requires a smaller number of Web site versions—one for each group. For example, a Web site may have one view for corporate users and another view for individual users, or one view for domestic visitors and another view for international visitors.

Depending on the way it is performed, adaptation can be classified as content-based or as access-based. Content-based adaptation involves presenting and organizing Web pages according to their content. Access-based adaptation is based on the way visitors interact with a Web site. It involves tracking users' activity and personalizing content and layout according to users' navigation patterns.

The problem of designing personalized Web sites is complicated by several factors. First, different users may have different goals and needs. Second, the same user may have different goals at different times. Third, a Web site may be used in a way different from the designer's expectations. It is still not clear what kind of adaptation can be automated and what is the appropriate tradeoff between user-controlled and automatically guided navigation.

The idea of adaptive Web sites was popularized by Perkowitz and Etzioni (2000). They proposed the PageGather algorithm, which automatically generates index pages that facilitate navigation on a Web site. An index page is a page consisting of links to a set of existing but currently unlinked pages that cover a particular topic of interest. In order to find a collection of related pages on a Web site, the PageGather algorithm employs cluster mining. The algorithm takes the Web server access log, computes the co-occurrence frequencies between pages, and creates a similarity matrix. The matrix is then transformed into a similarity graph, and maximal cliques are found. Each maximal clique represents a set of pages that tend to be visited together.

Recommender Systems

Recommender systems (Schafer, Konstan, & Riedel, 2001) have been used in B-to-C e-commerce sites to make product recommendations and to provide customers with information that helps them decide which product to buy. Recommender systems provide a solution to the problem of how to choose a product in the presence of an overwhelming amount of information. Many e-commerce sites offer millions of products, and therefore, choosing a particular product requires processing large amounts of information, making a consumer choice difficult and tedious.

Recommender systems contribute to the success of e-commerce sites in three major ways (Schafer et al., 2001). First, they help to improve cross-sell. Cross-sell is usually improved by recommending additional products for the customer to buy. For example, by looking at the products in the customer's shopping cart during the checkout process, a system could recommend additional complimentary products. Second, recommender systems could help convert occasional visitors into buyers. By providing a recommendation, a retailer could deliver customized information, increase the amount of time spent on a Web site, and finally, increase the customer's willingness to buy. Third, recommender systems help build loyalty and improve customer retention. Personalized recommendations create a relationship between a customer and a Web site. The site has to invest additional resources into learning customers' preferences and needs; on their part, customers have to spend time teaching a Web site what their preferences are. Switching to a competitor's Web site becomes time-consuming and inefficient for customers who have to start again the whole process of building personalized profiles. In addition, customers tend to return to Web sites that best match their needs.

Recommender systems use different methods for suggesting products (Schafer et al., 2001). One of the most common methods is item-to-item correlation. This method relates one product to another using purchase history, attribute correlation, etc. CDNOW, for instance, suggests a group of artists with styles similar to that of the artist that the customer likes. Another recommendation method is user-to-user correlation. This method recommends products to a customer based on a correlation between that customer and other customers visiting the same Web site. A typical example is "Customers who bought" in Amazon.com. When a customer is buying or browsing a selected product, this method returns a list of products purchased by customers of the selected product. Other recommendation methods include statistical summaries. For example, the Purchase Circles feature of Amazon.com allows customers to view the "top 10" list for a given geographic region, company, educational institution, government, or other organization.

CDNOW enables customers to set up their own music stores, based on albums and artists they like. Customers can rate albums and provide feedback on albums they have purchased. The system keeps track of previously purchased albums and predicts six albums the customer might like based on what is already owned.

A recent study by Haubl and Murray (2001) shows that recommendation algorithms have the potential to manipulate and influence user preferences in a systematic fashion. The authors performed a controlled experiment showing that the inclusion of a product feature in a recommendation renders the feature more prominent in customers' purchase decisions.

Adaptive Web Stores

Adaptive Web stores are a special type of adaptive Web sites that can use a customer profile to suggest items best fitting the customer's needs. The main difference between adaptive Web stores and adaptive Web sites is that Ardissono and Goy (2001) describe a prototype toolkit (SETA) for creating adaptive Web stores. In contrast to other adaptive Web stores, SETA adapts not only item selection, but also layout and content selection to the preferences and expertise of customers. SETA chooses a catalog presentation style (item description, background colors,

font face and size) that best fits customer preferences and perceptivity.

In order to provide personalized interaction, SETA employs user's models. A user model consists of a fixed part, containing a set of domain-independent user's attributes, and a configurable part, containing the user's preferences for domain-dependent product properties. An example of a user model is given in Figure 3.

Data in a user model are represented as a list of <feature, value> pairs. The value slot represents a probability distribution over the set of possible values for a given feature. For example, the user presented in Figure 3 prefers high-quality products with probability 0.8 and medium and low quality products with probability 0.1. The importance slot describes the system's estimate of the relevance of a particular preference. Following the previous example, the user attaches an importance of 0.8 to product quality.

SETA divides all customers into groups according to the similarity of their preferences. All customers belonging to one group are described by a group profile called a stereotype. The classification into stereotypes is used to evaluate how closely a customer visiting a Web store matches a stereotypical description. The stereotype closest to a customer's properties is used for predicting his preferences, his product selection, and the interface design. Every stereotype consists of a conditional part and a prediction part. The conditional part describes the general properties of a group of customers. For example, the conditional part may assert that 30% of customers in a group are below 30 years of age, 60% of customers are between 30 and 50, and 10% are above 50 years of age. The prediction part of a stereotype is similar to a user model and describes group preferences for product properties.

When a user visits a Web store, the system tries to predict the user preferences by computing the degree of matching between the user's profile and each stereotype. The predictions of all stereotypes are merged as a weighted sum of predictions suggested by each stereotype, where the weights represent the user's degree of matching with a stereotype.

The main advantage of SETA is that the system tailors graphical design, product selection, page content and structure, and terminology to customers' receptivity, expertise, and interests. In addition, it maintains a model of each customer and of large groups of customers. On the other hand, SETA depends essentially on customer registration. The system is unable to observe customers' behavior in order to automatically build individual profiles. Another drawback of SETA is that stereotypes (group profiles) are prepared manually and, therefore, may not reflect the actual dynamic properties of customer population. An alternative approach is to use data mining techniques that automatically build and dynamically update group profiles.

Customer Relationship Management

Customer relationship management (CRM) refers to providing quality service and information by addressing customer needs, problems, and preferences. CRM can include sales tracking, transaction support, and many other activities. A CRM system usually consists of a database of customer information and tools for analyzing, aggregating, and visualizing customer information. To achieve its goal, CRM makes extensive use of personalization and customization technologies such as log-file analysis, data mining, and intelligent agents. For example, many CRM systems store and analyze consumer profiles in order to develop new products, increase product utilization, optimize delivery costs, etc.

The market for integrated solutions for online CRM is growing at a rapid pace. BroadVision (http://www.broadvision.com), for example, provides solutions for contextual personalization with its one-to-one portal and one-to-one commerce center. BroadVision combines rule-based personalization with intelligent agent matching to dynamically tailor relevant information to customers.

They also provide profile generation, session and event-based monitoring.

NetPerceptions (http://www.netperceptions.com) is another provider of CRM systems, based on collaborative filtering. NetPerceptions provide tools for one-to-one marketing and for real-time cross-sell and up-sell recommendations. The core technology is the GroupLens software for generating product recommendations.

Vignette Corporation is another provider of software for dynamic content management. Their Vignette V6 relationship manager server uses rule-based filtering, user's viewing activities, and historical data to generate customized recommendations. The system also allows business users to define their own rules for content delivery.

PERSONALIZATION AND PRIVACY

With personalized online service, concerns about privacy arise. In general, e-commerce sites must strike a difficult balance: they must recognize a returning customer without violating his privacy. According to Alan Westin (1997) privacy is "the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others." Many personalized Web sites collect and store personal information, keep track of user online behavior, or build individual profiles without the consumer's consent. On June 13, 2000, the Federal Trade Commission (FTC) issued *Online Profiling: A Report to Congress*. The report found that many banner ads displayed on Web sites are selected and delivered by networks of advertising companies (such as 24/7 Media, AdForce, AdKnowledge, Avenue A, Burst Media, DoubleClick, Engage, and MatchLogic) without the consent and knowledge of customers. Advertising networks can track consumer behavior over large networks of interrelated Web sites and build consumer profiles. Although the profiles are usually anonymous (i.e., they are linked to a cookie or a session ID number), many advertising networks also have sociodemographic profiles (acquired from third parties) that could eventually be linked to anonymous profiles. For example, in 1999 DoubleClick purchased Abacus, a direct marketing company, with a database of over 88 million buyers profiles collected from catalog retailing. DoubleClick planned to merge that database with its own database containing clickstream browsing patterns for over 10 million Internet users.

Some privacy advocates believe that even anonymous profiles permit *digital redlining* and *weblining*. Digital redlining refers to the ability of a Web site to limit the information customers want to see to that chosen by marketers. This holds the potential of manipulating the shopping environment to the advantage of the merchant and influencing customers' purchasing decisions and buying habits. The concept of weblining refers to discriminating between customers based on their profiles and charging selected customers higher prices.

The FTC report outlined the following fair information practices:

Notice: Web sites collecting data must disclose their information practices before collecting personal information from users.

Choice: Users must be given choice with respect to whether and how personal information collected from them may be used.

Access: Users should be able to access and check the accuracy and completeness of information collected about them.

Security: Web sites collecting personal data must ensure that these data will not be used without authorization.

There are many technology-based solutions for privacy protection. One expected to have significant impact is the Platform for Privacy Preferences (P3P) proposed by the World Wide Web Consortium. P3P is designed to enable users to exercise preferences over Web sites privacy practices. It allows users to compare a Web site's privacy policy to their own standards prior to visiting a Web site or disclosing private information. P3P includes a standard vocabulary for describing privacy policies, a set of base data elements that Web sites can use in their policies, and a protocol for requesting privacy policies. Privacy policies are specified in XML format and can automatically be fetched and analyzed by a Web browser. If the Web site's policies do not agree with the user's privacy preferences, the browser can either warn the user or disable certain functionality. P3P automates privacy statement disclosure and eliminates the tedious and repetitive process of reading privacy statements.

P3P has received a lot of criticism, mostly because it does not address the issue of enforcement of privacy agreements between users and sites. P3P does not establish specific privacy standards; instead, it provides a framework on which to build privacy mechanisms.

Another type of privacy protection tools is anonymizers (Anonymizer.com, Zero Knowledge Systems, safeWeb). They serve as proxies between browsers and Web sites and hide the user's identity. Many of them offer anonymous browsing, file downloads, e-mail, etc. The main disadvantage of anonymizers is that they cannot support e-commerce transactions, which usually require the transfer of financial and personally identifiable information.

Many personalization advocates believe that the Internet will make a significant leap forward in efficiency when it will automatically recognize the digital identities of individual users. Digital identity is the codification and archiving of personally identifiable information, i.e., information from which a person can be identified (such as name, address, SSN, fingerprints, and retinal scan). Currently there are two prevailing identity services: Liberty Alliance Project Liberty 1.0 and Microsoft.Net Passport. Both of them rely on the concept of federated authentication, which allows a user to visit several Web sites with a single sign-on. For example, in Microsoft.Net Passport the user profile is stored on a Microsoft server that (with the user's approval) shares the information with participating Web sites. This raises some doubts as to whether digital identity services provide sufficient protection of privacy. Users can easily lose the ability to control how and to what extent information about them is shared with marketing firms, governmental agencies, and other third parties.

Liberty Alliance does not centralize personal information. Instead, information is distributed across several

participating companies, such as Citigroup, General Motors Corporation, and Sony Corporation, which together form the Liberty Alliance Network. Liberty Alliance also allows users to decide whether to link their accounts to different participating sites. For example, users can choose to opt out and not link their accounts to a specific site. The main difference between Microsoft Passport and Liberty Alliance is that Microsoft keeps all the data about individual users, whereas Liberty Alliance allows the data to be owned by many Web sites.

CONCLUSION

Personalization and customization are among the fastest growing segments of the Internet economy. They provide several advantages to both businesses and customers. Customers benefit from personalization by receiving customized experience, reduced information overload, and personalized products and services. Businesses benefit from the ability to learn consumers' behavior, provide one-to-one marketing, increase costumer retention, optimize product selection, and provide build-on-demand services.

Due to the large variety of personalization techniques and applications, this survey is by no means exhaustive. Recent developments in Web services, for example, offer new prospects for personalization and customization. SUN recently presented a new vision of context-sensitive Smart Web services, which can adapt their behavior to changing conditions. A smart Web service can adapt depending on a user's location or preferences.

Personalization is by no means limited to Web site data mining, machine learning, or statistical analysis. Personalization can use any technology that provides insight into customer behavior and customer preferences. It is our hope and expectation that the near future will offer new challenging technologies and that personalization will continue to be one of the most exciting fields in the modern Internet economy.

GLOSSARY

Anonymizer A proxy between a browser and a Web site which hides the user's identity.

Collaborative filtering Recommendation technology that makes a suggestion to a target customer by finding a set of customers with similar interests.

Content-based recommendation Recommendation technology that makes a suggestion to a target customer by finding items similar to those he or she has liked or has purchased in the past.

Cookie The data sent by a Web server to a Web client, stored locally by the client and sent back to the server on subsequent requests.

Customer profile A collection of data describing an individual user or a group of users.

Data mining The nontrivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data.

Intelligent agent A software program which can act as a proxy of a human user by learning and reasoning about users' preferences.

Log file A file generated by a Web server, which keeps a record for every transaction.

Personalization Using user information to better design products and services tailored to the user.

Privacy The claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others.

User identification The process of associating Web site visits and navigation behavior with a particular user.

User session All activities performed by a user during a single visit to a Web site.

Web bug A hidden image in a Web page that activates a third-party spying device without being noticed by the Web page visitors.

Physical Security

Mark Michael, *King's College*

INTRODUCTION

Digital information is at the heart of every Internet transaction. The confidentiality, integrity, and availability of that information depends on the security of the following physical constituents of any computing environment:

1. hardware, in the broadest sense—machines, storage media, and transmission media;
2. the physical expression of the zeroes and ones that represent digital information (data and programs);
3. electricity, without which no digital information could change, move, or incite action; and
4. humans and the information they possess to run the system.

Internet security can be divided into two distinct areas: cybersecurity and physical security. The former term pertains to threats and defenses mounted via the same channels as legitimate exchanges of digital information. Encryption of information falls into this category. The role of physical security is to guard the four physical ingredients just outlined in two ways. First, it must protect the integrity and availability of resources for legitimate use. Second, it must prevent the misuse of resources, for example, by breaches of confidentiality or theft of services.

Physical security and cybersecurity complement one another. Where an organization's control over the physical ingredients ends, encryption and the like must take over. When cyberdefenses are strengthened, physical vulnerabilities become more inviting targets. Physical security serves cybersecurity. A breach of physical security, such as a password in the trash, can give a cyberattacker a foothold. The advent of biometrics and smart cards can be viewed either as an expansion of physical security into cybersecurity territory or as a blurring of the line between the two forms of security.

Physical security issues extend as far as an organization's resources. Because human knowledge is one of those assets, physical security concerns can span as far as information can spread. For instance, sensitive information could be revealed by an indiscreet question posted on a newsgroup. Thus, physical security is not constrained by a geographical footprint.

Physical security is intractable in the sense that certain events cannot be prevented. We cannot stop someone from demanding an off-duty employee's password at gunpoint, for instance. Redundancy is the last line of defense for the integrity and availability of resources. Confidentiality, on the other hand, cannot be "backed up"; some damage, such the as revelation of personal information, can never be repaired.

PHYSICAL THREATS TO INTEGRITY AND AVAILABILITY OF RESOURCES

Basic Environmental Threats to Computing Resources

Four basic threats to the physical health of computing equipment are inappropriate temperature, inappropriate humidity, foreign particles, and water.

Table 1 Temperature Thresholds for Damage to Computing Resources

COMPONENT OR MEDIUM	SUSTAINED AMBIENT TEMPERATURE AT WHICH DAMAGE MAY BEGIN
Flexible disks, magnetic tapes, etc.	38°C (100°F)
Optical media	49°C (120°F)
Hard-disk media	66°C (150°F)
Computer equipment	79°C (175°F)
Thermoplastic insulation on wires carrying hazardous voltage	125°C (257°F)
Paper products	177°C (350°F)

Temperature and Humidity

The internal temperature of equipment can be significantly higher than that of the room air. Although increasing densities have brought decreasing currents at the integrated circuit level, dissipation of heat is still a major concern. If a cooling system fails, a vent is blocked, or moving parts create abnormal friction, temperature levels can rise rapidly.

Excessively high temperatures can decrease performance or even cause permanent damage to computer equipment and media. The severity of the damage increases with temperature and exposure time, and its onset depends on the type of resource, as detailed in Table 1. Media may be reconditioned to recover data, but the success rate drops rapidly above these thresholds. Magnetism—the essence of much data storage—can be affected by temperatures higher than those listed; therefore, damage to magnetic media occurs first in the carrier and binding materials. On the other hand, silicon—the foundation of current integrated circuitry—will lose its semiconductor properties at significantly lower temperatures than what it takes to melt the solder that connects a chip to the rest of the computer.

To put these temperatures in perspective, some heat-activated fire suppression systems are triggered by ambient temperatures (at the sensor) as high as 71°C (160°F). Even in temperate climates, the passenger compartment of a sealed automobile baking in sunlight can reach temperatures in excess of 60°C (140°F). If media or a mobile computer is directly in sunlight and absorbing radiant energy, the heating is more rapid and pronounced, especially if the encasing material is a dark color, which, in the shade, would help radiate heat. (Direct sunlight is bad for optical media even at safe temperatures.)

Although excessive heat is the more common culprit, computing equipment also has a minimum temperature for operation. Frigid temperatures can permanently damage mobile components (e.g., the rechargeable battery of a laptop computer), even when (in fact, *especially* when) they are not in use. Plastics can also become more brittle and subject to cracking with little or no impact.

High humidity threatens resources in different ways. For electrical equipment, the most common problem is the long-term corrosive effect. If condensation forms, however, it brings the dangers posed by water (detailed later). Magnetic media deteriorate by *hydrolysis,* in which polymers "consume" water; the binder ceases to bind magnetic particles to the carrier and sheds a sticky material (which is particularly bad for tapes). Obviously, the rate of decay increases with humidity (and, as for any chemical process, temperature). Formation of mold and mildew can damage paper-based records, furniture, and so on. It can also obstruct reading from optical media. A bigger concern for optical media is corrosion of the metallic reflective layer. In tropical regions, there are even documented cases of fungi burrowing in CDs and corrupting data; high humidity promotes the fungal growth.

On the other hand, very low humidity may change the shape of some materials, thereby affecting performance. A more serious concern is that static electricity is more likely to build up in a dry atmosphere.

Foreign Particles

Foreign particles, in the broad sense intended here, range from insects down to molecules that are not native to the atmosphere. The most prevalent threat is dust. Even fibers from fabric and paper are abrasive and slightly conductive. Worse are finer, granular dirt particles. Manufacturing by-products, especially metal particles with jagged shapes, are worse yet. A residue of dust can interfere with the process of reading from media. Dirty magnetic tape can actually stick and break. Rotating media can be ground repeatedly by a single particle; a head crash is a possible outcome. A massive influx of dust (such as occurred near the World Trade Center) or volcanic ash can overwhelm the air-filtering capability of *HVAC* (heating, ventilation, and air-conditioning) systems.

Dust surges that originate within a facility due to construction or maintenance work are not only more likely than nearby catastrophes, they can also be more difficult to deal with because there is no air filter between the source and the endangered equipment. A common problem occurs when the panels of a suspended ceiling are lifted and particles rain down.

Keyboards are convenient input devices—for dust and worse. The temptation to eat or drink while typing only grows as people increasingly multitask. Food crumbs are stickier and more difficult to remove than ordinary dust. Carbonated drinks are not only sticky but also far more corrosive than water. In industrial contexts, other handborne substances may also enter.

Some airborne particles are liquid droplets or *aerosols*. Those produced by industrial processes may be highly corrosive. A more common and particularly pernicious aerosol is grease particles from cooking, perhaps in an employee lunchroom; the resulting residue may be less obvious than dust and cling more tenaciously.

Smoke consists of gases, particulates, and possibly aerosols resulting from *combustion* (rapid oxidation, usually accompanied by glow or flame) or *pyrolysis* (heat-induced physiochemical transformation of material, often prior to combustion). The components of smoke, including that from tobacco products, pose all the hazards of dust and may be corrosive as well.

Removable storage media often leave the protection of a controlled environment. They can suffer from contact with solvents or other chemicals.

There is an ever-growing list of potential chemical, biological, and radiological contaminants, each posing its own set of dangers to humans. Most are eventually involved in storage or transportation mishaps. More and more are intentionally used in a destructive fashion. Even if humans are the only component of the computing environment that is threatened, normal operations at a facility must cease until any life- or health-threatening contamination is removed.

Water

Water is a well-known threat to most objects of human design. Damage to paper products and the like is immediate. Mold and mildew will begin growing on certain damp materials. Sooner or later, most metals corrode (sooner if other substances, such as combustion by-products, are present).

The most critical problem is in energized electrical equipment. Water's conductive nature can cause a *short circuit* (a current that flows outside the intended path). When the improper route cannot handle the current, the result is heat, which will be intense if there is *arcing* (a luminous discharge from an electric current bridging a gap between objects). This may melt or damage items, even spawn an electrical fire.

Invasive water comes from two directions: rising from below and falling from above. Either may be the result of nature or human action. Floodwater brings two additional threats: its force and what it carries. The force of moving water and debris can do structural damage directly or indirectly, by eroding foundations. In some cases, natural gas lines are broken, which feed electrical fires started by short-circuiting. Most flood damage, however, comes from the water's suspended load. Whereas falling water, say from a water sprinkler or a leaking roof, is fairly pure and relatively easy to clean up, floodwater is almost always muddy. Fine particles (clays) cling tenaciously, making cleanup a nightmare. A dangerous biological component may be present if sewage removal or treatment systems back up or overflow or if initially safe water is not drained promptly. Another hazard is chemicals that may have escaped containment far upstream. When flooding or subsequent fire has disabled HVAC systems in the winter, ice formation has sometimes added further complications. Freezing water wedges items apart. Obviously, recovery is further delayed by the need to first thaw the ice.

Fire

Throughout history, fire has been one of the most important threats to human life, property, and activity when measured in terms of frequency, potential magnitude, and rapidity of spread. Fire presents a bundle of the previously mentioned environmental threats. By definition, combustion involves chemical and physical changes in matter, in other words, destruction of what was. Even away from the site of actual combustion, heat can do damage, as detailed earlier. Smoke can damage objects far from the site of combustion. More critical to humans are the irritant, toxic, asphyxial, and carcinogenic properties of smoke; it is the leading cause of death related to fire. With the advent of modern synthetic materials, fires can now produce deadlier toxins. Hydrogen cyanide, for instance, is approximately 25 times more toxic than carbon monoxide.

Sometimes the cure can be worse than the disease. If water is the suppressing agent, it can wreak havoc on adjacent rooms or lower floors that suffered no fire damage at all. Some modern fire suppressants decompose into dangerous substances. A comprehensive tome on fire is Cote (1997).

Power Anomalies

Electrical power is to electrical equipment what oxygen is to humans. Both the quantity and quality of electricity supplied to equipment are important. Just as humans can suffer, even die, from too much or too little air pressure, electrical equipment may malfunction or be permanently damaged when fed the wrong amount of current or voltage. This accounts for approximately half of computer data loss. Just as a properly pressurized atmosphere may carry constituents harmful to the immediate or long-term health of people, problems can arise when the power being supplied to a computer is itself conveying "information" in conflict with the digital information of interest.

Power Fluctuations and Interruptions

Low-voltage equipment such as telephones, modems, and networks are susceptible to small changes in voltage. Integrated circuits operate on very low currents (measured in milliamps); they can be damaged by minute changes in current. Power fluctuations can have a cumulative effect on circuitry over time, termed "electronic rust." Of the data losses due to power fluctuations, about three fourths of culpable events are drops in power.

The power grid, even under normal conditions, will deliver transients created as part of the continual balancing act performed in distributing power. Loose connections, wind, tree limbs, and errant drivers are among causes of abnormalities. Both the power grid and communications can be affected by so-called space weather. The Earth's magnetic field captures high-energy particles from the solar wind, shielding most of the planet while focusing it near the magnetic poles. Communications satellites passing between oppositely charged "sheets" of particles (seen as the Aurorae Borealis and Australis) may suffer induced currents, even arcing; one was permanently disabled in

1997. A *surge* (sudden increase in current) due to a 1989 geomagnetic storm blew a transformer, which in turn brought down the entire HydroQuébec electric grid in 90 seconds. The periods of most intense solar activity generally coincide with *Solar Max,* when the cycle of sunspot activity peaks every 10.8 years (on the average). The most recent peak was in July 2000.

A more frequent source of surges is lightning. In addition to direct hits on power lines or a building, near-misses can travel through the ground and enter a building via pipes, telecommunication lines, or nails in walls. Even cloud-to-cloud bolts can induce voltage on power lines.

Although external sources are the obvious culprits, the reality is that most power fluctuations originate within a facility. A common circumstance is when a device that draws a large inductive load is turned off or on; thermostatically controlled devices, such as fans and compressors for cooling equipment, may turn off and on frequently.

An *ESD* (electrostatic discharge) of *triboelectricity* (static electricity) generated by friction can produce electromagnetic interference (see below) or a *spike* (momentary increase in voltage) of surprisingly high voltage. Among factors contributing to a static-prone environment are low relative humidity (possibly a consequence of heating) and synthetic fibers in floor coverings, upholstery, and clothing. Especially at risk is integrated circuitry that has been removed from its antistatic packaging just before installation.

Electromagnetic Interference

Digital and analog information is transmitted over conductive media by modulating an electrical current or is broadcast by modulating an electromagnetic wave. Even information intended to remain within one device, however, may become interference for another device. All energized wires have the potential to broadcast, and all wires, energized or not, may receive signals. The messages may have no more meaning than the "snow" on a television screen. Even with millions of cell phones on the loose, much of the "electromagnetic smog" is incidental, produced by devices not designed to broadcast information.

The terms *EMI* (electromagnetic interference) and *RFI* (radio frequency interference) are used somewhat interchangeably. *Electrical noise* usually indicates interference introduced via the power input, though radiated energy may have been among the original sources of the noise; this term is also used with regard to small spikes. *EMC* (electromagnetic compatibility) is a measure of a component's ability neither to radiate electromagnetic energy nor to be adversely affected by electromagnetic energy originating externally. Good EMC makes for good neighbors. The simplest example of incompatibility is *crosstalk,* when information from one cable is picked up by another cable. By its nature, a digital signal is more likely to be received noise-free than an analog signal.

EMI from natural sources is typically insignificant (background radiation) or sporadic (like the pop of distant lightning heard on an amplitude modulated radio). Occasionally, solar flares can muddle or even jam radio communications on a planetary scale, especially at Solar Max. Fortunately, a 12-hour window for such a disruption can be predicted days in advance.

Most EMI results from electrical devices or the wires between. Power supply lines can also be modulated to synchronize wall clocks within a facility; this information can interfere with the proper functioning of computer systems. For radiated interference, mobile phones and other devices designed to transmit signals are a major hazard; according to Garfinkel (2002), they have triggered explosive charges in fire-extinguisher systems. Major high-voltage power lines generate fields so powerful that their potential impact on human health has been called into question. Motors are infamous sources of conducted noise, although they can radiate interference as well. For an introduction to electromagnetic interference, see the glossary and the chapter "EMI Shielding Theory" in Chomerics (2000).

Computing Infrastructure Problems

Hardware failures will still occur unexpectedly despite the best efforts to control the computing environment. Hard-drive crashes are one of the most infamous malfunctions, but any electronic or mechanical device in the computing environment can fail. In this regard, critical support equipment, such as HVAC, must not be overlooked. After the attack on the Pentagon Building, continued computer operations hinged on stopping the hemorrhage of chilled water for climate control.

The Internet exists to connect computing resources. Loss of telecommunications capabilities effectively nullifies any facility whose sole purpose is to serve the outside world. The difficulty may originate internally or externally. In the latter case, an organization must depend on the problem-solving efficiency of another company. In situations in which voice and data are carried by two separate systems, each is a possible point of failure. Although continuity of data transfer is the highest priority, maintenance of voice communications is still necessary to support the computing environment.

Physical Damage

Computers can easily be victims of premeditated, impulsive, or accidental damage. The list of possible human acts ranges from removing one key on a keyboard to formatting a hard drive to burning down a building. The focus here is on the fundamental forces that can damage equipment. Although computers and their components have improved considerably in shock resistance, there are still many points of potential failure due to shock. Hard drives and laptop *LCD* (liquid crystal display) screens remain particularly susceptible. More insidious are protracted, chronic vibrations. These can occur if fixed equipment must be located near machinery, such as HVAC equipment or a printer. Mobile equipment that is frequently in transit is also at higher risk. Persistent vibrations can loosen things, notably screws, that would not be dislodged by a sharp blow.

Removable storage media are more vulnerable to damage because they are more mobile and delicate. They can be damaged by bending, even if they appear to return to their original shape. Optical media, for instance, can

suffer microscopic cracking or *delamination* (separation of layers). Scratches and cracks on the data ("bottom") side of the disc will interfere with reading data. Cracks or delamination may also allow the incursion of air and the subsequent deterioration of the reflective layer. That layer is actually much closer to the label ("top") side and therefore can be easily damaged by scratches or inappropriate chemicals (from adhesives or markers) on the label side.

Although physical shocks can affect magnetic media by partially rearranging ferromagnetic particles, a far more common cause for magnetic realignment is, of course, magnetic fields. The Earth's magnetic field, averaging about 0.5 Gauss at the surface, does no long-term, cumulative damage to magnetic media. Certain electrical devices pose hazards to magnetic media; among these are electromagnets, motors, transformers, magnetic imaging devices, metal detectors, and devices for activating or deactivating inventory surveillance tags. (X-ray scanners and inventory surveillance antennae do not pose a threat.) Degaussers (bulk erasers) can produce fields in excess of 4,000 Gauss, strong enough to affect media not intended for erasure. Although magnetic media are the obvious victims of magnetic fields, some equipment can also be damaged by strong magnetic fields.

Local Hazards

Every location presents a unique set of security challenges. There are innumerable hazards the probability and impact of which are location-dependant. Often, a pipeline, rail line, or road in the immediate vicinity carries the most likely and most devastating potential hazard. Two of the local hazards with the greatest impact on human life, property, and activity are flooding and geological events.

Flooding

As many have learned too late, much flood damage occurs in areas not considered flood-prone. Government maps depicting flood potential are not necessarily useful in assessing risk, because they can quickly become outdated. One reason is construction in areas with no recorded flood history. Another is that urbanization itself changes drainage patterns and reduces natural absorption of water.

Small streams react first and most rapidly to rainfall or snowmelt. Even a very localized rain event can have a profound effect on an unnoticed creek. Perhaps the most dangerous situation is in arid regions, where an intermittent stream may be dry or nearly dry on the surface for much of the year. A year's worth of rain may arrive in an hour. Because such flash floods may come decades apart, the threat may be unrecognized or cost-prohibitive to address.

Usually, advance warning of floods along large rivers is better than for the small rivers that feed them. Having a larger watershed, large rivers react more slowly to excessive rain or rapidly melting snow. Formation of ice jams, breaking of ice jams, structural failure of dams, and landslides or avalanches into lakes, however, can cause a sudden, unexpected rise in the level of a sizeable river.

Coastal areas are occasionally subjected to two other types of flooding. The storm surge associated with a hurricane-like storm (in any season) can produce profound and widespread damage, but advanced warning is usually good enough to make appropriate preparations. Moving at 725 km (450 miles) per hour on the open ocean, *tsunamis* (seismic sea waves) caused by undersea earthquakes or landslides arrive with little to no warning and can be higher than storm surges. Although tsunamis most often strike Pacific coastlines, a much larger (and rarer) *mega-tsunami* could effect much of the Atlantic if a volcano in the Canary Islands collapses all at once.

An urban area is at the mercy of an artificial drainage system, the maintenance of which is often at the mercy of a municipality. A violent storm can itself create enough debris to greatly diminish the system's drainage capacity.

Not all flooding originates in bodies of water. Breaks in water mains can occur at any time, but especially during winter freeze-thaw cycles or excavation. Fire hydrants can be damaged by vehicles. Pipes can leak or commodes overflow. Although safest from rising water, the top floor is the first affected if the roof leaks, collapses, or is blown away.

Geological Events

Geological hazards fall into a number of categories. These events are far more unpredictable than meteorological events, although some, notably landslides and mudslides, may be triggered by weather. Earthquakes can have widespread effects on infrastructure. The damage to an individual structure may depend more on *where* it was built than on *how*. Buildings on fill dirt are at greater risk because of potential *liquefaction,* in which the ground behaves like a liquid. Earthquake predictions are currently vague as to time and location.

Landslides and mudslides are more common after earthquakes and rainstorms, but they can occur with no obvious triggering event. Anticipating where slides might occur may require professional geological consultation. As an illustration, a cliff with layers of clay dipping toward the face of the cliff is an accident waiting to happen.

Volcanic ash is one of the most abrasive substances in nature. It can occasionally be carried great distances and in great quantities. If it does not thoroughly clog up HVAC air filters between outside and inside air domains, it may still be tracked in by people. Most volcanic eruptions are now predictable.

Humans

Humans are often referred to as the "weakest link" in computing security, for they are the computing environment component most likely to fail. Despite their flaws, humans have always been recognized as an essential resource. Before the attacks on New York and Washington, however, the sudden disappearance of large numbers of personnel was simply not anticipated by most business continuity planners or disaster recovery planners. All planners, whether focused on preservation of processes or assets, now have a different outlook on preservation of life.

Aside from mass slaughter, there are other circumstances in which human resources may be lacking. Severe weather may preclude employees from getting to work. Labor disputes may result in strikes. These may be beyond the direct control of an organization if the problems

are with a vendor from whom equipment has been bought or leased or with a contractor to whom services have been outsourced. A different kind of discontinuity in human expertise can come with a change of vendors or contractors.

Even the temporary absence or decreased productivity of individuals soon adds up to a major business expense. Employers may be held responsible for a wide range of occupational safety issues. Those specific to the computing environment include

1. carpal tunnel syndrome (from repetitive actions, notably typing),
2. back and neck pain (from extended use of improper seating), and
3. eye strain and headaches (from staring at a computer screen for long periods).

PHYSICAL MEANS OF MISAPPROPRIATING RESOURCES

I now turn to the misappropriation of assets that can be possessed in some sense—physical objects, information, and computing power. (Some acts, such as physical theft, also impinge on availability). Misuse may entail use by the wrong people or by the right people in the wrong way. The transgressions may be without malice. A pilferer of "excess" computing power may view his or her actions as a "victimless crime." In other cases, insiders create new points of presence (and, therefore, new weak points) in an attempt to possess improved, legitimate access. See Skoudis (2002) for discussions of many of these issues.

Unauthorized Movement of Resources

For computing resources, theft comes in several forms. Outsiders may break or sneak into a facility. Insiders may aid a break-in, may break into an area or safe where (or when) they are not entitled to access, or they may abuse access privileges that are a normal part of their job. Physical objects may be removed. Information, whether digital or printed, may be duplicated or merely memorized; this is classified as theft by copying.

A different situation is when items containing recoverable data have been intentionally discarded or designated for recycling. The term *dumpster diving* conjures up images of an unauthorized person recovering items from trash bins outside a building (although perhaps still on an organization's property). In fact, discarded items can also be recovered from sites inside the facility by a malicious insider. At the other extreme, recovery could, in theory, take place thousands of miles from the point at which an object was initially discarded. A large fraction of the "recycled" components from industrialized countries actually end up in trash heaps in Third World countries. The legality of dumpster diving depends on local laws and on the circumstances under which an item was discarded and recovered.

Perhaps the most obvious candidate for theft is removable storage media. As the data density of removable storage media increases, so does the volume of information that can be stored on one item and, therefore, the ease with which a vast amount of information can be stolen. Likewise, downloading from fixed media to removable media can also be done on a larger scale, facilitating theft by copying.

By comparison, stealing hardware usually involves removing bigger, more obvious objects, such as computers and peripherals, with the outcome being more apparent to the victim. Garfinkel (2002) reports thefts of random access memory (RAM); if not all the RAM is removed from a machine, the loss in performance might not be noticed immediately.

Social Engineering and Information Mining

Human knowledge is an asset less tangible than data on a disk but worth possessing, especially if one is mounting a cyberattack. An attacker can employ a variety of creative ways to obtain information. *Social engineering* involves duping someone else to achieve one's own illegitimate end. The perpetrator—who may or may not be an outsider—typically impersonates an insider having some privileges ("I forgot my password . . . "). The request may be for privileged information ("Please remind me of my password . . . ") or for an action requiring greater privileges ("Please reset my password . . . "). Larger organizations are easier targets for outsiders because no one knows everyone in the firm. Less famous than social engineering are methods of mining public information. Some information must necessarily remain public, some should not be revealed, and some should be obfuscated.

Domain name service information related to an organization—domain names, *IP* (Internet protocol) addresses, and contact information for key information technology (IT) personnel—must be stored in an online "whois" database. If the name of a server is imprudently chosen, it may reveal the machine's maker, software, or role. Such information makes the IP addresses more useful for cyberattacks. Knowing the key IT personnel may make it easier to pose as an insider for social engineering purposes.

Currently, the most obvious place to look for public information is an organization's own Web site. Unless access is controlled so that only specific users can view specific pages, anyone might learn about corporate hardware, software, vendors, and clients. The organizational chart and other, subtler clues about corporate culture may also aid a social engineering attack. Of course, this information and more may be available in print.

Another dimension of the Internet in which one can snoop is newsgroup bulletin boards. By passively searching these public discussions ("lurking"), an attacker might infer which company is running which software on which hardware. He or she may instead fish actively for information. An even more active approach is to provide disinformation, leading someone to incorrectly configure a system.

Unauthorized Connections and Use

Wiretapping involves making physical contact with guided transmission media for the purposes of intercepting information. Wired media are relatively easy to tap, and

detection (other than visual inspection of all exposed wires) may be difficult. Contrary to some rumors, fiber-optic cable remains far more difficult to tap, and detection (without visual inspection) is highly likely; any light that can be made to "leak" from a cable is not useable for recovering data.

A specific type of wiretapping is a *keyboard monitor,* a small device interposed between a computer and its keyboard that records all work done via the keyboard. The attacker (or suspicious employer) must physically install the item and access it to retrieve stored data. (Hence, keyboard logging is more often accomplished by software.)

A variation on wiretapping is to use connectivity hardware already in place, such as a live, unused *LAN* (local area network) wall jack; a live, unused hub port; a LAN-connected computer that no longer has a regular user; and a computer in use but left unattended by the user currently logged on. For the perpetrator, these approaches involve varying degrees of difficulty and risk. The second approach may be particularly easy, safe, and reliable if the hub is in an unsecured closet, the connection is used for sniffing only, and no one has the patience to check the haystack for one interloping needle.

Phone lines are connectivity hardware that is often overlooked. A naïve employee might connect a modem to an office machine so it can be accessed (for legitimate reasons) from home. This gives outsiders a potential way around the corporate firewall. Even IT administrators who should know better leave "back-door" modems in place, sometimes with trivial or no password protection. Sometimes the phone service itself is a resource that is misappropriated. Although less common now, some types of *PBX* (private branch exchange) can be "hacked," allowing an attacker to obtain free long-distance service or to mount modem-based attacks from a "spoofed" phone number.

A final asset is an adjunct to the phone service. Employee voice mail, even personal voice mail at home, has been compromised for the purpose of obtaining sensitive information (e.g., reset passwords).

Appropriate access through appropriate channels does not imply appropriate use. One of the biggest productivity issues nowadays is employee e-mail and Internet surfing unrelated to work. If prohibited by company policy, this can be viewed as misappropriation of equipment, services, and, perhaps most important, *time*. Although text-based e-mail is a drop in the bucket, downloading music files can "steal" considerable bandwidth; this is especially a problem at those academic institutions where control of students' Internet usage is minimal.

Eavesdropping

Eavesdropping originally meant listening to something illicitly. Although capture of acoustic waves (perhaps with an infrared beam) is still a threat, the primary concern in the computing environment involves electronically capturing information without physical contact. Unguided transmission media such as microwave (whether terrestrial or satellite), radio (the easiest to intercept), and infrared (the hardest to intercept) should be considered fair game for outsiders to eavesdrop; such transmissions must be encrypted if security is a concern. Among guided transmission media, fiber-optic cable stands alone for its inability to radiate or induce any signal on which to eavesdrop. Therefore, the interesting side of eavesdropping is tempest emissions. Electrical devices and wires have long been known to emit electromagnetic radiation, which is considered "compromising" if it contains recoverable information. Mobile detectors have been used to locate radios and televisions (where licensing is required) or to determine the stations to which they are tuned. Video displays (including those of laptops) are notorious emitters; inexpensive equipment can easily capture scan lines, even from the video cable to an inactive screen.

The term *tempest* originated as the code word for a U.S. government program to prevent compromising emissions. (Governments are highly secretive in this area; contractors need security clearance to learn the specifications for equipment to be tempest-certified.) Related compromising phenomena are as follows:

1. *hijack*—signals conducted through wires (and perhaps the ground, as was noted during World War I);
2. *teapot*—emissions intentionally caused by an adversary (possibly by implanted software); and
3. *nonstop*—emissions accidentally induced by nearby radio frequency (RF) sources.

One attack is to irradiate a target to provoke resonant emissions—in other words, intentional nonstop. (This is analogous to how an infrared beam can expropriate acoustic information.) Interestingly, equipment certified against passive tempest eavesdropping is not necessarily immune to this more active attack. (Compare the infrared device to a parabolic microphone, which is merely a big ear.) Although these emissions were formerly the concern only of governments, increasingly less expensive and more sophisticated equipment is making corporate espionage a growing temptation and concern. An excellent introduction to this area is chapter 15 of Anderson (2001). A well-known portal for tempest information is McNamara (2002).

PREVENTIVE MEASURES

To expand George Santayana's famous quote, those who are ignorant of history are doomed to repeat it, but those who live in the past are also doomed. Although an understanding of past disasters is essential, not all that *will* happen (in your neighborhood or in the world) *has* happened. The key to preventing physical breaches of confidentiality, integrity, and availability of computing resources is to anticipate as many bad scenarios as possible. A common flaw is to overlook plausible combinations of problems, such as the incursion of water while backup power is needed.

History has taught us that, regardless of the time, effort, and money invested, preventing *all* bad events is impossible; there *will* be failures. For integrity and availability of resources, redundancy can be used as a parachute

when the worst-case scenario becomes reality. Unfortunately, there is no comparable preventive measure for confidentiality.

Control and Monitoring of Physical Access and Use

There are several philosophical approaches to physical access control, which can be used in combination with one another:

1. Physical contact with a resource is restricted by putting it in a locked cabinet, safe, or room; this would deter even vandalism.
2. Contact with a machine is allowed, but it is secured (perhaps permanently bolted) to an object difficult to move; this would deter theft. A variation of this allows movement, but a motion-sensored alarm sounds.
3. Contact with a machine is allowed, but a security device controls the power switch.
4. A machine can be turned on, but a security device controls log-on. Related to this is the idea of having a password-protected screensaver running while the user is away from the machine.
5. A resource is equipped with a tracking device so that a sensing portal can alert security personnel or trigger an automated barrier to prevent the object from being moved out of its proper security area.
6. An object, either a resource or a person, is equipped with a tracking device so that his, her, or its current position can be monitored continually.
7. Resources are merely checked in and out by employees, for example by scanning barcodes on items and ID cards, so administrators know at all times of who has what, but not necessarily where they have it.

Yet another approach can be applied to mobile computers, which are easier targets for theft. More and more high-density, removable storage options are available, including RAM-disks, DVD-RAMs, and memory sticks. This extreme portability of data can be turned to an advantage. The idea is to "sacrifice" hardware but preserve the confidentiality of information. If no remnant of the data is stored with or within a laptop (which may be difficult to ensure), the theft of the machine from a vehicle or room will not compromise the data. The downside is that the machine is removed as a locus of backup data.

There are also a multitude of "locks." Traditional locks use metal keys or require a "combination" to be dialed on a wheel or punched on an electronic keypad. Another traditional "key" is a photo ID card, inspected by security personnel. Newer systems require the insertion or proximity of a card or badge; the types of cards include magnetic stripe cards, memory cards, optically coded cards, and smart cards (either contact or contactless). The most promising direction for the future appears to be biometric devices, the subject of a separate article; a major advantage of these is that they depend on a physiological or behavioral characteristic, which cannot be forgotten or lost and is nearly impossible to forge.

To paraphrase General George C. Patton, any security device designed by humans can be defeated by humans. Each type of locking device has its own vulnerabilities and should be viewed as a *deterrent*. In some cases, even an inexpensive, old-fashioned lock is an adequate deterrent—and certainly better than nothing (as is often the case with wiring cabinets). In assessing a candidate for a security device or architecture, the time, resources, and sophistication of a likely, hypothetical attacker must be correlated with both the security scheme *and* the assets it protects.

An example may be helpful. To determine the suitability of smart cards, first research the many potential attacks on smart cards and readers. Then estimate how long an outsider or malicious insider might have unsupervised access to a smart card or reader of the type used or in actual use. Finally, make a guess as to whether the assets at stake would motivate an adversary to invest in the necessary equipment and expertise to perform a successful attack given the level of access they have.

It is sometimes appropriate for an organization to allow public access on some of its computers. Such computers should be on a separate LAN, isolated from sensitive resources. Furthermore, to avoid any liability issues, the public should not be afforded unrestricted access to the Internet.

A different aspect of access is unauthorized connections. A multipronged defense is needed. Checking for renegade modems can be done either by visually inspecting every computer or by war-dialing company extensions. Hubs must be secured and their ports should be checked to verify that they are used only by legitimate machines. Unused jacks or jacks for unused computers must be deactivated. Computers that are no longer on the LAN must be locked away or at least have their hard drives sanitized. To prevent wiretapping, all wires not in secured spaces should be enclosed in pipes (which can themselves be protected against tampering). Unprotected wires can periodically be tested by sending pulses down the wires; exhaustive visual inspections are impractical.

A more complex issue is that of improper use of services, especially e-mail and Internet access, whose proper use may be an essential part of work-related duties. Companies are within their rights to limit or track the usage of their resources in these ways, even if employees are not forewarned. Many employers monitor e-mail passing through company hardware, even that for an employee's personal e-mail account. In addition, they use *activity monitors,* software to record keystrokes, to capture screen displays, or to log network access or use of applications. (These monitoring activities can in turn be detected by employees with suitable software.) Alternatively, inbound or outbound Internet traffic can be selectively blocked, filtered, or *shaped*; the last is the least intrusive because it limits the portion of bandwidth that can be consumed by certain services while not prohibiting them entirely.

Control and Monitoring of Environmental Factors

HVAC systems should have independently controlled temperature and relative humidity settings. Each variable should be monitored by a system that can issue alerts

when problems arise. Ideally, HVAC units should be installed in pairs, with each unit being able to carry the load of the other should it malfunction.

Although some information is only of transitory value, other data, such as official records of births, deaths, marriages, and transfers of property ownership, should be kept in perpetuity. Standards for long-term preservation of data stored in magnetic or optical format are far stricter than guidelines for ordinary usage. As a sample, for preservation, the prescribed allowable temperature variation in 24 hours is a mere $\pm 1^{\circ}$C (2°F). See International Advisory Committee for the UNESCO Memory of the World Programme (2000) for detailed preservation guidelines. One such guideline is that magnetic media, both tapes and disks, be stored in an upright orientation (i.e., with their axes of rotation horizontal). The exclusion of light is important for extending the useful life of optical media incorporating dyes (writeable discs). All media should be stored in containers that will not chemically interact with the media. Projected life spans for properly archived media are considered to be 5–10 years for floppy diskettes, 10–30 years for magnetic tapes, and 20–30 years for optical media. These estimates are conservative to ensure creation of a new copy before degradation is sufficient to invert any bits.

For optical media, life expectancies are extrapolated from accelerated aging tests based on assumptions and end-of-life criteria that may be invalid. Numerous factors influence longevity. Write-once formats have greater life expectancies than rewriteable formats. The bit-encoding dye phthalocyanine (appearing gold or yellowish green) is less susceptible than cyanine (green or blue-green) to damage from light after data has been written; yet manufacturers' claimed life expectancies of up to 300 years are not universally accepted. What appears to be a major determiner of longevity is the original quality of the stored data. This in turn depends on the quality of the blank disc, the quality of the machine writing the data, and speed at which data was written. Hartke (2001) gives an enlightening look at the complexities of this issue.

All archived data of critical importance should be sampled periodically and backed up *well before* the rate of correctable errors indicates that data might be unrecoverable at the next sampling. Even physically perfect data has been effectively lost because it outlived the software or hardware needed to read it. Therefore, before its storage format becomes obsolete, the data must be converted to an actively supported format.

There are devices or consumable products for cleaning every type of storage medium and every part of a computer or peripheral device. Backup tapes that are frequently overwritten should be periodically removed from service to be tested on a *tape certifier,* which writes sample data to the tape and reads it back to detect any errors; some models incorporate selective cleaning as an option. Read-write heads for magnetic media typically need to be cleaned far more often than the medium that moves by them. For optical media, clean discs are usually the concern. Compressed air should not be used; the resulting drop in temperature produces a *thermal shock* (rapid temperature change) for the disc. If the problem is scratches rather than dirt, polishing may be required.

Keeping a computing area free of foreign particles is a multifaceted task. Air filters should remove fine dust particles because outdoor dust is brought in on clothes and shoes. Filters must be cleaned or replaced on a regular schedule. Periodically, air-heating equipment should be turned on briefly even when not needed. This is to incrementally burn off dust that would otherwise accumulate and be converted to an appreciable amount of smoke when the equipment is activated for the first time after a long period of disuse. Vacuuming of rooms and equipment should also involve filters. Food, drink, and tobacco products should be banned from the computing area.

Water detectors should be placed above and below a raised floor to monitor the rise of water. An automatic power shutdown should be triggered by a sensor that is lower than the lowest energized wire. Degaussers and any other equipment that produces strong magnetic fields should be kept in a room separate from any media not scheduled to be erased. Although the intensity of most magnetic fields decreases rapidly with distance, it is very difficult to shield against them. Likewise, computers should be kept away from sources of vibrations, including printers. If this cannot be arranged, vibration-absorbing mats can be placed under the computer or the offending device.

Health and Safety Issues

The humans in the computing environment have additional needs. Some general health issues that may arise are *sick building syndrome* (symptoms arising from toxic mold) and *Legionnaire's disease* (a form of pneumonia transmitted via mist and sometimes associated with large air conditioning systems). Human-friendly appointments pertinent to a computing environment include the following:

1. special keyboards or attachments that optimize wrist placement;
2. comfortable, adjustable chairs that properly support backs; and
3. special lighting, monitor hoods, or screen coverings that reduce glare and, therefore, eyestrain.

There is currently no consensus on the long-term effects of *extremely low-frequency* (ELF) emissions (below 300 Hz), magnetic fields emitted by a variety of devices, including high-tension lines and cathode ray tube monitors (but not LCD displays). Laboratory tests with animals have found that prolonged exposure to ELF fields may cause cancer or reproductive problems. Studies of pregnant CRT users have produced conflicting data. Pending conclusive evidence, some recommend keeping 60 centimeters (2 feet) away from such monitors, which may not be practical. There are similar concerns and uncertainty with regard to cellular phones. It is known that people with pacemakers should avoid devices creating strong magnetic fields, such as degaussers. Although the World Health Organization acknowledges the need for continued research in certain areas, its latest position is that there is no evidence of health risks associated with EMF exposures *below* the levels set forth by the

International Commission on Non-Ionizing Radiation Protection (1998).

Depending on the overall security architecture, the criticality of the facility, and the anticipated threats, it may be advisable to implement any or all of the following:

1. stationed or roving security guards;
2. surveillance cameras, monitored in real time and recorded on videotape;
3. motion detectors;
4. silent alarms (of the type used in banks); and
5. barriers that prevent unauthorized vehicles from approaching the facility.

Fire Preparedness

For the survival of people and inanimate objects, the most critical preparations are those regarding fire.

Fire Detection

Automatic fire detectors should be placed on the ceilings of rooms as well as in hidden spaces (e.g., below raised floors and above suspended ceilings). The number and positioning of detectors should take into account the location of critical items, the location of potential ignition sources, and the type of detector. Fire detectors are based on several technologies:

1. *Fixed-temperature heat detectors* are triggered at a specific temperature. Subtypes are
   (a) *fusible*—metal with a low melting temperature;
   (b) *line type*—insulation melts, completing a circuit; and
   (c) *bimetallic type*—bonding of two metals with unequal thermal expansion coefficients, bends when heated (the principle in metal-coil thermometers), completing a circuit (until cooled again).
2. *Rate-compensation detectors* trigger at a lower temperature if the temperature rise is faster.
3. *Rate-of-rise detectors* react to a rapid temperature rise, typically 7–8°C (12–15°F) per minute.
4. *Electronic spot type thermal detectors* use electronic circuitry to respond to a temperature rise.
5. *Flame detectors* "see" radiant energy. They are good in high-hazard areas. Subtypes are
   (a) *infrared*—can be fooled by sunlight, but less affected by smoke than ultraviolet detectors; and
   (b) *ultraviolet*—detects radiation in the 1850–2450 angstrom range (i.e., almost all fires).
6. Smoke detectors usually detect fires more rapidly than heat detectors. Subtypes are
   (a) *ionizing*—uses a small radioactive source (common in residences); and
   (b) *photoelectric*—detects obscuring or scattering of a light beam.

A third type of smoke detector is the *air-sampling type*. One version, the *cloud chamber smoke detector,* detects the formation of droplets around particles in a high-humidity chamber. Another version, the *continuous air-sampling smoke detector,* is particularly appropriate for computing facilities. It can detect very low smoke concentrations and report different alarm levels.

For high-hazard areas, there are also automatic devices for detecting the presence of combustible vapors or abnormal operating conditions likely to produce fire; said another way, they sound an alarm *before* a fire starts.

Some fire detectors, especially the fusible type, are integrated into an automatic fire suppression system. This means that the first alarm could be the actual release of an extinguishing agent. Because an event triggering a fire may also disrupt the electrical supply, fire detectors must be able to function during a power outage. Many fire detectors are powered by small batteries, which should be replaced on a regular schedule. Some components of detectors, such as the radioisotope in an ionizing smoke detector, have a finite life span; the viability of such a detector cannot be determined by pushing the "test" button, the purpose of which is merely to verify the health of the battery. Such detectors must be replaced according to the manufacturer's schedule.

Fire Prevention and Mitigation

Better than detecting a fire is preventing it from starting. The two things to avoid are high temperatures and low ignition points. It is usually possible to exclude highly flammable materials from the computing environment. Overheating is a possibility in almost any electrical device. In some cases a cooling system has failed or has been handicapped. In other cases, a defective component generates abnormal friction. The biggest threat comes from short circuits; the resulting resistance may create a small electric heater or incite arcing.

Some factors that may lead to a fire, such as short circuits within a machine or a wall, are beyond our control. Yet many precautions can be taken to lessen the chances of a fire. Vents should be kept unobstructed and air filters clean. Power circuits should not be asked to carry loads in excess of their rated capacity. Whenever possible, wires should run below a raised floor rather than on top of it. If wires must lie on a floor where they could be stepped on, a sturdy protective cover must be installed. In any case, wires should be protected from fatiguing or fraying. See National Fire Protection Association (1999) for fire prevention guidelines for the computing environment. As of this writing, the newest electrical code pertaining specifically to computing equipment is from the International Electrotechnical Commission (2001).

Many fires are actually the culmination of a protracted process. Another preventive measure is for employees to use their eyes, ears, noses, and brains. Damage to a power cord can be observed if potential trouble spots are checked. Uncharacteristic noises from a component may be symptomatic of a malfunction. The odor of baking thermoplastic insulation is a sign that things are heating up.

Given that a fire may have an external or deliberate origin, preventing the spread of fire is arguably more important than preventing its ignition. It certainly requires greater planning and expense. The key ideas are to erect fire-resistant barriers and to limit fuel for the fire between the barriers.

Table 2 Comparison of Types of Surge Protectors

TYPE OF SURGE PROTECTOR	CHARACTERISTICS
MOV (Metaloxide Varistor)	Inexpensive, easy to use, but progressively degrades from even minor surges (possibly leading to a fiery demise)
Gas Tube	Reacts quickly, can handle big surges, but may not deactivate until an alternating circuit polarity flip (which may mean the computer shuts down in the meantime)
SAD (Silicon Avalanche Diode)	Faster than an MOV (1 ns vs. 5 ns), but has a limited power capacity
Reactive Circuit	Also smoothes out noise but can only handle *normal-mode* surges (between hot and neutral lines) and may actually cause a *common-mode* surge (between neutral and ground lines), which is thought to be the more dangerous type of surge for desktop computers

For computing environments, the choice of construction materials, design, and techniques for mitigating the spread of fire should exceed the minimum standards dictated by local building codes. Because fires can spread through unseen open spaces, including ventilation systems, a *computing area* is defined to be all spaces served by the same HVAC system as a computing room. Air ducts within that system should have smoke dampers. The computing area must be isolated in a separate *fire division*. This means the walls must extend from the structural floor to the structural ceiling of the computer area and have a *one-hour rating* (resistance to an external fire for one hour). Care should be taken to ensure that openings where pipe and cables pass through the fire-resistant boundaries of the separate fire division are sealed with material that is equally fire-resistant.

Many fires affecting a computer area do not actually originate in that area. Even if a fire does not technically spread into a computing area, its products—heat, smoke, and *soot* (carbon deposits)—may. Consequently, the level of fire protection beyond the computing area is still of critical concern. *Fully sprinklered* buildings (protected by sprinkler systems throughout) are recommended. Concern should extend beyond the building if it is located in an area with high hazards, such as chemical storage or periodically dry vegetation. In the latter case, a *fire break* should be created around the building by removal of any vegatation likely to fuel a fire.

The standards prescribed by the National Fire Protection Association (1999) for fire protection of computing equipment set specifications for wall coverings, carpet, and furnishings (which are relaxed in fully sprinklered buildings). They also limit what other materials can be present. They do not take into account that even high-hazard areas have computers present. In interpreting those standards, determine which dangerous materials are absolutely essential for operations, and work to minimize any unnecessary hazards. Due to their potential contribution to fire (as well as being a more likely starting point for a fire), materials that could contribute to a *Class B* fire (including solvents, paints, etc.) should not be stored in a computing area except in a fireproof enclosure. Materials that could contribute to a *Class A* fire, such as paper, should be kept to the minimum necessary.

Raised floors are standard features of many computer facilities, allowing for cables to connect equipment without the need to cover cables to prevent fraying and electrical shorting. The use of junction boxes below the floor should be minimized, however. The needed equipment for lifting the heavy removable panels to gain access to the space between the raised floor and the structural floor must be easy to locate, even in the event of a fire.

Power Maintenance and Conditioning

The most basic necessity for the functioning of computer resources is maintenance of power. *Power conditioning* refers to smoothing out the irregularities of that power.

Surge Protectors and Line Filters

A *surge protector* is designed to protect against sudden increases in current. It forms a second line of defense, the circuit breaker being the first. Neither should be counted on to protect against a direct hit by lightning. There is no substitute for unplugging home computers during an electrical storm. A large building should have a separate lightning protection system in any case. Surge protectors are currently based on four technologies, described in Table 2.

Metaloxide varistor (MOV), gas tube, and silicon avalanche diode (SAD) surge protectors short out the surge and isolate it from the protected equipment. The reactive circuit type uses a large inductance to spread a surge out over time. All should have lights to indicate if they are in functioning order. MOVs and SADs are the types preferred for computing environments because of their reaction times. All surge protectors require a properly grounded electrical system in order to do their job.

Line filters clean power at a finer level, removing electrical noise entering through the line power. Their concern

is not extreme peaks and valleys in the alternating current (AC) sine wave, but modulation of that wave. Their goal is to restore the optimal sine shape. Power purity can also be fostered by adding circuits rather than filters. The most important precaution is to keep large machinery off any circuit powering computing equipment. If possible, it is preferable to have each computer on a separate circuit.

The dangers of static electricity can be reduced by inhibiting its buildup, providing ways for it to dissipate gradually (rather than discharge suddenly), or insulating vulnerable items. Antistatic techniques include the following:

1. keeping the relative humidity from dropping too low (below 40%);
2. avoiding the use of carpets and upholstery with synthetic fibers, or spraying them with antistatic sprays;
3. using antistatic tiles or carpets on floors;
4. not wearing synthetic clothing and shoes with soles prone to generating charges;
5. using an *ionizer* (which sends both positive and negative ions into the air as a neutralizing influence); and
6. keeping computers away from metal surfaces or covering metal surfaces with dissipative mats or coverings.

When installing electronic circuitry, technicians should ground themselves. A variety of conductive "garments" can be worn, including bracelets and straps for wrists and ankles, gloves, finger cots, and smocks.

Uninterruptible Power Supplies (UPS)

Although an *uninterruptible power supply,* by definition, counteracts a loss of power, it typically provides surge protection as well. This is accomplished by means of separate input and output circuits. The input circuit induces current in the output circuit. A UPS may also incorporate noise filtering. UPS systems fall into three categories. An *online* system separates the input and output with a buffer, a battery that is constantly in use and (almost) constantly being charged. This is analogous to a water tank providing consistent water pressure, regardless of whether water is being added to it. This is the original and most reliable design for a UPS. In the strictest sense, this is the only truly uninterruptible power supply; its transfer time (defined below) is zero milliseconds. An *offline* system sends the primary current straight through in normal circumstances, but transfers to backup power if its detection circuit recognizes a problem with the primary power. The problem might be a complete drop in primary power, but it might also be a spike, a surge, a *sag* (drop in voltage), or electrical noise. A *line interactive* system is similar to an offline system, but its output waveform will be a sine wave (as is the input waveform) rather than a square or step wave. Aside from its basic type, the most important characteristics of a UPS are its

1. *capacity*—how much of a load it can support (measured in volt-amps or watts);
2. *voltage*—the electromotive force with which the current is flowing (measured in volts);
3. *efficiency*—the ratio of output current to input current (expressed as a percentage);
4. *backup time*—the duration during which it can provide peak current (a few minutes to several hours);
5. *transfer time*—the time from the drop in primary power until the battery takes over (measured in milliseconds);
6. *battery life span*—how long it is rated to perform as advertised;
7. battery type—a small Ni-MH (nickel metal hydride) battery support of an individual machine, whereas lead-acid batteries for an entire facility may require a room of their own; and
8. output waveform—sine, square, or step (also known as a modified sine) wave.

A final consideration is the intended load: *resistive* (as a lamp), *capacitive* (as a computer), or *inductive* (as a motor). Because of the high starting current of an inductive load, the components of an offline UPS (with its square or step wave output) would be severely damaged. Actually, an inductive load will still have a similar but less severe effect on other types of UPS systems (with sine wave output).

Large battery systems may generate hydrogen gas, pose a fire hazard, or leak acid. Even a sealed, maintenance-free battery must be used correctly. It should never be fully discharged, it should always being recharged immediately after usage, and it should be tested periodically.

Some UPS systems feature scalability, redundancy, and interface software, which can

1. indicate the present condition of the battery and the main power source;
2. alert users when backup power is in operation, so that they can shut down normally; or
3. actually initiate a controlled shutdown of equipment prior to exhaustion of backup power.

A UPS should come with a warranty for equipment connected to the UPS; the value of any lost data is typically not covered.

When limited resources do now allow for all equipment to be on a UPS, the process of deciding which equipment is most critical and therefore most deserving of guaranteed power continuity should consider two questions. First, if power is lost, will appropriate personnel still receive automated notification of this event? Second, is the continued functioning of one piece of equipment moot if another component loses power?

The existence of any UPS becomes moot whenever someone accidentally flips the wrong switch. The low-cost, low-tech deterrent is switch covers, available in stock and custom sizes.

There are occasions (e.g., fires and floods) when power must be cut to all equipment except emergency lighting and fire detection and suppression systems (which should have self-contained power sources). This includes disconnecting a UPS from its load. Any intentional disruption of

power should be coordinated with computers via software to allow them to power down gracefully.

Electromagnetic Shielding

Because of their inherent vulnerability to interception, wireless transmissions should be encrypted (or scrambled, in the case of analog voice communication) if confidentiality, integrity, or authentication is essential. Electromagnetic shielding is in direct opposition to wireless communication. The purpose of shielding is to block outbound compromising emissions and inbound radiated interference. The key idea is a *Faraday cage* (i.e., a conductive enclosure). This can be accomplished at several levels.

Shielding entire rooms and buildings with metal, conductive wall coverings, conductive windows, and so forth to control outbound radiation has been primarily an endeavor of governments. (Building underground has been an alternative approach.) A future technique at this scale may be to use conductive concrete, originally developed to melt snow. (Preparing the concrete is tricky, so only prefabricated slabs are commercially available at present.)

Wider application of shielding at the level of components and their connecting wires seeks to improve EMC so that each component functions properly. All computers emit RF radiation, and government regulations limit how much radiation is acceptable and where computers may be used. To achieve EMC in components, there are specially designed, conductive enclosures, gaskets, meshes, pipes, tapes, and sprays. The simplest EMC measure is to use shielded cables and keep them separated to prevent crosstalk. Given what was said earlier about nonstop emissions, RF emitters such as mobile phones should be kept away from computers with sensitive data.

Attenuation (lessening) of emissions is measured in decibels (dB). Each 10-dB drop cuts the strength of the signal to one tenth of what it was, so a 20-dB drop means only 1% of the energy is escaping.

A recent discovery, dubbed *Soft Tempest*, provides an inexpensive, partial solution for video display emissions (comparable to attenuation of 10–20 dB). Special fonts, which appear "antialiased" but crisp on the user's screen, are illegible on monitoring equipment because key information about vertical edges is not radiated. GIF (graphic interchange format) versions of such fonts can be downloaded from http://www.cl.cam.ac.uk/~mgk25/st-fonts.zip. See Anderson (2001) for discussions of this and of a perfect software defense against monitoring of keyboard emissions.

Weather Preparedness

Many regions of the world are subject to seasons when monsoons, hurricanes (typhoons), tornadoes, damaging hail, ice storms, or blizzards are more likely to occur, but weather is inherently chaotic. Even if an event arrives in its proper season, that arrival may be unexpected. In general, the larger the scale of the weather event, the farther in advance it can be anticipated. Despite dramatic advances in the accuracy and detail of regional forecasting, the granularity of current weather models does not allow precise forecasting of highly localized phenomena beyond saying, "Small, bad things may happen within this larger area." As the probability of any specific point in that area being hit with severe weather is small, such generalized warnings often go unheeded.

Fortunately, the formation of small, intense weather events can be detected by modern radar, and warnings of potential and imminent danger can be obtained through a variety of means. There are radio receivers that respond specifically to warnings transmitted by meteorological agencies or civil authorities. The Internet itself can be the messenger. One mode of notification is e-mail. Other services run in the background on a client machine, checking with a specific site for the latest information. Some of these services are free (though accompanied by advertising banners). There are also commercial software products and services that give highly detailed predictions in certain situations. For example, one suite of hurricane-related products can predict peak winds, wind direction, and the arrival time of damaging winds at specific locations.

Fitted covers for equipment can be quickly deployed to protect against falling water from a damaged roof, overhead pipe leaks, or sprinkler systems. They can also be used as dust covers when equipment is moved or stored, during construction work, or when the panels of a suspended ceiling need to be lifted.

As noted earlier, lightning can be surprisingly invasive, penetrating where rain and wind do not. Moreover, it does not always hit the most "logical" target, and it can arrive unexpectedly. A bolt was documented to have traveled horizontally 16 km (10 miles) before landfall; it appeared to come out of a blue sky when, in reality, it originated in a cloud hidden behind a hill. In any case, few businesses will be willing to disconnect from the electric grid every time the potential for lightning exists. Consequently, it is essential that a building have a lightning protection system in place and that surge protection be provided for equipment. As a secondary precaution, magnetic media and sensitive equipment should be kept away from metal objects, especially structural steel. On the other hand, storage *within* a metal container affords the same protection that passengers enjoy within the metal body of an automobile; this is called the *skin effect* because the current passes only through the outer skin of the metal. (The rubber tires would need to be a mile thick to provide equivalent protection.)

It is now possible to receive automated alerts regarding impending adverse space weather. The service can be tailored with regard to the means of notification (e-mail, FAX, or pager), the type of event expected (radio burst, geomagnetic impulse, and so forth), and the threshold at which a warning should be reported. See Space Environment Center (2002).

Earthquake Preparedness

Certain regions of the world have a well-known history of frequent earthquakes, and planning for the inevitable is second nature. Complacency prevails where damaging earthquakes strike decades or centuries apart; earthquake survivability features may not be required by building codes (although some cities are waking up to the importance of such measures) or may not be calculated

to be cost-effective. The collapses of the buildings at the World Trade Center had earthquake-like effects on neighboring buildings. (Even the initial crashes registered on seismographs.) Because disasters can occur in anyone's neighborhood, any structure may be subjected to "seismic" forces.

Regardless of construction techniques, how the occupants furnish buildings is largely their own responsibility. Some precautions can be taken with relatively little expense or intrusion to normal operations. Following are three suggestions from Garfinkel (2002) based on the simple principle that objects will move and perhaps fall from high places to lower places:

1. Place computers under sturdy tables, not on high surfaces or near windows.
2. Do not place heavy objects so that they could fall onto computers.
3. Restrain the possible movement of computers with bolts and other equipment.

The first two recommendations also help in case damaging wind (including the force of an external explosion) blows out a window or damages a roof. The last could also serve as a theft deterrent, depending on the type of restraint used. There are also relatively easy ways to secure things other than computers. For example, bookcases can be bolted to walls so they cannot topple, and books can be restrained by removable bars or straps.

Ruggedization of Equipment

With the upsurge in mobile computing comes an increased risk of damage from shock, vibration, dust, water, and extremes of temperature and humidity. One survey found that 18% of corporate laptops in "*non*rugged" applications had suffered substantial damage (averaging about half the purchase price), implying that more people could benefit from tougher equipment. Laptops and other mobile devices can be *ruggedized* by adding characteristics such as the following:

1. having an extra-sturdy metal chassis, possibly encased in rubber;
2. being shock- and vibration-resistant (with a floating LCD panel or gel-mounted hard drive);
3. being rainproof, resistant to high humidity and tolerant of salt fog;
4. being dustproof (with an overlay panel for the LCD screen);
5. being able to withstand temperature extremes and thermal shock; and
6. being able to operate at high altitude.

Touchscreens, port replicators, glare-resistant coatings for the LCD screen, and modular components are available on some models. Some portable ruggedized units resemble a suitcase more than a modern laptop.

Ruggedization techniques can also be used for any computer that must remain in areas where explosions or other harsh conditions may be encountered. Accessories available are ruggedized disk drives, mouse covers, keyboard covers, and sealed keyboards. (Some keyboards can be rolled up.) Some biometric devices can be used in demanding environments.

Redundancy

Redundancy is the safety net for ensuring integrity and availability of resources. Because of the many facets of the computing environment, redundancy takes many forms. The first thing that comes to mind is backing up data. If only a single copy of information exists, it may be difficult, if not impossible, to reconstruct it with complete confidence in its validity. Not to be overlooked are system software and configurations. They should also be backed up in such a way that restarting the system or restoring it to a nominal condition can be accomplished expeditiously.

There are a wide variety of schemes for creating backups. Most are based on some type of high-density tape. Capacities for some are measured in terabytes. The backup procedure can be either manual or automated. The latter approach is safer because it removes the potential for human error in the process, but an automated procedure should issue a notification if it encounters problems while performing its duties. Backups can be made, managed, and used remotely. Some systems allow access to other cartridges while one cartridge is receiving data. Scalability is an important feature available. As mentioned earlier, tapes that are subjected to repeated reuse should periodically be tested and, if necessary, cleaned by a tape certifier.

Backups should be kept at a separate location, preferably far enough away from the site of origin that a single storm, forest fire, earthquake, or dirty bomb could not damage both locations. At a bare minimum, backups should be kept in a fireproof, explosion-resistant safe; it must include insulation so that heat is not conducted to its contents. Backups that are going off-site (perhaps via the Internet) should be encrypted. In all cases, access to backups should be restricted to authorized personnel.

Point-in-time recovery requires not only periodic backups but also continual logging of changes to the data since the last complete backup so that files can be reconstructed to match their last version. Although the need to backup digital information is well recognized, essential printed documents are sometimes overlooked. These can be converted to a more compact medium (e.g., microfilm).

Redundancy in the availability of power can be achieved using a UPS (discussed previously). Some systems themselves have redundant batteries and circuitry. Nonetheless, most UPS systems have backup times designed only to allow controlled shutdown of the system so that no data is lost or equipment damaged. For continued operation during extended blackouts, a backup generator system will also be necessary. It is tempting to place large UPS systems and generators in a basement, but that can backfire if the power outage is concurrent with water entering the building. It is important to anticipate plausible combinations of calamities.

Telephone redundancy has its difficulties. Cellular communications should be available in case wired phone

service to a building is interrupted, but phone systems in general become overloaded and may sustain damage as a result of a major event. Or cellular services could be shut down (as occurred on September 11, 2001, for fear they might be used to trigger bombs). An alternative emergency communication system would be a battery-powered, two-way radio that broadcasts on a frequency monitored by emergency agencies. In any case, RF-emitting devices must not be active near equipment that could suffer from the emissions.

ISP (Internet service provider) redundancy is also complicated. Politically, operationally, and economically, it may make sense to have a single ISP. From the standpoint of robustness, it is better to have at least two service providers and to have their respective cables exit the organization's physical perimeter by different routes (so that any careless excavation cannot damage both lines). Internally, the organization must be able to switch critical services promptly from one provider to the other.

The ultimate redundancy is a hot site, ready to take over operations. This does not need to be owned outright; services of this sort can be contracted.

Sanitization of Media

At some point in time, every piece of storage media of every type will cease to play its current role. It may be reused to store new information, it may be recycled into a new object, or it may be "destroyed" in some sense (probably not as thoroughly as by incineration). If the media is to be used by another individual not authorized to access the old information, the old information must be purged. In the case of recycling or destruction, the original user of the media may assume that no attempt to access the old information will be made after it leaves his or her possession; as was pointed out in the discussion of dumpster diving, this is a foolhardy assumption. Sanitization of media that held sensitive information at any time is the responsibility of its owner.

Printed media holding sensitive information can be shredded. Some shredders are worthless, slicing pages into parallel strips, which can be visually "reassembled." At the other extreme is government equipment that liquefies documents to the point that they cannot be recycled (due to the destruction of the paper fibers). In between are crosscut shredders that produce tiny pieces of documents, a reasonable approach.

For magnetic media, one of the best known vulnerabilities comes from "deleting" a file, which really only changes a pointer to the file. There are commercial, shareware, and freeware tools for (repeatedly) overwriting files so that each byte is replaced with random garbage. Echoes of the original information may remain in other system files, however. Another potential problem is that sectors that have been flagged as bad might not be susceptible to overwriting. Special, drive-specific software should be used to overwrite hard drives because each has its own way of using hidden and reserved sectors.

Even after all sensitive bytes have been overwritten by software, there may still be recoverable data, termed *magnetic remanence*. One reason is that write heads shift position over time, that is, where new bytes are written does not perfectly match where the old bytes were written. Hence the use of a degausser (bulk eraser) is generally recommended. Some models can each accommodate a wide range of magnetic media, including hard drives, reel or cartridge tape, and boxed diskettes. Degaussers are rated in Gauss (measuring the strength of the field they emit), in Oersteds (measuring the strength of the field within the media they can erase), or in dB (measuring on a logarithmic scale the ratio of the remaining signal to the original signal on the media). A degausser generates heat rapidly and cannot be operated continuously for long periods; it should be equipped with an automatic shutoff feature to prevent overheating. Even degaussing may leave information retrievable by an adversary with special equipment. Another suggestion is to grind off the surface of a hard drive. For more information on magnetic remanence, see National Computer Security Center (1991), also known as the Forrest Green Book in the Rainbow Series.

Guidelines for sanitizing write-once or rewritable optical media are not as clear. In theory, even write-once disks can be overwritten, but this is not reliable. Two "folk remedies," breaking the disk or placing it in a microwave oven for two seconds, should *not* be used. Another suggestion, scratching, may be ineffective because there are commercial products and services for repairing scratched disks by polishing. Therefore, if complete destruction of the disk is not possible, it should be ground to the point of obliterating the layer on which the data is actually stored.

For maximum security in recycling or disposing of media, study forensic science as it applies to computing (a separate article), and learn to think forensically—if a government agency could recover information from your media, so could a sufficiently sophisticated adversary.

Physical Security Awareness Training

Because security is everyone's business, education is one of the most important aspects of physical security. It is also cost-effective. Proper practices cannot replace expensive security equipment, but improper practices can negate the value of that equipment. All personnel should be trained how to react in case of a fire, the most likely threat to life in a computing facility. The most important aspect is *practicing* egress procedures. In the areas where total flooding (to be discussed later) is to be employed, occupants of those areas must understand the different alarms, must know how to proceed when the first alarm sounds, and must appreciate the seriousness of that environment. (A short science lesson might help.) All personnel should be acquainted with the location and proper use of portable fire-suppression devices. If more than one type is available, they must know which type is suitable for which kinds of fires. Depending on how many operations are automatic, certain people (enough so that an adequate number are always on duty) must be trained to perform extra duties, including shutting off electricity and natural gas, calling emergency officials, and operating special fire systems (hoses, wheeled portable units, manually controlled sprinklers, etc.).

The variety of possible disasters is so broad (e.g., fallen space debris—with or without radioisotopes), it is impossible to educate employees with regard to every

eventuality. The solution is to teach general principles. In the case of hazardous materials, personnel should just call the proper agencies and get out.

All employees need to know how intruders might enter, how to recognize intruders, and how to react—whom to call and what to do until they arrive. Custodial personnel may need additional training and oversight. They often work at night, a time favored by certain types of intruders. Cleaning crews also are prone to breach security protocols to streamline their work, for example, by leaving offices open and unattended for periods of time. For this reason, education should be reinforced by spot checks to see what is actually going on.

Maintenance and construction workers (whether they are employees or not) must be made of aware of the dangers posed by dust, even from something as simple as accessing the space above a suspended ceiling. When dust-producing activities are anticipated, other employees should know to take precautions, such as installing dust covers on equipment.

All employees who know anything that might be useful to a potential attacker need social engineering awareness training. They should also be educated as to the kind of information that might leak onto a newsgroup bulletin board and why this is bad. For both of these, sample scenarios should be described.

Perhaps the most sensitive area of training regards malicious insiders. Again, sample scenarios can help. Smaller institutions in which everyone knows everyone else are especially likely to have coworkers who are overly trusting of one another. The trick is to preserve the esprit de corps and avoid breeding mistrust among coworkers. The corporate culture should foster "collegial paranoia." Physical security is just another problem that needs to be attacked with teamwork, a highly valued corporate virtue. That means everyone should expect cooperation from everyone else in adhering to physical security protocols. Everyone should believe that an unattended computer is a bad thing. Everyone should expect to be turned down when asking to "borrow" someone else's account; this kind of rejection should not be perceived as a bad thing. (Incidentally, system administrators need to keep in mind that no group of people should be given a common account name and password because this complicates tracing malfeasance to a single person.) Given what has been said about theft of bandwidth and time, appropriate-use policies must be communicated and justified. This is an area where the rules may be less clear-cut than for dealing with colleagues.

Ultimately, the goodwill of employees is invaluable. Managers at all levels must be educated to appreciate the crucial role they play in maintaining an environment which does not turn employees against the organization. Understanding that most attacks are from within is the first step.

REACTIVE MEASURES

Despite the best preventive measures, things will go wrong. Defense in depth requires us to be prepared to react to those calamities. This is most critical when lives are in danger.

Fire Suppression

Fire suppression systems generally release water, dry chemical, or gaseous agents. The release can be from portable devices, from a centralized distribution system of pipes (perhaps with hoses which will be manually directed), or from modular devices in fixed locations. Fire can be extinguished by displacing oxygen, by breaking the chemical reaction, by cooling the fire's fuel below its point of ignition, or by a combination of these.

Any fire in a computing environment should be considered a *Class C* fire because of the presence of electricity. Electrical power should be cut as soon as possible, regardless of whether a conductive fire-suppression agent is used, because any electrical shorting will work against the suppressant. Obviously, automatic fire suppression systems must be able to function independent of the facility's main power supply.

When possible, it is preferable to extinguish a fire immediately with portable extinguishers aimed at the base of the fire before it can grow. Each device should have one or more letters on the label, indicating the class(es) of fires on which it can be used. For most computing facilities, a dry chemical extinguisher rated A-B-C will cover all situations. The dry chemical will leave a residue, but if the fire can be caught early, this is a small price to pay.

Countermeasures must match the potential conflagration, both in quantity and quality. The presence of flammable materials requires greater suppression capacity. In addition, special tools and techniques are needed for special fires. A *Class D* fire (involving combustible metals such as magnesium) requires the application of a metal-specific *dry powder* (so named to distinguish its purpose from that of ordinary dry chemical with B-C or A-B-C ratings). Recently certified, specialized (wet chemical) extinguishing equipment should be installed if there is the potential of a *Class K* fire (involving cooking equipment using oils and fats at high temperature).

Total Flooding with Gaseous Agents

Total flooding seeks to release enough of a gaseous agent to alter the entire atmosphere of a sealed area (with openings totaling no more than 1% of the total surface area of the enclosure). The term *clean agent* is often used to indicate that the gas itself leaves no residue (although its decomposition by-products will). Ordinarily, the air-agent mixture alone would be safe for humans, but fires always produce toxic smoke.

Consequently, the best protocol is to have an alarm continuously announce the impending release of a flooding agent, allow a reasonable time period for personnel to evacuate and seal the area, and sound a second alarm to announce the actual release. Doors must be self-closing and have "panic hardware" for easy exit. Warning signs must proclaim the special nature of the area. Self-contained breathing equipment must be available for rescuing people.

The sudden release of a highly pressurized gaseous agent has several side effects. The gas undergoes a dramatic decrease in its temperature. Reportedly, skin in direct contact with a release could suffer frostbite. Equipment could suffer as well. The force of the exhaust is

considerable and should be taken into account when placing the vents. The noise of a release is loud but not damaging to hearing.

Gaseous fire-suppression systems can be either centralized or decentralized. In the former, a network of pipes delivers the suppressant from a single tank to multiple nozzles operating simultaneously; this is the more traditional and common approach. In the latter, independent units each have a tank, triggering device, and nozzle; they can be equipped for remote triggering or monitoring. Centralized systems are generally custom fitted for a particular installation. Decentralized systems are modular, so there is greater flexibility in placing the individual units or repositioning them (upon expert advice) if the layout of a facility changes. On the negative side, the individual units, being self-contained, are heavier and bulkier than the outlets and pipes of a centralized system. Therefore, they must be supported from a structural ceiling rather than a suspended ceiling. Moreover, each cylinder must be anchored very securely to prevent Newton's Third Law of Motion from turning it into a projectile upon the release of gas. Gaseous agents that have been used in computing facilities include carbon dioxide, argon, nitrogen, halogenated agents (halons), newer replacements for halons, and mixtures of these. (Pure CO_2 at the concentration needed for total flooding is hazardous to humans.)

For decades, the fire-suppression technique of choice in computing facilities was total flooding with Halon 1301 (bromotrifluoromethane or $CBrF_3$). (Halon 1211, a liquid streaming agent, was also used in portable extinguishers.) Because of their ozone-depleting nature, proportionally worse than CFCs (chlorofluorocarbons), halons were banned by the Montréal Protocol of 1987. Disposal and recycling of Halon 1301 must be performed by experts, because it is contained under high pressure. Consult Halon Recycling Corporation (HRC; 2002) for advice and contacts. Although no new halons are being produced, existing systems may remain in place, and the use of recycled Halon 1301 in new systems is still allowed by the protocol (on a case-by-case basis) for "essential" use (not synonymous with "critical" as used by the HRC). Because the world's supply has been decreasing since 1994, a concern when relying on Halon 1301 is its future availability.

Halon 1301's effectiveness is legendary. One factor is its high *thermal capacity* (ability to absorb heat). More important, it also appears to break the chemical chain reaction of combustion. Although the mechanism by which it does this is not perfectly understood (nor, for that matter, is the chemistry of combustion), the dominant theory proposes that the toxins into which it decomposes at about 482°C (900°F) are essential for chemical inhibition.

In low-hazard environments, a concentration of approximately 5% Halon 1301 by volume suffices. Short-term exposure at this level is considered safe but not recommended for humans; dizziness and tingling may result. An even lower concentration is adequate when the Halon 1301 is delivered with a dry chemical that inhibits reignition. Regardless of the concentration applied, immediately after exposure to Halon 1301 (perhaps from an accidental discharge), a victim should not be given adrenaline-like drugs because of possibly increased cardiosensitivity. The real risk comes when fire decomposes Halon 1301 into deadly hydrogen fluoride, hydrogen chloride, and free bromine. Fortunately, these gases, being extremely acrid, are easy to smell at concentrations of just a few parts per million.

In addition to the natural inert gases, there are a numerous replacements for Halon 1301 in the general category of halocarbon agents. Subcategories include: hydrofluorocarbons (HFCs), hydrochlorofluorocarbons (HCFCs), perfluorocarbons (PFCs and FCs), and fluoroiocarbons (FICs). None of these or blends of them seem to be as effective, that is, more of the substance is needed to achieve the same end. The search for better clean agents continues. See National Fire Protection Association (2000) for guidelines regarding clean agents.

Water-Based Suppression

Despite its reputation for doing as much damage as fire, water is coming back in favor. Because water's corrosive action (in the absence of other compounds) is slow, computer equipment that has been sprinkled is not necessarily damaged beyond repair. In fact, cleanup from water can be much simpler and more successful than from other agents. Water also has an outstanding thermal capacity. Misting is now used as an alternative to Halon 1301. The explosive expansion of the steam contributes to displacing oxygen at the place where the water is being converted to steam, namely, the fire. (Steam itself has been used as a suppressant.) Pipes for hose, sprinkler, and mist systems should remain dry until needed to reduce the risk of accidental leakage.

First Response to Other Types of Incidents

One of the most likely incidents demanding an immediate response is an unwanted intruder. In general, it is safer to summon security personnel, particularly if the incident warrants detaining the person for civil authorities. Less likely but potentially more dangerous are incidents involving hazardous materials. It is possible to know in advance precisely which ones are in nearby pipelines and storage facilities, but not which ones pass by on transportation arteries. Therefore, it is essential to know whom to call should a *HAZMAT* (hazardous material) event occur or appear to be imminent. The safest course of action in case of pipeline leaks, derailments, truck accidents, or deliberate attacks is to evacuate immediately unless the substance is known with certainty to be benign.

Because of the tremendous variety of characteristics of modern contaminants, a facility contaminated by chemical, biological, or radiological agents should not be reentered until local authorities and appropriately trained professionals give clearance. Some contaminants, such as sarin gas, dissipate on their own. Some, such as the anthrax spores, require weeks of specialized decontamination. Others, such as radiation, effectively close down an area indefinitely.

Disaster Recovery

Disaster recovery can take as many forms as the disasters themselves. A single event may be handled in different

ways or may require a combination of remedies. Data may be retrieved and equipment rehabilitated on- or off-site. Simultaneously, operations may be (partially) restored on-site or transferred off-site. In most disaster recovery planning (the subject of a separate article), the first priority is maintaining operations or restoring them as soon as possible. There are a variety of services that can be contracted for this purpose. Some are mobile facilities.

We concentrate here on the physical aspects of rehabilitating buildings, equipment, and media. Professional disaster recovery services should always be employed for this purpose. Because such specialized companies are not based in every city, however, their response time does not match that of emergency personnel. Yet for many physical disasters, the first 24 hours are the most important in limiting progressive damage, for example, from water and smoke. Consequently, knowledge of what to do during that crucial time frame is essential. Good references in this regard are McDaniel (2001) and the "What to do in the first 24 hours!" links at the BMS Catastrophe Web site (http://www.bmscat.com/were/press.shtml)

Recovering from Fire Damage

Even when a fire has been extinguished, other problems remain. By-products of the fire, perhaps because of the type of suppressant used, may be toxic to humans or corrosive to equipment. As soon as practical after a fire has been extinguished, thorough ventilation should take place. Only appropriately trained and equipped experts should enter to begin this dangerous procedure. Aside from the initial health hazard, improper procedures may worsen the situation. Active HVAC equipment and elevators might spread contamination to additional areas.

Once air quality has returned to a safe level, resources should be rehabilitated. In some cases, equipment will never again be suitable for regular use; however, it may be brought to a condition from which any important data can be backed up, if necessary. The same is true of removable storage media. Paper documents can be restored provided they have not become brittle.

The combustion by-products most devastating electronic equipment are corrosive chloride and sulfur compounds. These reside in particulate residue, regardless of whether dry chemical (which itself leaves a film) or a clean agent (a somewhat misleading term) was applied. In either case, time is of the essence in preventing the progression of damage. Some types of spray solvents may be used for preliminary cleanup. In the case of fire suppression by water, the procedures outlined below should be followed.

Recovery from Water Damage

The first rule of rehabilitating electrical equipment exposed to water is to disconnect it from its power source. Energizing equipment before it is thoroughly dried may cause shorting, damage, and fire. The second rule is to expedite the drying process to prevent the onset of corrosion. Low ambient humidity speeds drying, whereas high humidity (and, even more so, dampness) speeds the corrosive action of any contaminants. If the HVAC system cannot (or should not) be used to achieve a relative humidity of 40–50%, then wet items should be moved to a location where this can be done. Actively applying heat significantly above room temperature must be done with caution, recalling from Table 1 the temperatures at which damage can occur to media and equipment. Handheld dryers can be used on low settings. An alternative is aerosol sprays that have a drying effect. Even room-temperature air moved by fans or compressed air at no more than 3.4 bar (50 psi) can be helpful. In any case, equipment should be opened up as much as possible for the greatest effect. Conversely, equipment should not be sealed, because this may cause condensation to develop inside. Low-lint cotton-tipped swabs may be used to dab water from hard-to-reach areas.

PHYSICAL ASPECTS OF COMPUTER AND NETWORK SECURITY PLANNING

Computer and network security planning traditionally starts by identifying assets. Physical security planning would best begin before there were any assets to protect. Whereas cyberattacks and cybersecurity have little to do with where resources are located, the earliest stages of physical security planning should consider and dictate location.

Locating a facility in a particular region is usually done with an eye to the bottom line. A variety of regional characteristics influence the difficulty of maintaining physical security and can ultimate affect profit: the availability of electrical power and a skilled workforce; the frequency of earthquakes, hurricanes, tornadoes, or wildfires; and the likelihood of terrorism, civil unrest, or regional conflict. The natural traits will stay fairly constant, whereas the political, social, and economic ones may vary dramatically over time.

Locating a facility at a specific site within a region may have an even more profound influence on total risk. New factors, such as topography and neighbors, enter into the equation at this level. A small difference in elevation can make a big difference where flood plains and storm surges are concerned. Higher terrain may initially look safer than a valley but may be dealt bigger surprises due to steep land gradients. The ground underneath may hold more surprises, such as mine subsidence. Rail lines, major thoroughfares, massive electrical lines, natural gas pipelines, and even major water mains pose potential threats. Adjacent establishments may be high-profile targets, have hazardous operations, or produce abundant electromagnetic pollution. Choosing to have no close neighbors may have long-term consequences if adjoining parcels of land are later occupied by high-risk establishments. Being in an isolated area has implications for emergency services.

Locating departments within a building should ideally influence its design and construction. Critical departments and support equipment (including backup power) should be in the safer areas, not in the basement or on the top floor. Within departments, the most crucial resources should preferably be placed away from windows and overhead plumbing. Safes for any on-site backups should be in windowless, interior rooms with high fire ratings. Flammable and hazardous material must be contained

and isolated to the extent possible. Fire divisions inhibit the spread of fire. Other construction techniques brace for earthquakes or high winds.

Once assets are in place, the physical perimeter of the organization must be defined; beyond some point, the responsibility for physical security switches to others (e.g., ISPs and civil authorities). This footprint (often a collection of widely scattered toeprints), determines where certain physical access controls can be installed.

Physical security doesn't stop at the door. Events outside—riots, dust storms, rolling brownouts—can disturb operations inside. Physical security policies must provide for timely, two-way flow of information (e.g., monitoring of weather forecasts and prompt reporting of internal incidents to relevant authorities).

Moreover, there is a virtual perimeter far more vast and complex than the geographic perimeter. Wherever the organization's employees carry assets, physical security is an issue. Although physical access controls, such as biometric devices on laptops, help, mobile assets are at greater risk and, therefore, in greater need of encryption and redundancy. Crafting and communicating clear, effective policies regarding off-site resources are critical. In the end, the competence and trustworthiness of employees are the best defense.

Even if employees leave all physical objects at work, their knowledge remains with them. The usual nondisclosure agreements must be complemented by policies regarding appropriate usage of newsgroup bulletin boards.

Policies for work-related behavior should address the following:

1. access to facilities and services (when and where who can do what);
2. appropriate use (how each allowed service may and may not be used);
3. integrity of accounts (leaving computers unattended, lending accounts); and
4. data management (backing up files, recycling and disposing of media).

The most ticklish of these is appropriate use. Some employers prohibit even personal e-mail saying, "I have to work late." Others seem not to care about misuse of resources until glaring abuses arise. Neither policy extreme is optimal; research has shown that productivity is actually best when employees are allowed modest time for personal e-mail and Internet access. An alternative to written policy (and some form of enforcement) is to block specific Web sites or to allow only specific sites. The former is inadequate, and the latter is too restrictive in most cases. Yet another alternative is filtering software for Web usage or e-mail. If activity monitoring is used, notification of employees is not legally required. Nonetheless, it is best to spell out both what an employer expects in the way of behavior and what employees might expect with regard to what they may see as their "privacy." In practice, monitoring should be used to control problems before they get out of hand, not to ambush employees. Activity monitoring as described actually covers a small fraction of the spectrum of security-related behavior.

Appropriate-use policy raises issues larger than the impact on profitability. Allowing an organization's resources to be used to illegally duplicate copyrighted material contributes to a large and growing societal problem. There is an ethical (if not legal) obligation to consider not only theft of one's own bandwidth, but also the theft of another's intellectual property.

Every policy needs to be enforced, but the difficulty of doing so ranges from trivial to highly impractical. Whereas compliance in some areas (e.g., periodic changing of passwords) can be enforced automatically, checking to see where passwords have been written down is a completely different matter.

Additional security policies should be written specifically for human resource departments (e.g., background checks for certain categories of personnel), for managers (e.g., activity monitoring protocols), and for IT administrators (e.g., least privilege, to name only one of many).

The final component, as noted before, is education and enlightenment with regard to physical security. Policies cannot work if employees do not understand the policies *and* their rationales. Policies that are considered to be frivolous or unnecessarily restrictive tend to be ignored or circumvented. (Doors will be propped open.) That belief in policies must come from the top. This may require educating and enlightening corporate leaders, who must then lead by communicating down the chain of command their belief in the importance of physical security.

CONCLUSION

Physical security tends to receive less attention than it deserves. Yet cybersecurity depends on it. The two pillars of security must be balanced to defeat malicious insiders and outsiders. Ultimately, physical security is the greater challenge, because nature can be the biggest foe. Physical security involves a broad range of topics outside the normal sphere of IT expertise. Consequently, to obtain the best protection, professionals in other fields should be consulted with regard to fire detection and suppression, power maintenance and conditioning, access to and monitoring of buildings and rooms, forensic science, managerial science, and disaster recovery. A basic understanding of how these areas relate to physical security facilitates communication with consultants. Combining information with the imagination to expect the unexpected leads to better physical security planning and practice.

The scope of physical security is wider than is immediately evident. It concerns an organization's resources, wherever they go. An asset often forgotten is employees' knowledge. Equally important are their intentions. Thus, physical security involves everyone, all the time. It relates to intangibles such as trust and privacy, and it must look inward as well as outward.

GLOSSARY

Class A fire Fire involving ordinary *combustibles* (e.g., wood, paper, and some plastics).

Class B fire Fire involving *flammable* or *combustible* liquid or gas (e.g., most solvents).

Class C fire *Class A* or *B* fire amid energized electrical wiring or equipment, which precludes the use of extinguishing agents of a conductive nature (e.g., water or foam).

Clean agent Gaseous fire suppressant that technically leaves no residue; residues will result when the agent breaks down under the heat of combustion.

Combustible Capable of burning at normal ambient temperature (perhaps without a flame).

Degausser or **bulk eraser** Alternating current-powered device for removing magnetism (*Degausser* is often applied specifically to wands that rid cathode ray tube monitors of problems displaying colors. The latter term indicates that data is wiped en masse rather than sequentially.)

Electrical noise electromagnetic interference, especially interference conducted through the power input, or minor *spikes*.

Electromagnetic interference (EMI) Undesired electrical anomalies (imperfections in the desired waveform) due to externally originating electromagnetic energy, either conducted or radiated.

Flammable Capable of burning with a flame; for liquids, having a flash point below 38°C (100°F).

Halon or **halogenated agent** *Clean agent* formed when one or more atoms of the halogen series (including bromine and fluorine) replace hydrogen atoms in a hydrocarbon (e.g., methane).

Heating ventilation air conditioning (HVAC) Equipment for maintaining environmental air characteristics suitable for humans and equipment.

Line filter Device for "conditioning" a primary power source (i.e., removing electrical noise).

Radio frequency interference (RFI) Sometimes used as a synonym for *EMI,* but technically the subset of EMI due to energy in the "radio" range (which includes frequencies also classified as microwave energy).

Sag or **brownout** Drop in voltage.

Smoke Gaseous, particulate, and aerosol by-products of (imperfect) combustion.

Spike or **transient** or **transient voltage surge (TVS)** Momentary (less than 1 cycle) increase in voltage.

Surge Sudden increase in electrical current; also used for *spike,* because the two often arrive together.

Tempest or **compromising emissions** Electromagnetic emanations from electrical equipment that carry recoverable information, popularly referred to by the code word for a U.S. government program to combat the problem.

Uninterruptible power supply (UPS) Device to provide battery power as a backup in case the primary source of power failures.

Politics

Paul Gronke, *Reed College*

INTRODUCTION

Holding torches to light the night sky in October 1876, nearly 4,000 people rallied around a temporary platform in New Haven, Connecticut's sixth electoral ward. One hundred twenty-two years later, nearly 2 million "hits" were recorded on the "Jeb Bush for Governor" Web page, 4,000 Wisconsin citizens signed up for e-mail "listserv" distribution of information about Russell Feingold's (D-WI) Senatorial campaign, and more than 14,000 users posted messages on an electronic bulletin board maintained by the campaign of Jesse "The Body" Ventura (ex-wrestler, talk show host, and current governor of Minnesota). The 1998 election was heralded as the first to demonstrate the potential of the "e-campaign."

By the 2000 campaign, presidential candidate John McCain raised $500,000 in a single day over the World Wide Web. National voter information portals reported hundreds of thousands of hits daily as the election approached, and on election day, governmental sites with real-time election results experienced daily hit rates of 75,000 (Dallas) to 1,000,000 (Washington Secretary of State) on election day (Sarkar, 2000). And when the 2000 presidential contest was thrown into doubt, nearly 120,000 users *per hour* bottlenecked the Florida Secretary of State's Web site. Clearly, e-politics is here to stay.

However, just like the old rules of the stock market, many of the old rules of politics have proved to be surprisingly resilient. Even before the January 2001 presidential inauguration, many of the major politics "portals" had shuttered their electronic doorways or were undergoing strategic makeovers. Media companies that had spent millions of dollars developing an online presence were finding that Internet news sites not just failed to make money but were major sources of revenue loss (Podesta, 2002). Internet connectivity rates had flattened. Clearly, e-politics is off in the distant future.

The reality lies somewhere between these two extremes. The rapid penetration of electronic mail and World Wide Web access into homes and offices, the proliferation of Web sites, and the emergence of the Internet as a new forum for communication present vast new opportunities for citizen participation in the political process. Traditional—and increasingly nontraditional—political organizations (candidate campaigns, political parties, and interest and activist groups) cannot ignore the power of the Internet to *mobilize* citizens.

This chapter will review the impact of the Internet on political participation, using the rational choice model of participation as a lens. According to the rational choice theory of participation, unless individual citizens, after assessing the costs and benefits of political action, find it in their self-interest to participate, they will decline to do so. Although the Internet may lower one cost of participation—easy access to information—the glut of information on the Internet may increase the costs of selection and comprehension. The result may be that citizens will be overwhelmed, continuing to feel that politics is distant, complicated, and marginal. Thus, many citizens continue to have little motivation to get informed and participate. There is little indication that e-politics will change this in the foreseeable future. This same "rational choice" perspective, however, points to those actors and organizations that do benefit directly from politics: political candidates and parties, interest and lobbying groups, and activist organizations. The Internet has had, and will continue to have, its greatest impact as a tool for mobilization efforts by political organizations. In the following sections, I provide a more detailed summary of the rational choice model of political participation, followed by an analysis of how the Internet may change the logic of participation for individuals, and close by extending the review to cover political organizations, parties, and the mass media.

"MACHINE" POLITICS IN AN ELECTRONIC AGE: WHO IS BEING SERVED?

The old political machine, symbolized by Tammany Hall and Boss Tweed of New York or Richard Daley of Chicago,

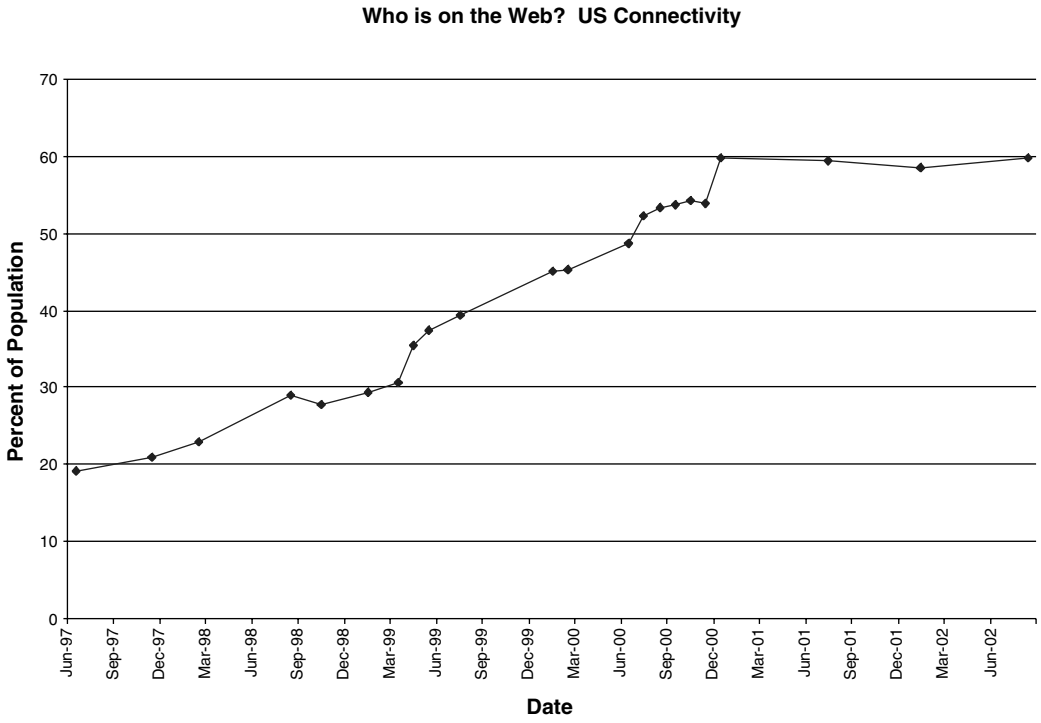

Figure 1: Who is on the Web in the United States? (Data source: NUA Internet Surveys.)

lowered transaction costs for new immigrants and poorly educated urbanites, provided jobs and social welfare (via the patronage system), and encouraged political involvement. This is why, in some quarters, "boss politics," although corrupt by modern standards, is celebrated as a reasonable adjustment of the political system to an undereducated, rapidly urbanizing population.

Is it accurate today to refer to a new "political machine"? Today's political machine is the personal computer, powered by the Internet. Many trumpet the political potential of the Web-connected PC for many of the same reasons that some celebrate the old political machine. The PC and the Internet, they argue, will lower the costs of political information and involvement, make politics more relevant to our daily lives, and consequently substantially increase rates of political participation. The rapid growth of the Internet means that it is far too important for any political candidate or organization to ignore. As shown in Figure 1, Internet penetration rates in the U.S. have climbed dramatically over the past decade and are currently estimated at 60% (though showing little growth in the past year). Perhaps most importantly, the more wired segments of the population—those with higher levels of education, income, and occupational status—are the same segments who are more likely to volunteer, donate money, and vote (Bimber, 2002; Davis, 1999; Rosenstone & Hansen, 1993). A significant proportion (35%) of Americans report going on the Internet at least once a week to get news, although, parallel to penetration rates, this proportion has slowed significantly from its rapid growth in the late 1990s and still lags far behind traditional media sources (Pew Center, 2002). Users with high-speed connections—currently estimated at 21% of U.S. users—report far higher rates of Internet utilization for newsgathering (Horrigan & Rainie, 2002). The Internet is clearly a mass medium for communication.

International Internet penetration rates, however, although they continue to climb rapidly, remain below 10% (NUA Internet Surveys, 2002). As Pippa Norris has shown, this difference means that, except for a few more highly connected European countries, e-politics will remain a distinctly American phenomenon (Norris, 2001).

The new political machine holds the potential for a more egalitarian, democratized, and decentralized political system, whereas the old political machine was the very essence of centralized political control. The machine metaphor is appropriate, furthermore, because it focuses our lens on the area where the Internet has already had, and is likely to continue to have, its greatest impact—on the ability of political elites and organizations to communicate with, mobilize, and potentially control public attitudes and political activities. The Internet has become a central tool for mobilization efforts by political organizations. The rapid penetration of electronic mail and World Wide Web access into homes and offices, the proliferation of Web sites, and the emergence of the Internet as a new forum for communication present vast new opportunities for citizen participation in the political process. The Internet's potential to broaden and increase participation by changing the behavior of individual citizens, however, runs squarely into one of the most widely recognized social dilemmas: the logic of collective action.

RATIONAL CHOICE AND DEMOCRATIC PARTICIPATION

In *Strong Democracy*, political philosopher Benjamin Barber argues that neighborhood assemblies and town

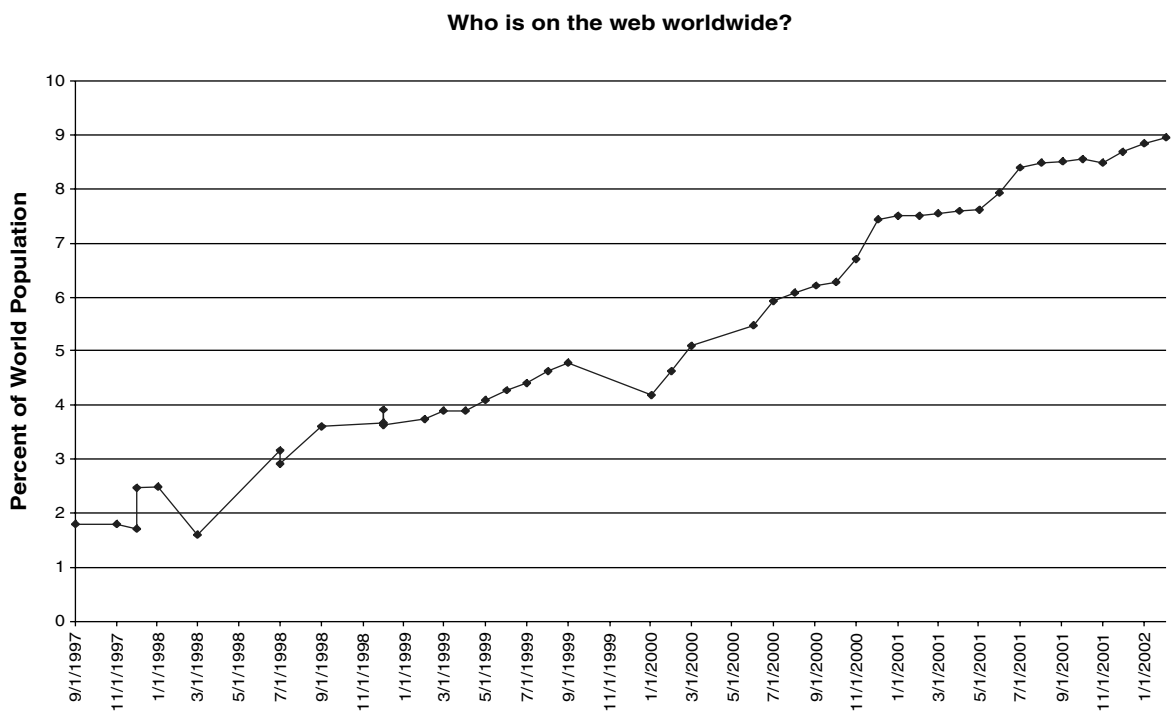

Figure 2: Who is on the Web worldwide? (Data source: NUA Internet Surveys.)

meetings are necessary to create a democracy that relies upon what he calls "strong talk," a democratic community relying upon increased political participation via public discussion and debate (Barber, 1984). Barber addresses the problem of the "zookeeper" mentality of liberal democracies: a system that acts more to *defend* individual preferences and liberty from one another than *promote* shared commitments and civic engagement. The critical missing element, Barber believes, is greater participation. Citizens in most liberal democracies are only "free" every 2, 4, or 6 years—only when they vote.

Whether or not we agree with Barber, few would assert that greater civic participation poses a problem for republican democracy. Though James Madison argues in *Federalist 10* (Hamilton, Madison, & Jay, 1961) that the public opinion of a majority must be filtered by a republican government, nearly everyone agrees that greater involvement in the political and civic sphere adds to the credibility of liberal democracy and that current levels of disengagement in the U.S. are a serious area of concern (Putnam, 2000). However, Barber's strong talk, Putnam's "social capital," and other participation-inducing devices have always encountered problems with real world application: the seeming irrationality of political participation.

Within political science, the dominant perspective for understanding political participation is *rational choice*. According to this view, a rational individual chooses whether to engage in political activity (writing a letter, joining a protest march, voting, etc.) only if the benefits exceed the costs. The argument is deceptively simple, but leads to powerful conclusions:

$$\text{Participate (e.g., Vote) only if } Probability * Benefits - Costs > 0.$$

Verbally, this equation tells us that individuals engage in a particular political act if the *benefits* (say, a particular candidate winning office) exceed the *costs* of participation. Even stated this way, ignoring the other elements, participation looks irrational. The direct benefits to most individuals of, say, George Bush winning the presidency are quite low. These are quickly overwhelmed by the costs of being informed, registering to vote, and actually getting to the polling place and casting a ballot.

The problem becomes insurmountable when we add the *"probability"* term. This term captures what social scientists refer to as the "collective action problem." An election outcome, such as a Bush victory, is a "public good." Public goods, such as clean water or clean air, are defined as goods that everyone can enjoy, regardless of whether or not he or she helped provide the good. An election outcome is a "good" (or "bad" for those on the losing side) which we "enjoy" whether or not we voted. Thus, unless we believe that our single vote will be decisive in the outcome—represented as *"probability"* above—then we are better off staying at home. In most elections the value of *probability* is vanishingly small. The rational citizen should not vote, and certainly should not engage in Barber's strong democracy. This is, of course, the Achilles heel for this theory, because many people *do* vote. As a consequence, some scholars have posited a "consumptive" benefit to participation (a *Duty* term), something that we enjoy whether or not our candidate wins. Although for some, the inclusion of *Duty* solves the puzzle of participation, for others, this reveals the poverty of this approach to political action. For a summary of the rational choice theory of voting, see Aldrich (1993). For a critique of this viewpoint, see Green and Shapiro (1996).

Regardless of the debate, the fact remains that the "equation of political participation" provides a structured

way to think about the impact of the Internet on politics and political action. In general, early commentaries assumed that the Internet would work its wonders on the cost side of the equation, making it easy and cheap for citizens to learn about candidates, and allowing citizens to personalize their Internet experience, so that a participatory revolution would result. These early analyses failed to take into account the fundamental barrier to participation: interest and motivation. We are already buried under an avalanche of political information; increasing the flow will only make it harder to manage the "information tide" (Graber, 1984, 2001). There is little indication, at present, that the Internet has significantly lowered the costs of participation (Davis, 1999).

But the Internet may work changes in the future. The Internet might inflate perceived benefits, if it provided a way for candidates and parties to contact voters and let them know about the advantages of one party over another. The Internet could allow citizens to see interests where they did not exist before, by allowing the creation of "virtual communities" of interest (Davis, 1999, Chap. 6; Turkle, 1997; but see also Bimber, 1998, for a cautionary view). Or it may provide an avenue for organizations to encourage political participation as an act of civic duty. This may mean that mobilization efforts will be cheaper and easier. Finally, it is possible that, by disseminating more accurate information on the relative support for each candidate, the Internet could lead to more precise estimates of "*probability,*" most likely depressing levels of participation. I examine each of these possibilities below.

A second theory, the *institutional model* of politics, dovetails nicely with this model of participation. Political action does not occur in a vacuum: individuals are embedded within a larger set of social and political institutions. Intermediary organizations, such as interest groups, political parties, and the mass media, communicate the preferences of the mass public to governmental actors, educate the mass public about the activities of government, and mobilize the public to participate in politics (Verba, Schlozman, & Brady, 1995; Rosenstone & Hansen, 1993). In an institutional model of politics, special interests, lobbying groups, "issue publics," and political elites are important engines of political change, with the mass public primarily choosing among the contestants at election time. With respect to the Internet, the institutionalist model turns us away from the mass public, and instead asks how the new tools of e-politics may have strengthened or weakened the influence of pre-existing intermediary organizations and possibly allowed new organizations to enter the fray.

Second, the institutionalist model highlights the importance of *political information* for understanding political power and influence. Whether elites control the mass public or vice versa, the primary point to remember is that the cost, accessibility, and accuracy of political information are a key part of democracy, just as obviously, information flow is the *sine qua non* of the Internet. Beyond its role as a tool for intermediary organizations to mobilize the public and influence the government, the Internet could provide a way for citizens to influence government *directly*, bypassing intermediary institutions.

To summarize, the political world consists of the mass public, elites, and pre-existing political institutions. A careful survey of politics must consider the motivations and interests of each set of actors in the political process if we want to understand how a new and potentially revolutionary medium such as the Internet may change the political world. Although the Internet may not change politics in one realm (e.g., it is unlikely to fundamentally change citizen interest or perceived benefits from participation in politics), it could provide invaluable tools in another realm (e.g., making it far easier to raise money, recruit volunteers, and mobilize voters).

THE MASS PUBLIC

Lowering the Costs of Participation via Low-Cost Computing

In the poorest sections of New York City and in the Indian reservations of Arizona, most households deem themselves lucky to have a telephone, much less a computer with access to the Internet. For all of its promise as a mobilizing force, the World Wide Web is simply useless in such places today. Before a move occurs to widespread online voting or Internet domination of political discussions, a larger portion of the population must have access to personal computers than is the case today. Luckily, the price of a PC has declined in a relatively predictable manner for almost two decades in concert with a steady rise in computing capabilities. Such trends will almost undoubtedly continue for at least several years into the future.

Several characteristics of personal computers improve so steadily as to have "laws" coined based on their progress. For example, "Moore's Law" states that the number of transistors on a microchip doubles each year (Moore, 1965). Likewise, the cost per megabyte of DRAM falls by an average of 40% each year (Hennessy & Patterson, 1990, p. 8). Because a recent estimate of low-end machines placed the percentage of material costs attributable solely to DRAM at 36% (the highest ratio of any component), there is significant room for improvement despite the seeming bargains found in retail stores. Gains made in video systems and monitors (summing to another 36%) will also contribute strongly. As long as the price for which a machine is sold does not fall below its material costs and construction overhead, computer manufacturers will attempt to sell PCs in bulk and profit from volume.

The commoditization of the Internet PC may someday make the machine as widespread as the telephone or the television. When the computer achieves such household status, it indeed seems likely that it will become the primary means by which political information is gathered if not the primary method by which political participation takes place. But if previous telecommunications revolutions have not transformed political participation, why will the Internet?

New Tools for Political Learning and Interaction

Information is the *sine qua non* of the Internet. In the near future, changes in technology may lower the costs of

participation in forums such as Barber's electronic town hall, especially as a faster and more interactive Internet allows more flexibility and greater ease of use. Two areas of enhancement in particular, the increasing use of audiovisual components in Web pages and the increasing spread of residential high-speed Internet connections (via both cable and phone lines), should allow citizens to participate in virtual local government assemblies or neighborhood forums with the same effectiveness and clarity as if all participants had actually gathered in the same physical meeting space. Thus, participation itself might have a tangible benefit—entertainment and enjoyment—even if it does not translate into direct "benefits" from a political outcome. In the next section, we chart the advance of these technologies and speculate as to what effects these advances might have on political participation, town hall meetings, interactive government, and online deliberation and discussion.

AudioVisual Services

Like the transition from newspaper to radio and then to television during the first half of the 20th century, the Internet has undergone in the past five years a transition from a primarily text- to image-based form of communication. Increasing bandwidth, short attention spans, and a need to differentiate a site from its competitors have driven this increase in audio and video online. As was the case with the first Web pages, audiovisual plug-ins began to appear on large commercial sites with plentiful resources, as well as on the Web sites of educational institutions. And just as the second generation of HTML editors made writing a Web page as easy as typing in a word processor, the newest generation of editors is slowly democratizing these technologies by lowering the learning curve required to incorporate them. The first decade of the 21st century will likely see the reinvention of the Web as a multimedia communications center.

The move to augment text with voice has been slow (in Internet time) but steady. Common e-mail applications such as Eudora and Outlook have for several years included audio plug-ins, allowing users of a single application to exchange messages in this way. The lack of an industry standard has slowed the popularization of voice messaging, allowing it to be overshadowed by more recent innovations such as Web telephony, music downloads, and even online wake-up calls. Although many netizens are just becoming accustomed to exchanging electronic voice mail and publishing musical compositions online, power users have begun to tinker with online video. The ability to publish home videos and self-produced animations, combined with the growing popularity of DVD recorders and other such devices, opens up doors previously unimaginable.

As these multimedia tools are simpler to use, and broadband connections become more common, multimedia creations will become commonplace. This is already evident at political Web sites: a study by Kamarck and Nye (1999) found that, even by 1998, most Congressional candidates' Web sites incorporated audiovisual, multimedia, and interactive services as part of their content (see also Wu, 1999). The move to a more visually compelling Internet presages the day when Web-based political communications will rival those currently available only on television and radio.

High Speed Internet for Everyone?

A precursor to the use of the Internet as a visually compelling medium for political information gathering, however, is a broadband connection. Although multimedia-enhanced newsgroups, streaming discussion groups, and even searchable archives of campaign videos are already available, experiencing them becomes an almost painful experience without sufficient bandwidth. On the client side, the race between cable modems and ADSL connections has brought the price of both services within reach of those of modest incomes, although not as inexpensive as was first hoped by Congressional advocates of telecommunications reform in 1996 (as illustrated in the debate over the 2002 Tauzin–Dingell Broadband Deployment Act).

Whether via coaxial cable or twisted-pair copper, nearly 25 million Americans have already found their way onto the high-speed Internet (Horrigan & Rainie, 2002). As the technologies mature, monthly fees should continue to fall and the move to ADSL and cable will accelerate.

Will broadband make a difference in the political impact of the Internet? Early indications are that broadband access will be decisive. Horrigan and Rainie's recent study, undertaken as part of the Pew "Internet and American Life" project, indicates that broadband "transforms" the Internet experience. Broadband users are far more likely to access the Internet on a daily basis and are two to three times as likely to use the Internet to collect news, product, travel, and educational information. Most importantly, for anyone who subscribes to Barber's model of a "strong" democracy consisting of active, participatory, and community-minded citizens, broadband users are far more likely to be *content providers*, setting up Web pages, storing photos online, and sharing information with others (Horrigan & Rainie, 2002, pp. 12–14). Again, for these users, the direct benefits of "participating" (in this case, setting up a Web site) seem to exceed the costs. However, this same study shows that broadband access is heavily skewed toward the same groups that have been traditionally advantaged in the political realm—well-educated, higher income, and now technologically savvy segments of the population. Far from democratizing, the Internet might even exacerbate income, educational, and racial disparities.

A Case Study in the Internet as a Tool of Mass Participation: E-voting

In the March 2000 Arizona Democratic Presidential primary, the first-ever binding Internet vote in a Presidential primary, a vast number of Arizona Democrats participated relative to previous elections (Chiu, 2000). Many speculated that Internet voting mobilized the electorate and provided lower costs to voting—thus creating a higher turnout. If we believe that some of the high turnout for Arizona's primary can be attributed to Internet voting, than electronic referenda could gain support as an untapped resource for furthering political participation.

Online voting could have a substantial impact on the greatest flaw of the suffrage: decreased turnout. In

addition, online voting might lower the cost of voting for those without adequate transportation. Though this would involve a significant change in the Internet usage rate among the poor in the United States, this mobilizing effect remains a possibility. If universal Internet access became a reality, the increased percentages of racial minority voters could help assuage the concerns of critics concerned about the protection of racial minority interests in an election. Finally, if electronic balloting is preceded by widespread "strong talk" and/or "deliberative polls" (Fishkin, 1991), this ongoing democratic conversation could substantially improve the quality of democratic dialogue and decision-making.

On the other hand, critics of Arizona's election, such as the nonprofit Voting Integrity Project and the National Commission on Federal Election Reform, believe online voting is not currently technically feasible (or, if feasible, would require violations of privacy that would be objected to by most Americans) (Phillips, 1999). Internet voting could also lead to discrimination against those without access to the Internet and opens up the possibility of election fraud (Phillips, 2000). Others argue that it erodes civil society by individualizing what used to be a community-based participatory act (Hansen, 2001). Though it seems evident that low-cost computers and Internet access might someday soon be universally available, that day is not yet here. Activist organizations and scholars continue to criticize online voting for its promotion of unequal opportunities in a participatory democracy.

In sum, low-cost computers and universal Internet access have the *potential* to revive the movement toward national referenda (Barber, 1984, p. 281), enhance democratic discussion, and increase voting turnout. However, the *reality* is far less certain. Most importantly, the Internet could make it even less likely that an individual will find it rational to participate. Anything that increases the size of the electorate will simultaneously decrease the probability that an individual vote will be decisive. More likely, however, the Internet will provide new channels for political organizations to *mobilize* citizens and increase participation. Only time will tell whether enhanced mobilization will equalize political influence, or only exacerbate existing inequalities, as current mobilization efforts do (Rosenstone & Hansen, 1993). Internet voting is coming to a computer near you in the next decade, but likely later rather than sooner.

The Mass Public in a Wired World: Old Wine in New Bottles?

In 1984, Barber imagined televised town meetings, which could allow citizens to become more involved in civic affairs. Today, his vision of a televised town hall could evolve into a teleconferencing meeting that could allow thousands to participate. The key is the technological capability and bandwidth to simultaneously stream unlimited numbers of audio and visual inputs into one electronic meeting room.

This is an alluring vision, but what is the reality of participation via the Internet? In electronic town halls, each participant in the electronic town hall must have the technological capacity—and desire—to participate. If town halls were *exclusively* electronic, than the universal availability of high-speed Internet service and fast computers would be a necessity in order to avoid barriers to participatory democracy. And if just the most politically interested entered this conversation, the dialogue would be just as biased toward certain segments of society as it was in the pre-Internet period.

Unfortunately for optimists predicting a participatory revolution fueled by the lower communication costs of the Internet, few studies indicate that the Internet will have any mobilizing effect—a force that makes political activists out of current nonactivists (e.g. Davis, 1999). Although the Internet may have reduced some costs of getting informed, it has not, as yet, increased citizen interest and motivation.

Furthermore, it is not clear that the Internet will necessarily serve as a force for citizen control. Lawrence Lessig notes that although the Internet as currently constructed is a venue for democratized information flow, there is no reason that it needs to be constructed in this way. It is just as likely, via control of *code*, that elites, corporations, and governments will use the Internet to monitor and control our daily lives. Our cyberidentities and cybercommunication are ultimately subject to the restrictions placed upon us by those who write the software and manufacture the hardware. In Lessig's view, the Internet may just as likely strengthen the hands of large, centralized corporations and governments. Witness the Communications Decency Act (CDA) in the U.S. and the many efforts by other governments (e.g., China, Singapore) to control the flow of information available on the Web (Lessig, 1999, 2002). Cass Sunstein points out that the very element of the Internet that many celebrate—individualized control over the interactive experience—could hamper political and civic life. A healthy democratic polity requires that we confront viewpoints that are opposed to our own. A personalized Internet experience, however, could result in reading only news that we agree with, participating in discussion forums with like-minded partisans, and learning about candidates for whom we are already inclined to vote (Sunstein, 2002). And there is no guarantee that the interest groups, news organizations, and other well-funded organizations that sponsor such "forums" or town meetings will allow dissenting voices. What sort of democratic polity would result from such a "personalized" world of political interactions? According to Bruce Bimber, the most likely outcome is "accelerated pluralism," where America's already fragmented political community becomes even more divided (1998). This is a worrisome vision.

Finally, would an electronic town hall be more effective and mobilize new participants in the political arena? A February 2000 article in *The San Francisco Chronicle* detailed the efforts of ActionForum (www.actionforum.com,) a new Web site in Berkeley, California, designed to promote increased civic and political discussions. The city wanted to boost its civic participation because only 418 of its 108,000 citizens spoke at city council meetings in 1999. The site, which consists of an upscale newsgroup bulletin board, received 75 postings in its first month of use. The *Chronicle* reported that most of the authors were familiar faces on the political participation circuit (Holtz, 2000).

Those who had the civic sense or personal motivation to participate via traditional methods simply reappeared in the new forum.

The general mobilizing effects of teleconferencing or high-speed Internet access seem nearly impossible to prove. Most studies to date, including the Pew Research Center for the People and Press's 1996 and 2002 studies, conclude that the Internet, thus far, acts more often as a "re-enforcement" agent, which merely changes the venue in which political participation takes place (Pew Research Center, 1996, 2002). Richard Davis points out that most political activities on the Internet are electronic analogs of activities carried out via older media such as television, newspaper, radio, and mail. In fact, Davis further argues that the Internet could lead to greater political apathy by providing a politically apathetic generation of young Americans with individually tailored, nonpolitical news (see Sunstein for a contrary viewpoint). However, the specific mobilizing or re-enforcement tendencies of high-speed Internet connections and audiovisual enhancements cannot yet be determined, because no strong evidence for either argument yet exists. These conclusions echo the findings of scientific studies of participation conducted over the past 30 years. Participation is skewed towards the well off, well educated, and politically motivated (Rosenstone & Hansen, 1993; Verba et al., 1995). New modes of participation, such as the Internet, are unlikely to change this state of affairs.

POLITICAL INSTITUTIONS: THE INTERNET AS A TOOL OF MOBILIZATION

"Intermediary" organizations—such as political parties, candidate organizations, interest groups, and the mass media—are not hampered by the logic of collective action or by the irrationality of political action. Quite the opposite: for these organizations (as well as for political candidates and entrepreneurs), the benefits of political activity outweigh the costs; otherwise they would not exist (Olson, 1971; Rosenstone & Hansen, 1993). It is no surprise, then, that it is among these pre-existing organizations that the Internet has proved to be a truly revolutionary force. The Internet is a tool to more efficiently and more cheaply communicate their positions to the mass public and mobilize citizens for political action. In this respect, then, the Internet will change mass democracies, not by transforming the public, but by transforming elites, making it easier, cheaper, and quicker for candidates to mobilize supporters and for interest groups to recruit members. Note that "elites" refers to a far broader segment of the population than just the moneyed or politically powerful. It may also include antiestablishment groups, such as the WTO activists, who very successfully organized via the Internet.

Campaign Use of the Internet

In the years between 1992 and 1996, campaign Web sites went from novelty to necessity. In 1996, Bob Dole concluded the second of his Presidential debates with Bill Clinton by plugging his campaign Web site. The era of the campaign Web site as an integral part of the campaign process had begun. Easy-to-follow guidebooks for setting up a campaign Web site are readily available (Democracyonline.org's "Online Campaigning: A Primer") and the Federal Election Commission has clarified the place of campaign Web sites in the campaign finance system (Corrado, 2000). By the 2000 campaign, virtually every candidate for federal office and many state and local candidates had a campaign Web site.

Recent elections have shown that the Internet is a new and important source of campaign funding (Thornburg, 2001). In the 2000 presidential election, Republicans George W. Bush and John McCain and Democrats Bill Bradley and Al Gore used the Internet to solicit funds, with McCain raising more than $500,000 the first day his Web site came online. Internet donations are a small part of overall campaign funding but they have the potential to become much larger, because of low cost and ability to target supporters. In most forms of solicitation, the more people the candidate wishes to reach, the higher the cost. However, there is very little difference in cost for a candidate having 10 or 100,000 people view a Web site. Similarly, the Internet provides a way for candidates to better target supporters. An example would be e-mail lists; they can be set up to better find those who support the candidate and are likely to give him or her money. Because it is so cheap and so effective, the Internet will make it easier for less well-known candidates, parties, and groups to make their voice heard in elections.

Early campaign Web sites, in many cases, were nothing more than electronic brochures, Web-formatted versions of the same leaflets that campaign volunteers had previously passed out on street corners. In short, politicians failed to produce "sticky" Web sites that increased the amount of time spent at a site and the frequency with which users returned to that site. In their study of both political and e-commerce Web pages, James Sadow and Karen James (1999) found that the political sites in 1996 and 1998 lacked the interactive elements that would make the sites more effective in drawing surfers and retaining interest. Citing several studies of e-commerce sites, their study claims that greater interactivity, defined as "the extent to which users can participate in modifying the form and content of a computer mediated environment in real-time," leads to more positive attitudes about specific Web sites and a greater ability to attract consumers (also see Ariely, 1998; Wu, 1999).

Two short years later, the world of the Internet campaign could not be more different. Few Web sites shy away from such interactive features today. Success stories such as those cited at the beginning of this chapter demonstrate the potential of the Internet as a tool for recruiting volunteers, controlling press coverage, and amassing a campaign war chest. More recent studies of campaign use of the Web demonstrate that the sites have become graphically rich and highly interactive, with significant issue content and an overwhelmingly positive tone (Greer & LaPointe, 2001). The "rational" campaign, today, is partially an Internet campaign.

Individualized Campaigns?

The ability to create an "enhanced" Web site is a double-edged sword. On one hand, building in audio and video

extensions increases stickiness and improves a page aesthetically. Likewise, added customizability allows site owners to tailor messages to a specific audience, be that audience political or commercial. With such advantages come tradeoffs, however, both in time and money and in heightened consumer expectations.

The incorporation of images, sound, and movies was described previously in emphasizing the democratization of new technologies for the purposes of discussion and debate. These same technologies tend to originate in the hands of those with a major Web presence: large and well-established interest groups, political parties, and their preferred candidates. Smaller interest groups, fringe political parties, and less well-funded political candidates have slowly followed suit. The same trickle-down trends have held for extensions of Web pages, such as message boards, chat rooms, and opinion polls. To enhance a site in these ways requires significant monetary investments for both site creation and maintenance. The sites are physically larger, consuming disk space, processor capacity, and bandwidth that previously were unneeded. Content creation requires yet more equipment as well as user training and the time inherent in recording, editing, and polishing. Finally, software packages for features such as message boards may be used "off the shelf," but typically customization is needed above and beyond installation (not to mention policing of posts and other clerical work). The payoff cited by Sadow and James in the commercial realm is tangible, but so are the expenses.

Customization is another dilemma altogether. As the drive to push campaigning online grows in coming years, candidates and interest groups will feel obligated to adjust their sites to the desires of each individual user (or at the very least each class of users). Business has already begun to deal with the pros and cons of customizing sites, and the experiences of such corporations are instructive for coming applications to the political sphere. J. Scott Sanchez, formerly employed by Procter & Gamble and now part of Intuit's Quicken team, notes that

> One of the long held goals of traditional marketers has been to send the right message to the right person, since every consumer tends to have a slightly different view of things. In the past, this was impossible and marketers just relied on mass advertising to try to get a consistent message to as many people as possible. However, with the advent of the Internet, it will now be possible to tailor messages to specific individuals. (Sanchez, 2000)

Replace the word "consumer" with "voter" and "marketers" with "campaign workers" and it yields an equally compelling message.

The promise of customization is one of the driving forces behind numerous online ventures, from Internet portals (My Yahoo) to music sites (My.MP3.Com). Often in registering for a custom site a user will provide the site owner with marketing information such as an e-mail address as well, adding to the allure. Although Sanchez notes that "the message is perfectly targeted and its effectiveness rockets upwards," he also points out that "one of the interesting repercussions of this individualized marketing, however, is that companies now may be held more accountable for their promises. Because individuals are receiving a tailored e-mail that promises to do a certain task in a certain way, such as 'gets the whites whiter,' consumers may feel betrayed if it does not." Again, a parallel exists in politics. Cass Sunstein, a legal scholar at the University of Chicago, worries about the customization of our Internet experience, because we are not forced to confront opinions and ideologies different from our own (Sunstein, 2002). Personalization of campaigns is problematic for campaigns as well. Although it does allow a custom message to be delivered to a potential voter, a politician or interest group opens the door to conflicting or at mutually nonsatisfiable promises. After all, one of the main reasons for political parties and elections is that people are forced to choose among "bundles" of less than ideal, yet feasible, alternatives. In the individualized world of the Internet, everyone might feel that government must satisfy his or her particular bundle of desires. The result, according to one observer, could be "accelerated pluralism," a further breaking down of coherent political communities (Bimber, 1998).

Thus, candidates have found the Internet to be a viable source for recruitment, campaign fundraising, and mobilizing voters. The Internet, then, may empower individuals, but only if they are the sort of individuals that candidates wish to reach. Furthermore, even if candidates, by using the Internet, motivate far more citizens to participate, the individualization of the Internet experience may result in an electorate that is more polarized and pluralized than at present.

Interest Groups and Political Parties on the Web

The Internet thus far has revolutionized commerce, as well as much of day-to-day social interaction. The capability of the Internet to act as a post office and an interactive, worldwide accessible bulletin board, as well as a real-time source of information, will likely impact the political arena in important ways. Beyond political candidates, the role of intermediary groups in politics is likely to be affected dramatically simply because the essence of the Internet lies in its potential to connect. Intermediary groups, organizations who act as the connecting tissue between the mass public and the governmental elite, are the political players most likely to benefit from the convenient tools for communication and organization that the Internet makes readily available.

The Internet lowers the cost of communication. There are a number of regular chores the Internet makes easier and faster. Because of the low transaction costs, some have claimed that the Internet will result in a more even playing field between interest groups with abundant resources and those with much less. Indeed, some have even gone so far as to say that the Web is "potentially the greatest thing since the postal system and the telephone for political groups" (Hill & Hughes, 1998, p. 133). Others however, have claimed that, although the Internet may make things cheaper overall, there are still prohibitive costs, and there, as everywhere else, resources still matter. Regardless, the

spread of the Internet has already affected the way that interest groups conduct their activities and will continue to do so in the future.

The importance of fundraising for any interest group is readily apparent; groups require financial support to continue operating. As Richard Davis notes, "[g]roups have formed in competition with each other, but they are not guaranteed equal voices or shares in power . . . (m)ost policy maker attention is centered on groups who possess substantial resources" (Davis, 1999, p. 81). Fundraising can take a variety of forms, especially with regard to groups dependent on businesses or other special parties for support. This fundraising carried out by interest groups is a type of direct mobilization, where political leaders communicate directly with citizens and provide an opportunity for political action. A request for members to volunteer time to support the organization is one common example of this. Another important way direct mobilization occurs is in the basic task of educating the public and the group's members along with informing them of news and events related to the group. This process is vital because an informed membership is more likely to care about the group's issues and actively support the group in some way.

Other types of direct mobilization include requests to sign petitions and write letters to political representatives. These efforts to encourage individuals to contact the government, described as "outside" lobbying by Ken Kollman or "grassroots" lobbying by Mark Petracca, constitute an important tactic for interest groups to use to achieve results. Kollman argues that this outside lobbying performs the dual tasks of "communicat[ing] aspects of public opinion to policymakers" and "influenc[ing] public opinion by changing how selected constituents consider and respond to policy issues" (Kollman 1988). Petracca (1992) emphasizes its widespread use, stating that "interest groups across the political spectrum now pursue grassroots lobbying with a vengeance." In this way, interest groups encourage direct contact between their members and government to further their own ends.

Because communication is so central to an interest group, this has the consequence of making its main cost the cost of communication. The traditional methods of mass media advertising, telephone campaigns, and mass direct mailings all incur significant costs to the group performing them. The potential of the Internet, then, becomes clear. The difference in cost between 1,000 and 100,000 people reading an informative Web site put up by an interest group is most likely trivial (due to bandwidth charges) or zero; however, the cost of printing and mailing 100,000 brochures is presumably much higher than that of doing so for only 1,000. Thus interest groups can reach a much larger audience without incurring higher transaction costs through use of the Internet.

A similar logic can be applied to member responses to group requests as well as member communication to a group or the government in general. Well-written form letters can be sent online with the mere click of a button. People would (generally) like to spend less time on the task and therefore prefer the easier online method. This can be extended to essentially all exchanges that take place between a member and a group: joining, donations and sales, getting current news and events, and providing feedback to the group.

The Internet also presents the opportunity for groups to make communication between and among members easier. Web forums and online services, such as electronic greeting cards, enable Web sites to develop a community made up of regular visitors to the site. Fronting the resources necessary for this effort can pay off for the interest group as well, because these new social networks will discourage members from quitting, encourage members to be active, and possibly even attract new members, as entrance to this online community becomes another type of solidary incentive (Olson, 1971).

In summary then, an interest group's or political party's success is affected significantly by three types of communication: group-to-member, member-to-group, and member-to-government. Also, the interest group can help itself by encouraging social networks among its members, or member-to-member interaction. The Internet has the potential to greatly decrease the transaction costs for all of these types of communication.

This suggests that interest groups should and will pursue online options for their activities. This capability of the Internet to decrease costs and provide alternative methods of communication is precisely what gives it huge relevance to politics. So, in theory, Internet usage is a valuable pursuit for interest groups in a variety of ways. However, the issue of efficiency is still largely ignored. The common thinking goes that, because Web site construction and Internet use are relatively cheap, then if such efforts produce any results, they must be worthwhile. With these low production costs, it should be expected that there would be roughly equivalent Web usage across interest groups with different budgets. Or if differences in breadth of group interests are considered, then there should be at least no direct correlation between a group's budget and its Web presence, as the whole concept is that the low cost enables any group to provide as large an online presence as it desires.

As with studies of campaign communications, however, there are few up-to-date studies of the efficacy of interest group and political party activities on the Internet(although see the studies conducted for the author by Tang and Looper [1999] and Casey, Link, and Malcolm [2000] available online at http://www.reed.edu/~gronkep/webofpolitics). It is clear that the Web sites are being created, but at what cost and for what impact? Can interest groups enhance democratic politics by substantially increasing political participation? Those few studies that have been conducted examine political party Web sites and conclude that established interests dominate this new medium as they did traditional avenues of political competition (Gibson & Ward, 1998; Margolis, Resnick, & Wolfe, 1999). No comparable studies of interest group sites have been conducted. For now, the question remains open.

The Hotline to Government? The Internet and Direct Democracy

Imagine that a federal agency such as the Environmental Protection Agency is holding a hearing on a new set of

regulations in the year 2010. Rather than simply scheduling a public comment session in Washington, anyone is allowed to register opinions via Internet teleconferencing. Local citizens, concerned politicians, and informed observers play on a level playing field with the moneyed interests and high-powered lobbyists who so often seem to dominate federal decision making.

Alternatively, imagine a world (already in place) where broadband could provide the electorate insider access to all levels of government. C-SPAN already provides gavel-to-gavel coverage of congressional debates and hearings. Audiovisual technologies might replace e-mails to a congressman, which usually receive an automatic response reply, with short question and answer sessions conducted live over Internet teleconferencing (with a congressional aide, if not with the congressman himself).

The most groundbreaking aspect of the Internet might be the ability of citizens to express their opinions *directly*, bypassing parties and interest groups. Political scientists have long realized that citizens vary in their preference for different "modes" of political participation. Some vote, others attend rallies, still others prefer to write letters. This is precisely what we would expect when individuals vary so much in their access to political resources and their integration into social networks (Rosenstone & Hansen, 1993). What difference might the Internet make? In a wired world, it is far easier (perhaps too easy) to dash off an e-mail to a member of Congress or offending bureaucrat. At the same time, just as members have had to contend with reams of postcards generated by grassroots lobbying efforts, universal access to e-mail is likely to reduce its impact. Ironically, then, the Internet and e-mail have made the old-fashioned handwritten and signed letter far more effective, simply by contrast.

Are these visions likely to become a reality? Due to the stipulations of the 1974 Administrative Procedures Act (A.P.A.), these agencies are obligated to hear from everyone who would like to speak on an issue facing the agency prior to the agency's ruling. The procedure further states the agency must take all arguments into account when rendering a ruling and provide reasons for its decision. Currently, speaking before an agency like the E.P.A. carries the high costs of a trip to Washington D.C. With the advent of e-mail and the World Wide Web, citizens can easily collect information and express their opinions on new regulations and public laws. Once the aforementioned technological enhancements become commonplace, it may even be possible for "teletestimony" to be given at congressional hearings and agency public comment sessions.

Some optimists, such as Andrew Shapiro, further predict that individualized *control* over the means and modes of contact with government will empower individuals (Shapiro, 1999). As Kevin Hill and John Hughes point out, the Internet's low costs have created tremendous new opportunities for fringe groups seeking to become more recognized. A fringe political group with limited resources can create a Web page that differs little in quality from a Web site for a well-financed political party (Hill & Hughes, 1998, p. 134). This logic also applies to fringe group participation in local, state, and federal political activities. Via Internet teleconferencing, a radical environmentalist group operating on a budget of $10,000 a year could afford to present its ideas before the E.P.A. in the same manner as the Sierra Club.

In addition to fringe groups, teleconferencing also aids those political activists confined by the costs of mobility. This group includes stay-at-home mothers and fathers, senior citizens who are unable to travel without assistance, and the disabled. Assuming that a person in one of these groups was politically motivated yet constrained by his or her situation, teleconferencing could mobilize that citizen by allowing him or her to participate. In theory, the mobilizing effects of ubiquitous high-speed Internet access and enhanced audio/visual capabilities could create an even more powerful lobbying force for organizations such as the A.A.R.P. or women's rights movements, assuming that these organizations are stripped of some influence by "immobile" members who might otherwise directly participate in lobbying, protesting, or debating before a governmental body.

CONCLUSION

E-commerce was supposed to revolutionize the business world, making "bricks" a thing of the past. The post-Internet hangover has demonstrated the importance of the "old rules" of investment and the preference among consumers for bricks over clicks. Similarly, the "old rules" of politics, the basic relationships between individual motivations, organizational effort, and political action, have remained stubbornly resistant to the lure of computer revolution. Picnics and pig pickin's, state fairs, and outdoor rallies remain an important part of the "retail center" of American politics. Most candidates still spend the vast bulk of their advertising dollars on traditional media outlets (television, radio, and newspapers) or direct mail contacts, rather then choosing to contact voters via the Internet. Most political parties continue to spend tens of millions of dollars each campaign cycle on traditional political activities, such as voter registration drives, political canvassing, and "get out the vote" efforts. Even so-called "high-tech lobbying" efforts (West & Loomis, 1998), although taking full advantage of electronic technologies in order to educate citizens and mobilize participants, continue to focus their efforts on traditional media outlets, grassroots organizing, and old-fashioned lobbying in the halls of the Capitol.

The Internet *has* become a central tool for mobilization efforts by political organizations, as the rational choice approach to voting would predict. The individual has little incentive to get involved politically, but organizations have great incentives to mobilize. The increase in electronic mail and Web access, the growth in broadband access, and the seeming inevitability of Internet commerce, has opened up a new frontier for both citizens and elites. Enhancements in audiovisual capabilities could lower the costs of participation for groups that previously could not overcome the high costs of transportation to Washington. Candidates could attract new political participation via "stickier" Web sites. The promise of online voting remains unproven, but given the rapid expanse of Internet access and computer ownership, online voting and referenda could mobilize previously underrepresented portions of the population.

Yet, although the "new political machine" holds the potential for a more democratized and decentralized political system, to date it has primarily reinforced preexisting biases in political participation and influence. The Internet has not changed significantly the way we have understood mass democracy for over 200 years (Bimber, 1999). Changes in the means of participation will constantly evolve to match the most current technology available; anticipating changes in the number and type of people who participate will continue to be an unpredictable science.

GLOSSARY

Collective action problem A situation where individuals choose not to work toward the provision of a public good because the costs to them individually exceed the benefits which they receive, so that no one participates in the provision of public goods.

Deliberative polling A survey polling technique promoted by James Fishkin, where poll respondents participate in an open discussion for a period of time before choosing options.

Grassroots lobbying Lobbying efforts that focus on stimulating activities by citizens, such as formation of local groups, letter-writing, and e-mailing.

Individualization The ability of an Internet user to individualize or personalize his or her news-gathering experience. Also referred to as "customization" and "personalization."

Intermediary organizations Organizations, such as political parties or interest groups, that stand in between the mass public and government.

Mass public Contrasted with elites, the mass public comprises the vast bulk of the population.

Mobilization Efforts by organizations and individuals to stimulate and encourage political involvement and participation.

Modes of political participation The varied ways that citizens may choose to influence government, including campaigning, writing letters, joining groups, and protesting.

Netizens Term used to describe "citizens" of an Internet community.

Political elites Contrasted with the mass public, elites are that segment of the population that is better informed, educated, and interested in politics. Sometimes used to describe decision makers.

Political machine Tightly organized political organizations that tend to exchange benefits (jobs, social welfare) for votes; existed in many American urban areas in the early 20th century. Also sometimes described as "boss politics."

Public good A good such that if it is provided to anyone in a group, it must be provided to everyone in a group (e.g., national defense, clean air). Public goods often suffer from the collective action problem.

Rational choice Theory of individual action that assumes goal-seeking behavior, while maximizing benefits and minimizing costs.

Rational ignorance Assumption that some individuals will choose to ignore political events, news, and the like because the costs of being informed exceed the benefits from such information.

Referendum Election format where voters choose among a set of legislative options; also described as "direct democracy" and "initiative government." Common in the Western United States.

Solidary incentive The feelings of belonging and community that accrue to those who join a group working to provide public goods.

Stickiness Characteristic of a Web site that encourages viewers to remain on that site.

Strong talk Theory of democracy promoted by Benjamin Barber that encourages high levels of citizen discussion, deliberation, and participation.

Social capital The web of social and personal relationships that encourage participation in community and civic affairs.

Town meetings Form of political decision making where the members of a community gather together, discuss options, and vote on alternatives.

Virtual community Contrasted with physical communities, which are defined by geographic space, virtual communities exist in virtual or cyberspace.

Privacy Law

Ray Everett-Church, *ePrivacy Group, Inc.*

INTRODUCTION

Understanding privacy is a true challenge, in no small part because of the difficulty in defining the concept of privacy itself. The textbook definition of privacy only begins to scratch the surface of a deeply complex issue, made all the more complex because of the strong personal feelings evoked by privacy breaches. Accounting for privacy concerns can be a daunting task, especially when one is building Internet-based services and technologies for which success can depend on not offending consumers' mercurial sensibilities about the value of their privacy versus the value of those services that depend on free-flowing personal data.

This chapter discusses the roots of privacy law, including the various ways that privacy matters are dealt with under constitutional law, statutes, and common law. With the fundamentals established, the rest of this chapter discusses how many of those principles have come to be applied in today's Internet-oriented privacy terrain and how businesses must prepare for doing business in this new environment.

PRIVACY LAW BASICS

Privacy Defined

The *Merriam-Webster Dictionary of Law* defines privacy as "freedom from unauthorized intrusion: state of being let alone and able to keep certain especially personal matters to oneself." Within this broad "state of being let alone," particular types of privacy intrusion have been recognized under law. How one defends oneself against intrusions differs, however, based on who is doing the intruding.

Constitutional Privacy

Even though one will find no trace of the word "privacy" in the U.S. Constitution, a series of Supreme Court decisions beginning in the 1920s began to identify the modern concept of privacy. As the court refined its views on the subject, it found the idea of privacy within the spirit of the Constitution's protections, if not in the plain language of the document. In 1928, in a landmark wiretapping case (*Olmstead v. United States,* 1928), Supreme Court Justice Louis Brandeis articulated the following ideas in some of the most important words ever written about privacy:

> The makers of our Constitution undertook to secure conditions favorable to the pursuit of happiness. They recognized the significance of man's spiritual nature, of his feelings and of his intellect. They knew that only a part of the pain, pleasure and satisfactions of life are to be found in material things. They sought to protect Americans in their beliefs, their thoughts, their emotions, and their sensations. They conferred, as against the Government, the right to be let alone — the most comprehensive of rights and the right most valued by civilized men. (Brandeis dissenting, *Olmstead* at 478)

Brandeis's phrase "the right to be let alone" is one of the most often-repeated ideas in privacy and has influenced the court's inquiry beyond the plain words of the Bill of Rights to find other privacy rights that are logical extensions of the meaning contained in the original words, including the following:

- The First Amendment right of free speech has been read to include the right to speak anonymously. Free speech has also been interpreted in reverse: You have the right to not be forced to say certain things.
- The First Amendment right of free association means that you can join clubs and affiliate yourself with anyone you choose. Inherent in that right, according to the

court, is the right not to say with whom you're associating.
- The Fourth Amendment prohibits the government from searching your home and property and from seizing your papers or possessions, except under very specific circumstances. The Fourth Amendment has also been read to give certain rights against government wiretaps and surveillance.
- The Fifth Amendment includes various rights of due process, which means that if the government is interested in depriving you of any of your rights—throwing you in jail, for example—it must first follow strict procedures designed to protect your rights. Among those is the right against being forced to incriminate yourself.

The equal protection clause of the Fourteenth Amendment requires that both sexes, all races, and all religions be given equal protection under all the laws of the United States and all the laws of every state. This protection comes despite other amendments that can be read to permit some types of discrimination. These rights aren't absolute, however. For example, consider the following:

- The government can set up wiretaps, perform surveillance, and perform searches and seizures if it has reasonable belief ("probable cause") that a crime has been committed and if given permission (a "warrant") by a judge.
- The government can establish secret wiretaps and surreptitiously search your home or car, without a normal warrant, if you are suspected of being a terrorist or an "agent of a foreign power."
- Certain sexual activities, even between consenting adults in the privacy of their bedroom, can be illegal.
- It can be illegal to keep certain materials in your home, such as drugs or child pornography.
- Certain public organizations (such as the Jaycees, which was the subject of a lawsuit that established this precedent) cannot use the First Amendment right of free association to exclude protected classes of people, such as women or certain minorities. On the other hand, at the time this book was written, the Boy Scouts could discriminate against gay people.

But the Constitution only affects privacy issues involving the government. What are your rights against people who are not part of the government, such as individuals and corporations? That's where a patchwork of common-law privacy protections and several statutes comes into play.

Common-Law Privacy

The common law is a set of rights and obligations first recognized by courts rather than by legislatures. Just because it is "judge-made" law, however, one cannot discount the common law as being less forceful. In fact, many common-law rights have been enforced for centuries and are some of the most powerful precedents in our legal system. They are rarely overturned by legislatures, and many state and federal laws are simply codifications of common-law ideas that have been around for hundreds of years.

In a groundbreaking law review article in 1960, William Prosser set out four broad categories of common law that underlie privacy-related torts:

- Intrusion into one's seclusion,
- Disclosure of private facts,
- Publicizing information that unreasonably places one in a false light, and
- Appropriation of one's name or likeness.

Intrusion

The tort of intrusion recognizes the value of having your own private space and provides relief from those who would seek to violate it. Eavesdroppers and "peeping toms" are two examples of activities considered intrusion.

Disclosure

The tort of disclosure recognizes that making public certain private facts can cause harm to an individual. For example, disclosures about someone's health status, financial records, personal correspondence, and other kinds of sensitive personal information can cause harm if made public.

False Light

The tort of false light is similar to libel in that it involves publicizing falsehoods about someone, but it is subtly different. One famous case of false light, *Cantrell v. Forest City Publishing Co.* (1974), involved a family who was inaccurately portrayed in a news article in a humiliating fashion that brought shame and embarrassment. Another, *Douglass v. Hustler Magazine* (1985), involved a model who posed nude for a popular pornographic magazine, which were instead published with embarrassing captions by a notoriously vulgar magazine instead.

Appropriation

This tort involves using the name or likeness of someone for an unauthorized purpose, such as claiming a commercial endorsement by publishing someone's image (or even that of a look-alike impersonator) in an advertisement.

In this age of modern technology, there appear to be many new ways of violating these centuries-old privacy torts. The prevalence of miniature "Web-cams," highly sophisticated digital photo editing applications, and the vigorous online trade in pornographic imagery, have each added to the ways in which individual privacy can be violated.

PRIVACY LAWS IN THE UNITED STATES AND ABROAD

In a 1973 report to Congress, the U.S. Department of Health, Education and Welfare (HEW) outlined four tenets of fair information practices. These guidelines were groundbreaking in that they set forth four characteristics that any fair policy regarding the collection and use of

personal information had to take into account. The four tenets were as follows:

1. *Notice*. Details of information practices and policies should be disclosed to data subjects.
2. *Choice*. Data subjects should be given the ability to exercise choices about how data may be used or disclosed.
3. *Access*. Data subjects should be permitted access to data gathered and stored about them.
4. *Security*. Holders of personal data should be responsible for providing reasonable levels of security protection for data in their possession (HEW, 1973).

Since then, there have been a number of laws enacted in the United States dealing with individual privacy. The standard U.S. approach is, however, to focus on particular types of information used by or about specific sectors:

- *Banking records.* Your personal banking information is protected by law, up to a point, including under provisions of a new law called the Financial Services Modernization Act (also known by its authors as the Gramm–Leach–Bliley Act).
- *Credit reports.* The Fair Credit Reporting Act (FCRA) require that credit bureaus handle your data in certain ways.
- *Medical and Health Insurance Records.* Laws and regulations governing how medical records can be used have been in place for several decades, and provisions of a new law called the Health Insurance Portability and Accountability Act (HIPAA) are creating new rights for patients to protect and access their own health information (U.S. Department of Health and Human Services, 2002).
- *Government records.* The Privacy Act of 1974, which included the original tenets outlined in the HEW report, sets limits on how government agencies can collect and use personal information, whereas laws like the Freedom of Information Act of 1966 require government to give all citizens access to certain government records, provided that the government also take precautions not to breach privacy when making that information public.
- *Children's Privacy.* Although not limited to one business sector, a law called the Children's Online Privacy Protection Act of 1998 (COPPA) places restrictions on online organizations that seek to collect data from one sector of the public: children under the age of 13. COPPA requires the publication of a privacy policy to explain data practices relating to children's information, requires verifiable parental consent before any personally identifiable information may be collected from children over the Internet, and limits companies ability to share children's information with third parties.

International Privacy Law

The recognition of privacy rights in international law goes back to December 10, 1948, when the United Nations (UN) adopted the Universal Declaration of Human Rights. Article 12 of that document says, "No one shall be subjected to arbitrary interference with his privacy, family, home or correspondence, nor to attacks upon his honour and reputation. Everyone has the right to the protection of the law against such interference or attacks" (UN, 1948).

Building on that foundation and applying the four tenets articulated in 1973 by the U.S. government, in 1980 the multinational Organization for Economic Cooperation and Development (OECD), of which the United States is a member, issued its eight Principles of Fair Information Practices. These principles consisted of the following:

- *Collection Limitation.* There should be limits to the collection of personal data, and any such data should be obtained by lawful and fair means and, where appropriate, with the knowledge or consent of the data subject.
- *Data Quality.* Collection of personal data should be relevant to the purposes for which they are to be used and, to the extent necessary for those purposes, should be accurate, complete and kept up-to-date.
- *Purpose Specification.* The purposes for which personal data are collected should be specified not later than at the time of data collection and the subsequent use limited to the fulfillment of those purposes or such others as are not incompatible with those purposes and as are specified on each occasion of change of purpose.
- *Use Limitation.* Personal data should not be disclosed made available or otherwise used for purposes other than those specified in accordance with principle of purpose specification, unless done with the consent of the data subject or by authority of law.
- *Security Safeguards.* Personal data should be protected by reasonable security safeguards against such risks as loss or unauthorized access, destruction, use, modification or disclosure of data.
- *Openness.* There should be a general policy of openness about developments, practices, and policies with respect to personal data. Means should be readily available of establishing the existence and nature of personal data, and the main purposes of their use, as well as the identity and usual residence of the data controller.
- *Individual Participation.* An individual should have the right to obtain from a data controller confirmation of whether data is held about the individual, to be given access to the data in an intelligible form, and to have the data erased, rectified, completed or amended.
- *Accountability.* A data controller should be accountable for complying with measures that give effect to the principles. (OECD, 1980)

The European Union has taken the OECD principles and incorporated them into a sweeping Data Privacy Directive that establishes these principles in law. The directive mandates the following minimum standards in all countries that are members of the European Union (EU):

- Companies can only collect information needed to complete the transaction, and must delete it after the transaction is over, unless they have explicit permission.

- Consumer's personal information must be kept up to date, or deleted.
- The purpose for collecting data must be given at the time that data is collected.
- An individual's personal information cannot be used for any other purpose (such as mailing catalogs or coupons) unless a company has explicit permission.
- Companies must have appropriate security safeguards in place to guarantee privacy of any data in their possession.
- Companies must keep consumers advised in a clear and open manner about their data practices and how consumer's privacy will be impacted by any changes.
- Consumers must be permitted to see any information a company has on file about them, must be permitted to correct any errors, and must be allowed to delete data unless there's a legally mandated reason for keeping it.
- Companies who keep consumer information must have someone in the company accountable for ensuring that the privacy laws are being adhered to.
- Companies may not transfer data outside of the EU unless the country to which the data is being transferred has privacy laws as strict as those in the EU (European Commission, 1995)

It should also be noted that these restrictions apply to all data in a company's possession, whether customer data or employee data. And these are minimum standards; individual member countries can—and have—enacted laws that are even stricter. To enforce their privacy laws, many EU member countries have established data protection authorities—government agencies whose mandate is the policing of data practices within, and crossing, national borders. These authorities often require corporations who possess personally identifiable information about any citizen of their nation to register with the agency and file detailed statements of what data is collected and how it is used.

In addition, whereas U.S. law focuses on certain categories of information, such as financial or healthcare data, holders of the data such as credit bureaus, or categories of data subjects such as children, the EU law gives special consideration to data about

- Race,
- Religious affiliation,
- Membership in political parties and trade unions, and
- Criminal records.

These topics are of particular concern to Europeans, in part because of how records containing information about race, religion, and trade union memberships were gathered and used by the Nazi regime in Germany and in its occupied countries to decide who should be shipped off to concentration camps. For Europeans, the threat of private information being misused is more than a test of wills between marketers and consumers, but has meant the difference between life and death for the parents and grandparents of today's European lawmakers.

Cross-Border Data Flow

The issue of cross-border data flow has been particularly vexing for U.S. corporations, especially given the number of Internet-based firms with operations in the European Union that depend upon data flows from the EU back to the United States. Because the United States does not have broad privacy-protecting statutes on par with the EU, U.S. corporations face the prospect of being unable to communicate customer data, or even personnel records, back to U.S.-based facilities.

Recognizing the potential for numerous disputes, the United States and EU entered into a series of negotiations in the late 1999 and 2000, culminating in an agreement to create a Safe Harbor program. This program permits U.S. corporations to assert their adherence to an array of basic privacy requirements, with the assumption that those who certify compliance and bind themselves to enforcement measures in the event of misbehavior will be permitted to continue transferring data from the European Union into the United States (DOC, 2000).

BALANCING PRIVACY AND LAW ENFORCEMENT

In post-September 11 America, a great deal of public concern centers around the extent to which new antiterrorism intelligence-gathering will negatively affect the privacy of average citizens. Although few individuals will ever believe they merit the kind of surveillance activities implemented for mafia dons, drug kingpins, or terrorists, many are concerned that ubiquitous surveillance capabilities will result in less privacy for everyone, average citizens and mafia dons alike. Therefore, it is appropriate to discuss briefly the kinds of issues raised by increasing surveillance capabilities and to discuss a number of programs and laws that are adding to the pressures on personal privacy. More significantly, given the extent to which American business is increasingly becoming the repository of detailed information about the lives and business transactions of individuals, it is also appropriate to discuss how businesses are increasingly being called upon to aid law enforcement in their investigatory efforts, and why businesses need to exercise some judgment in deciding when and how to comply with law enforcement requests.

Surveillance, searches and wiretaps raise extremely complex legal and technical issues that are impossible to cover in this brief space. Should these issues arise in your personal or professional activities, it will not be possible for you to deal with them without the assistance of qualified legal counsel. There are, however, some things to keep in mind that will help you to understand how an organization may be affected.

Most domestic wiretapping is governed by the Electronic Communications Privacy Act of 1986 (ECPA). In addition, the Foreign Intelligence Surveillance Act of 1978 (FISA) governs wiretaps and surveillance of those considered "agents of a foreign power." Both ECPA and FISA were modified, clarified, and in some cases expanded significantly, by the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and

Obstruct Terrorism Act of 2001, or USA PATRIOT Act for short.

ECPA

ECPA generally prohibits providers of communications services (e.g., Internet service providers) from disclosing the contents of an electronic communication, whether it is in transmission or in storage, to any person other than the intended recipient. ECPA also contains a number of exceptions, however, some of which include the following:

Service providers may make disclosures to law enforcement if proper warrants are presented. ECPA explains those procedures in some detail.

ECPA's limitations only apply to services offered to the public, not to operators of, for example, an internal corporate system.

ECPA does not restrict the collection, use, or disclosure to nongovernmental entities, of transactional information such as email addressing and billing information.

Disclosures to private parties pursuant to subpoenas issued by civil courts may also be permitted.

In addition, ECPA permits the government to request "dialing and signaling" information from telephone companies. Under these so-called "trap and trace" orders, law enforcement can use devices known as "pen registers" to capture the numbers being called and other information about the communications, short of the actual contents of the calls themselves. The contents of the calls can also be gathered, but only under a separate warrant that requires much more rigorous procedures and additional judicial review.

FISA

In cases in which information is sought about the activities of agents of foreign powers, such as terrorists or spies, law enforcement may seek disclosure of information relevant to an investigation through a special warrant procedure. There are two noteworthy differences between standard warrants and FISA warrants: First, FISA creates a system of special "FISA courts" in which judges meet, hear evidence, and issue warrants in total secrecy. Second, FISA warrants are much more sweeping than normal warrants and are not required to meet the same evidentiary standards as normal warrants. These differences raise significant Constitutional questions that have been raised in recent challenges to the activities of the FISA courts. Ironically, the FISA courts themselves have not been oblivious to the questions their seemingly unchecked powers have raised: A recently released decision of the FISA appeals court—the first document ever released publicly by the body—cited dozens of cases in which law enforcement provided deceptive or outright false information to the court in support of wiretap applications. Appealing to the U.S. Supreme Court, the Bush administration successfully overrode the FISA appeals court's objections to expanded wiretap procedures (EPIC FISA Archive, 2003).

Concerns about state-sponsored collection of data about individuals are nothing new. Privacy watchdogs and investigative journalists have widely publicized programs such as the FBI's "Carnivore" (a device for intercepting and recording Internet-based communications; EPIC Carnivore Archive, 2001), "Magic Lantern" (a piece of software that can be surreptitiously installed on a targeted computer, allowing law enforcement to capture every keystroke; Sullivan, 2001), and the rumored international wiretapping consortium called "Echelon" (EU Parliament, 2001).

Most recently, the U.S. Department of Defense sought funding of an antiterrorism program called "Total Information Awareness" which would have compiled electronic records on nearly every business, commercial, and financial transaction of every U.S. citizen. The massive database would then be analyzed in an effort to uncover transactions and patterns of behavior that could be deemed suspicious. Although the Total Information Awareness program was stripped of most of its funding by Congress in early 2003, the Department of Defense has vowed to keep researching the issues and technologies needed to undertake such a program (EPIC Total Information Awareness Archive, 2003).

Business Issues Under Wiretap Laws

The wiretap activities under ECPA and FISA have until recently been relatively limited in their effects on businesses. Aside from telephone companies and some Internet service providers, few businesses were affected by these procedures. Under recent changes to FISA made by the USA PATRIOT Act, however, law enforcement is now permitted to request business records from nearly any business to assist it in foreign intelligence and international terrorism investigations.

Previously, FISA only allowed law enforcement to request business records from certain categories of businesses, such as common carriers, hotels, and car rental facilities. Under the new rules, subpoenas can be issued without limit to particular categories, including banks, retailers, and any other entity within the government's reach. The USA PATRIOT Act also expanded the search and seizure from merely "records" to "any tangible things," such as computer servers.

The pen register and trap–trace provisions of ECPA have been expanded under the USA PATRIOT Act to add "routing" and "addressing" to the phrase "dialing and signaling," making it clear that these activities now include Internet traffic, not just telephone calls. The act does specify that the information retrieved through this process "shall not include the contents of any communication." There will undoubtedly be significant litigation in coming years to define where the dividing line falls between "content" and "addressing." For example, entering a search term or phrase into a search engine may cause the content of that search to be embedded in the address of the Web page on which the results are displayed.

PRIVACY ISSUES FOR BUSINESSES

In a widely published 2000 survey of more than 2,000 U.S. corporations, the American Management Association (AMA) discovered that 54% of companies monitor their employees' use of the Internet, and 38% monitor their employees' e-mail. In a follow-up survey in 2001, the percentage of companies doing Internet monitoring

rose to 63%, with 47% monitoring e-mail (AMA, 2001).

The rise in monitoring tracks with the rise in potential problems that can flow from providing access to the Internet. Along with the ability to work more efficiently, companies are now finding themselves held responsible when bad things find their way onto employees' desktops. In the same AMA study, 15% of the companies surveyed have been involved in some kind of legal action concerning employee use of e-mail or Internet connections. In several noteworthy cases, companies have been held liable for sexual harassment-related claims from harassment occurring over employer-operated message boards, employees leaving pornographic images on computer monitors, employees distributing sexually explicit jokes through office e-mail.

In response to these concerns, many companies have installed filtering mechanisms on their e-mail traffic looking for unacceptable language. Other companies have implemented software that blocks pornographic Web sites. Still others have opted for the low-tech approach of implementing zero-tolerance policies regarding the use of office computers for anything inappropriate.

Unfortunately, in some instances, these measures have resulted in confusion or wound up creating problems for both innocent and not-so-innocent people. For example, it was widely reported in 1999 that 23 employees of the *New York Times* were fired for trading dirty jokes over the office e-mail system (Oakes, 1999). Yet in other cases, recipients of unsolicited e-mail have opened the fraudulently labeled mail and been subjected to a barrage of pornographic images and salacious Web pop-up ads (Levine, Everett-Church, & Stebben, 2002).

Because Web monitoring logs and filtering systems may not be able to differentiate between Web pages viewed accidentally and those viewed purposefully, innocent workers can (and have) been left fearing for their jobs. For these reasons, companies are beginning to adopt internal privacy policies that help set better guidelines and establish reliable procedures for dealing with trouble when it arises.

Employee Privacy Policies

In most circumstances, there are few legal restrictions on what employers can do with their own computers and networks, up to and including monitoring of employee's communications. Although some firms quietly implement employee monitoring policies and wait to catch unsuspecting employees in unauthorized activities, many firms give notice to their employees that they may be monitored. Still others require employees to relinquish any claims of privacy as a condition of employment.

Increasingly, however, companies are recognizing the negative impact of paternalistic monitoring practices on employee morale. So to engender trust rather than inspire fear, increasing numbers of firms have begun providing their employees with privacy statements in their corporate employee handbooks or by publishing policy statements on internal Web sites. According to the AMA's 2001 survey, four out of five respondent firms have a written policy for e-mail use, and 77% for Internet use, 24% have training programs to teach these policies to employees, and an additional 10% plan one (AMA, 2001).

As noted earlier with regard to the European Union's Data Privacy Directive, companies with operations in the EU are already familiar with the mandate to provide data subjects—in these cases, employees—with information about the company's data-gathering and usage policies. Although there is currently no U.S. equivalent to these requirements, a growing number of firms are proactively recognizing that a well-defined set of privacy policies and practices can avoid misunderstandings and can even provide the basis of a legal defense in cases where companies are accused of failing to act on claims of Internet-based sexual harassment.

Developing an Employee Privacy Policy

The creation of a privacy policy for internal use in an organization can be as simple or as complex as the organization itself. Most companies collect information from their employees in the form of personnel records. Firms may also collect personal information from customers or clients. An internal privacy policy should address acceptable practices with regard to each type of information maintained by the company.

A good internal privacy policy should define what standards of behavior are expected of those who have responsibility over the data held by the company—including both employee data and the personal data of a company's customers—and should inform employees about the consequences of noncompliance. Additional topics that can be covered in a privacy policy include procedures for reporting breaches, procedures for allowing employees to access and correct their own personnel records, procedures regarding access to proprietary records such as customer lists, and procedures for auditing compliance and for training employees how to comply with the company's guidelines.

CONSUMER INTERNET PRIVACY

Before the Web existed, companies gathered whatever information they could get about their customers from a variety of sources, such as real estate transaction records, credit bureaus, court documents, and motor vehicle records. For many companies, among the most elusive, and hence the most valuable information—what you are interested in buying and exactly when you are ready to buy—was largely unavailable. Occasionally a clever marketer could devise an algorithm or a statistical model that might be used to infer some purchase preference from the tidbits of information that might be gathered about a customer from scattered sources. The Internet has made such information gathering much more commonplace.

Browser Privacy Issues

Many of the average computer user's online activities revolve around the two most popular Web browsers, Internet Explorer and Netscape. Browsers continue to evolve and improve, especially where privacy and security issues are involved. Even the most recent versions have some fundamental privacy problems that arise not by accident

but by design, however. In many cases, there are default settings that permit the collection and storage of usage data. These include the following:

- Browsers regularly tell Web sites what kind and what version of browser is being run, the operating system it is running on, and even what Web site "referred" the user to the current page.
- Some browsers have settings that permit users to capture and enter user IDs and passwords automatically for Web sites, as well as other personal information such as credit card numbers. These "wallet" features provide convenience but also present a privacy risk should anyone gain access to that machine and use it to log into sites or access users' personal information.
- Browsers can be instructed by Web sites to store little text files, called cookies, on local hard drives. Cookies can be used to store personal information or to assign unique identifiers that allow sites to identify users individually on future visits.
- Browsers can keep a log of every Web site a user visits and may even keep copies of the pages and images the user has viewed. The "history" function can log this data for days, weeks, or even months. Depending on the size of the hard drive and the default settings for a browser, it may also store days or weeks of Web page files and images in a "cache" folder.

Internet Explorer and Netscape have their own built-in privacy settings and controls. They vary in the level of control they allow over elements such as cookies, however. The "help" file that comes with each browser explains the browser's privacy settings and describes how to control them.

IP Addresses and Browser Data

In 1990, an engineer at a Swiss physics laboratory, Tim Berners-Lee, invented a new data-exchange standard in an effort to speed the sharing of information between researchers at widely dispersed locations. His creation was the hypertext transport protocol, or HTTP, and it made data sharing across the Internet literally as easy as point-and-click (Cailliau, 1995).

When the first Web servers and Web browsers were developed, however, not much attention was paid to subjects such as security and privacy. Because Berners-Lee and other engineers needed to troubleshoot their fledgling Internet connections, they built many automatic reporting features that would let them easily get to the root of the problem when something went haywire. This need for information such as browser type, version, operating system, and referring page was built into the earliest browsers and persists today.

Although not a tremendous privacy concern, the collection of this browser data is a standard function of most Web server software. Most sites collect this data for troubleshooting purposes and then delete it after some period of time, mostly because it can become very voluminous very quickly and its usefulness diminishes over time.

One element of the data that is also captured in the process of requesting and serving Web pages is the IP (Internet protocol) address of the user's computer. An IP address is a formatted string of numbers that uniquely identifies a user's computer out of all of the other computers connected to the Internet. IP addresses, which look something like 192.168.134.25, are assigned in blocks to Internet service providers, who in turn dole them out to their customers. With most dial-up Internet access accounts, users are assigned a "dynamic" IP address, meaning that the IP address assigned to a computer changes every time the user log onto his or her ISP, and gets tossed back into the ISP's pool of addresses when the user disconnects. By contrast, dedicated servers and some desktop computers in corporate or academic settings may have a "static" IP address, which is unique to that machine and may persist for the life of the equipment.

In this age of always-on Internet connections, however, such as those provided by DSL (digital subscriber lines) or cable modem services, it is possible for an average user's computer to have the same IP address for days, weeks, or months on end. From a privacy perspective, a static IP address can compromise one's privacy because an unchanging IP address make it easier for the truly determined to track an individual's Internet usage. For example, a site that collects IP addresses in its server logs may be able to correlate with other transactional records (e.g., purchase history or search parameters) to associate a unique IP address with a unique user and his or her online activities.

Given that most consumers use Internet service providers that regularly use dynamic IP addressing (as most of the DSL and cable modem providers claim), IP addresses are not considered a reliable means of allowing Web sites or online advertisers to track users uniquely. This lack of reliability should not be confused with anonymity. As a routine bookkeeping matter, many service providers log which IP address was allocated to which user's account at a given period of time. These connection records are frequently sought by prosecutors investigating criminal activities perpetrated via the Internet and by parties in private lawsuits over online activities. In recent years, dozens of companies have successfully uncovered the identities of "anonymous" critics by obtaining court orders for the release of user identities. Not every Internet service provider has willingly provided that information; in 2002, Verizon Internet fought attempts by the Recording Industry Association of America to release records identifying users accused of illegally trading music files. As of this writing, the federal district court in Washington, DC, held that Verizon was required to reveal the user's identity; however Verizon has appealed (McCullagh, 2003).

Cookies

Connections made using HTTP are called "stateless," which means that after the user's computer receives the content of a requested page, the connection between the computer and the faraway Web server is closed. Rather than maintain a constant open connection "state," each file that makes up the page (such as each of the graphics on a page) creates a new and separate connection (Privacy Foundation, 2001). This is why, for example, it is

sometimes possible to receive all the text of a Web page, but not the images; if the Web browser breaks the connection, or the distant server is too busy, it will not be able to open the additional connections needed to receive the additional data.

The benefit of a stateless connection is simple: It enables one machine to serve a much higher volume of data. The downside to a stateless connection is that on occasion it might be helpful for a server to remember who you are. For example, when someone logs onto his or her stock portfolio, privacy and security dictate that the server not reveal account information to anyone else; however, efficiency demands that every time the user loads a page, he or she should not have to reenter the user ID and password for every new connection the browser makes to the remote computer. So how do users make a server remember who they are? They do so by creating a constant state in an otherwise stateless series of connections. The method for doing this is the cookie.

Cookies contain a piece of data that allows the remote Web server to recognize a unique connection as having a relationship to another unique connection. In short, the cookie makes sure that the server can remember a visitor through many steps in a visit or even when time has passed between visits. As a basic security measure, it should be noted that cookies are designed to be read only by a server within the same domain that created it. So, for example, only a server in the yahoo.com domain can read cookies set by a server in the yahoo.com domain.

Cookies enable myriad helpful features, such as the ability to personalize a Web site with the user's choice of colors, or language, or stock symbols on a stock ticker. It also enables features such as shopping carts on e-commerce Web sites, permitting the user to select multiple items over the course of a long visit and have them queued for purchase at the end of a visit.

Not all cookies are used for collecting or retaining information over a long period of time, such as those used by advertisers. For example, many Web sites contain a great deal of frequently changing content and generate their Web pages from large databases of text. In some of these cases, the Web servers require cookies to help determine, for example, what page it should serve up to a user based on the search terms that he or she entered into a search engine.

A special type of cookie, called a session cookie, is set to be automatically deleted after a relatively short period of time, usually within about 10 minutes after a user leaves a site. This type of cookie is typically used for remembering information over a short duration, such as what you may have stored in a shopping cart. Because session cookies are so short-lived, they do not have quite the same privacy implications as their longer-lived cousin, the persistent cookie. Persistent cookies often have expiration dates set many years in the future.

Most Web browsers have settings that allow a user to accept or reject certain cookies. For example, an alternative brand of Web browser called Opera, favored among the privacy community, allows users to accept or reject cookies based on whether it is a first-party cookie being set by the site the user is actively visiting or whether it is a third-party cookie, which is being set by some other entity such as an advertising service via an ad banner appearing on the site.

Web Bugs

Another popular technology for tracking users' activities online is the Web bug, also called "Web beacons," "1-by-1 pixels," or "clear GIFs." (GIF, which stands for graphics interchange format, is a particular type of file format for images.)

Web bugs are special links imbedded in Web pages, or other HTML-coded documents such as some types of e-mail, that allow the link's creator to track every instance in which the document is viewed (Smith, 2001). As discussed earlier, every time a Web page is loaded, images on the page are loaded in a separate transaction with the Web server. When a Web bug is programmed into a Web page, its code looks similar to the code for just about any graphic image appearing on that page. In reality, though, it has three differences:

1. The Web bug graphic can be called from any site, most often from a third-party site, allowing that site to record details about the user's visit.
2. The Web address used to call in the Web bug graphic is often encoded with specific data relating to the page being visited, or, in the case of HTML e-mail, it may be encoded with information about the user's e-mail address.
3. The graphic image associated with the Web bug is deliberately made to be so tiny that it is invisible to the naked eye.

Most Web bugs are the size of a single screen pixel. What is a pixel? Every image on a computer screen is composed of very tiny dots. The smallest unit of dot on a computer screen is the pixel. Even a single pixel can still be visible, however, so Web bug images are often made of a graphic image called a clear GIF, or a transparent GIF, which allows the background color or image to show through it, rendering it effectively invisible.

Because Web bugs can be embedded in any Web page or HTML document, they can also be included in e-mail, allowing sites to track details about when a message is read and to whom the message might be sent. This versatility is why Web bugs have become so widely used. It is also why an industry group called the Network Advertising Initiative, which represents a growing category of online advertising firm called ad networks, responded to pressure from privacy advocates and legislators by agreeing to a set of guidelines for notice and choice when Web bugs are in use.

Ad Networks

Some sites rent out space on their Web pages to third parties, often for placement of advertisements. Along with those ad banners, many third-party advertising companies also try to set their own cookie on users' browsers. These cookies can be used for things such as managing ad frequency (the number of times an advertisement is shown to a particular individual) and to track users'

movements between the many sites on which the advertising companies place their cookies. These ad networks are a type of advertising agency that rents space on dozens or hundreds of Web sites, and frequently uses cookies placed on all of the sites in their network to build a profile about the kinds of Web sites a particular user likes to visit.

What is increasingly a marketer's paradise is becoming a consumer's nightmare: the deluge of commercial messages in e-mail inboxes, parades of pop-up advertisements, and even solicitations arriving by cellular phone and pager are making consumers leery of the alleged benefits of this ubiquitously wired world. In response to growing consumer concerns, companies have sought to develop privacy polices that help consumers better understand how their information is gathered and used.

PRIVACY POLICY FUNDAMENTALS

According to the Federal Trade Commission (FTC), if a company makes a promise that it does not keep, it is considered an unfair or deceptive trade practice, for which the offender can be fined up to $11,000 per violation, in addition to other legal remedies (FTC Office of the General Counsel, 2002). Central to the FTC's advocacy of greater consumer privacy protections has been the call for companies to adopt privacy policies that provide consumers with useful information about how their personal information is gathered and used. Although there are no federal laws that require the publication of a privacy policy, except when data collection from children is involved, it is widely considered an industry "best practice" to publish a privacy policy on any public Web site.

Considering the liability created by writing a privacy policy that a company cannot deliver, the drafting of a privacy policy is not something to be undertaken lightly or without advice of legal counsel. However, good privacy policies tend, at minimum, to address those elements contained in the widely accepted fair information principles, which have also been endorsed by the FTC: notice, choice, access, and security. I discuss the FTC's role in policing privacy matters later in this section, but it should also be noted that legal actions by state attorneys general, as well as private lawsuits, are also driving companies towards some level of uniformity in privacy disclosures.

Those privacy policies cited by privacy advocates as being "best of class" also include the elements of the OECD's principles of fair information practices. There are also a number of online privacy policy generators that allow one to create policies by picking and choosing from predefined language based on the applicable situation. According to the privacy organization, TRUSTe, their recommended Model Privacy Statement has several key elements that echo the OECD principles:

- What personally identifiable information the company collects,
- What personally identifiable information third parties collect through the Web site,
- What organization collects the information,
- How the company uses the information,
- With whom the company may share user information,
- What choices are available to users regarding collection, use, and distribution of the information,
- What types of security procedures are in place to protect the loss, misuse, or alteration of information under the company's control, and
- How users can correct any inaccuracies in the information (TRUSTe, 2002).

Once a company has surveyed its data practices and articulated them clearly in a privacy policy document, the next most important task is to ensure that the company lives up to its promises. There are three ways to do this: manage privacy matters internally, look to industry-sponsored groups for guidance on compliance, or wait for law enforcement to come after you.

Chief Privacy Officers

As the importance of privacy has grown in the corporate setting, and as the risks from privacy problems have increased, companies have begun to create a new management position, the chief privacy officer (CPO), as the designated point-person for managing privacy policies and practices.

Since the first CPO position was created in 1999 at the start-up Internet advertising firm AllAdvantage.com, the CPO job description (if not always the title) has been rapidly adopted across corporate America; by the end of 2000, a significant number of Fortune 100 firms had a CPO-type position, often reporting to the senior-most levels of the organization. According to the Privacy Working Group of the advocacy group Computer Professionals for Social Responsibility, there are many benefits to appointing a CPO:

> A talented and properly-positioned CPO will add value across corporate divisions from development to customer relations, from liability mitigation and risk management to increased market share and valuation. Perhaps most importantly, the Chief Privacy Officer promotes an essential element of new economy corporate citizenship-Trust. (Enright & McCullough, 2000)

The CPO has both an internal and an external role at his or her company. The internal role includes participation in companywide strategy planning, operations, product development and implementation, compliance monitoring and auditing, and employee training and awareness. The external role of the CPO involves enhancing the company's image as a privacy-sensitive organization, through fostering positive relationships with consumers and consumer groups, privacy advocates, industry peers, and regulators.

In many respect, the CPO becomes the focal point for a company's privacy activities and in turn can become the company's public face on the privacy issue. The position is most effective if it is perceived as objective, with ombudsman-like qualities, serving as a protector of consumer interests while seeking balance between those interests and the interests of the company. Yet there are other organizations offering assistance in the ombudsman role: trustmark organizations.

Trustmarks

There are several independent, industry-sponsored organizations that will certify a company's privacy policy to improve consumer perceptions. Upon certification, they permit sites to use their "seal of approval," sometimes referred to as a trustmark, to demonstrate to the public their commitment to privacy concerns. The most popular privacy seal programs—TRUSTe, BBBOnline, and CPA WebTrust—certify the validity of the policies on many thousands of Web sites. The growing use of these trustmarks does seem to be having an effect: an August 1999 study found that 69 percent of Internet users said that they recognize the TRUSTe seal, the most widely adopted of the privacy seal programs.

Seal programs verify that a Web site's privacy policy covers certain privacy topics (like the use of cookies and sharing data with third-party marketers). The seals do not set any specific quality standards, benchmarks, or specific data handling practices, however. As such, a company's site could, theoretically, earn a seal for making the required disclosures, even if in the course of the disclosure it reserves for itself the right to make whatever use of personal information it sees fit. This has been one of the criticisms leveled at the seal programs, as has their dependence on licensing fees from those entities they are asked to police.

Federal Trade Commission

Under their broad legislative mandate to proscribe deceptive and unfair trade practices, the FTC began reviewing online marketing practices back in 1996. Soon the FTC's investigators were uncovering evidence of some egregious behavior by a few online marketers. Major corporations quickly distanced themselves from the bad actors but acknowledged that privacy was a growing concern for online consumers and promised the FTC that the industry would do better at policing itself.

After numerous public controversies over well-known corporations continuing to abuse consumer privacy, and despite repeated pledges to adhere to standards promulgated and policed by the industry itself, surveys have continued to show that consumer perceptions of the potential for privacy abuses by online marketers continues to be a factor in consumer hesitance to embrace Internet commerce fully. In response, the FTC has sought on numerous occasions to assist companies in adopting practices that are more conducive to consumer confidence. These efforts have focused on the well-worn mantra: notice, choice, access, and security.

In December 1999, the FTC convened an Advisory Committee on Online Access and Security (ACOAS) to provide advice and recommendations to the agency regarding implementation of these basic fair information practices. The committee, consisting of representatives from the online industry, trade groups, academia, and privacy advocates, sought to provide guidance on how to solve the last two elements of fair information practices: access and security. Their report outlines many of the problems with setting universal standards for access and security, and in the end the committee came to few conclusions (FTC ACOAS, 2000).

Some six years after first looking into online privacy issues, the FTC is still warning online companies that if they do not clean up their act, stricter measures might be required. During the intervening years, however, the FTC has not been completely idle. In 1998, the FTC reached a settlement with GeoCities, a personal Web site hosting service, over charges that it misrepresented how user information would be used and engaged in deceptive practices relating to its collection of information from children. Part of the settlement required GeoCities (now owned by Yahoo!) to post, "a clear and prominent Privacy Notice, telling consumers what information is being collected and for what purpose, to whom it will be disclosed, and how consumers can access and remove the information." The notice, or a link to it, was required on the Web site's home page and on every page where information was collected (FTC, 1998).

In 1999, the FTC issued regulations implementing the Children's Online Privacy Protection Act, which requires online businesses to seek permission from parents before gathering personally identifiable information from children under age 13. It has since brought several enforcement actions to punish Web sites that have ignored those regulations (FTC, 2003). In recent years, the FTC has filed numerous actions against Internet-based fraudulent schemes, get-rich-quick scams, and quack medical remedies promoted via e-mail and on the Web. In 2000, the FTC intervened in the bankruptcy sale of a customer list belonging to defunct online toy retailer Toysmart.com. The basis of the action was to prevent the list from being used in any way inconsistent with the privacy policy under which it was gathered (FTC, 2000). In 2001, the FTC settled with pharmaceutical firm Eli Lilly and Company over an e-mail that improperly disclosed the e-mail addresses of hundreds of users of a prescription reminder service at the Web site Prozac.com, in violation of the site's privacy policy (FTC, 2002).

The FTC has steadfastly refused to seek greater legislative authority than its already broad mandate under the Federal Trade Act to police unfair or deceptive trade practices. The agency has threatened the industry that it will indeed seek more specific privacy-oriented enforcement authority if companies do not improve their self-regulatory efforts. It must also be noted that the FTC is just one governmental authority with the ability to prosecute privacy violations: Most state attorneys general have state versions of the Federal Trade Act that enable them to seek remedies similar to those available to the FTC. Indeed, attorneys general in Michigan, Washington, California, and Massachusetts have all been active in undertaking privacy-related enforcement actions, and the National Association of Attorneys General (2001) has held many seminars on investigating and prosecuting Internet privacy matters.

CONCLUSION

Consumers and businesses alike are grappling with the complex privacy concerns that the Internet era has brought to the fore. This chapter is a necessarily brief overview of the privacy landscape. Indeed, entire books can—and have–been written about the ways Internet

technologies have created new challenges to the average person's desire to "be let alone." As this chapter has shown, however, a number of concepts find their way into privacy-related policies and practices. Among these, the fundamental principles of notice, choice, access, and security are driving both consumer expectations and business planning. Keeping these principles in mind, many who are called on to seek privacy solutions in their own particular business or personal context have a conceptual framework within which to arrive at their own conclusion.

GLOSSARY

Ad network A consortium of Web sites linked together by an advertising agency for purposes of aggregating advertising placements and tracking consumers movements among and between member sites.

Cookies A small file saved by a Web browser, at the direction of a Web site, containing data that may be later retrieved by that Web site. See also persistent cookies, session cookies, third-party cookies.

Children's Online Privacy Protection Act of 1998 (COPPA) Legislation that limits operators of commercial Web sites and online services from collecting personal information from children under age 13.

Electronic Communications Privacy Act of 1986 (ECPA) Legislation governing the use of wiretaps for domestic law enforcement activities.

Foreign Intelligence Surveillance Act of 1978 (FISA) Legislation governing the use of wiretapping and physical searches in investigations involving terrorists and agents of foreign powers.

Gramm–Leach–Bliley Act (GLB) Also known as the Financial Services Modernization Act. Legislation that instituted major changes to the U.S. banking system. In pertinent part, GLB requires that organizations providing financial services disclose their data collection practices to customers and to provide the ability to opt-out of those practices.

Health Insurance Portability and Accountability Act of 1996 (HIPAA) Legislation that instituted a number of changes to health insurance practices. In pertinent part, HIPAA included privacy-related provisions applicable to health information created or maintained by health care providers, health plans, and health care clearinghouses.

Internet protocol (IP) address The unique numerical address assigned to each computer connected to the Internet. An address may be assigned temporarily (called a dynamic IP address) or may be assigned for long periods (called a static IP address).

Organization for Economic Cooperation and Development (OECD) A group of 30 democratic, market economy countries working collaboratively on economic, social, and trade issues.

Persistent cookies Cookie files designated to be stored for long periods, sometimes as long as 10 years.

Privacy Freedom from unauthorized intrusion. A state of being let alone and able to keep certain especially personal matters to oneself.

Safe harbor A legal concept that permits an entity to reduce or avoid legal liability by agreeing to adhere to certain standards or procedures. In the context of Internet privacy, safe harbor refers to an agreement between the United States and the European Union which permits U.S. companies to certify that they adhere to the stricter privacy standards required by European law, thereby avoiding a more burdensome set of country-by-country registration procedures.

Session cookies Cookie files designated to be stored for only the duration of a visit to a Web site; usually 10 minutes or less.

Third-party cookies A cookie file set by some entity other than the operator of the Web site being visited by the user. Third-party cookies are often used by advertising services to track user movements between multiple Web sites over periods of time.

Trustmark A symbol used to identify those companies whose Web sites have subjected their privacy policy to review by a third-party watchdog organization.

Web bugs Also called Web beacons, 1-by-1 pixels, or clear GIFs. Special links imbedded in Web pages, or other HTML-coded documents such as some types of e-mail, that allow the link's creator to track every instance in which the document is viewed.

Project Management Techniques

Kathy Schwalbe, *Augsburg College*

INTRODUCTION

Although projects have been managed in some fashion for thousands of years, changes in society, the workforce, and technology have sparked interest in the topic of modern project management. The Project Management Institute (PMI), a professional society with more than 100,000 members worldwide, estimates that the United States spends more than $2.3 trillion on projects every year, or one quarter of the nation's gross domestic product (PMI, 2001a). Many of these projects involved information technology and the Internet. According to the Standish Group, there has been an information technology "project gold rush." In 1998, corporate America issued 200,000 new-start application software development projects. During 2000, there were 300,000 new starts, and more than half a million new start application software development projects were initiated during 2001 (Standish Group, 2001). These changes have fueled the need for more sophisticated and better project management. In fact, today's corporations are recognizing that to be successful, they need to be conversant with and use modern project management techniques.

What Is a Project?

To discuss project management techniques, it is important to first understand the concept of a project. A project is a temporary endeavor undertaken to accomplish a unique purpose. Projects should be aligned with organizational objectives. For example, if an organization is trying to develop new products, decrease time to market, increase revenues, or cut costs, projects should be initiated to support those goals. The following attributes help to further define a project:

A project has a unique purpose. Every project should have a well-defined objective. For example, a company might want to develop an intranet to streamline internal operations and cut costs. They might estimate that they can save thousands of dollars on printing and training costs by putting information on a well-designed Intranet. The project purpose must state clearly what outcomes and deliverables are expected from the project, which departments and processes in the organization are involved, and so on.

A project is temporary. A project has a definite beginning and a definite end. If a company is doing a project to develop an intranet, it should decide when the project is expected to begin and end. The project team should define and then produce deliverables along the way, such as a concept document, preliminary design, test site, and so on. The temporary nature of projects most distinguishes them from normal operations in an organization.

A project requires resources, often from various areas. Resources include people, hardware, software, or other assets. Many projects cross departmental or other boundaries to achieve their unique purposes. For an intranet project, people from information technology, marketing, sales, distribution, and other areas of a company would need to work together to develop ideas. They might also hire outside consultants to provide input on the design of the intranet and which technologies to use for the project. Once the project team finishes its intranet design, they might find that the company requires additional hardware, software, and network resources. People from other companies—product vendors and consulting companies—would also become resources for meeting project objectives. Resources, however, are not unlimited. They must be used effectively in order to meet project and other corporate goals.

A project should have a primary sponsor or customer. Most projects have many interested parties or stakeholders, but someone must take the primary role of sponsorship. The project sponsor usually provides the direction

and funding for the project and helps make major decisions.

A project involves uncertainty. Because every project is unique, it is sometimes difficult to clearly define the project's objectives, estimate how long it will take to complete, or how much it will cost. This uncertainty is one of the main reasons project management is so challenging, especially on projects involving new technologies.

Every project is also constrained in different ways by its scope, time goals, and cost goals. These limitations are sometimes referred to in project management as the triple constraint. To create a successful project, scope, time, and cost must all be taken into consideration, and it is the project manager's duty to balance these three often-competing goals. Project managers must consider the following:

Scope: What is the project trying to accomplish? What unique product or service does the customer or sponsor expect from the project? What is and is not included in the project scope? Who will verify the project scope and each deliverable?

Time: How long should it take to complete the project? What is the project's schedule? Which tasks have dependencies on other tasks? What is driving the project completion date?

Cost: What should it cost to complete the project? How will costs be tracked? How will cost variances be handled?

Project success is often measured by meeting scope, time, and cost goals. Note that each area—scope, time, and cost—has a target at the beginning of the project. For example, an intranet project might initially involve six departments, an estimate of one hundred Web pages, and four internal database applications. The project team might estimate that developing this new intranet will save the organization $300,000 within 1 year after implementation. The initial time estimate for this project might be 9 months, and the cost estimate might be $200,000. These expectations would provide the targets for the scope, time, and cost dimensions of the project as well as the organizational benefits.

Project teams do want to meet scope, time, and cost goals, but they must also focus on satisfying project stakeholders and supporting organizational objectives. Project management, therefore, involves several other dimensions or knowledge areas.

What Is Project Management?

Project management is "the application of knowledge, skills, tools, and techniques to project activities in order to meet project requirements" (PMBOK® Guide, 2000 Edition, 2000, p. 4). Project managers must not only strive to meet specific scope, time, and cost goals of projects, they must also meet quality goals and facilitate the entire process to meet the needs and expectations of the people involved in or affected by project activities.

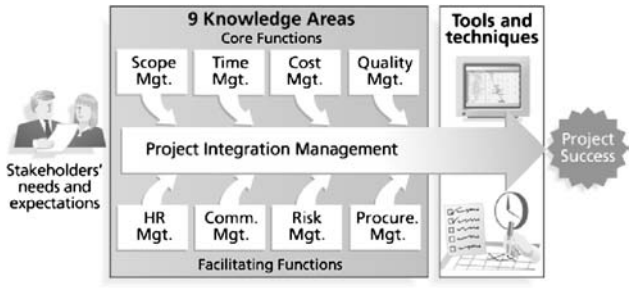

Figure 1: Project management framework.

Figure 1 provides a framework for beginning to understand project management. Key elements of this framework include the project stakeholders, project management knowledge areas, and project management tools and techniques.

Stakeholders are the people involved in or affected by project activities and include the project sponsor, project team, support staff, customers, users, suppliers, and even opponents to the project. People's needs and expectations are important in the beginning and throughout the life of a project. Successful project managers work on developing good relationships with project stakeholders to ensure their needs and expectations are understood and met.

Knowledge areas describe the key competencies that project managers must develop. The center of Figure 1 shows the nine knowledge areas of project management. The four core knowledge areas of project management include project scope, time, cost, and quality management. These are considered to be core knowledge areas because they lead to specific project objectives. Brief descriptions of each follow.

1. *Project scope management* involves defining and managing all the work required to successfully complete the project.
2. *Project time management* includes estimating how long it will take to complete the work, developing an acceptable project schedule and ensuring timely completion of the project.
3. *Project cost management* consists of preparing and managing the budget for the project.
4. *Project quality management* ensures that the project will satisfy the stated or implied needs for which it was undertaken.

The four facilitating knowledge areas of project management are human resources, communications, risk, and procurement management. These are called facilitating areas because they are the means through which the project objectives are achieved. Brief descriptions of each follow.

1. *Project human resource management* is concerned with making effective use of the people involved with the project.
2. *Project communications management* involves generating, collecting, disseminating, and storing project information.

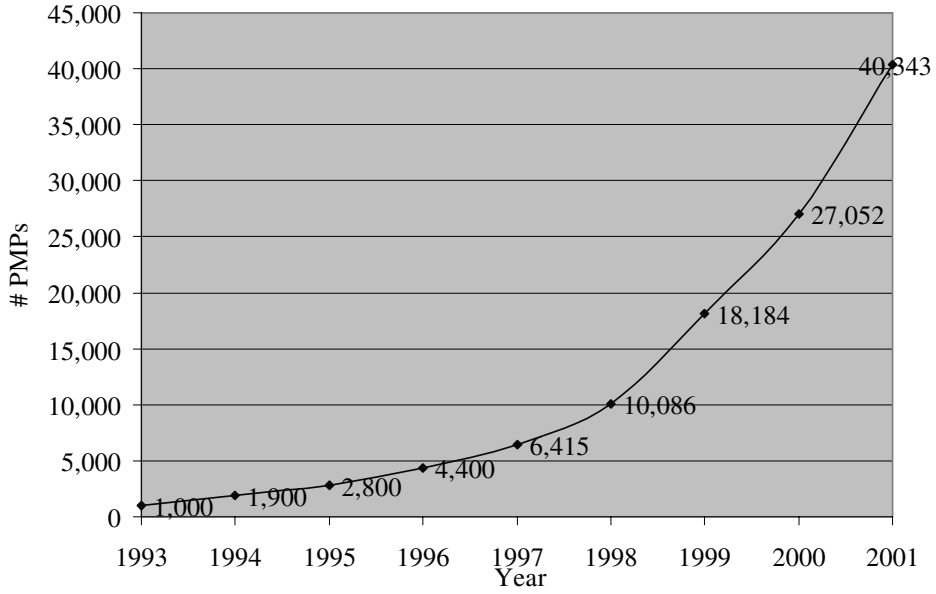

Figure 2: Growth in Project Management Professional certification, 1993–2001.

3. *Project risk management includes* identifying, analyzing, and responding to risks related to the project.
4. *Project procurement management* involves acquiring or procuring goods and services that are needed for a project from outside the performing organization.

Project integration management, the ninth knowledge area, is an overarching function that affects and is affected by all of the other knowledge areas. Project managers must have knowledge and skills in all nine of these areas.

BRIEF BACKGROUND ON THE PROJECT MANAGEMENT PROFESSION

Most people in the information technology field work on projects in some capacity. Some people become project managers, at least on a part-time basis, early in their careers. Many people think one needs many years of experience and vast technical knowledge to be a project manager. Although this need for experience and knowledge might be the case for large, complex, and expensive projects, many information technology projects can be, and are, led by project managers who are just starting their careers. Project managers need some general management and technical knowledge, but they primarily need the skills and desire to be project managers. Project team members should also understand project management to contribute effectively to projects.

The project management profession is growing at a rapid pace. Fortune magazine called project management the "number one career choice" in its article "Planning a Career in a World Without Managers" (Stewart & McGowan, 1996). PMI, an international professional society for project managers, estimated that the average salary for a project manager was more than $81,000 (PMI, 2000a). Although many professional societies are suffering from declining memberships, PMI membership continues to grow at a rapid pace, and the organization included more than 100,000 members worldwide in early 2003. A large percentage of PMI members work in the information technology field, and many pay additional dues to join the Information Systems Specific Interest Group.

Professional certification is an important factor in recognizing and ensuring quality in a profession. PMI provides certification as a Project Management Professional (PMP)—someone who has documented sufficient project experience and education, agreed to follow the PMI code of ethics, and demonstrated knowledge of the field of project management by passing a comprehensive examination. The number of people earning PMP certification continues to increase. In 1993, there were about 1,000 certified project management professionals. By the end of 2001, there were more than 43,000 certified project management professionals. Figure 2 shows the rapid growth in the number of people earning project management professional certification from 1993 to 2001, based on data provided in PMI's annual reports.

As information technology projects become more complex and global in nature, the need for people with demonstrated knowledge and skills in project management will continue. Just as passing the certified public accountant exam is a standard for accountants, passing the PMP exam is becoming a standard for project managers. Some companies are requiring that all project managers be PMP certified. Project management certification is also enabling professionals in the field to share a common base of knowledge. For example, any PMP should be able to describe the nine project management knowledge areas and apply many of the tools and techniques discussed in this chapter. Sharing a common base of knowledge is important because it helps advance the theory and practice of project management.

KEY PROJECT MANAGEMENT TOOLS AND TECHNIQUES

There are many tools and techniques available to project managers and their teams to assist them in all of the knowledge areas. This section highlights just a few of them. Consult the PMBOK Guide (PMI, 2000b), *Information Technology Project Management* (Schwalbe, 2002), or other references for more detailed information.

Project Selection Techniques

Some of the most important decisions organizations must make involve which projects to pursue. It does not matter if a project is highly successful in meeting scope, time, and cost goals if the project itself is not important to the organization. Therefore, organizations should develop and follow a logical process for selecting and continuing projects. Four common techniques for selecting projects include the following:

1. *Focusing on broad organizational goals:* Organizations often cite broad needs, such as improving customer relationships, increasing market share, and so on. Senior managers often like to see strong financial justification for projects, but sometimes it is sufficient to show that projects support high-level strategies that meet broad organizational needs.
2. *Categorizing projects:* Not all projects can be high priority or tied to meeting a critical corporate goal. Projects are often started to address problems, opportunities, or directives that arise. Projects can also be categorized based on the resources they need in terms of time and cost.
3. *Performing net present value and other financial analyses:* Financial considerations are often an important aspect of the project selection process, especially in tough economic times. The primary methods for determining projected financial value of projects include net present value analysis, return on investment, and payback analysis. These techniques are not unique to project management. Any financial analyst can describe these techniques and their importance to senior managers. Consult a good finance or project management textbook or Web site (http://www.investopedia.com) for descriptions of these techniques.
4. *Using a weighted scoring model:* A weighted scoring model is a tool that provides a systematic process for selecting projects based on many criteria. These criteria can include factors such as meeting broad organizational needs; addressing problems, opportunities, or directives; the amount of time it will take to complete the project; the overall priority of the project; projected financial performance of the project; and so on.

The first step in creating a weighted scoring model is to identify criteria important to the project selection process. It often takes time to develop and reach agreement on these criteria. Holding facilitated brainstorming sessions or using groupware to exchange ideas can aid in developing these criteria. Some possible criteria for information technology projects include the following:

- Supports key business objectives
- Has strong internal sponsor
- Has strong customer support
- Uses realistic level of technology
- Can be implemented in 1 year or less
- Provides positive net present value
- Has low risk in meeting scope, time, and cost goals

Next, the manager assigns a weight to each criterion. These weights indicate how much stakeholders value each criterion or how important each criterion is. Weights can be assigned based on percentages, and the total of all of the criteria's weights must total 100%. The manager then assigns numerical scores to each criterion (for example, 0 to 100) for each project. The scores indicate how much each project meets each criterion. At this point, the manager can use a spreadsheet application to create a matrix of projects, criteria, weights, and scores. Figure 3 provides an example of a weighted scoring model to evaluate four projects. After assigning weights for the criteria and scores for each project, the manager calculates a weighted score for each project by multiplying the weight for each criterion by its score and adding the resulting values.

For example, one could calculate the weighted score for Project 1 in Figure 3 as follows:

$$25\% * 90 + 15\% * 70 + 15\% * 50 + 10\% * 25 + 5\% * 20 + 20\% * 50 + 10\% * 20 = 56.$$

Note that in this example, Project 2 would be the obvious choice for selection because it has the highest weighted score. Creating a bar chart to graph the weighted scores for each project allows one to see the results at a glance. If a manager creates the weighted scoring model in a spreadsheet, he or she can enter the data, create and copy formulas, and perform "what if" analysis. For example, suppose the manager changes the weights for the criteria. By having the weighted scoring model in a spreadsheet, he or she can easily change the weights, and the weighted scores and charts are updated automatically.

Many organizations are striving to select and manage projects better by using project portfolio management, enterprise project management, and multiproject management techniques, all topics beyond the scope of this chapter.

Formalizing Projects With a Project Charter

Once an organization has decided which projects to pursue, it is important to authorize those projects formally and inform other people in the organizations about the project objectives, schedule, and so on. One common tool used for this project authorization is a project charter. Project charters can take several forms, such as a simple letter of agreement, a formal contract, or an organization's project charter format. Key project stakeholders should sign the project charter to acknowledge agreement on the need and intent of the project. A project charter is a key output of project initiation.

Table 1 provides a sample of a project charter for upgrading a company's information technology

infrastructure. Because many projects fail because of unclear requirements and expectations, starting with a simple project charter makes a lot of sense.

Defining Project Scope With a Scope Statement and Work Breakdown Structure

A project charter helps define the high-level scope of a project, but much more work must be done to clarify the work to be done. Two important tools for further defining project scope are the scope statement and the work breakdown structure. A scope statement is a document used to develop and confirm a common understanding of the project scope. The scope statement should include a project justification, a brief description of the project's products, a summary of all project deliverables, and a statement of what determines project success. Scope statements vary significantly by type of project. Large, complex projects have long scope statements. Government projects or contracts often include a scope statement known as a statement of work (SOW). Some SOWs are hundreds of pages long, particularly if they include detailed product specifications. As with many other project management documents, the scope statement should be tailored to meet the needs of the particular project.

After completing scope planning, the next step in project scope management is to further define the work required for the project and to break it into manageable pieces. Breaking work into manageable pieces is called scope definition. Good scope definition is important to project success because it helps improve the accuracy of time, cost, and resource estimates, it defines a baseline for performance measurement and project control, and it aids in communicating clear work responsibilities. The output of the scope definition process is the work breakdown structure for the project.

A work breakdown structure (WBS) is a deliverable-oriented grouping of the work involved in a project that defines the total scope of the project. A WBS shows work decomposition, meaning each descending level shows a more detailed breakout of the level above it. It is a foundation document in project management because it provides the basis for planning and managing project schedules, costs, and changes. Project management experts believe that work should not be done on a project if it is not included in the WBS. PMI recently published its first practice standard on the topic of work breakdown structures (PMI, 2001) due to member requests for more guidance on developing and applying this important project management tool.

A WBS is often depicted as a task-oriented family tree of activities. It is usually organized around project products or by phases. It can also be organized using the project management process groups. It can look like an organizational chart, which can help people visualize the whole project and all of its main parts. A WBS can also

Project Title: Information Technology (IT) Upgrade Project

Project Start Date: March 4, 2002 **Projected Finish Date:** December 4, 2002

Project Manager: Kim Nguyen, 691–2784, knguyen@abc.com

Project Objectives: Upgrade hardware and software for all employees (approximately 2,000) within 9 months based on new corporate standards. See attached sheet describing the new standards. Upgrades may affect servers and midrange computers, as well as network hardware and software. Budgeted $1,000,000 for hardware and software costs and $500,000 for labor costs.

Approach:

- Update the information technology inventory database to determine upgrade needs
- Develop detailed cost estimate for project and report to CIO
- Issue a request for quotes to obtain hardware and software
- Use internal staff as much as possible to do the planning, analysis, and installation

Roles and Responsibilities:

NAME	ROLE	RESPONSIBILITY
Walter Schmidt, CEO	Project Sponsor	Monitor project
Mike Zwack	CIO	Monitor project, provide staff
Kim Nguyen	Project Manager	Plan and execute project
Jeff Johnson	Director IT Operations	Mentor Kim
Nancy Reynolds	VP, Human Resources	Provide staff, issue memo to all employees about project
Steve McCann	Director of Purchasing	Assist in purchasing hardware and software

Signoff: (Signatures of all the above stakeholders)

Comments: (Handwritten comments from above stakeholders, if applicable)

This project must be done within 10 months at the absolute latest. Mike Zwack, CIO.

We are assuming that adequate staff will be available and committed to supporting this project. Some work must be done after hours to avoid work disruptions, and overtime will be provided. Jeff Johnson and Kim Nguyen, Information Technology Department

be shown in tabular form as an indented list of tasks to show the same groupings of the work. Figure 4 shows a WBS for an intranet project. Notice that product areas provide the basis for its organization. In this case, there is a main box or item on the WBS for developing the Web site design, the home page for the intranet, the marketing department's pages, and the sales department's pages.

In contrast, a WBS for the same intranet project can be organized around project phases, as shown in Figure 5. Notice that project phases of concept, Web site design, Web site development, roll out, and support provide the basis for its organization.

This same WBS is shown in tabular form in Table 2. The items on the WBS are the same, but the numbering scheme and indentation of tasks show the structure. This tabular form is used in many documents, such as contracts. It is also used in project management software, such as Microsoft Project.

The work breakdown structures in Figures 4, 5, and 6 and in Table 2 present information in hierarchical form. The top level of a WBS is the 0 level and represents the entire project. (Note the labels on the left side of Figure 5). The next level down is Level 1, which represents the major

products or phases of the project. Level 2 includes the major subsets of Level 1. For example, in Figure 5 the Level 2 items under the Level 1 item called "Concept" include the following: evaluate current system, define requirements, define specific functionality, define risks and risk management approach, develop project plan, and brief Web development team. Under the Level 2 item called "Define Requirements" are four Level 3 items on the WBS: define user requirements, define content requirements, define server requirements, and define server owner requirements.

In Figure 5, the lowest level provided is Level 3. The lowest level of the WBS represents work packages. A work package is a deliverable or product at the lowest level of the WBS. As a general rule, each work package in a WBS should represent roughly 80 hours of effort. One can also think of work packages in terms of accountability and reporting. The WBS should partition the work to allow semiautonomous work assignment for individuals and teams. If a project has a relatively short time frame and requires weekly progress reports, a work package might represent 40 hours of work. On the other hand, if a project has a long time frame and requires quarterly progress reports, a work package might represent more than 100 hours of work.

The sample WBSs shown here seem fairly easy to construct and understand. Nevertheless, it is difficult to create a good WBS. To create a good WBS, a project manager must understand both the project and its scope and incorporate the needs and knowledge of stakeholders. The manager and the project team must decide as a group how to organize the work and how many levels to include in the WBS. Many project managers have found that it is better to focus on getting the top three levels done well before getting too bogged down in more detail.

Another concern when creating a WBS is how to organize it so it provides the basis for the project schedule.

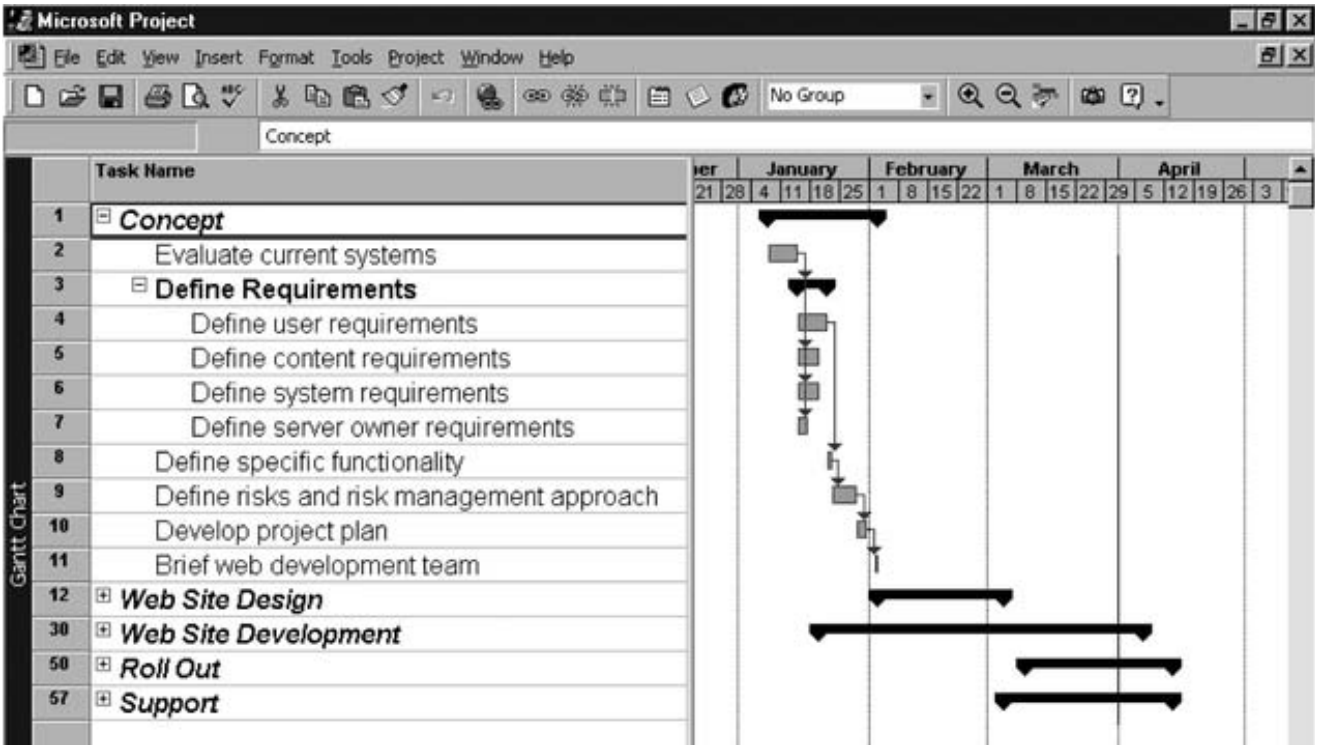

Figure 6: Intranet work breakdown structure and Gantt chart in Microsoft Project.

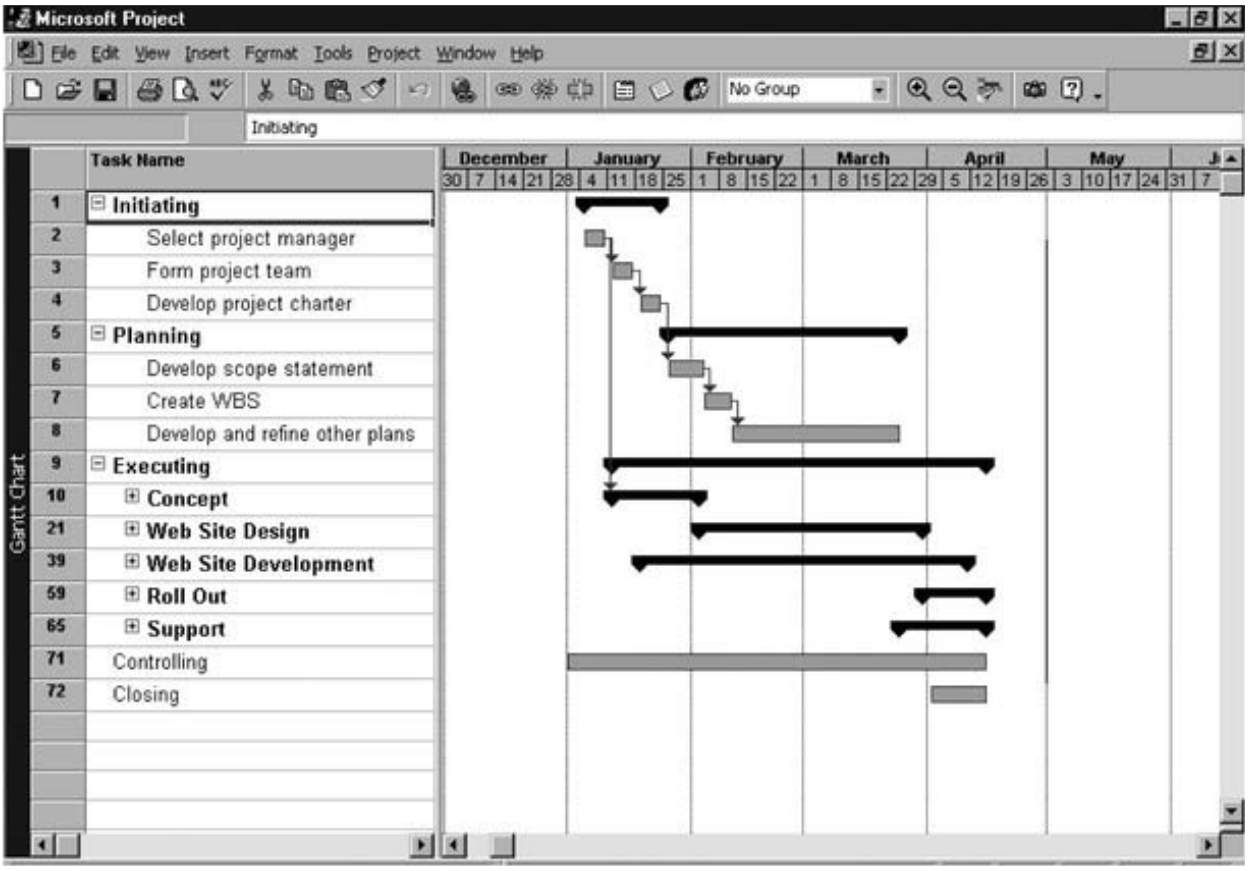

Figure 7: Intranet work breakdown structure and Gantt chart organized by project management process groups.

Some managers suggest creating a WBS using the project management process groups of initiating, planning, executing, controlling, and closing as Level 1 in the WBS. By doing this, not only does the project team follow good project management practice, but the WBS tasks can also be mapped more easily against time. For example, Figure 7 shows a WBS and Gantt chart for the intranet project organized by the product phases described earlier. Tasks under initiating include selecting a project manager, forming the project team, and developing the project charter. Tasks under planning include developing a scope statement, creating a WBS, and developing and refining other plans, which would be broken down in more detail for a real project. The tasks of concept, Web site design, Web site development, and roll out, which were WBS Level 1 items in Figure 6, now become WBS Level 2 items under executing. The executing tasks would vary the most from project to project, but many of the tasks under the other project management process groups would be similar for all projects.

It is important to involve the entire project team and customer in creating and reviewing the WBS. People who will do the work should help to plan the work by creating the WBS. Having group meetings to develop a WBS helps everyone understand what work must be done for the entire project and how it should be done, given the people involved. It also helps to identify where coordination between different work packages will be required.

Assigning Resources With a Responsibility Assignment Matrix

There are many tools and techniques to assist in managing people on projects. One simple yet effective tool to help clarify roles and responsibilities is the responsibility assignment matrix (RAM). A responsibility assignment matrix (RAM) is a matrix that maps the work of the project as described in the WBS to the people responsible for performing the work as described in an organizational breakdown structure (OBS). Figure 8 shows an example of a RAM. The positions of the WBS and OBS can be reversed, if desired. The RAM allocates work to responsible and performing organizations, teams, or individuals, depending on the desired level of detail. For smaller projects, it would be best to assign individual people to WBS activities. For large projects, it is more effective to assign the work to organizational units or teams.

In addition to using a RAM to assign detailed work activities, project managers can also use a RAM to define general roles and responsibilities on projects. This type of RAM can include the stakeholders in the project. Figure 9 provides a RAM that shows whether stakeholders are accountable or just participants in part of a project and whether they are required to provide input, review, or sign off on parts of a project. This simple tool can be an effective way for project managers to communicate roles and expectations of important stakeholders on projects.

PROJECT SCHEDULING TOOLS AND TECHNIQUES

When many people think of project management tools and techniques, they think of Gantt charts and network diagrams. Of course all nine knowledge areas are important in project management, but scheduling problems often cause the most conflicts on projects. This section briefly describes Gantt charts, network diagrams, and a more recent development in project scheduling called critical chain scheduling.

Gantt Charts

Figures 6 and 7 show how a WBS is a basis for creating a Gantt chart. Project managers must know what work needs to be done in order to develop a project schedule. Gantt charts provide a standard format for displaying project schedule information by listing project activities and their corresponding start and finish dates in a calendar format. Henry Gantt developed the first Gantt chart during World War I for scheduling work in job shops. Early versions simply listed project activities or tasks in one column to the left, calendar time units such as months to the right, and horizontal bars under the calendar units to illustrate when activities should start and end. Gantt charts normally do not show relationships between project activities as network diagrams do, however.

Today most people use project management software to create more sophisticated versions of Gantt charts and allow for easy updates of information. This chapter includes several figures created with Microsoft Project 2000. There are many other project management software tools available (see http://www.infogoal.com/pmc/pmcswr.htm or www.allpm.com). Note that project management software can do much more than just create Gantt charts.

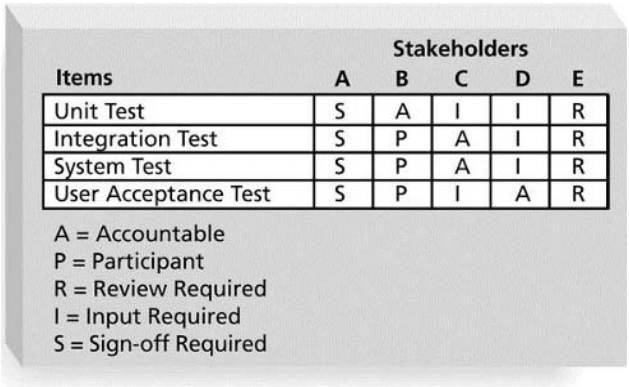

Figure 9: Responsibility assignment matrix showing stakeholder roles.

Figure 10 shows a Gantt chart based on a software launch project, one of the template files that Microsoft provides with Microsoft Project. Recall that the activities or items in the Task column on the left side of the figure coincide with the activities on the WBS for the project. Notice that the software launch project's Gantt chart contains milestones, summary tasks, individual task durations, and arrows showing task dependencies.

Notice the different symbols on the software launch project's Gantt chart (Figure 10):

The black diamond symbol represents a milestone—a significant event on a project with zero duration. In Figure 10, Task 1, "Marketing Plan distributed," is a milestone that occurs on March 17. Tasks 3, 4, 8, 9, 14, 25, 27, 43, and 45 are also milestones. For large projects, senior managers might want to see only milestones on a Gantt chart.

The thick black bars with arrows at the beginning and end represent summary tasks. For example, activities 12 through 15—"Develop creative briefs," "Develop concepts," "Creative concepts," and "Ad development"—are all subtasks of the summary task called Advertising, Task 11. WBS activities are referred to as tasks and subtasks in most project management software.

The light gray horizontal bars represent the duration of each individual task. For example, the light gray bar for Subtask 5, "Packaging," starts in mid-February and extends until early May.

Arrows connecting these symbols show relationships or dependencies between tasks. Gantt charts often do not show dependencies, which is their major disadvantage. If dependencies have been established in Project 2000 or other project management software, they are automatically displayed on the Gantt chart.

Tracking Gantt charts can also be used to display planned versus actual schedule progress (Schwalbe, 2002). The main advantage of using Gantt charts is that they provide a standard format for displaying project schedule information, and they are easy to create and understand. The main disadvantage of Gantt charts is that they do not usually show relationships or dependencies between tasks. If Gantt charts are created using project management software and tasks are linked, then the dependencies would be displayed, but not as clearly as they would be displayed on project network diagrams.

Project Network Diagrams

A project network diagram is a schematic display of the logical relationships or sequencing of project activities. To use critical path analysis, one must determine task relationships. A critical path for a project is the series of activities that determines the earliest time by which the project can be completed. It is the longest path through the network diagram and has the least amount of slack or

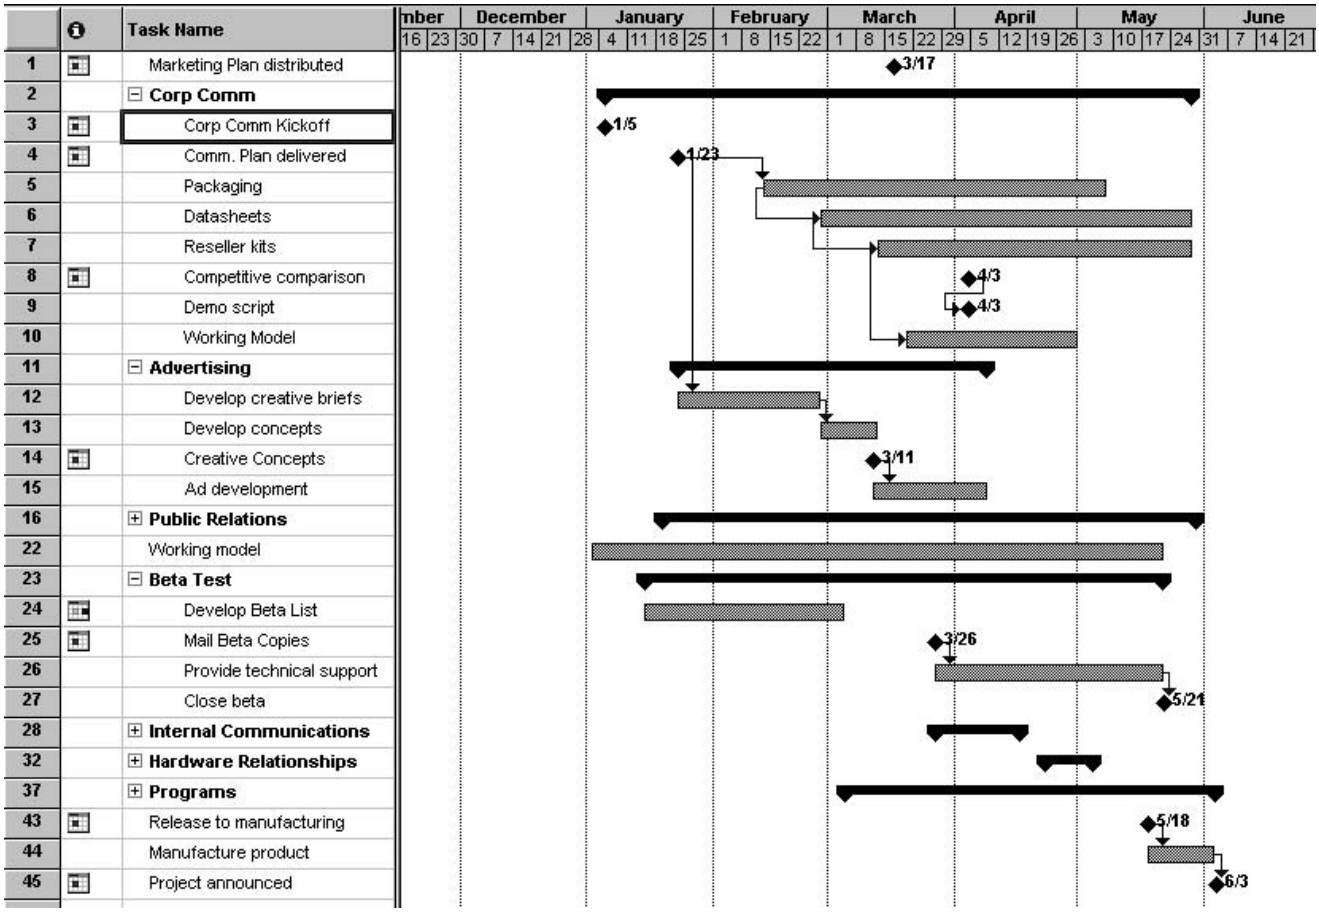

Figure 10: Gantt chart for software launch project in Microsoft Project.

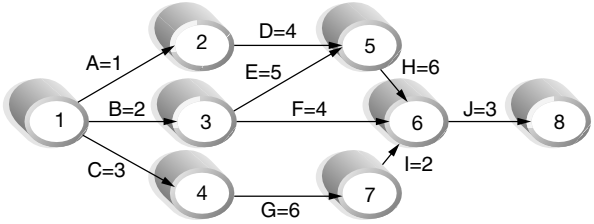
float. Slack or float is the amount of time an activity may be delayed without delaying a succeeding activity or the project finish date.

To find the critical path for a project, a project manager should first develop a good network diagram, which, in turn, requires a good activity list based on the WBS. Once a project network diagram has been created, the manager must also estimate the duration of each activity to determine the critical path. Calculating the critical path involves adding the durations for all activities on each path through the project network diagram. The longest path is the critical path.

Figure 11 provides an example of a project network diagram using the activity-on-arrow format for simplicity. Note that each of the four paths starts at the first node (1) and ends at the last node (8) on this diagram. This figure also shows the length or total duration of each path through the project network diagram. These lengths are computed by adding the durations of each activity on the path. Because path B-E-H-J at 16 days has the longest duration, it is the critical path for the project.

Figure 12 shows the network diagram and critical path when the same project information is entered into Microsoft Project 2000. This format is called the precedence diagramming method (PDM) and is used by most software packages. Project management software can definitely help in creating network diagrams and determining critical paths and slack amounts for all project tasks.

What does the critical path really mean? The critical path shows the shortest time in which a project can be completed. Even though the critical path is the longest path, it represents the shortest time it takes to complete a project. If one or more of the activities on the critical path takes longer than planned,the whole project schedule



Note: Assume all durations are in days.

Path 1:	A-D-H-J	Length = 1+4+6+3 = 14 days
Path 2:	B-E-H-J	Length = 2+5+6+3 = 16 days
Path 3:	B-F-J	Length = 2+4+3 = 9 days
Path 4:	C-G-I-J	Length = 3+6+2+3 = 14 days

Since the critical path is the longest path through the network diagram, Path 2, B-E-H-J, is the critical path for Project X.

Figure 11: Using a project network diagram to determine the critical path.

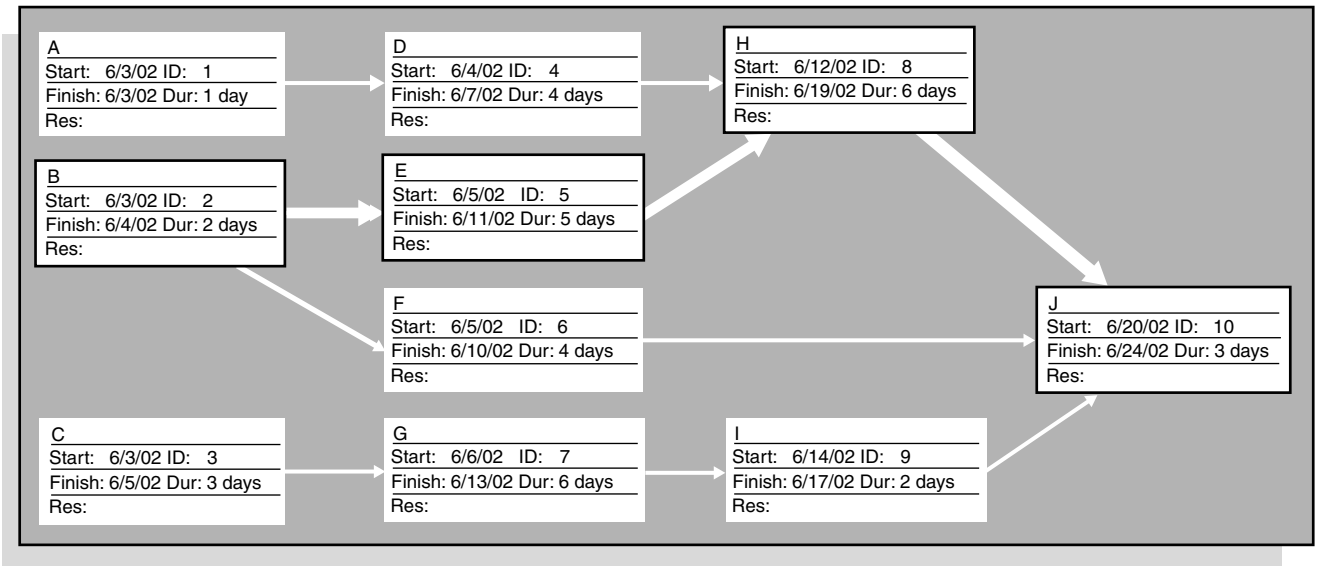


Figure 12: Network diagram and critical path in Project 2000.

will slip unless the project manager takes corrective action.

People are often confused about what the critical path is for a project or what it really means. Some people think the critical path includes the most critical activities, but it is concerned only with the time dimension of a project. Just because its name includes the word critical does not mean that it includes all critical activities. For example, Frank Addeman, executive project director at Walt Disney Imagineering, explained in a keynote address at the May 2000 PMI-ISSIG Professional Development Seminar (http://www.pmi-issig.org) that growing grass was on the critical path for building Disney's Animal Kingdom theme park! This 500-acre park required special grass for its animal inhabitants, and some of the grass took years to grow. Another misconception is that the critical path is the shortest path through the project network diagram. In some areas, for example, transportation modeling, similar diagrams are drawn in which identifying the shortest path is the goal. For a project, however, each activity must be done to complete the project. It is not a matter of choosing the shortest path.

Program Evaluation Review Technique

Another project time management technique is the Program Evaluation and Review Technique (PERT), a network analysis technique used to estimate project duration when there is a high degree of uncertainty about the individual activity duration estimates. PERT applies the critical path method to a weighted average duration estimate.

PERT uses probabilistic time estimates—duration estimates based on using optimistic, most likely, and pessimistic estimates of activity durations—instead of one specific or discrete duration estimate. Like the critical path method, PERT is based on a project network diagram, normally the PDM method. To use the PERT method, one calculates a weighted average for the duration estimate of each project activity using the following formula:

PERT weighted average = optimistic time + 4X most likely time + pessimistic time

The main advantage of PERT is that it attempts to address the risk associated with duration estimates. PERT has three disadvantages: it involves more work because it requires several duration estimates, there are better probabilistic methods for assessing risk (such as Monte Carlo simulation), and it is rarely used in practice. In fact, many people confuse PERT with project network diagrams because the latter are often referred to as PERT charts.

Critical Chain Scheduling

A variation of critical path analysis that addresses the challenge of meeting or beating project finish dates is an application of the theory of constraints called critical chain scheduling. The theory of constraints is based on the fact that, like a chain with its weakest link, any complex system at any point in time, often has only one aspect or constraint that limits its ability to achieve more of its goal. For the system to attain any significant improvements, that constraint must be identified, and the whole system must be managed with it in mind. Critical chain is a method of scheduling that takes limited resources into account when creating a project schedule and includes buffers to protect the project completion date.

One can find the critical path for a project without considering resource allocation. For example, task duration estimates and dependencies can be made without considering the availability of resources. In contrast, an important concept in critical chain scheduling is the availability of resources. If a particular resource is needed full-time to complete two tasks that were originally planned to occur simultaneously, critical chain scheduling acknowledges that one of those tasks must be delayed until the resource is available or another resource must

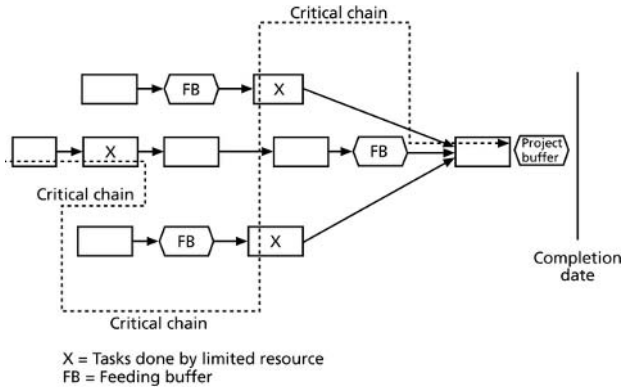

Figure 13: Example of critical chain scheduling.

be found. In this case, accounting for limited resources often lengthens the project finish date, which is not most people's intent.

Other important concepts related to critical chain include multitasking and time buffers. Critical chain scheduling assumes that resources do not multitask. Someone cannot be assigned to two tasks simultaneously on the same project using critical chain scheduling. Likewise, critical chain theory suggests that projects be prioritized so people working on more than one project at a time know which tasks take priority. Preventing multitasking avoids resource conflicts and wasted setup time caused by shifting between multiple tasks over time. Critical chain scheduling also changes the way most people make task duration estimates. People often add a safety or buffer, which is additional time to complete a task added to an estimate to account for various factors. These factors include the negative effects of multitasking, distractions and interruptions, fear that estimates will be reduced, Murphy's Law, and so on. Critical chain scheduling removes buffers from individual tasks and instead creates a project buffer, which is additional time added before the project's due date. Critical chain also protects tasks on the resource-constrained critical path from being delayed by using feeding buffers, which are additional time added before critical path tasks that are preceded by non-critical-path tasks.

Figure 13 provides an example of a project network diagram constructed using critical chain scheduling. Note that the critical chain accounts for a limited resource, X, and the schedule includes use of feeding buffers and a project buffer in the network diagram. The task estimates in critical chain scheduling should be shorter than traditional estimates because they do not include their own buffers. By not having task buffers, there should be less occurrence of Parkinson's Law, which states that work expands to fill the time allowed. The feeding buffers and project buffers protect the date that really needs to be met—the project completion date (Goldratt, 1997).

TECHNIQUES FOR SHORTENING A PROJECT SCHEDULE

It is common for stakeholders to want to shorten a project schedule estimate. By knowing thecritical path, the project manager and his or her team can use several duration compression techniques to shorten the project schedule. One simple technique is to reduce the duration of activities on the critical path. The manager can shorten the duration of critical path activities by allocating more resources to those activities or by changing their scope. Two other techniques for shortening a project schedule are crashing and fast tracking.

Crashing is a technique for making cost and schedule trade-offs to obtain the greatest amount of schedule compression for the least incremental cost. For example, suppose one of the items on the critical path for a project was entering data into a database. If this task is yet to be done and was originally estimated to take 2 weeks based on the organization providing one part-time data-entry clerk, the project manager could suggest that the organization have the clerk work full-time to finish the task in 1 week instead of 2. This change would not cost the organization more money, and it could shorten the project end date by 1 week. By focusing on tasks on the critical path that could be done more quickly for no extra cost or a small cost, the project schedule can be shortened. The main advantage of crashing is shortening the time it takes to finish a project. The main disadvantage of crashing is that it often increases total project costs.

Another technique for shortening a project schedule is fast tracking. Fast tracking involves doing activities in parallel that would normally be done in sequence or in slightly overlapping time frames. For example, a project team may have planned not to start any of the coding for a system until all of the analysis was done. Instead, team members could consider starting some coding activity before all of the analysis is complete. The main advantage of fast tracking, like crashing, is that it can shorten the time it takes to finish a project. The main disadvantage of fast tracking is that it can end up lengthening the project schedule because starting some tasks too soon often increases project risk and results in rework.

PROJECT COST MANAGEMENT AND PERFORMANCE TRACKING TECHNIQUES

Many information technology projects are never initiated because information technology professionals do not understand the importance of knowing basic accounting and finance principles like net present value analysis, return on investment, and payback analysis. Likewise, many projects that are started never finish because of cost management problems. An important topic and one of the key tools and techniques for controlling project costs is earned value management.

Earned value management (EVM) is a project performance measurement technique that integrates scope, time, and cost data. Given a cost performance baseline, project managers and their teams can determine how well the project is meeting scope, time, and cost goals by entering actual information and then comparing it to the baseline. A baseline is the original project plan plus

Table 3 Earned Value Formulas

approved changes. Actual information includes whether a WBS item was completed or approximately how much of the work was completed, when the work actually started and ended, and how much it actually cost to do the work that was completed.

Earned value management involves calculating three values for each activity or summary activity from a project's WBS. Table 3 summarizes important earned value formulas. Note that having a good WBS is an important prerequisite for using earned value management, just as it is for critical path analysis.

1. The planned value (PV), formerly call the budgeted cost of work scheduled (BCWS), also called the budget, is that portion of the approved total cost estimate planned to be spent on an activity during a given period.
2. The actual cost (AC), formerly called the actual cost of work performed (ACWP), are the total direct and indirect costs incurred in accomplishing work on an activity during a given period.
3. The earned value (EV), formerly called the budgeted cost of work performed (BCWP), is the value of the physical work actually completed.

Note that in general, negative numbers for cost and schedule variance indicate problems in those areas. Negative numbers mean the project is costing more or taking longer than planned. Likewise, CPI and SPI less than one or less than 100% also indicate problems.

Earned value calculations for all project activities (or summary level activities) are required to estimate the earned value for the entire project. Some activities may be over budget or behind schedule, but others may be under budget and ahead of schedule. By adding all of the earned values for all project activities, one can determine how the project as a whole is performing.

The project manager can graph earned value information to track project performance. Figure 14 shows an earned value chart for a 1-year project after 5 months. Viewing earned value information in chart form helps

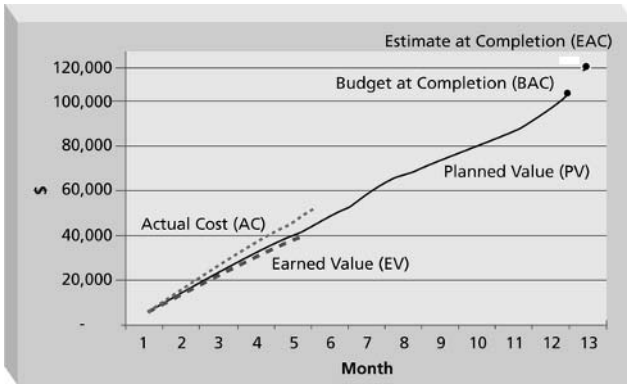

Figure 14: Sample earned value chart.

to visualize how the project is performing. For example, one can see the planned performance by looking at the planned value line. If the project goes as planned, it will finish in 12 months and cost $100,000, represented by the budget at completion (BAC) point. Notice in this example that the actual cost line is always right on or above the earned value line. When the actual cost line is right on or above the earned value line, costs are equal to or more than planned. The planned value line is pretty close to the earned value line, just slightly higher in the last month. This relationship means that the project has been right on schedule until the last month, when the project got a little behind schedule.

Senior managers overseeing multiple projects often like to see performance information in a graphical form like this earned value chart. Earned value charts allow one to see quickly how projects are performing. If there are serious cost and schedule performance problems, senior management may decide to terminate projects or take other corrective action. The estimates at completion are important inputs to budget decisions, especially if total funds are limited. Earned value management is an important technique because, when used effectively, it helps senior management and project managers evaluate progress and make sound management decisions. Many Government projects use earned value, and more private corporations are starting to use this powerful tool (Office of Undersecretary of Defense, n.d.).

OTHER IMPORTANT TOOLS AND TECHNIQUES

As mentioned earlier, there are several project management tools and techniques for each of the nine project management knowledge areas. There are also many tools and techniques used in general management and in application areas that can be applied to projects. This chapter describes just a few of the most common project management tools and techniques. Table 4 lists these and some other common tools and techniques for managing projects. There are many more. Consult PMI (2000b), Schwalbe (2002), or other resources for additional information.

CONCLUSION

Despite all the uncertainty in the world, one can be certain that there will continue to be a need for projects and better ways to manage them. Many organizations have improved project success rates by applying some standard project management processes and using appropriate tools and techniques. This chapter summarizes a few of the common tools and techniques used in project management. Because every project is unique, project managers and their teams must have a good understanding of what tools and techniques are available before they can make the more difficult decisions of which ones to use on their projects and how to implement them.

GLOSSARY

Activity or task An element of work, normally found on the work breakdown structure, that has an expected duration, cost, and resource requirements.

Baseline The original project plan plus approved changes.

Crashing A technique for making cost and schedule trade-offs to obtain the greatest amount of schedule compression for the least incremental cost.

Critical chain scheduling A method of scheduling that takes limited resources into account when creating a project schedule and includes buffers to protect the project completion date.

Critical path The series of activities that determines the earliest time by which the project can be completed.

Earned value management A project performance measurement technique that integrates scope, time, and cost data.

Fast tracking Compressing a schedule by doing activities in parallel that you would normally do in sequence or in slightly overlapping time frames.

Gantt chart A standard format for displaying project schedule information by listing project activities and their corresponding start and finish dates in a calendar format.

Knowledge areas Topics that describe key competencies project managers must develop to manage projects effectively. (The nine knowledge areas in project management are project integration, scope, time, cost, quality, human resource, communications, risk, and procurement management.)

Milestone A significant event on a project with zero duration.

Organizational breakdown structure A structure that describes the people responsible for performing project work.

Program evaluation review technique A network analysis technique used to estimate project duration when there is a high degree of uncertainty about the individual activity duration estimates.

Project charter A document that formally recognizes the existence of a project and provides direction on the project's objectives and management.

Project management The application of knowledge, skills, tools, and techniques to project activities in order to meet project requirements.

Project network diagram A schematic display of the logical relationships or sequencing of project activities.

Project A temporary endeavor undertaken to accomplish a unique purpose.

Responsibility assignment matrix A matrix that maps the work of the project to the people responsible for performing the work.

Slack or float The amount of time an activity may be delayed without delaying a succeeding activity or the project finish date.

Stakeholders The people involved in or affected by project activities.

Statement of Work A form of a scope statement often used by the government or in contracts.

Triple constraint A project's scope, time, and cost goals or constraints.

Weighted scoring model A tool that provides a systematic process for selecting projects based on many criteria.

Work breakdown structure A deliverable-oriented grouping of the work involved in a project that defines the total scope of the project.

Work package A deliverable or product at the lowest level in a work breakdown structure.

Propagation Characteristics of Wireless Channels

P. M. Shankar, *Drexel University*

INTRODUCTION

Wireless systems encompass a wide range of information transmission mechanisms, including cordless phones, paging systems, cell phones, satellite communication systems, maritime-mobile systems, industrial and medical monitoring systems, infrared (IR) remote controls, and so on. These systems have unique operating frequency bands. The choice of the frequencies is often determined by the range of operation (a few meters for a cordless phone to thousands of kilometers for satellite communication systems), the medium through which the signal traverses (e.g., urban areas with tall structures, vast empty spaces in rural areas, and multilevel, multistructure environments in factories and malls), the amount of data to be transmitted (low volume of data in maritime mobile systems and IR-based remote control systems to Gbits/s in satellite systems). The other factors that are equally important are the size of the transmitting and receiving antennas and the cost and maintenance of installations. A broad classification of various frequencies used in wireless communications is shown in Table 1; abbreviation in table are used subsequently in text.

Two important considerations of communication systems must be kept in mind:

1. The physical dimensions of an antenna are inversely proportional to its frequency. Thus, at low frequencies, the size of the antenna may be too large for these frequencies to be used in mobile systems. For example, at 30 kHz, the wavelength is 10,000 m:

$$\left[\text{wavelength} = \frac{\text{velocity}}{\text{frequency}} = \frac{3 \times 10^8}{30 \times 10^3} = 10{,}000 \text{ m}\right].$$

   Note that the required sizes of the antennas will be on the order of a half wavelength. This means that for transmission at 30 kHz, we would require an antenna of length 5,000 m.
2. The amount of data that can be transmitted is directly proportional to the frequency. The data rates at 30 kHz will be less than 30 kbps, whereas the data rates at 1 GHz can be on the order of 1 Gbps. The actual data rates will be determined by a number of factors such as the transmission distance, the characteristics of the intervening medium, and the modulation–demodulation schemes.

Once we take these considerations into account, it is clear that the very low frequencies can be eliminated from the range of operation of the practical wireless communication systems, which demand transmission at very high data rates, portability (i.e., mobile systems), and compact-size. The large size of antennas and low data rates associated with low frequencies eliminate them from considerations in modern wireless communication systems and networks. Even though the frequencies on the higher end of the spectrum (Table 1) appear to offer smaller size antennae and higher data rates, their use in wireless systems is limited by other factors. The primary reason for their unsuitability is that these frequencies are severely attenuated by "obstructions" in their path. A case of a direct path (line of sight [LOS]) between the transmitter and a receiver is shown in Figure 1.

In a typical urban environment containing tall buildings and other structures, these signals (EHF) will be unable to penetrate and reach the transmitter (Bertoni, Honcharenko, Maciel, & Xia, 1994; Jakes, 1974; Pardo, Cernicharo, & Serabyn, 2001; Parsons, 1996; Saunders, 1999; Steele & Hanzo, 1999). They require a clear line of sight between the transmitter and receiver, making them well suited for satellite-to-ground (or ground-to-satellite) transmission or satellite-to-satellite transmission. They may also be used in very specific applications involving short-range transmission of a large volume of data in confined spaces with no obstructions. Thus, it is possible to narrow down the choice of the frequencies for practical wireless systems based on the additional consideration of the manner in which the signals reach the receiver from the transmitter. Frequencies that can penetrate buildings, be reflected, refracted, diffracted, and scattered from buildings, trees, and still reach the receiver must be available. The important considerations for the choice of frequencies can now be restated as follows:

1. Size of the antenna
2. Ability and convenience to mount the antenna on portable units, moving vehicles, and so on
3. Ability to reach the receiver even when a LOS path is not available
4. Data rates

These important factors narrow the frequencies to UHF or typically in the range of 900 MHz to 3 GHz. Additional factors that affect the performance of the wireless systems will be discussed later.

Table 1 Various Frequency Bands Used in Wireless Systems, Their Identification, and Their Characteristics

FREQUENCY BAND	FREQUENCY RANGE	ANTENNA SIZE	DATA RATE
VLF (very low frequency)	3–30 kHz	Large	Low
Low frequency (LF)	30–300 kHz	↑	↓
Medium frequency (MF)	300 kHz–30 MHz		
High frequency (HF)	3–30 MHz		
Very high frequency (VHF)	30–300 MHz		
Ultra high frequency (UHF)	300 MHz–3 GHz		
Super high frequency (SHF)	3–30 GHz		
Extra high frequency (EHF)	30–300 GHz	Small	High

Having narrowed the operational frequency bands in practical wireless systems, we now look at two key factors that have a significant impact on the performance of wireless communication systems: the signal strength received and any variability of the signal strength. These factors play a major role in determining how far the signal will travel (i.e., separation between transmitter and receiver) and how much data can be transmitted usefully. The former is dictated by the level of loss suffered by the signal as it reaches the receiver, and the latter is dictated by the level variations. Both are uniquely determined by the terrain between the transmitter and receiver.

PROPAGATION OF SIGNALS

The following sections consider the attenuation and the signal variability experienced by the wireless signals.

Transmission Loss

As the electromagnetic waves travel from the transmitter to the receiver, they encounter various objects in their path. In typical urban environments, it may not be possible to have an LOS path between the transmitter and the receiver. The signal leaving the transmitter reaches the receiver through a number of mechanisms, such as reflection, diffraction, and scattering (Feher, 1995; IEEE, 1988; Jakes, 1974; Rappaport, 2002; Shankar, 2001). These are depicted in Figure 2. Reflection occurs when the signal encounters objects that are much larger than the wavelength. This is shown in Figure 2 (left). While reflection is taking place, refraction of the wave may also take place, in which case the signal will penetrate the object, which may be a wall or a partition. The signal may also undergo diffraction (i.e., bending over obstacles) when the signal encounters sharp boundaries as seen in Figure 2 (center). Scattering occurs when the surface of the object is rough and is on the order of the wavelength. The signal is scattered in all directions as seen in Figure 2 (right) as opposed to getting reflected in a specific direction in the case of reflection where the angle of incidence is equal to the angle of reflection. Thus, in outdoor areas, a signal reaches the receiver through reflection, scattering, and diffraction, as it encounters building, trees, and other artificial or natural objects. In indoor areas, such as in malls, factories, and office buildings, the signal will reach the receiver penetrating floors, walls, ceilings, and so on while undergoing effects of reflection, scattering, and diffraction.

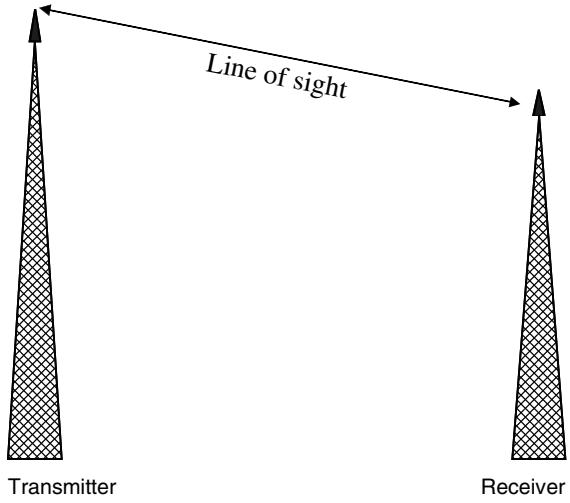

Figure 1: A line of sight propagation is shown.

A typical signal received in urban wireless systems is shown in Figure 3a. It is seen that the received power decreases as the distance increases. The power is plotted in dBm. (The relationship between power in watts and dBm is given in the Appendix.) In a short segment of this curve, as shown in Figure 3b, the power loss is not a straight line. The power fluctuates as it decreases. These fluctuations are referred to as long-term fading or shadowing (Pahlavan & Levesque, 1993; Parsons, 1996). Zooming further into the power versus distance curve, the power fluctuates around a mean value (Fig. 3c). These fluctuations are of short duration compared with those seen in Figure 3b and are referred to as short-term fading. They are also known as Rayleigh fading, based on the statistical fluctuations in the received envelope of the signal (Rappaport, 2002; Shankar, 2001; Steele & Hanzo, 1999; Stein, 1987). Nakagami fading and Rician fading are also used to describe short-term fading.

It is thus clear that the signal undergoes attenuation and fluctuations as it reaches the receiver. The fluctuations introduce random variations in the received power, making it necessary to take additional steps to design the link. The next section explores ways of modeling the power loss and the fluctuations in power.

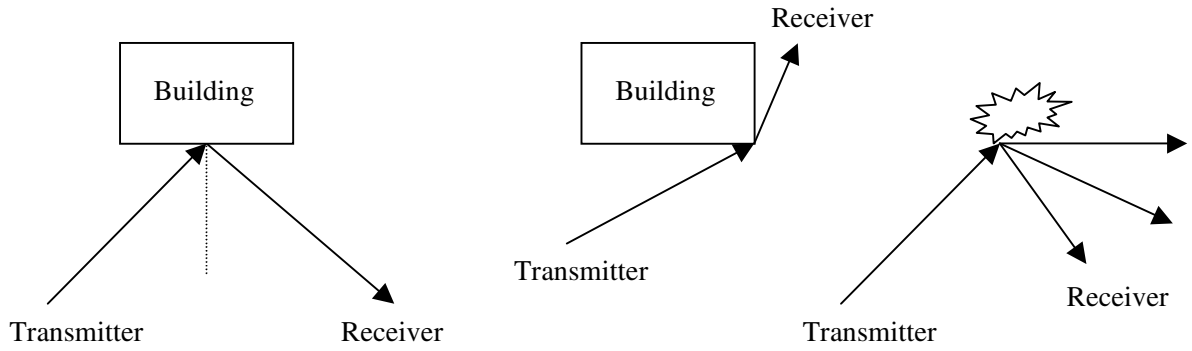

Figure 2: Various propagation mechanisms are shown: reflection (left), diffraction (center), and scattering (right).

Modeling of Power Loss

Several models are available to predict the median value of the received power (Har, Xia, & Bertoni, 1999; Hata, 1980; Lee, 1986; Oda, Tsunkewa, & Hata, 2000; Okumura, Ohmori, & Fukuda, 1968; Vogel & Hong, 1988). These are available for propagation outdoors and indoors (Bultitude, Mahmoud, & Sullivan, 1989; Durgin, Rappaport, & Xu, 1998; Harley, 1989; Lott & Forkel, 2001; Rappaport & Sandhu, 1994). They are also available for various frequency bands that are of interest in wireless communications. Instead of concentrating on these models, I initially describe one of the simple ways of predicting loss based on the concept of the *path loss exponent*. To understand this concept, consider the case of a line-of-sight propagation in free space as shown in Figure 1. If P_t is the transmitted power in W (Watts), the received power P_d (W) at a distance d from the transmitter is given by Friis formula (IEEE, 1988),

$$P_d = P_t G_t G_r \left(\frac{\lambda}{4\pi d}\right)^2 W, \tag{1}$$

where G_t = gain of the transmitting antenna, G_r = gain of the receiving antenna, and λ = free space wavelength = $\frac{c}{f_0}$,

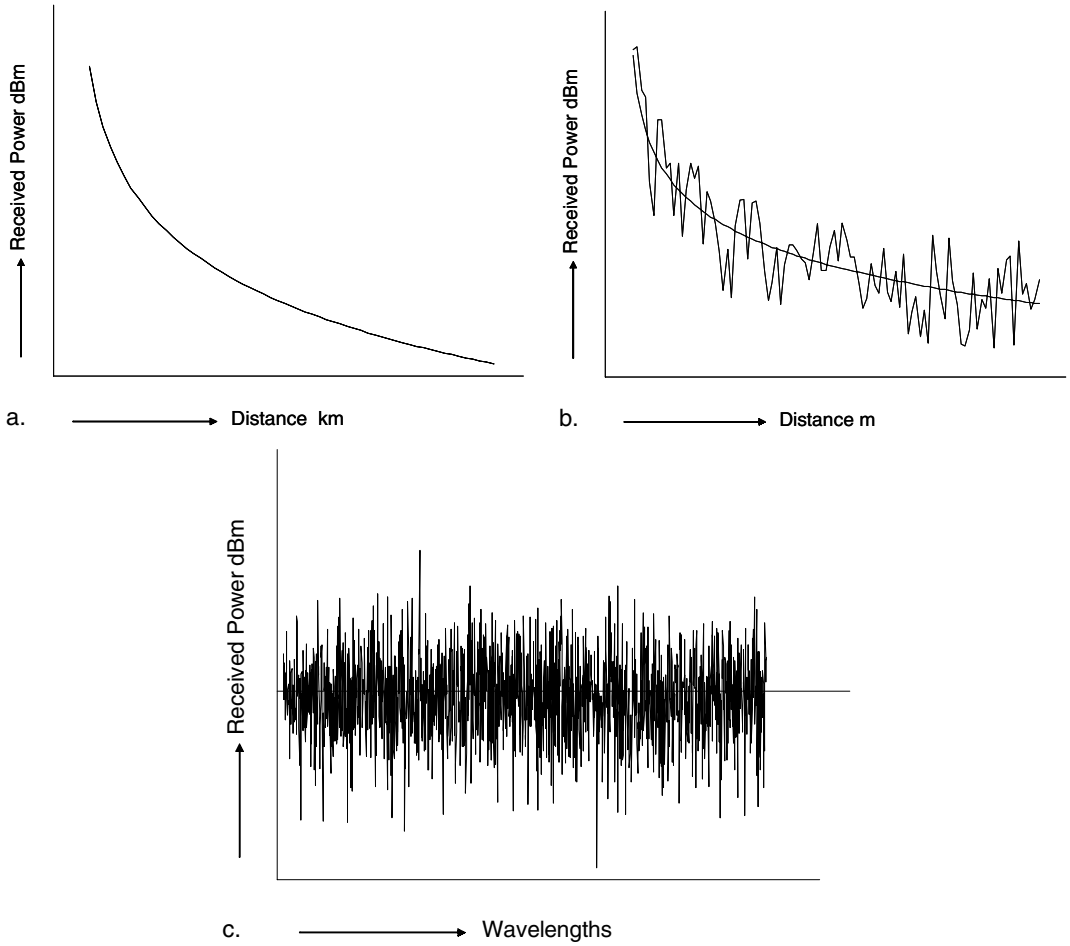

Figure 3: The plot of the received signal: (a) attenuation; (b) long-term fading; (c) short-term fading.

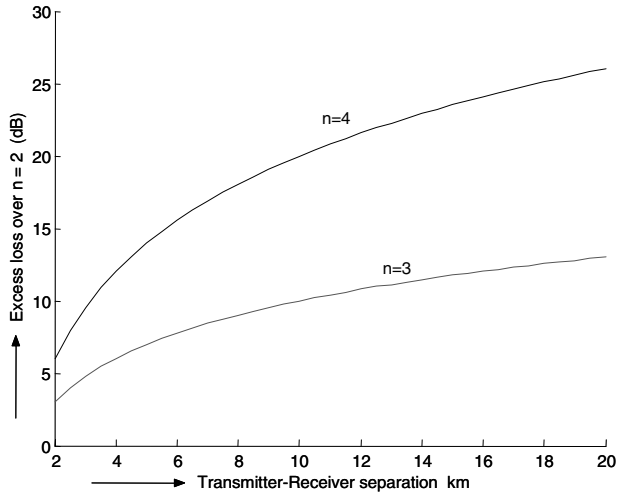

Figure 4: The losses at $n = 3$ and $n = 4$ are compared with the free space loss ($n = 2$).

c being the velocity of light and f_0 the frequency. Note that G_t, and G_r, are dimensionless (i.e., numbers) and d and λ must have the same units (centimeters, meters, or kilometers). Assuming equal gain antennas ($G_t = G_r$), the received power can be expressed as inversely proportional to the square of the distance

$$P_d \propto \frac{1}{d^2}.$$

Conversely, we can say that the loss experienced by the signal is directly proportional to the square of the distance. The path loss exponent or the path loss coefficient determines the decay of the power as distance increases and is denoted by n. In free space under LOS conditions, the path loss exponent n is 2. Because there are no obstacles in the path of the signal in LOS propagation in free space, no reflection, diffraction, or scattering takes place, $n = 2$ will be the best case scenario expected in signal transmission. In a general case, where propagation takes place in a region containing obstacles, the path loss exponent will be larger than 2, pointing to higher path loss as n increases. The excess loss over $n = 2$ is plotted in Figure 4 as a function of the distance. The loss at a given distance increases as n goes up. Note that the path loss exponent n is also sometimes referred to as power decay index, distance power gradient, or slope factor.

It must be noted that the low values of n also increase cochannel interference, namely, the interference coming from other cells using the same channel. As the value of n increases, the interference goes down, leading to an improvement in the capacity of the cellular communication systems.

Calculation of the Received Power at Any Distance

Power received at any distance d is inversely proportional to the nth power of the distance,

$$P_d \propto \frac{1}{d^n}. \tag{2}$$

Equation 2 cannot be applied directly because of the need to evaluate the proportionality factor. This is done by applying Frii's equation (Feher, 1995) at a very short distance d_0 from the transmitter, where it can be assumed that free space LOS conditions exist. If P_{d_0} is the power at a distance of d_0 from the transmitter ($G_t = G_r = 1$),

$$P_{d_0} = P_t \left(\frac{\lambda}{4\pi d_0}\right)^2. \tag{3}$$

Using Equation 2 one can now write

$$\frac{P_d}{P_{d_0}} = \frac{d_0^n}{d^n}. \tag{4}$$

Taking the logarithm, one arrives the expression for the received power at a distance d ($d > d_0$) from the transmitter to be

$$P_d(dBm) = P_{d_0}(dBm) - 10n\log_{10}\left(\frac{d}{d_0}\right), \tag{5}$$

where

$$P_{d_0}(dBm) = P_t(dBm) + 20\log_{10}\left(\frac{\lambda}{4\pi d_0}\right). \tag{6}$$

Note that in Equations 5 and 6, the power is expressed in decibel units (dBm). The question is now what value of d_0 is appropriate. Typically, this value, known as the *reference distance* ($\lambda < d_0$), is chosen to be 100 m in outdoor environments and 1 m in indoor environments (Pahlavan & Levesque, 1995; Rappaport, 2002; Shankar, 2001).

The models described thus far can be applied for calculating the received power at various operating frequencies indoors and outdoors. A few points are in order. The received power according to Frii's equation (Equation 3) decreases as the wavelength decreases. This means that as one moves from 900 MHz band to the PCS (personal communication systems) operating at the 1,800 to 2,000-MHz band, the received power decreases. As wireless communication systems move into the 4–6 GHz band, the received power decreases further as the wavelength decreases (Table 1). Another factor that becomes critical as the frequencies increase is the inability of the signal to penetrate buildings. For example, compared with 900-MHz signals, 2-GHz signals will not travel far from the transmitter. Signals may even be blocked by a single building between the transmitter and receiver. Thus, the LOS propagation becomes the predominant means by which the signal reaches the receiver. In the case of a microwave signal, a truck obstructing the path can bring down the received signal to extremely small levels (IEEE, 1988).

The approaches based on the path loss exponent are not the only ones to estimate the loss suffered by the signal as it reaches the receiver. The disadvantage of the path-loss-based approach is that it does not directly take into account a number of system dependent factors such the heights of the transmitting and receiving antennas and their locations. Models such as Lee's (1986) model, Hata's

(1980) model, and the Walfish and Bertoni model (Har et al., 1999; Ikegami, Tekeuchi, & Yoshida, 1991; Oda et al., 2000; Okumura et al., 1968; Vogel & Hong, 1988) are also available to calculate the received power. These models take into account the antenna heights and other factors. Yet another approach is to use a two exponent model, where instead of using a single exponent, two values, n_1 and n_2, are used. The loss increases slowly (i.e., the loss occurs as if we have propagation in free space with $n = n_1 = 2$) until a break point is reached. Beyond that point, the loss goes up at a higher rate, with n taking value of n_2 in the range 3 to 9 (Bertoni et al., 1994; Rappaport & Sandhu, 1994). Even though this double exponent approach may appear to lead to better results, some of the path loss prediction models can be used to get more satisfactory results. I now describe the Hata (1980) model for the calculation of the loss suffered by the signal as it travels from the transmitter to the receiver. The loss L_p in decibels (dB) is

$$L_p = P_t(dBm) - P_d(dBm), \tag{7}$$

where the transmitted power P_t and the received power P_d are once again expressed in decibel units.

Hata Model

Based on measurements in a number of cities, Hata (1980) proposed a model to predict the median loss suffered by the wireless signal. This model is an improvement over that proposed by Okumura et al. (1968) because it incorporates correction factors to account for the antennae height based on the geographical location. When one moves from large cities to rural areas, the reduction in power loss can be accommodated with correction factors for the antenna height. The median loss in urban areas according to Hata model, L_p is given by

$$\begin{aligned} L_p(dB) \;=\; & 69.55 + 26.16\log_{10}(f_0) \\ & + (44.9 - 6.55\log_{10} h_b)\log_{10} d \\ & - 13.82\log_{10} h_b - a(h_{mu}), \end{aligned} \tag{8}$$

where f_0 is the carrier frequency (MHz), $400 \le f_0 \le 1500$; d is the separation between base station and mobile unit (km), $d > 1$; h_b is the height of the base station antenna (m); h_{mu} is the height of the mobile unit antenna (m); and $a(h_{mu})$ is the correction factor for mobile unit antenna height.

For large cities, the correction factor $a(h_{mu})$ is given as

$$a(h_{mu}) = 3.2[\log_{10}(11.75\,h_{mu})]^2 - 4.97 \quad (f_0 \ge 400\,\text{MHz}). \tag{9}$$

For small and medium cities, the correction factor is

$$a(h_{mu}) = [1.1\log_{10}(f_0) - 0.7]h_{mu} - [1.56\log_{10}(f_0) - 0.8]. \tag{10}$$

For suburban areas, the median loss, L_{sub} is given by

$$L_{sub}(dB) = L_p - 2\left[\log_{10}\left(\frac{f_0}{28}\right)\right]^2 - 5.4, \tag{11}$$

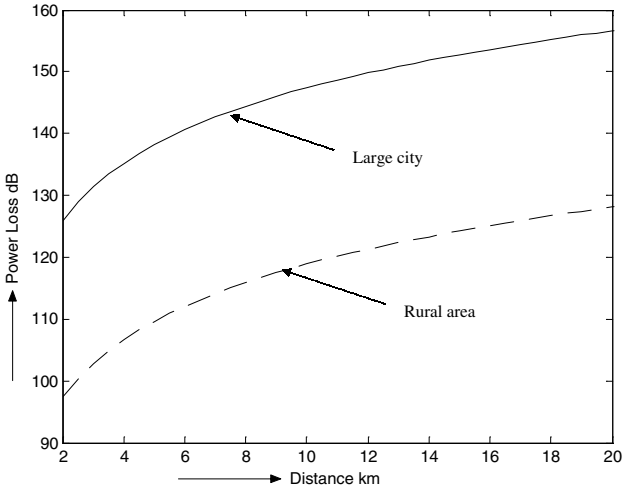

Figure 5: Loss predictions based on Hata model are shown. The radio frequency signal is at 900 MHz. The base station antenna height is 150 m, and the mobile unit antenna height is 1.5 m.

where L_p is the median loss in small–medium cities. For rural areas, the median loss, L_{rur} is given by

$$L_{rur}(dB) = L_p - 4.78[\log_{10}(f_0)]^2 + 18.33\log_{10} f_0 - 40.94. \tag{12}$$

The loss observed in large cities and rural areas is shown in Figure 5. It is easily seen that the losses are higher in urban areas.

The Hata model is not capable of predicting losses in the frequency bands used in some of the present-day systems operating in the 1,500–2,000 MHz band. The Hata model can be extended to cover this range (Rappaport, 2002; Saunders, 1999; Shankar, 2001) and the median power loss in urban areas, $L_P(dB)$ can be expressed as

$$\begin{aligned} L_P(dB) = {} & 46.3 + 33.93\log_{10}(f_0) - 13.82\log_{10}(h_b) \\ & - a(h_{mu}) + [44.9 - 6.55\log_{10}(h_b)]\log_{10} d \\ & + Corr \end{aligned} \tag{13}$$

where $Corr$ is the additional correction factor given by

$$Corr = \begin{cases} 0 & dB \text{ for medium city and suburban areas} \\ 3 & dB \text{ for metropolitan areas} \end{cases}$$

This model is valid for the following parameters only:

f_0 : 1,500–2,000 MHz
h_b : 30–200 m
h_{mu} : 1–10 m
d : 1–20 km

This model is applicable only for distances beyond 1 Km and thus is not applicable in microcells and picocells in which the distances between the transmitter and receiver may be only a few hundred meters. Other models

are available for loss prediction over short ranges (Har et al., 1999; Harley, 1989; Ikegami et al., 1991).

Indoor Wireless Systems

The loss calculation in indoor wireless systems is less straightforward than outdoor systems. It is possible to use Equations 5 and 6 to calculate the received power or predict the loss. Based on empirical measurements conducted indoors and outdoors, the range of values of n has been proposed by several researchers. Note that these values depend on the environments in which the wireless signal is propagating, and in indoor propagation, the values of n are strongly influenced by factors such as the building materials used, floor arrangement, location of the transmitting antenna (inside the building or outside the building), height of the transmitting antenna, frequency used. The values of n range from 2 to 4 as one moves from an open space where free space LOS propagation is possible to urban areas with tall buildings and other structures. In indoor environments, the value of n less than 2 has been observed in grocery stores and open-plan factories (Dersch & Zollinger, 1994; Durgin et al., 1998; Rappaport & Sandhu, 1994). This low value (lower than $n = 2$ in free space) has been attributed to the strong reflections contributed to the received signal by the metallic structures in those places, resulting in higher power levels compared with a completely open space ($n = 2$). Inside the buildings, n can take values in the range of 1.5–4 depending on the number of floors, location of the transmitter, and type of partition (hard vs. soft) used.

A typical indoor propagation scenario is shown in Figure 6. The base station is outside the building. It is also possible to have the base station inside the building depending on the complex. It is easy to see that the signal may have to travel through multiple floors and multiple walls, each of which may be of a different type, to reach the receiver. The loss calculations are therefore complicated, and the wireless systems would have to be designed specifically for a given complex or building. It is nonetheless possible to write a general equation for the calculation of the loss. The loss at a distance d, L_p can be expressed as

$$L_p(d)dB = L_p(d_0)dB + 10n_{eff}\log_{10}\left(\frac{d}{d_0}\right) + \sum_{k=1}^{K} P_k, \qquad (14)$$

where n_{eff} is the effective loss exponent taking into account the multiple floors and walls in the building through which the signal traverses (Durgin et al., 1998; Rappaport and Sandhu, 1994). The other factor in Equation 14, P_k, is the specific material attenuation in dB suffered by the signal as it traverses through K floors/walls. The loss at a distance of $d_0 = 1$ m is given by $L_p(d_0)$.

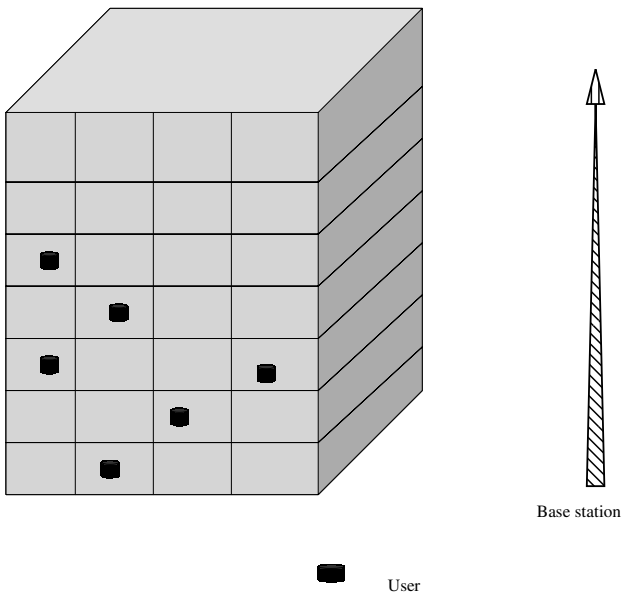

Figure 6: An indoor wireless system with the base station (BS) serving all the users inside. The BS may also be inside the building. The signals between the BS and the users may have to travel through several floors and partitions.

Signal Variability and Fading

I now briefly review the origins of signal variability seen in wireless systems. The signal variability may be caused by short-or long-term fading, or both. Short-term fading may result from multipath fading and Doppler fading. The next sections explores these fading mechanisms and diversity techniques used to mitigate the problems caused by fading.

Multipath Fading

The second characteristic of the wireless signal is the signal variability seen in wireless systems (Feher, 1995; Hashemi, 1993; Kennedy, 1969; Pahlavan & Levesque, 1995; Rappaport, 2002). The signal variability is the lack of predictability of the loss or received power. We had seen in Figure 3 that the power loss fluctuates as the distance increases, with the mean or median fluctuations obeying the nth power of the distance. This random nature of the wireless signals is termed *fading*. This can lead to occasional loss of the signal and network break down because the systems require a minimum amount of power (threshold) to perform satisfactorily and power fluctuations may bring the power below this threshold. This can be taken into consideration by providing a power margin.

Even though the obvious effect of the fading is the random fluctuations of the received power, fading also is responsible for limiting the bandwidth capability of the wireless systems. I first attempt to explain the reasons for the fluctuation in power and effects of fluctuations on data transmission and then explain why the fading limits the bandwidth.

In a typical wireless environment, the signal reaches the receiver after being reflected, scattered, diffracted, or refracted from a number of objects in its path (Jakes, 1974; Shankar, 2001). Thus, the signal does not take a single path to reach the receiver. Instead, the signal reaches the receiver through multiple paths, as shown in Figure 7.

These signals with various amplitudes and phases combine at the receiver. This multipath phenomenon is responsible for the fluctuations in the signal power observed in Figure 3c. This fluctuation in power or fading is short-term fading, of which there are two major consequences. First, the random nature of these fluctuations

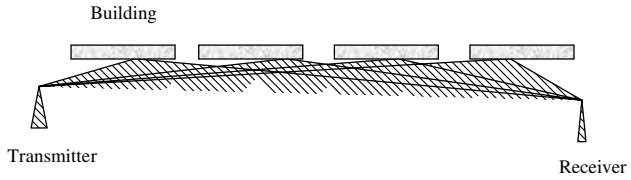

Figure 7: The existence of multiple paths between the transmitter and receiver.

(some times termed *Rayleigh fading*) increases the uncertainty in the received signal power, making it necessary to develop methods to mitigate fading through diversity. Second, the paths shown in Figure 7 take different times leading to a broadening of the received pulse as shown in Figure 8. Figure 8a shows a transmitted pulse $p(t)$. This pulse takes multiple paths and the received pulse $r(t)$ can be expressed as

$$r(t) = \sum_{k=1}^{N} a_k p(t - t_k), \tag{15}$$

where a_k is the strength of the pulse and t_k the time taken by the k^{th} pulse. These delayed pulses of different strengths overlap, broadening the pulse at the receiver seen in Figure 8b. Note that the data rate is inversely proportional to the pulse duration and any broadening of the pulse will lead to overlapping of adjoining pulses resulting in inter symbol interference (ISI). ISI increases the bit error rate (BER). To prevent pulse broadening, it becomes necessary to operate at a lower data rate when fading is present. If pulse broadening leads to a reduction in data rate or makes it necessary to put in place additional signal processing methods to mitigate the effects of pulse broadening, the medium or channel in which this takes place is referred to as *a frequency selective fading channel*. On the other hand, if the pulse broadening is negligible, the medium or channel is referred to as a *flat fading channel*.

Regardless of whether the channel is flat or frequency selective, the fluctuations of power are associated with fading. The fluctuations in power cause an increase in the BER, making it necessary to operate at higher powers. This case is illustrated in Figure 9, which shows the BERs when no fading is present and also when Rayleigh fading is present. To maintain a BER of 1 in 1,000 would require an additional signal-to-noise ratio of approximately 17 dB when fading is present, demonstrating the problems associated with fading.

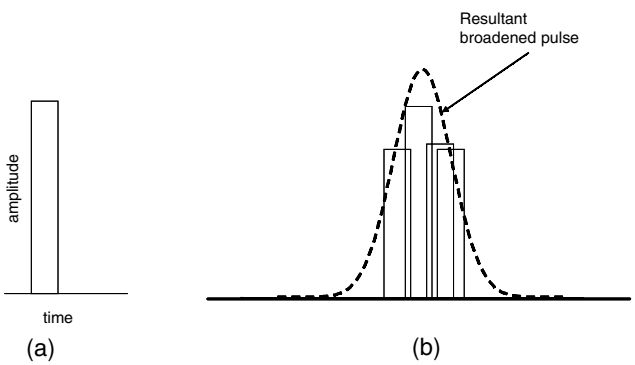

Figure 8: Transmitted pulse (a) and the received pulse (b).

Now consider a signal-to-noise ratio of 10 dB. The results shown in Figure 9 indicate that in the presence of fading a signal-to-noise ratio of 10 dB is not sufficient (Shankar, 2001) to have an acceptable level of performance (say, 1 in 1,000). This leads to outage.

It is possible to have a direct path (LOS) between the transmitter and the receiver in addition to the multiple paths. This condition is more ideal than a pure multipath scenario because the LOS component provides a steady component to the signal. As the strength of the steady component increases (over the multipath components), the deleterious effects of fading decrease. This fading channel is known as the *Rician channel*. It can be shown that as the strength of the LOS component increases, the Rician channel starts approaching the ideal *Gaussian channel,* thus reducing the severity of fading.

Doppler Fading

Multipath fading does not take into account any relative motion of the transmitter and receiver. If the wireless receiver (or transmitter) is mounted on a moving vehicle, the motion introduces Doppler broadening. Motion-induced fading is referred to as *Doppler fading* and is responsible for further degradation in the performance of the wireless systems. If a pure tone of frequency f_0 is transmitted, the received signal spectrum will broaden (Doppler broadening) and contain spectral components raging from $f_0 - f_d$ to $f_0 + f_d$, where f_d is the Doppler shift. If the bandwidth occupied by the information is much greater than the spectral broadening, Doppler spread does not lead to any significant problems in transmission and reception. The channel in this case is referred to as a *slow channel*. If the bandwidth is smaller than the Doppler spread, motion leads to channel varying rapidly within the duration of the pulse. In this case, the channel is referred to as a *fast channel*. Thus, multipath fading decides whether the channel is flat or frequency selective, and Doppler fading decides whether the channel slow or fast (Jakes, 1974; Parsons, 1996). Whereas multipath fading leads to pulse spreading (time), Doppler fading leads to frequency spreading. The different types of fading are summarized in Figure 10.

Long-Term Fading

As shown in Figure 3, power fluctuations have a longer period in Figure 3b than the fluctuations in Figure 3c. These fluctuations with larger periods are statistically described in terms of lognormal fading (Jakes, 1974). Whereas short-term fading is caused by the existence of multipath, long-term fading is caused by the existence of multiple reflections. This means that the signal in a single path cannot reach the transmitter after a single reflection or scattering process but must travel through several structures, causing a "shadowing effect" caused by the presence of many tall structures. The power expressed in decibels in this case is normally distributed, and the power in watts will therefore be lognormally distributed (Jakes, 1974; Rappaport, 2002; Steele & Hanzo, 1999). These

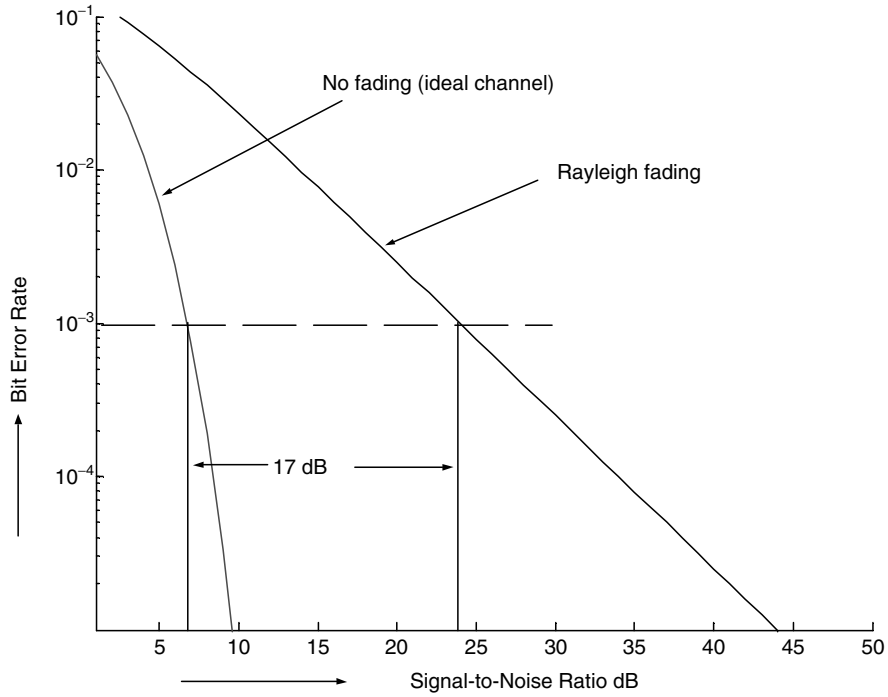

Figure 9: The bit error rate (BER) in an ideal channel and a fading channel. The increased signal-to-noise ratio required to maintain a BER of 1 in 1,000 when fading is present is indicated (17 dB).

situations arise even in indoor channels. To account for the lognormal fading or shadowing, the loss terms in Equation 7 are modified by introducing a term X to the equation for the loss. X is a zero mean normal random variable with a standard deviation of σ_{dB} to take lognormal fading into consideration.

$$Loss = L_p(d) + X \tag{16}$$

The loss calculated now becomes the average of a normally distributed random variable with a standard deviation determined by the severity of the lognormal fading. Long-term fading will also cause outage if the variation in loss is not taken into account during the design of the wireless systems. This situation is handled by including a power margin in the link budget calculations.

Diversity Techniques

Effects of short-term fading can be mitigated through diversity techniques that exploit the randomness existing in the channel. Consider a scenario for which it is possible to

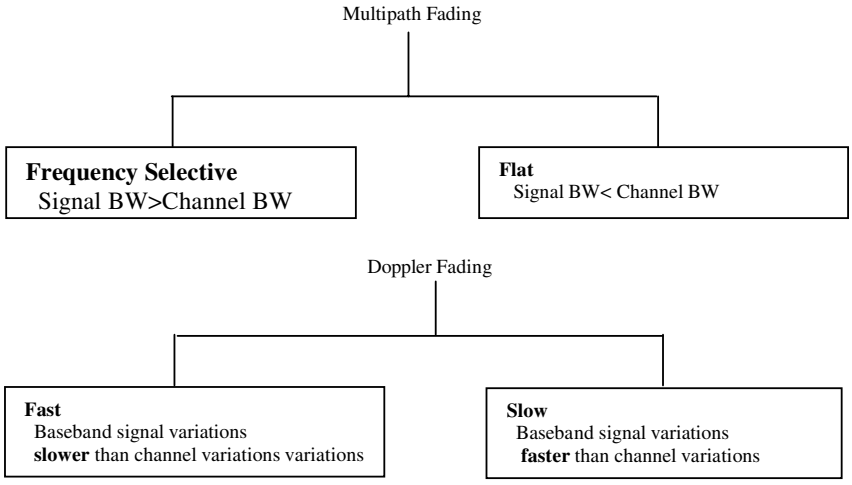

Figure 10: Overview of short-term fading. Pulse broadening taking place in frequency selective channel can be described in terms of the relationship between the message bandwidth and channel bandwidth. Doppler fading can be described in terms of the variations in the channel relative to the signal.

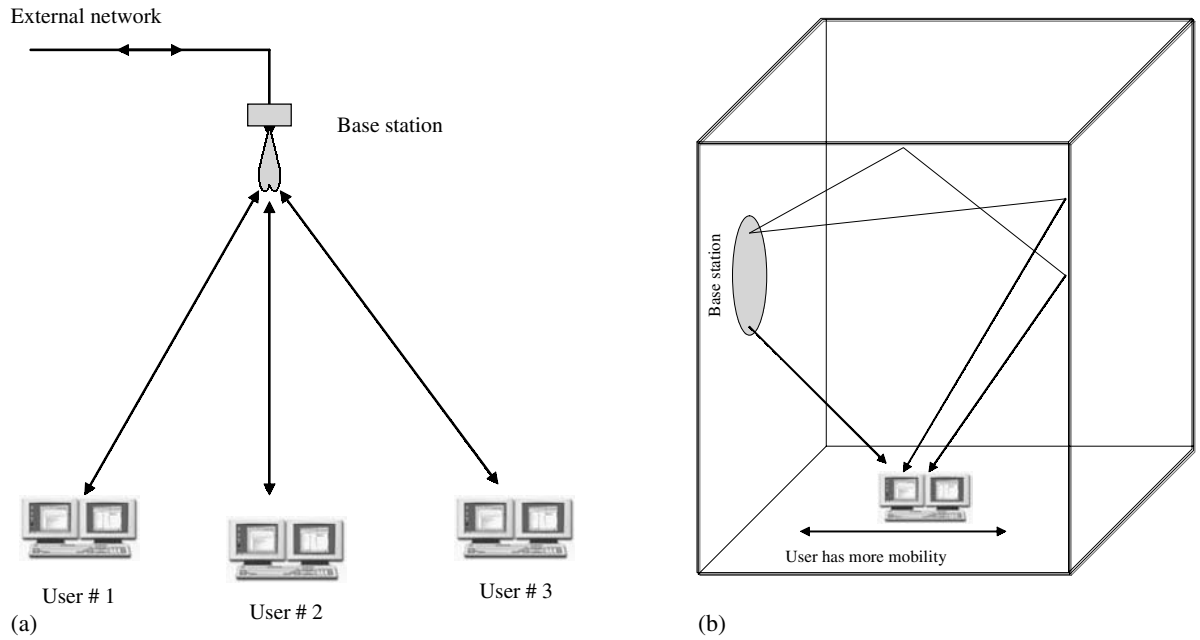

Figure 11: (a) A line-of-sight optical wireless system. (b) An indoor optical wireless system using diffuse light.

create $N\,(N > 1)$ multiple (diverse) independent (at least uncorrelated) versions of the signal. If the probability that signal goes below a threshold is p, the probability that that all these multiple versions of the signals will go below that threshold *simultaneously* is p^N. In other words, if one were to choose the strongest signal from this set, the probability that this chosen signal is above the threshold is $(1 - p^N)$, leading to fading mitigation lessening the chances of outage. The signal processing in terms of choosing the strongest signal is known as selection diversity. Other forms of diversity, such as processing, maximal ratio combining, and equal gain combining, are also available to combine the signals from the diverse branches (Stein, 1987).

Diversity is implemented in the spatial domain (spatial diversity) by having multiple transmitters or multiple receivers or in the frequency domain (frequency diversity) by transmitting the same information over multiple frequency bands, and so on. Other forms of diversity, such as angle diversity, polarization diversity, time diversity, and rake receiver, are also available (Shankar, 2001; Stein, 1987).

Although the techniques described here constitute examples of microscopic diversity to mitigate effects of short-term fading, long-term fading or shadowing can be mitigated through macroscopic diversity techniques. Choosing the best base station that provides the strongest signal to serve a subscriber is a form of macroscopic diversity. It is also possible to combine the signals from different base stations to reduce the effects of long-term fading further.

OPTICAL WIRELESS SYSTEMS

Optical wireless networks offer a simple solution to problems of electromagnetic interference in traditional indoor wireless systems (ElBatt and Izadpanah, 2001; IEEE, 1998; Heatley & Neild, 1999; Pohl, Jungnickel, & von Helmolt, 2001). They are also not subject to any license regulation requirements. They are simple to implement so as to cover a large room or area without any signal leaking through the walls or partitions. This confinement of the signal also offers a form of security from snooping from the adjoining rooms. Because most of the systems depend on LOS, fading problems associated with multipath will be less.

The optical wireless systems fall in two groups, one using LOS systems and the other using diffuse systems. An indoor system based on LOS is shown in Figure 11a.

The signal from the base station reaches the users via direct paths. These LOS conditions exist in the confined space that may also provide a limited mobility and roaming. It is possible to create greater mobility using a diffuse system in which multiple paths exist between the user and the base station. This is shown in Figure 11b. The drawback of the existence of multiple paths is that it leads to the fading condition described earlier in connection with wireless systems in the 900- to 1,800-MHz band.

The indoor optical wireless systems use light emitting diodes and laser diodes operating around 900 nm (900–1,100). The receiver may be a photodiode (p-i-n) or an avalanche photodiode (APD). These systems also have a few major drawbacks. The interference from ambient light is a major problem. The second is the issue of eye safety, which may make it necessary to operate at lower power levels. Because of these factors, the data rate is a few hundred Mbit/s with a range of operation of a few meters (IEEE, 1998).

APPENDIX: POWER UNITS

The power is normally expressed in decibel units. Power (P_0) in milliwatts (mW) can be expressed in terms of decibel units, dBm, as

$$P_0(dBm) = 10\log_{10}\left[\frac{P_0\,(mW)}{1\,mW}\right]. \tag{A-1}$$

Thus, the power in dBm is an absolute measure of power in mW. 10 mW power is 10 dBm, 1 W is 30 dBm, and 1 μW is –30 dBm. The unit dB, on the other hand, is the ratio of two powers in identical units. For example, if the average signal power is P_0 (mW) and the average noise power is P_n (mW), the signal-to-noise ratio (S/N) can be expressed as

$$(S/N)\,dB = 10\log_{10}\left[\frac{P_0\,(mW)}{P_n\,(mW)}\right]. \tag{A-2}$$

Thus, signal-to-noise ratio expressed in dB carries information on the strength of the signal relative to the noise. If the signal-to-noise ratio is 0 dB, the signal power and noise power are equal. If the signal-to-noise ratio is 20 dB, the signal is 100 times stronger than the noise. If the signal-to-noise ratio is –3 dB, the signal is only 50% of the noise. Loss or attenuation can be expressed in dB units as

$$Loss\,(dB) = Transmit\ power\,(dBm) - Receive\ power\,(dBm). \tag{A-3}$$

If the transmitted power is 10 mW and the received power is 1 μW, one can calculate the transmission loss as $10\log_{10}(10\ mW) - 10\log_{10}(1\,\mu W) = 10 - (-30) = 40\ dB$.

GLOSSARY

Base station (BS) A fixed station in a cellular system that communicates with the mobile units within a cell and may be located at the center (or the edge of the cell). A BS has transmitting and receiving antennas mounted on a tower and is the link between a mobile unit and a mobile switching center.

Bit error rate (BER) The ratio of the number of bits received in error to the total number of bits received.

Cell A geographic region served by a base station.

Doppler shift The upshift or downshift in frequency resulting from the motion of the transmitter with respect to the receiver or vice versa. If the relative speed is v, the Doppler shift is

$$f_d = \frac{v\cos(\theta)}{c}\,f_0,$$

where c is the speed of the electromagnetic wave (3×10^8 m/s), f_0 is the carrier frequency, and θ is the angle between the directions of the transmitter and receiver.

Hand set See mobile unit.

Inter symbol interference (ISI) The interference caused by the overlapping of adjoining symbols or pulses resulting in signal distortion. Viewed in the frequency domain, existence of ISI implies that the channel cannot carry all frequencies with equal gain, with gain decreasing as the frequencies go up.

Link budget The process of computing the maximum transmission distance taking into account the transmitted power, loss or attenuation, and power margin.

Macrocell, microcell, and picocell Microcell typically will cover a few hundred meters while picocells are formed when the base station antenna is located within a building. The coverage of the picocell will be a few meters or less. Macrocells typically cover a few kilometers.

Mobile station (MS) See mobile unit.

Mobile unit (MU) A mobile unit is carried by the subscriber. It may be handheld or vehicle mounted.

Outage Whenever the performance of the wireless system does not reach the minimum acceptable levels, the system goes into outage. For example, if a user requires a minimum power of P_{th} to have an acceptable performance, any time the received power goes below P_{th}, the system goes into outage. The rate at which this happens is the outage probability.

Power margin The excess power budgeted to account for any effects other than the attenuation or the loss of the signal. For example, if a user requires a threshold power of P_{th} (dBm) to maintain acceptable performance and M dB is the power margin to account for fading, the user will require that the minimum acceptable power $P_{\min}$ (dBm) at the receiver be set to $P_{\min} = P_{th} + M$. This has the effect of reducing the available separation between the transmitter and receiver.

Prototyping

Eric H. Nyberg, *Carnegie Mellon University*

OVERVIEW OF THE SOFTWARE LIFE CYCLE

The conception, implementation, and evolution of software will follow a particular life cycle, depending on the problem to be solved, the software and hardware chosen, and the inevitable changes to system requirements and functionality that happen over time. It can be extremely useful to construct a prototype system in advance of a full-scale implementation; because a prototype typically addresses all of the important aspects of a system to be built, it can be a means to sharpen the system requirements and focus the development team on the most important challenges and risks. In order to understand the role that prototyping can play in an e-commerce application, it is first necessary to understand the basic steps in the software life cycle.

Requirements Elicitation and Specification

The software process begins with requirements elicitation and specification. Through a set of communications with customer representatives, the software engineers begin to specify the system to be built by documenting its desired characteristics: functions provided to the user, user interface, interfaces to other software systems, desired performance criteria, required robustness, error handling and security, update mechanism(s), deployment platform(s), and so on. The result is a formal document, referred to as the Requirements Specification, which is typically used as the basis for detailed planning and contracting with the customer.

System Analysis

During the analysis phase, the engineers model the system by identifying all of the data objects and operations in the problem domain. In object-oriented analysis, domain data objects are represented in an initial class diagram, commonly constructed using the Unified Modeling Language (UML) (Pooley & Stevens, 1999). The functions of the system are broken down into particular interactions with the user, which may imply embedded interactions with remote systems (database lookup, credit transactions, etc.). The system's functions can be represented using a UML use case diagram. For each function or use case, the engineer may write several use case scenarios, prose narratives that describe in detail how the system will carry out a particular function under a variety of circumstances. Use case scenarios include "expected" scenarios, which describe the typical or usual case where no errors or unexpected conditions occur; and "unexpected" scenarios, which cover what might go wrong during the invocation of a particular function (page not found, invalid password, network error, etc.) (Pressman, 2001).

System Design

The design phase maps the functions described during the analysis phase into (a) a set of software modules and (b) a software architecture that integrates the modules into a complete system. At the module level, design has two aspects: (a) partitioning the system's functionality into specific modules (modular design) and (b) specifying the particular algorithms and data structures to be used by each individual module (detailed design). In object-oriented development, modules are typically classes in an object-oriented programming language such as Java. The artifacts produced by the engineer during the design phase might include a detailed UML class diagram, skeletal class files with documentation for data members and methods, and some form of architecture diagram showing how the modules are grouped into partitions (packages) and layers (Bruegge & Dutoit, 2000).

Implementation, Testing, and Maintenance

Once the design is complete, the system developers code the modules according to the design specifications. Implementation should begin with the creation of unit tests for

each module, followed by coding and testing of the module itself. As development progresses, the completed modules are integrated and tested as larger and larger subsets of the system's overall functionality are implemented. The integrated system is tested on the use case scenarios in the requirements specification to ensure that the system behaves as expected in all possible operating environments. As defects are discovered, updates to the system should be carried out using a version-control system to checkpoint stable working versions of the system. Once the system has been delivered to the customer, new releases of the software can be developed and delivered in a similar manner, using previously frozen versions of the system as a baseline.

THE ROLE OF PROTOTYPING IN SOFTWARE DEVELOPMENT

A typical prototype system will involve some level of development in all of the life-cycle activities (requirements, analysis, design, implement, and testing). How much emphasis is given to each life-cycle activity depends on the type of prototype to be constructed and the goals of the prototyping exercise. This section describes the different approaches to prototyping and provides some reasons that prototyping can be a useful first step in system development.

Approaches to Prototyping

The software components created in a prototyping exercise may or may not be part of a full-scale implementation, but a prototype should demonstrate some subset of the desired functionality and user interface. Prototypes can be classified into two broad categories: evolutionary prototypes and throwaway prototypes (Pressman, 2001). Each approach has specific advantages and disadvantages, depending on the goals of the prototyping exercise.

Throwaway Prototyping

A *throwaway prototype* is constructed to demonstrate a simulated capability or user interface, but the software is not intended for use in the final system. Throwaway prototypes can be constructed quickly, using scripting languages (e.g., PERL, Javascript) that may not be suitable for large-scale production. The advantage of a throwaway prototype is that it can be done quickly as a "proof of concept"; such prototypes can be very useful to stimulate discussion with the customer regarding detailed requirements. However, time spent on a throwaway prototype typically does not result in code that can be reused in a full-scale system, so excessive effort spent on a throwaway prototype can be wasteful.

Evolutionary Prototyping

Building an *evolutionary prototype* involves the analysis, design, and implementation of software modules that are intended for use in the final version of the system when it is constructed. An evolutionary prototype might therefore require a significant amount of development (both in time and in programming resources). The advantage of an evolutionary prototype is that "no code is wasted"; it is assumed that most of the effort put into the prototype will result in reusable code that will become part of the final system. However, an early investment in reusable code might not be justified, if the requirements or technology are not yet well understood.

Prototyping PROs and CONs

In an effort to streamline development schedules and minimize development costs, a project manager may be tempted to re-use code built during a throwaway prototyping exercise. This can wreak havoc on the development of a full-scale system, because a throwaway prototype may have been coded quickly, with no attention to proper analysis, design, or careful implementation. The platform used for a throwaway prototype may be completely inappropriate for a full-scale production system. For example, a throwaway prototype might be constructed using PERL scripts, flat data files, and hand-coded HTML, where a production-quality system might require the use of a session architecture, a relational database, and dynamically generated Web pages. Another characteristic of prototypes is that they almost always leave out certain functions or capabilities of the full-scale system. A prototype design that encompasses only a subset of the desired functionality may not be easy to extend to a full implementation. For example, a prototype which delivers Web content in a single language might not utilize a design that supports easy extension for multilingual content; if the full-scale system requires localization for several countries and languages, it will be necessary to re-design the data architecture for a full-scale system. In general, if the requirements aren't well understood at the outset, or the technology is new for the development team, then a throwaway prototype is appropriate, but management must be sensitive to the risks associated with reuse.

On the other hand, it may be tempting to declare that all prototyping will be of the evolutionary variety, so that "no effort will be wasted." This is a mistake if the problem or the technology isn't well understood, because the analysis and design may incorporate defects or misunderstandings that should be resolved before a full-scale system is built. When the team is experienced with the problem domain and the software technology, this risk is reduced, but it can be difficult to guarantee future reuse before construction and test of an initial system. When a new category of system is constructed for the fist time, prototyping becomes part of a "generate and test" paradigm for system design; design ideas are formulated and initial systems constructed as a means of evaluating tentative design decisions. In general, when the requirements aren't well documented, it is usually more appropriate to construct a throwaway prototype that can serve as the basis for a customer review and discussion regarding the emerging requirements and system design.

Why Do We Do Prototyping?

There are a variety of reasons to construct a prototype; most involve a desire to better understand the problem domain, the user's requirements, the technology to be used, or the trade-offs inherent in various system design choices (technology, architecture, etc.). Prototyping

is also extremely important in the presence of various software risks that may not be well understood.

Requirements Analysis and "Design by Example"

Requirements analysis for e-commerce systems presents two main challenges for the engineer: (a) it is generally difficult for a customer to provide a detailed specification for the visual components of a Web site (graphics content, layout, navigation, etc.); and (b) there are embedded functional layers which the customer may take for granted (database access, credit transactions, order fulfillment, etc.). Once a prototype has been constructed, it is fairly easy for the customer to provide feedback on what he or she likes or does not like about the proposed design of the interface. The construction of a prototype can also uncover a variety of assumptions regarding integration with existing systems; in reviewing a prototype Web site, the customer may realize that certain legacy functionality is missing, links to other corporate sites are required, other business units must be represented, etc. The customer is typically less well informed about the technical requirements of an application; the prototyping exercise can be used as a vehicle for initiating contact with all of the people "behind the scenes" who understand the low-level integration requirements of a particular application, including details of existing CRM and ERP systems, security requirements, etc.

Understanding the Problem Domain

The software development life cycle proceeds smoothly when the problem domain is well understood. When there are gaps in the engineer's understanding, even the best practice can fail to produce the desired result. When a development team begins working in a new area, prototyping is a useful way to immerse the team in the particulars of the problem before the team members are asked to design and implement a full-scale system. For example, a development team that shifts from the creation of static Web sites to the creation of shopping portals can take advantage of a prototyping exercise to learn the functional requirements of a shopping portal in detail. An analogous situation arises when a development team must learn a new technology; even with a relatively stable technology (e.g. Java), it is useful for the team to undertake a prototyping exercise as preparation for a full-scale project.

Reducing Technical Risk

Technical risks arise when new technology is used for the first time, or a novel combination of technologies is tried for the first time. In either situation, there is a significant probability that unexpected problems will arise, and a prototyping exercise can uncover these unknowns and improve the accuracy of time and cost estimates for a full-scale system. In the worst case, an initial technology decision may be abandoned as the result of a failed prototype, but this is clearly preferable to canceling or renegotiating a large-scale development contract that is already under way. In the world of e-commerce software development, technical risk is one of the biggest unknowns. As new paradigms are being created for distributed client–server solutions over the Internet, companies are compelled to adopt new technology before it has been widely tested, in order to remain competitive. Knowing when to invest in rapid prototyping to alleviate technical risk is an important strategic skill.

THE NATURE OF E-COMMERCE SOFTWARE

Software development is an inherently risky endeavor. Complex systems are difficult to deliver without significant defects, even when adequate time and resources are available. E-commerce systems are even more challenging, because they are subject to additional pressures that increase the risks associated with software delivery.

Development on "Internet Time"

Unlike company-internal software development, which proceeds according to schedules set within the organization, e-commerce systems are often developed under the pressures of "Internet time"—the expectation is that new technologies and solutions are rolled out every 3 to 6 months, under the credo "evolve rapidly, or die." This time pressure has an adverse effect on software development. In the absence of adequate time to complete the various phases in the software engineering life cycle, software quality degrades as less time is spent on analysis, design, and testing. With so little time available for development, one might question whether prototyping is an appropriate strategy, especially if a throwaway prototype (and its associated "waste" of resources) is being considered. On the other hand, one might argue that prototyping is absolutely essential to keep the development team on top of new technology, so that full-scale applications can be designed, implemented, and deployed as quickly as possible once the requirements are stabilized (Iansiti & MacCormack, 1997). Because prototyping can alleviate technical risk, it can improve the responsiveness of the development team and help to keep final product delivery on schedule, even if all requirements are not known until close to the planned delivery date.

Evolution and Obsolescence

When software is developed quickly with an ad hoc or nonexistent software process, the result is often code that is poorly designed, poorly documented, and difficult to maintain. When faced with a new project, the development team is likely to resist working with the old system, and will prefer to write a new system from scratch. The pressures of rapid development can feed this vicious cycle, and the result is a significant amount of time wasted on reimplementing modules when previous modules could have been reused—assuming they had been well-designed and well-documented in the first place. If a prototype is constructed in advance, a code review can be utilized to identify which portions of the system are likely to be general (and hence reusable). When the full-scale system is constructed, the design and implementation of those modules can be done in a manner that maximizes their future reusability. In the future, the most successful software companies will be those that minimize the amount of new code that is created in each new application, through

careful design and reuse of generic code libraries. This is difficult to achieve if every application the company constructs is a "first system."

> Your plans and your technology must be as fluid as the changing environment in which they operate. Your software, your systems, your entire technology architecture must naturally mold and adapt to changes without costly, time-consuming infrastructure overhauls. Your e-business software platform must provide a safe, yet powerful catalyst for ongoing innovation, increasing customer value-add, and continuing competitive advantage. (BEA Systems, 2002)

Architectural Complexity

A great number of e-commerce systems adopt the multitier approach to software architecture; the simplest (and most common) variation integrates a Web browser, a Web/application server, and a back-end database. If we think of these subsystems as residing in different architectural layers, then the boundary between each layer is an appropriate place for security measures such as firewalls and virtual private network routing (Zwicky, Cooper, & Chapman, 2000). When an e-commerce architecture is constructed for the first time, an initial prototype can be used to understand the complexities of integrating the various layers and their associated security protocols. A prototype is also a useful vehicle for analyzing the properties of a proposed architecture, such as

Scalability. How feasible is it to add multiple application servers or mirror the backend database? The proposed design can be evaluated in the context of the prototyping exercise, by attempting to show how multiple servers could be added to the system for load balancing, mirroring, etc.

Robustness. How will the system react under high network load and/or slow response times? What will happen if a particular networked service goes down? Once a prototype system has been constructed, the team can build test routines that simulate various operating conditions. It is useful to benchmark a Web application server by simulating an increasing number of simultaneous user accesses in order to understand how average response time degrades under increasing load. Simulation can also be used to test how the system responds when certain services become unavailable to overload conditions (network timeout) or system crashes.

Security. What points in the architecture are vulnerable to attack? Can we determine them using attack simulation software? If a prototype is constructed in a realistic operating environment (including firewalls, etc.) then simulation can be used to identify and remedy potential system vulnerabilities.

Integrity. Are there any circumstances where the user's data may be lost? To answer this question requires a solid understanding of scalability, robustness, and security characteristics of the system and how they impact the functional requirements. For each functional requirement or supported user action (login, place order, etc.) the prototype can be analyzed to determine whether known issues with robustness and security might impact the functional requirement. Information gathered from prototype evaluation can be extremely valuable in refining a system design before a full-scale system is constructed.

Technological Risk

During product development, an organization must often select between competing technologies (such as programming languages or program libraries) to implement parts of the product architecture or functionality. For example, in early 1996 NetDynamics had the choice of adopting the Java programming language or writing its own proprietary language for a major release of a database integration product (Iansiti & MacCormack, 1997). At that time Java showed promise as an emerging standard, but was still an immature platform for large-scale development. The engineers at NetDynamics developed a series of prototypes in order to understand the benefits and risks associated with each choice. The development drawbacks of working with an immature language (which may lack a stable, robust development tool suite) must be balanced against the longer-term advantages for the application programmer. This trade-off exists with every emerging technology, and iterative prototyping provides an effective means of evaluating the associated risks in each case.

PROTOTYPING FOR E-COMMERCE SYSTEMS

The preceding sections provide a motivation for prototyping in e-commerce system development. This section presents the various aspects of the e-commerce software life cycle that can benefit from prototyping, followed by specific life-cycle models that are adapted for Web-based applications and flexible product development on "Internet time."

Use Case Scenarios

A modern e-commerce system brings together content and functionality on several levels. In order to understand the overall flow of information in the system and how the various system modules must interact, it is essential for the engineer to analyze the different patterns of usage the system is expected to support. A use case analysis will identify the different users of the system (customer, installer, maintainer, content provider, administrator, etc.) as well as the functions to be provided for each user. An initial prototype should include a skeletal implementation or simulation of the interfaces and functionality for each user role. Following the construction of the prototype, a requirements review can be conducted with prospective members of each user group to determine whether the current understanding of the requirements (as embodied in the prototype) is complete and correct. At the earliest stages in development of an e-commerce site, it is useful to build a prototype of the system's front end (Web site,

applet, or application) as a tool for reaching consensus on the system's modes of operation, inputs, and outputs.

Object-oriented analysis (Bruegge & Dutoit, 2000; Coad & Mayfield, 1999) and the Unified Modeling Language (Pooley & Stevens, 1999) provide useful tools for use case analysis and requirements modeling. However, the resulting model diagrams cannot be discussed directly with a customer or user (unless he or she is skilled in UML, which is unlikely). It is more useful to construct a prototype that illustrates an initial version of each user function in a familiar interface (e.g., Web pages or applets). Once such a prototype has been constructed, the engineers can demonstrate the system for the customer, talking him or her through each proposed function for each user role. Feedback from this kind of prototype demonstration can be revealing. Often the initial requirements from the customer are vague or ambiguous; a prototype review can uncover potential misunderstandings. For example, an initial requirement might be specified as "provide a product search capability for the user," without being specific about the search criteria. If the prototype omits certain search criteria (e.g., particular product characteristics that are important to the customer), the customer will notice in the review, and the requirements document can be updated to reflect the more specific requirement.

Interface Prototypes

A typical Web-based system will include several pages or "screens" in support of each user interaction or user function. Each of these pages will contain a variety of user interface elements, such as hyperlinks, pull-down menus, fill-in forms, checkboxes, and radio buttons. The pages will be arranged in a particular hyperlinked structure, starting from the home page of the application. If possible, navigation should be transparent and effortless, so that the user can focus on the task at hand without being distracted by poorly designed navigation, or content that is difficult to scan visually (Nielsen, 2000). A prototype can be used to evaluate a set of criteria regarding the interface; questions to consider include the following:

Are the user interface elements the most appropriate ones for the task? In order to minimize the time it takes for the user to scan a Web page and make the appropriate selection or provide required data, it may be necessary to redesign the layout and interface components. For example, a long block of text with choice buttons at the bottom will be less effective than a short list of bullet items including hyperlinks. The former must be read in its entirety, whereas the latter can be scanned quickly for the desired choice. Fill-in forms should be constructed for easy visual scanning from field to field, and common conventions (e.g., tab key) should be utilized for switching the focus from field to field.

Do the user interface elements support an effective task flow? If a user task involves decision-making during a set of sequential steps, it is important not to force an early decision that might be retracted later based on the result of a subsequent step. Prototype evaluation should consider what will happen if the user changes his or her mind about the task at hand. Normal progress through a task should be streamlined and effective, but it must also be easy for the user to retract a choice, cancel a transaction, or start over.

Are suitable defaults provided for menu selections and fill-in forms? An initial requirements specification may not be detailed enough to provide information about the default content or behavior of fill-in fields, search parameters, date ranges, etc. which are part of a user input to the system. Effective defaults are an important part of streamlining the user's experience, especially when a lot of data must be entered and sensible defaults exist.

Does the system check for combinations of data values that are invalid for the application? It should not be possible for the user to enter combinations of values in a fill-in form that result in an invalid request or transaction. Testing a prototype can be an effective way to uncover such cases, if they have not been specified in detail in the initial requirements documentation.

Is it easy to navigate from page to page in the site or application? Effective Web applications are "training free"—the user can immediately intuit how to navigate through the site or application after briefly scanning the first page or screen. If the user has to stop and think about how to navigate, or worse, experiment with different mouse clicks to find what he or she needs, the effectiveness of the site will suffer and the user's subjective experience will degrade.

Can each part of the site or application be reached with a minimum number of mouse clicks? Even if intuitive navigation is provided, a particularly deep or content-rich site might require lots of user interaction to reach certain portions of the site content. A prototype evaluation can assess whether a reorganization of the site content or navigation structure might provide better accessibility. Secondary navigation mechanisms such as search engines or site maps can be valuable in this regard.

Although by no means exhaustive, this list illustrates how a prototype review can be used to improve the interface component of a Web application. By discussing these criteria with the customer and/or evaluating them in a more formal usability study, valuable information can be gathered which can trigger design improvements for a full-scale system.

Content Prototypes

The term *content* is used in an e-commerce context to refer to the parts of the site or application that are not directly related to navigation or data entry, which are typically presented as a combination of text, graphics, and/or multimedia. Content must simultaneously satisfy two basic criteria—it should be consistently presented and it must be easy for the user to scan and understand. The page designer determines how to partition and present information in a manner that is consistent with the overall visual design (look and feel) of the site. Choices of typeface, font size, spacing, color, and page size all have a dramatic effect on how easy it is for the user to assimilate the content (Siegel, 1996). Helping the user to complete the task

at hand is typically more important than sophisticated graphic design. The text should be optimized for scanning, not reading; short text segments, hyperlinks, and bulleted lists will allow the user to scan the current page quickly and determine his or her next action (Nielsen, 2000). The content must also meet the goals of the application. If the system is designed to support online sales of a particular product line, then the relevant content for each product should be available. Although prototype systems typically focus on determining the look and feel of a site via graphic design, it is clear that content should also be reviewed to ensure that it is optimized for usability.

In cases where multilingual or multicultural content is required, an additional set of criteria must be considered:

Translation of content. If the site or application is intended for global access, then it might be necessary to provide site content in more than one language. If this requirement is adopted, then for each language to be supported the system design must consider (a) which version or dialect to support, (b) which character sets to use, (c) which font encoding to use, and (d) how to provide text, graphics, and HTML in that language (O'Connor, 2001). Most translation work is handled by selection of an appropriate service bureau. It is useful to construct a multilingual prototype system, as this affords an opportunity to evaluate the quality of service provided by potential translations vendors. A prototype can also be evaluated for how well the site or application presents multilingual content to the end user; the selection of a language at run-time should be easy (or automatic). Sites such as Google (http://www.google.com) predict the desired language from the IP address of the Web browser when it contacts the site and redirect the HTTP request to an appropriate language server. Emerging standards such as Unicode provide a standardized way of encoding Web pages for multiple languages and character sets (Unicode Consortium, 2002).

Localization of content. Preparing content for a different language often implies preparing it for a different culture. *Localization* is the process that adjusts the translated material to fit the targeted culture. Simple forms of localization include changing the page layout to fit the translated material; because translated material can vary in length, the original layout may no longer be appropriate. More sophisticated forms of localization involve checking for culturally inappropriate use of graphics or other visual cues (for example, the use of a black border is typically reserved for death notices in the Japanese culture; use of a black border might be inappropriate in most other contexts). It is also possible that localized versions of a site, application, or service might differ in basic content or scope of service; not all information and/or functionalities may be available in all markets. Building and evaluating a prototype system is an excellent way to determine the exact nature of the localization requirements for a particular global market.

Infrastructure support. Typical e-commerce Web sites include various navigation mechanisms, application servers, back-end databases, external servers and services, etc. All of these layers in the computing infrastructure must be considered in designing a site for the global market. If a decision is made to translate and localize content and services, then the corresponding components in the infrastructure (product database, order fulfillment, etc.) must also be translated and/or localized. A Web site that provides product information in several languages but provides only a single language for check-out is not responsive to its customer base. It is much better to catch this type of oversight in a prototyping evaluation than to have it discovered by customers online.

Content maintenance. Although it is a challenge to launch a multilingual site, the ongoing cost of maintaining a site in multiple languages can also be significant. It is useful to identify, prototype, and evaluate a process for content update before a site "goes live." Ideally, translated content will be available as soon as primary content has been updated, but this can be difficult to achieve if the organization relies on outsourcing for translation and localization. Although automatic translation tools can be useful as human aids, the state of the art is still not quite good enough to be relied upon without human intervention, except in very narrow information domains. In addition, the tools used for page creation and overall site maintenance must be able to support multilingual content. Software that keeps track of the relationships between primary content pages and their translated equivalents is a must.

As it is typically very costly to create and provide content in multiple languages, it is important to ensure that the design of the site or application is sound before it is scaled up to include all target languages and markets. Prototyping can be an excellent way of creating and evaluating a design for multilingual content delivery, before full-scale development begins.

Architecture Prototypes

E-commerce architectures typically involve multitier integration of browsers, applets, servlets, application servers, and back-end services (databases, credit transactions, etc.). Most of the complexity (and most of the difficulty) in e-commerce development is associated with the integration and testing of the various components in the architecture. Even before the full content for the application has been prepared, it is useful to build a prototype implementation of the end-to-end system. As mentioned above, architectural prototyping can serve as the basis for a variety of tests, including the following:

Integration Testing. Do all of the components communicate as expected? A Web application typically relies on different Web browsers communicating with a Web server and/or application server; these in turn communicate with various back-end services (product database, order database, etc.). It is important to test assumptions regarding the connectivity of the chosen software and hardware for the project, as early as

possible. A prototype system with limited functionality (just a few services and limited content) can be used to test the integration of the chosen technologies.

Performance Testing. What is the average time required to service a typical user transaction? Is the system's response time acceptable? How does system performance vary as the transaction load is increased (e.g., in a simulated test environment)? Once a prototype has been constructed, the architecture can be tested via simulation of an ever-increasing number of page and transaction requests. In the course of such an evaluation, resource bottlenecks (such as an overloaded server) can be identified and addressed. If necessary, the original design can be revised to better support scalability (redundant servers with load balancing, mirrored databases, etc.).

Security Testing. Is the system vulnerable to any known exploits that could compromise system performance or data integrity? Attack simulation software can be used to test the security of the site once it has been prototyped. It is far better to uncover and address security problems before the full-scale site has been built and launched.

Early prototyping can also be used for comparative evaluation of competing technologies and to evaluate whether specific emerging technologies are appropriate for a given application. Several commercial Web application environments are available, and each makes certain assumptions about the operating environment (operating system, platform, etc.). How these application paradigms fit within a particular organization and integrate with existing legacy components is an important area for early investigation.

A Life-Cycle Model for Web Projects

An effective development model for Web-based e-commerce systems must support rapid development and continuous evolution. Web applications in particular are subject to constant improvement and content update. Copywriters, graphic designers, and Web designers provide content. Software engineers and developers provide the technical infrastructure. It is common that both content and technology are developed, deployed, and maintained simultaneously and somewhat independently. Pressman (2001) proposes the WebE process, an iterative life-cycle model that acknowledges the need to develop content and technology in parallel. The WebE process includes the following cyclic activities:

Formulation. Identify the goals of the application, the users, and the scope of both content and function. This process is like the normal requirements elicitation and specification in typical software engineering, but with important differences. It is important to identify all stakeholders associated with the application, as well as the content providers. A typical application requires assimilation of content from different organizational units, from print and online resources, in varying formats. Identifying these requirements early is important for an accurate estimate of the effort to build and maintain the site, which could involve significant amounts of content conversion.

Planning. Allocate appropriate resources and decompose development into appropriate phases, milestones, and schedules. This process must take into account special requirements regarding content acquisition, conversion, translation, and localization.

Analysis. Understand the details of the system's content, user interactions, specific functionalities, and software configuration. For each of these areas, construct an analysis model that identifies all of the data objects and operations on those objects.

Engineering. Design and implement the individual elements of the system. Content creation and system implementation take place in parallel. Content creation begins with content design, followed by a content production process that encompasses acquisition, conversion, translation and localization. System implementation includes architectural design, navigation design, and interface design.

Page Generation and Testing. Construct the actual pages for the site. All of the individual components (HTML and JSP pages, applets, servlets, CGI scripts, etc.) are integrated and tested by following all of the steps represented in the use case scenarios built during requirements formulation.

Customer Evaluation. Perform a detailed review of the application with intended users and gather feedback for next version of system.

Although the full set of WebE activities is appropriate for development of a complete application, the same steps can also be followed in the construction of an initial prototype system, with selection of an appropriate (reduced) scope. In projects where I have used this approach for prototyping, the initial focus is on the analysis and engineering steps. The team creates a set of analysis models (use case diagrams, usage scenarios, and a class diagram) and embodies them in a set of prototype Web pages that capture a proposed content style, navigation method(s), and user interface elements. The architecture is usually minimized or simulated. For example, the functions of the application server and product database may be simulated by simple CGI scripts. The customer evaluation step focuses on whether the proposed page design and navigation capture the desired task flow and information objectives. Customer feedback helps to refine the analysis models before development begins.

A second iteration typically involves the creation of an architecture prototype, where the prototype content and navigation are deployed in an end-to-end system that includes the final application server and database modules. The architecture prototype must contain only enough information content to test end-to-end integration; scaling the system up to full content can happen in subsequent iterations.

The WebE Process is flexible enough to support any number of successive prototypes or incremental versions leading up to a final product, while reinforcing the notion that each revision to a system should take place in a software engineering context. Each evolution includes

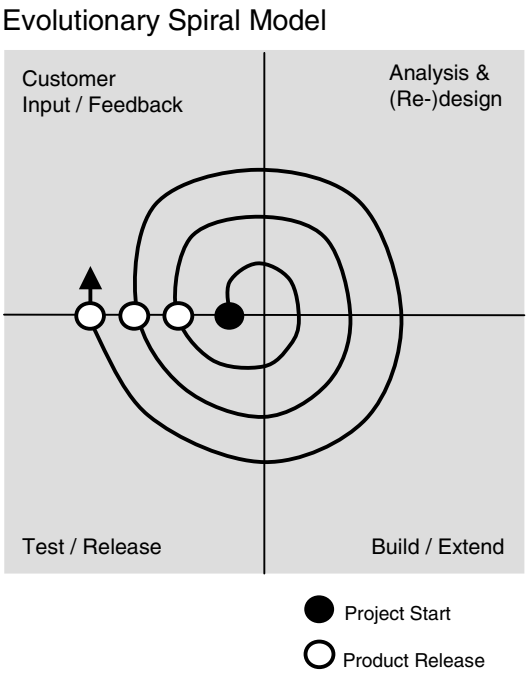

Figure 1: The spiral development model.

updates to the system's specifications, evaluation of existing modules for reuse, careful engineering and testing, and subsequent customer evaluation. Even if initial prototypes are not extended or reused, analysis and design can produce specifications that are useful for a full-scale implementation. Iterative prototyping fits a general form of the Spiral Model, a development process model first proposed by Boehm (1988); see Figure 1.

Flexible Product Development and the Evolutionary Development Model

Web-based applications are just one example of systems that are developed rapidly and evolve constantly over time. Many other types of applications are created in dynamic, unstable environments where technology and customer requirements are in constant flux. High-quality software can be developed in such an environment with the use of iterative, evolutionary prototyping in a flexible development process.

Early Prototyping in Product Development

A study of 29 completed development projects (MacCormack, Verganti, & Iansiti, 2001) showed that the creation of an early, incomplete prototype for customer evaluation is an important predictor of software quality in dynamic, unstable environments. After release of the first prototype, the development team must work to integrate the customer's feedback into the software design as it evolves towards the final deliverable. This implies an evolutionary development model, where active development of the final product begins before the final requirements are known. A series of evolutionary prototypes may be constructed and evaluated before the requirements are frozen for a major release of the product. Evolutionary development will be more successful when the team has made a substantial investment in a flexible, modular architecture that supports rapid adjustments to an evolving product design. Team members with past experience on several different projects and software versions are more likely to thrive in an evolutionary development environment.

A Flexible Development Process

The total time from project start to market introduction (*lead time*) can be divided into *concept time* and *response time* (Iansiti & MacCormack, 1997). Concept time is the window of opportunity for introducing requirements into the system concept, and matching the technology with users and application context. Response time is the time taken to produce the deliverable system after the system concept is frozen. In a traditional software development process, system implementation does not begin until all the requirements have been frozen. In a more flexible model, implementation (e.g., evolutionary prototyping) begins before the requirements are frozen, and response time can be shortened significantly. When several incremental product versions are to be developed, it is important to minimize the response time (during which requirements are frozen). In the most dynamic formulation, a flexible development process will constantly acquire new information about customer requirements, test alternative design solutions, and integrate both into coherent, high quality products. In a study by MacCormack (2001), the software system with the earliest beta release and the greatest number of beta releases—Netscape Navigator 3.0—also received the highest score for perceived software quality. See Figure 2.

Infrastructure Requirements

The flexible development process requires an investment in development infrastructure, primarily in version control and testing. Organizations that have demonstrated success with rapid product cycles, such as Netscape and

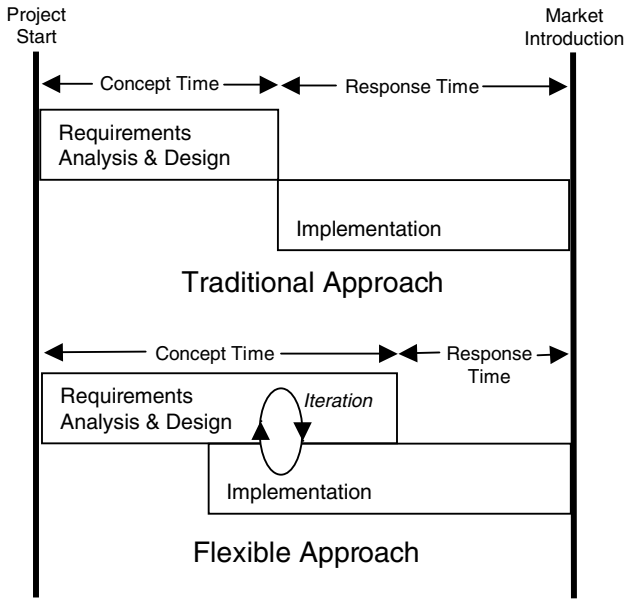

Figure 2: A flexible approach to development.

Microsoft (MacCormack, 1991), decompose a product into several subcomponents or "microprojects" that contribute to the overall functionality. Delivery of an early prototype requires that critical functionalities can be developed early, before all product functions are in place. This presupposes an ability to decompose the system into functional modules, which can be replaced by dummy code or simulated behavior before full implementations are available. In order to manage the complexity introduced by parallel development of different modules and different product releases, strong version control is necessary. Effective version control involves the use of a version control system (e.g., CVS, 2002) to manage and track updates to the source code, along with a test process that promotes global coherence of the overall product during parallel development. The *synchronize and stabilize* model developed by Microsoft (Cusamano & Selby, 1997) requires frequent synchronization and testing of the entire system under development. Intermediate testing is most effective when developers receive feedback as quickly as possible after a system update (MacCormack, 1991).

CONCLUSION

Prototyping is an important part of software engineering. Building a prototype can be an effective way to build customer consensus on requirements, gain clarity on the details of a complex architecture, determine the look and feel of a Web site, and alleviate the technical risk associated with emerging technologies. Although e-commerce developers are under pressure to produce working systems quickly, the use of an incremental prototyping model helps to improve the quality of delivered systems by uncovering defects and performance problems earlier in the development cycle. An iterative Web life-cycle model (such as Pressman's WebE process) involves all stakeholders early in the development process and gives explicit emphasis to content design and creation, which are a distinguishing (and challenging) characteristic of Web applications. A continuous prototyping effort can begin with content and navigation prototyping, followed by prototyping on an end-to-end architecture. At each step of the way, the existing requirements and design can be evaluated and updated to better reflect the emerging consensus about what the system should do, and how it should do it. Flexible development models, evolutionary prototyping, and component-based software development are important trends for ongoing and future development of e-commerce systems.

GLOSSARY

Analysis An activity in the software life-cycle that identifies and specifies the data objects and operations in a particular problem domain.

CRM (customer relationship management) The business process that captures and stores information about the customer, including preferences, past and present orders, business relationships, etc.

Content The information conveyed by a Web site, such as company information, product information, news releases, order history, and user preferences.

Design An activity in the software life-cycle that identifies and specifies a set of software modules that will be used to implement the data objects and operations in a given problem domain.

ERP (enterprise resource planning) The global management of business processes such as procurement, administration, project management, sales force automation, product development, and order fulfillment.

Evolutionary prototyping A prototyping effort that produces a software system where some (or all) of the modules can be reused as part of a full-scale, deployable application.

Java An object-oriented programming language that is often used to implement e-commerce software systems.

Life cycle The entire set of activities surrounding the conception, design, creation, testing, deployment, and long-term maintenance of a software system.

Problem domain A term used to describe the elements of the software operating environment, including users, maintainers, legacy systems, and interactions between users and the system.

Prototyping The creation of an initial version of a software system, often with limited functionality, to support problem analysis, requirements definition, interface design, etc.

Requirements The formal elements of a problem definition that must be satisfied by a software system; these can include functional capabilities, performance capabilities, platform capabilities, integration capabilities, etc.

Software architecture A description of how a set of software modules will be deployed, how they interact with each other, how they will be installed on various hardware devices, and how they will interact with existing systems and users.

Software complexity A measure of how difficult a software system is to design, implement, and deploy; systems that have a greater number of functional requirements, interactions with users, communications with legacy systems, etc. tend to be more complex.

Software evolution The process of maintaining a software system from initial deployment through retirement from active use; evolution involves updates to support operating system changes, changing user requirements, performance criteria, etc.

Software obsolescence Reached when a software system no longer meets the changing requirements of its users and can no longer be extended or maintained in a cost-effective manner.

Technical risk The uncertainty inherent in the use of new technology that has not been widely tested or in the novel use of existing technology in a new problem domain.

Throwaway prototyping A prototyping effort that produces a software system that should not be reused as part of a deployable application.

UML (unified modeling language) A graphical notation for analysis and design models that unambiguously specify the requirements and design elements for a software system.

Use case scenarios Textual descriptions of the functional requirements that must be met by the software; typically, scenarios outline all of the interactions with the user and other external systems.

User interface That portion of the software system which is visible to the end user; for e-commerce systems, this is often a Web page or applet viewed in a Web browser.

INTRODUCTION

Internet and E-business Overview

In the last decade, the Internet and World Wide Web (WWW) have changed the way people communicate, conduct business, and manage their daily lives. Early development of the Internet was supported by the Defense Advanced Research Project Agency (DARPA) of the Department of Defense (Greenstein & Vasarhelyi, 2002; Kogan, Sudit, & Vasarhelyi, 1998). The Internet came online in 1969 for scientists and researchers to keep in touch with one another and to share each other's computers (Deitel, Deitel, & Steinbuhler, 2001). At that time, the major benefit of the Internet was the capability of quick and easy communication via e-mail. The introduction of the WWW occurred in the early 1990s. Part of the Internet, the WWW allows users to locate and view multimedia-based documents (Awad, 2002).

Advances in hardware and software have led to explosive growth of the Internet and the WWW. In addition to launching us into the information age, electronic commerce (e-commerce) brings universal access via the Internet to the core business processes of buying and selling goods and services. The Internet's worldwide reach helps businesses discover new markets and increases the speed of access. Electronic business (e-business) is a broader term than e-commerce. E-business includes not only the exchange of information related to the actual buying and selling of goods or services over the Internet but also the circulation of information among employees and other external information users (Greenstein & Vasarhelyi, 2002).

Given the nature of a certified public accounting (CPA) firm's activities—tracking thousands of pieces of data, the need for up-to-date information, trusted client relationships, and high-quality service—broader usage of technology has long provided a benefit to CPAs. Various types of technology have led to increased efficiencies in CPA firms and have made it possible for the firms to provide new and enhanced services to their clients. The Internet and e-business applications will continue to improve and expand the range of services offered by CPA firms.

Technology Trends for the Accounting Profession

Every aspect of the accounting profession is being pervasively affected by advances in information technology (IT). IT has made CPA firms efficient in performing most accounting, audit, and tax functions more accurately, reducing the amount of paper they must maintain, and expanding the range of services they offer to clients. Time saved by using IT in making rote calculations (such as calculating depreciation expense), calculating projections, preparing tax returns and financial statements, and performing audits enables CPA firms to have more time to provide consulting services and personal attention to clients. Via the Internet, CPAs have increased mobility; that is, they have access to client information and reference materials 24 hours a day, 7 days a week (24/7), and from any location, which allows them to better serve clients and to have clients in many different locations. CPA firms with real-time access to information can provide more timely assistance to clients, which can improve efficiency and decision making for clients. The Internet and e-business also provide CPA firms with new promotional opportunities and more efficient research capabilities.

As mentioned earlier, since the rapid evolution of IT has had such a radical impact on the business environment, public accounting firms have responded by applying Internet and e-business in their daily operations. Each year around April, the American Institute of Certified Public Accountants (AICPA) Top Technologies Task Force provides the accounting profession with a list of what it considers to be the current top-10 technology issues (see http://www.toptentechs.com). From Table 1, we can see that the Internet and e-business issues have grown progressively more complex and increasingly urgent during the past few years. On the 1997 list, the Internet and e-commerce were ranked four and seven, respectively; in 1998, they were ranked one and five, respectively. In addition, more complex issues had developed concerning the Internet, such as intranets, private networks, and extranets. The Internet was listed as the number-two issue in 1999; e-business was listed number one and number two for years 2002 and 2001, respectively. In 2002, the Internet

Overview to Chapter

This chapter explains how CPA firms have used the Internet and e-business to expand the types of services they offer to clients and to enhance and streamline many of the existing services they provide, such as offering more timely information to clients. We focus on applications in the audit, assurance, financial analysis, and tax areas and discuss how the Internet can be used to access the various types of information that CPA firms need, along with how firms are using the Internet for promotional purposes. With increased use of the Internet, some issues arise, particularly with regard to data security and legal issues, including confidentiality of information. Finally, we explore some possible future developments for firms with respect to the Internet and e-business applications and how they may change the nature of CPA firms' practices.

KEY APPLICATIONS

Enhancing and Expanding Services

New Assurance Services

In late 1990s, the AICPA introduced two new assurance services (WebTrust and SysTrust) to address risks associated with information systems and to enhance systems reliability and e-business security (Boritz, Mackler, & McPhie, 1999; Koreto, 1998a, 1998b). WebTrust is an attest-level engagement provided by specially licensed public accountants to build trust between consumers and companies doing business over the Internet. A WebTrust seal on a company's Web site indicates that the company has a WebTrust audit performed on an average of every 180 days, and that the site complies with the WebTrust principles and criteria in all or part of the four areas: business practices and information privacy, transaction and service integrity, information protection/security and privacy, and availability and controls over certification authorities. CPAs interested in this assurance service niche need to have experience in attestation engagements and knowledge in information technology (for detailed information, see http://www.webtrust.org).

Technically, WebTrust, as the name implies, focuses on Internet-based systems only. On the other hand, SysTrust is an assurance service in which public accountants independently test and verify the reliability of a company's overall system, measured against the essential SysTrust principles: availability, security, integrity, and maintainability. SysTrust plays an important role in conducting e-business, because it is designed to increase the confidence of management, business partners, customers, stockholders, and government agencies in IT and systems that support business operations or any particular activity. Without sufficient confidence in a company's systems, business partners, employees, and external information users may not conduct e-business with the company. Public accountants interested in providing this assurance service must have information systems audit experience. It could be desirable to work with certified information systems auditors (CISAs) on SysTrust engagements. For detailed information, visit http://www.aicpa.org/assurance/systrust/and http://www.systrustservices.com.

Business and Financial Reporting Applications

Applications of technology for business and financial reporting purposes rose to the top of the 2002 top-10 technology issues list after being in third place in 2001. The AICPA has long foreseen the need for improved financial reporting capabilities, and its concern led to the creation of XBRL (extended business reporting language) in 2000. XBRL is an XML-based specification for preparing, distributing, and analyzing financial information (Strand, McGuire, & Watson, 2001). XBRL has been named as the next-generation digital language of business that can ensure the integrity of electronic financial reports (Rezaee, Hoffman, & Marks, 2001). Mike Willis, partner at PricewaterhouseCoopers (PWC) and chairman of the XBRL Project Committee, said, "It is a natural extension of today's Internet technology to the financial reporting process. XBRL provides a platform for the future of business reporting over the Internet, and it will be fundamental to the way companies communicate with stakeholders" (http://www.xbrl.org/). XBRL can standardize financial reporting over the Internet, and companies will be able to use the Web to report information in a timely and accurate manner.

Although XBRL's primary target is commercial and industrial companies for their external financial reporting needs, XBRL can also be used for data analysis, reporting needs, and governmental filings (Hannon, 2001). In 2002, the Securities and Exchange Commission (SEC) created an online repository of XBRL data and financial reports through its EDGAR (electronic data gathering analysis and retrieval) program (Edgar Online, 2002). In addition, XBRL can be implemented for various reporting needs in different industries and different countries. XBRL usage has grown around the world in countries such as Japan, Singapore, Germany, and South Africa (Hannon, 2002). XBRL is only beginning to gain visibility. Because most companies do not know enough about XBRL to understand how it can help their business and how to implement it, there are tremendous opportunities for CPAs to provide consulting services in this area such as choosing proper tools to link a client's internal financial reporting system to the client's Web site for external electronic reporting.

Online Services

The Internet allows CPA firms to interact with clients anytime and anywhere and thus allows for new business models for firms. Possible models include offering clients online audit/review and online consulting services. A few CPA firms have partnered with companies such as Intacct, Oracle Small Business Suite, and Creative Solutions to offer clients web-based accounting systems. With powerful and secure Internet data centers maintained by business partners, auditors have the confidence that clients' accounting systems are well-maintained and have fewer concerns about systems availability/reliability (personal communication, Robert L. Lewis, Jr., and Wendy Bednarz,

Intacct, May 8, 2002). There are significant security concerns for exchanging consulting information between the client and the CPA firms since most information is extremely sensitive, confidential, and damaging if it falls into the wrong hands. Thus, CPA firms must examine carefully whether proper encryption, authentication, and virtual private network technologies are implemented to secure information transmission of their online services.

The reliability and availability of online real-time systems have made continuous audit and assurance possible. According to Rezaee, Sharbatoghlie, Elam, and McMickle (2002, p. 145), continuous audit and assurance is defined as "a comprehensive electronic audit process that enables auditors to provide some degree of assurance on continuous information simultaneously with, or shortly after, the disclosure of the information." Moreover, both researchers and practitioners indicate that real-time financial reporting has necessitated continuous assurance (Elliott, 2002; Rezaee et al., 2002). As Alles, Kogan, and Vasarhelyi (2002) suggested, both WebTrust and SysTrust are continuous assurance services offered by the AICPA to respond to this need. Given the advances in technology, some companies have developed online audit and review tools for auditors to access the client's database and extract data anytime from anywhere for auditing purposes (e.g., Intacct). Since more and more companies are attempting to provide online real-time financial reports, XBRL also plays a critical role in continuous assurance. Clearly, changes in the audit paradigm will continue in order to meet assurance-user needs in the future. The short useful life of operating systems (OS) and applications may become an obstacle to implementing continuous audits, however. By the time a continuous audit tool is beta tested, installed, and implemented, the underlying OS or applications may be upgraded, patched, or replaced, rendering the audit tool inoperable or causing it to report false signals. CPA firms may need to work with their clients to develop long-term strategic plans regarding how to maintain the stability of the clients' OS and key applications to increase the feasibility of continuous audits.

Other than assurance services, some of the larger CPA firms have used the global 24/7 nature of the Internet to broaden clients' access to expertise within the firm. One of the first and probably best known Internet-based consulting services is "Ernie" created by the international accounting firm Ernst & Young (EY) in 1996. Ernie, later renamed Ernst & Young Online Services (n.d.), has been marketed as an online business consultant that provides low-cost access to EY experts in many areas including audit, tax, human resources, strategy, information technology, personal finance, and specified industries. EY routes questions submitted from subscribers to experts throughout its global practice, as needed, and clients typically are promised an answer within 2 days.

Ernie was designed to serve a market of new and small businesses with annual revenues under $250 million that would benefit from having access to outside experts in a variety of areas for which the business could not afford to have its own in-house expertise. It began by charging a fixed monthly fee and has evolved to be free for clients, with capped fees for online questions and charges for certain tools. Key benefits of the online consulting service is the quick turnaround on questions, because businesses today tend to want "just-in-time" information. In addition to answering online questions, EY Online provides a customized homepage for clients, access to a reference library and news items, access to the client's "EY Team," and some online tools for improved decision making.

Tax Applications and Services

Technology has proved to be a tremendous improvement in tax work due to the rote calculations involved, the link between financial records and tax records, and the nature of how tax returns are designed. For the past few decades, tax preparation software has been used to perform various tax functions, such as the calculation of depreciation on assets and printing of W-2 forms from electronic payroll data. Tax preparation software handles such functions as the flowing of data from financial records to tax returns and from tax form to related tax form, as well as error correction. Use of the Internet to enhance tax software applications allows for quicker and easier updates to the software, greater options for data storage, and links to tax information provided by the Internal Revenue Service (IRS) and state tax agencies, as well as by commercial providers of tax research information.

The Internet also allows a CPA firm to access needed tax information directly from a client's Web-based accounting systems. Web-based tax preparation tools allow CPA firms to manage their tax preparation work by tracking the status of return preparation—who is working on a particular return and how far along it is in the process. Web-based tax applications also allow for customized billing based on the detail needed by clients, and they provide access to tax preparation data and process from any location at any time. In addition, clients can easily e-mail data or files to their CPA firm in a more secure and timely manner than using the mail or a fax machine. Finally, many types of tax returns can be filed electronically today. During the 2002 filing season, the IRS reported that about 46 million taxpayers filed their tax return electronically. Also, about 105,000 tax preparers participated in the e-filing program (IRS News Release, IR-2002-53, April 25, 2002, available at Tax Analysts' Tax Notes Today, 2002 TNT 81-19). The benefits of e-filing include getting more accurate information into the IRS databases and quicker refunds.

Accessing Information

CPAs are dependent on information. They need access to the text of accounting pronouncements on generally accepted accounting principles (GAAP), tax research materials, ethics opinions and rules, and general business news and information. The ability to access much of this information on the Internet has greatly improved the efficiency and mobility of CPAs.

Tax Information

For decades, CPA firms relied on a physical library to access tax statutes, regulations, rulings, other tax research information, and tax forms. In the early 1990s, many of

the commercial providers of tax research materials also offered their materials on CD-ROMs. By the late 1990s, the primary commercial providers of tax research materials, such as the Research Institute of America (RIA) and the Commerce Clearing House (CCH), were providing the materials on the Web. Web-based access to tax research materials has several significant advantages over both paper and CD access. For example, providers can update the materials much more quickly and efficiently on the Web than can be done by sending new pages or CDs to customers. Less office space is needed with a Web-based library. Also, CPA firms have 24/7 access to the Web-based research materials and can access them from anywhere without the need to carry around several CDs. Web-based tax research is efficient because links are inserted into the online documents that enable users, for example, to click on a link in a document to see the full text of the cited case (rather than going to the physical library and pulling a book off the shelf). Finally, the search techniques using Web-based materials are superior to what is possible with a paper-based tax research tool.

Over the past several years, commercial providers of tax research materials have put more and more of their materials online, including treatises and journals. Much tax information is also accessible via the Web site of the IRS. In fact, the IRS Web site is one of the most frequently accessed sites, receiving heavy use by both taxpayers and practitioners. During the tax-filing season in early 2002, the IRS Web site had 1.97 billion hits, which was a 28% increase from 2001. On April 15, 2002, alone, there were 78 million hits to the site (IRS News Release, IR-2002-53, April 25, 2002, available at Tax Analysts' Tax Notes Today, 2002 TNT 81-19).

Other Information

Various commercial publishers provide Web-based access to accounting pronouncements, such as financial accounting standards and SEC documents. The Financial Accounting Standards Board ([FASB], 2000) Web site has information on current activity regarding drafting and reviewing new accounting standards and guidance. Copies of the various pronouncements can be ordered from the FASB Web site. Also, the SEC Web site has many types of items that previously could be obtained only by subscribing to a commercial service or by requesting them from the SEC. With the Web, this information is available immediately and at no cost. The SEC Web site provides links to statutes, press releases, special reports and studies, and regulatory actions. In addition, the well-known "EDGAR" service on the SEC Web site (http://www.sec.gov/) allows visitors to view or download copies of the reports (such as 10-Ks) filed by publicly-traded companies.

CPA firms also find value in using the Internet as an information source because many business journals, including the *Wall Street Journal,* can be viewed online, including archives of older articles. CPA firms can also access a variety of information useful in their work at portal Web sites designed specifically for CPAs. For example, the CPAnet.com site provides links to a wide range of accounting and tax news items, articles, conferences, job postings, and even accounting jokes. This portal also includes discussion groups where people can post questions and hope that another member of the discussion group offers an answer. These discussion groups significantly broaden the professional reach of a CPA, although they are not often used to their full potential.

CPA Organization Information

CPA firms can also find a great deal of useful information at Web sites run by accounting organizations, such as AICPA or state societies of CPAs. In March 2000, the AICPA and state CPA societies partnered to launch "CPA2Biz," a service to provide information and products to members (the state societies later left the arrangement). All AICPA products and services (such as registration at AICPA conferences) are only available at the CPA2Biz site. The site offers low-cost access to the AICPA's Resource Online, which enables users to search for documents or view specific accounting reference materials. CPA2Biz also offers online courses (there is a charge for most courses), business application software (such as for payroll and billing), job search and resume posting services, and accounting news and product updates via e-mail (*CPA Insider*). CPA2Biz has relationships with companies that have invested money in CPA2Biz, such as Microsoft (some of the CPA2Biz Web features are only supported by Microsoft's Internet Explorer) and Thomson (members can buy products from this company at the site).

Access and Controversy

CPA2Biz is marketed as a "revolutionary site" and a "single source" that will address all of a CPA's professional needs. The launch of the site caused some controversy between CPA2Biz and some CPA firms, however, primarily because of the AICPA's work in establishing and being an investor in a for-profit venture as well as the fact that AICPA's management received a small ownership percentage (1.6%). The AICPA, its members, and state CPA societies owned 40% of CPA2Biz. In March 2002, AICPA president and chief executive officer, Barry Melancon, announced that he was donating his 1% stock interest in CPA2Biz to the AICPA Foundation. In October 2001, national accounting firm BDO Siedman filed a lawsuit against CPA2Biz. BDO's complaint calls for an injunction based on such causes of action as unfair competition, restraint of trade, and breach of fiduciary duty. The litigation and the degree to which CPAs use the CPA2Biz site will certainly affect the future direction of this for-profit venture designed to provide quick access to products, services, and information for members.

Public Relations

The Internet has provided businesses, including CPA firms, another vehicle to promote themselves. Much of what is on a CPA firm's Web site is similar to what could be in a printed brochure. Many firms have taken advantage of the relatively low cost yet wide reach, of the Internet and provided more information about their firm on the Web than they would place in a brochure. For example, some CPA firms have financial "calculators" available on their Web site (although typically the calculators are not proprietary to the firms) to allow visitors to calculate such things as mortgage payments on a potential home purchase and

how much to save to reach a particular target. The set up of a Web site also enables clients and potential clients to get right to the information they want, even though the company may have a great deal of other, unrelated information on its Web site.

Key promotional items likely to be found at the Web site of many public accounting firms include the following:

- Contact information, firm history, firm mission statement and core values, and biographies of owners and key employees
- Press releases about personnel changes and new activities
- Promotional information—what is so special about the firm, why someone should hire the firm
- Description of services provided, often within industry areas of expertise (such as banking or real estate)
- Downloadable and Web-viewable newsletters and informational reports (such as to explain a tax or accounting rule)
- Tip of the week (typically a tax tip) that may lead clients and potential clients to visit the Web site more often
- Upcoming events, such as seminars
- Career information (types of career opportunities, positions available, how to apply, and ability to submit a resume via e-mail)

Some firms, particularly large international firms, maximize the technology and broad reach of the Internet in ways that go beyond just using the Web as an electronic marketing brochure. Some firms offer free webcasts of technical subjects to their clients and others. Such sessions may involve both a conference call and a Web-based presentation, as well as an option to allow participants to ask questions (either online or via phone). The sessions are typically run by the firm's experts on the particular topic. Because the presenters do not all have to be in the same room (or city), these types of educational programs enable the firms to avoid travel costs, as well as the costs of a room rental for traditional face-to-face seminars. Generally, the participants are offered continuing professional education credits (CPE) for their participation, which is an added incentive to participate. A firm benefits by exposing a large group of clients and nonclients to the firm's experts. Examples of topics covered in Web-based seminars include dealing with new IRS audit and appeals changes (Deloitte & Touche, May 2002) and proper application of Financial Accounting Standard #133 on derivatives (Ernst & Young LLP, December 2001). The presenting firms may also archive the presentations on their Web site for access by anyone at anytime.

As CPA firms expand their use of Web-based accounting tools, it is likely they will offer even more services to clients, such as access to their CPAs' calendars so clients can schedule appointments. Also, firms might set up their Internet services to allow clients to access their own tax returns and other documents prepared for that particular client, assuming that the obvious security concerns can be adequately addressed.

IMPLEMENTATION CONSIDERATIONS

System Reliability and Security

To provide services online, CPA firms must have systems with high reliability and security. System reliability is about a system's availability (available for operations and to be updated and maintained in a manner that continues to provide system availability) and its integrity. A reliable system can operate without material error, fault or failure during a specified time in a specified environment (Boritz et al., 1999).

System security is the ability to protect information resources from unauthorized access, modification, and destruction. Information resources in an Internet/e-business environment are hardware, software, and telecommunications. For CPA firms, online security is vital not only because it is required to protect the information assets, but also because of the long-term trusted relationship with clients. From a client viewpoint, security is the perceived guarantee that no unauthorized parties will have access to communications between the client and the CPA firm. The focus of online security is threefold: authentication, confidentiality, and integrity (Romney & Steinbart, 2000). Authentication is the ability of the system to verify that users are who they claim they are. Confidentiality refers to limiting data access or use to authorized individuals only. Online systems must be able to authenticate the identities of those who attempt to log on, allowing only legitimate users to access the information or database. Integrity refers to maintaining data accuracy and preventing hardware failure and unauthorized tampering. Current encryption technology (128-bit Data Encryption Standard) with public–private key usage and a good public key infrastructure (PKI) can accomplish these three goals. To have a good PKI, a firm needs to form consistent agreement between the practices of a certificate authority (CA) and the firm's certificate policies because the CA manages the firm's public keys.

In addition, properly trained IT professionals can play a key role to make an information system reliable and secure. It is also important that the top management of a firm maintain a well-established system development life cycle policy to assure the reliability and security of its information systems.

Training and Certification

During the 1990s and continuing today, CPA firms are devoting more time to training and education in IT areas, as evidenced by the number of IT conferences, the emergence of IT committees and IT newsletters within state CPA societies, and a new IT certification provided by the AICPA.

One of the premier IT conferences is the annual AICPA Tech conference. In 2002, this 4-day conference consisted of more than 50 sessions within the areas of consulting, technology, products, and IT management. Session topics dealing with the Internet and e-business included securing e-mail, Web collaboration tools, wireless technology and products, Web-based accounting software, e-commerce software systems, SysTrust and WebTrust, maximizing traffic to a Web site, and technology

consulting. Continuing education IT programs offered by state CPA societies include such topics as Web-based financial reporting and analysis (XBRL), security, and expanding a CPA firm's services through use of new technologies.

Many state CPA societies, as well as the AICPA, have IT committees to serve members who specialize in that area and members who want to increase their IT knowledge so they can expand and enhance the services they offer and can assist clients with their IT needs. For example, the Florida Institute of CPAs (n.d.; personal communication, Hue T. Reynolds, April 16, 2002; personal communication, Stam W. Stathis, April 24, 2002) has an E-Commerce Section that provides an Internet-based chat room for members, online expert Q &A, and a member directory. The institute is interested in helping its members expand their use of the Internet beyond just e-mail. The institute and its E-Commerce Section see IT as enabling members to expand their services into e-business opportunities and to share their IT expertise with clients who are seeking to expand their services through use of IT.

The AICPA's Information Technology Section is open to all AICPA members and qualifying non-CPAs. Members receive IT updates and a software news report (eight times per year), as well as Technology Alerts on major technology news. The ability to network with a large group of other CPAs involved with IT work is also a benefit of joining. The section also sponsors the annual AICPA Tech conference.

In 2000, the Information Technology Alliance (ITA) merged into the AICPA to form the IT Alliance. ITA was a 30-year old organization made up of value-added resellers, accounting software vendors, chief information officers (CIOs), chief technology officers (CTOs), and CPAs involved with technology. The ITA members joined AICPA members interested in IT consulting to form the new AICPA section. The IT Alliance existed within the AICPA along with the IT Section until they separated in April 2002 due to strategic decisions of both the ITA and AICPA. The AICPA continues to be an institutional member of the ITA, and the organizations will continue to work together in some ways. The primary focus of each organization varies somewhat in that the IT Section of the AICPA focuses more on assisting CPAs in using technology more effectively, whereas the ITA focuses on assisting members (which includes CPAs) in their roles as providers of IT-based solutions for clients.

Certified Information Technology Professional

In 2000, the AICPA began a new IT certification for CPAs. The designation is known as the Certified Information Technology Professional (CITP). The CITP designation helps the public to view CPAs as IT professionals, improves the quality of the IT services provided by CPAs, and aids in the development of practices in the IT area. A CITP is described by the AICPA as someone who serves in an organization as the "bridge between management and the technologist" (AICPA promotional literature). To become a CITP, a person must be a member in good standing of the AICPA, have a CPA license, pay a fee, submit a written statement of intent to comply with the requirements for reaccredidation and payment of the annual renewal fee, and generate at least 100 points through a combination of experience, lifelong learning (such as continuing education seminars), and examination results.

The type of experience that qualifies and that is covered on the CITP examination falls into the following eight categories:

1. Information technology strategic planning (18%)
2. Information systems management (15%)
3. Systems architecture (11%)
4. Business applications and e-business (16%)
5. Security, privacy, and contingency planning (11%)
6. System development, acquisition, and project management (13%)
7. Systems auditing/internal control (8%)
8. Databases and database management (8%)

The percentages shown indicate the weight given to that topic on the CITP examination. This 2-hour, computer-based exam is administered twice per year and consists of 100 objective questions. To pass, a member must answer at least 75 questions correctly. The CITP Web site provides considerable information on the eight topics, including links to articles on specific technologies, uses, and implementation. The CITP Web site is coordinated with the Top Tech site sponsored by the AICPA that provides background information on technology issues (such as security and disaster recovery), applications (such as data mining and document management), types of technology (such as wireless and authentication), emerging technologies (such as m-commerce and electronic evidence), and case studies (best practices shared by practitioners). The AICPA also offers training to help members earn the CITP designation.

Information Systems Audit and Control Association

Information systems (IS) audits have played an important role in the public accounting profession. Weber (1999) defined IS auditing as the process of collecting and evaluating evidence to determine whether an information system safeguards assets, maintains data integrity, achieves organizational goals effectively, and consumes resources efficiently. Sayana (2002) further stated that the purposes of IS auditing are to evaluate the system, to provide assurances that information in the system is being effectively used, and to make suggestions on how to improve the system. Bagranoff and Vendrzyk (2000) described IS audit practice as "stand alone with very close ties [to financial audit]." IS auditors support financial audits by providing risk assessment services to point out weaknesses that may impact the client's financial statements or impact the business as a whole. IS auditors also offer consulting services such as penetration testing and security diagnostics based on the system weaknesses they find in their audits. Most organizations that support IS auditing are involved with the overall improvement of auditing control objectives to limit organizational risk.

The Information Systems Audit and Control Association (ISACA, n.d.) is the most dominant organization in regard to information systems auditing and has an

aggressive vision: "to be the recognized global leader in IT governance, control and assurance" (http://www.isaca.org). ISACA accomplishes this goal by offering services such as research, setting industry standards, and providing information, education, certification, and professional advocacy.

One of the certifications ISACA oversees is the CISA (Certified Information Systems Auditor). It also operates the IT Governance Institute, believing information technology is no longer simply an enabler of an enterprise's strategy but is also an integral part of the strategy. ISACA has been leading the way by developing "globally applicable information systems auditing and control standards" (http://www.isaca.org).

As Gallegos, Manson, and Allen-Senft (1999, p. 6) indicated, "Technology has impacted the auditing profession in terms of how audits are performed (information capture and analysis, control concerns) and the knowledge required to draw conclusions regarding operational or system effectiveness, efficiency and integrity, and reporting integrity." CPA firms must face the challenges by providing more IT training to their staff so that they can broaden the range of services and effectively deliver those services to their clients.

Legal and Regulatory Issues

Much of the work of CPA firms involves financial data that clients want to protect, as appropriate. Thus, when more and more financial data and client communications about that data are performed or are made available electronically, CPA firms need to understand the technology, as well as the law, to be sure that confidential data is protected by privacy features in their system and their firm's office routines. In addition, a limited confidentiality privilege, added to the federal tax system in 1998, requires that CPA firms be aware of how the confidentiality of protected records is maintained so that clients do not lose any CPA–client privilege that may exist with respect to certain records. Another legal and regulatory concern for some CPA firms involves proper advising of clients subject to SEC rules to be sure that financial information posted to a Web site is properly and timely presented. These key concerns—privacy, confidentiality, and Web posting of financial data—are explained next.

Federal Privacy Law

Many CPA firms are subject to the privacy provisions of the 1999 Gramm–Leach–Bliley (GLB) Act. The privacy provisions apply to a broad range of financial services that includes preparation of nonbusiness tax returns and financial and tax planning. The act prohibits those subject to it from disclosing nonpublic personal information without authorization. The act also directs the Federal Trade Commission (FTC) to issue regulations on the disclosure required by companies subject to the privacy provisions. The FTC (2000) issued final regulations in May 2000 and CPAs had to be in compliance by July 1, 2001.

CPA firms subject to the FTC regulations must provide a disclosure notice to new clients and an annual disclosure to all clients that accurately depicts the firm's privacy policy. The disclosure must explain the firm's practices and policies regarding privacy, including such items as the categories of nonpublic personal information collected and other data the firm might disclose, the client's right to opt out of any disclosures by the firm, and how a client's nonpublic personal information is maintained in a secure and confidential manner. The AICPA Web site provides members with information about complying with the act, including sample disclosure letters that can be sent to clients.

The new disclosure rules are most relevant to a CPA in terms of the notice requirement. CPAs are already subject to disclosure and confidentiality rules by their licensing state, the AICPA, and the federal tax law. For example, Rule 301 of the AICPA Code of Professional Conduct states that "a member in public practice shall not disclose any confidential client information without the specific consent of the client." Internal Revenue Code (IRC) section 6713 imposes a penalty on any tax return preparer who discloses information provided to him or her for return preparation or uses such information for any purpose other than to prepare or assist in preparing a tax return. IRC section 7216 provides that such disclosure is a misdemeanor if the disclosure is done recklessly or knowingly.

Confidentiality Privilege

In 1998, the IRS Restructuring and Reform Act created a limited confidentiality privilege for clients of CPAs. This new provision (IRC section 7525) extends the common law attorney-client privilege of confidentiality with respect to tax advice to any federally authorized tax practitioner (attorneys, CPAs, enrolled agents, and enrolled actuaries). This privilege is intended to apply to the same extent as it would between a taxpayer and an attorney; however, it does not expand the attorney–client privilege.

The section 7525 privilege, if otherwise applicable, applies to *tax advice* furnished to a client-taxpayer or potential client-taxpayer. However, the privilege may only be asserted in a noncriminal tax matter before the IRS and any noncriminal tax proceeding in federal court by or against the U.S. "Tax advice" is defined as advice given by an individual with respect to a matter within the scope of the individual's authority to practice as a federally authorized tax practitioner (per Treasury Department Circular 230) that involve matters under the IRC. Thus, the section 7525 privilege cannot be asserted to prevent any other regulatory agency (such as the SEC) or person from compelling the disclosure of information. The section 7525 privilege does not apply to any written communication between a federally authorized tax practitioner and a director, shareholder, officer, or employee, agent, or representative of a corporation in connection with the promotion of the direct or indirect participation of the corporation in any tax shelter (per the definition at IRC section 6662(d)(2)(C)(iii)). CPAs need to check their state's law to see if the state has conformed to the federal privilege.

Section 7525 goes beyond Rule 301, Confidential Client Information, of the AICPA Code of Professional Conduct (noted earlier), because the section 7525 privilege is legally enforceable and generally will prevent disclosure, even if compelled by the IRS through a summons.

The existence of a CPA-client privilege means that CPAs need to understand the basics of the attorney–client

privilege as well as the limitations of section 7525. CPAs need to know what is considered a confidential communication and what types of tax work and documents are protectable. In addition, CPA firms will need to implement office practices to be sure that no disclosure occurs that may cause a client's privilege to be waived. For example, inadequate electronic storage or security over the storage may indicate that no confidentiality was intended, thus the information is not privileged. In addition, CPA firms need to evaluate whether any encryption or other precautions are needed to ensure that electronic transmissions protect confidential information.

Questions have been raised over the past several years by attorneys and bar associations as to whether e-mail is a confidential delivery vehicle such that information sent via e-mail is privileged (assuming it otherwise qualifies for protection under the privilege). Questions have also arisen as to whether certain rules, such as those dealing with solicitation, apply to e-mails and information provided on Web sites. Some states have issued guidance on these matters. For example, in 1997, the Illinois State Bar Association issued Advisory Opinion No. 96–10. The conclusion reached is that an attorney's duty to protect confidential client information is not violated by the attorney's use of e-mail and the Internet without encryption to communicate with clients unless unusual circumstances require enhanced security measures (such as when it is already known that break-ins have been attempted). The rationale is that the ability to intercept e-mail is about as difficult as intercepting a regular phone call. Also, intercepting e-mail is illegal under the Electronics Communications Privacy Act of 1986. Before communicating via e-mail with a client or potential client, however, consideration should be given to who else has access to the e-mail. For example, if the client is using the e-mail system at his or her job site and it is regularly reviewed by the systems administration staff or is shared e-mail, there is no expectation of privacy and thus no indication that the communication was intended to be confidential. (Also see American Bar Association Formal Opinion No. 99–413.)

There is little case law on the subject of e-mail and confidentiality, and no guidance with respect to the IRC section 7525 privilege. Several states, however, have issued opinions similar to that in Illinois, which may provide some general guidance for a CPA. CPA firms will need to consider the limited guidance that exists, the basics of the privilege, and the nature of the information involved and the security situation (for example, is it one prone to hackers?) in establishing the procedures needed to maintain the client's privilege under section 7525 with respect to electronic transmission of protected tax information. Future guidance from the IRS may provide some assistance on this matter as well.

Privacy in Practice

A CPA firm doing business over the Internet, such as online consulting, will need to demonstrate to clients that information transferred electronically and Web-based accounting information is secure from people who are not supposed to access it and view it. Clients will also need to know that the CPA firm's data storage systems are secure. Basically, to be successful and to operate within a CPA's professional responsibility, the CPA firm may want to provide the same key protections provided by a seal of approval such as CPA WebTrust (see earlier discussion of this service). The three assurances offered by WebTrust are proper disclosure of business practices for e-business transactions, integrity of transactions, and protection of information. In essence, CPA firms will certainly find that clients will want the same privacy and security protections from the online services they receive from their CPA that their CPA, as a trusted business advisor, should be recommending for the client's business.

Regulatory Considerations in Online Financial Reporting. Since 1995, the SEC has issued various releases providing guidance to companies and their financial advisors on procedures to allow for electronic delivery of financial information. Generally, use of technology to deliver information is encouraged because of its efficiency in allowing for quick and wide distribution of information in a cost-efficient manner. The 1995 and 1996 SEC releases provide guidance to ensure that the electronically delivered information is at least equivalent to paper delivery (Securities Act Releases Nos. 7233 [1995] and 7288 [1996]). The creation of XBRL has made use of the Internet to deliver and present all types of financial information in a standardized language, a reality. The usage of electronic financial reporting will continue to result in the need for more guidance to ensure that the information is as complete and reliable, however, as has been expected with paper disclosures. Securities Act Release No. 7856 (2000) addressed issues that can arise when a registered company's Web site includes links to Web sites of third parties that include financial information about the company. For example, to what extent is the company liable under the antifraud provisions of the securities laws for the financial information at the third party's Web site? The release states that the answer depends on the facts and circumstances of the particular situation. Three factors to be considered are the context of the hyperlink, the risk of investor confusion, and the presentation of the hyperlinked information. (View Internet-related SEC Interpretive Releases at http://www.sec.gov/divisions/enforce/internetenforce/interpreleases.shtml.)

Taxation. In 1998, the federal government enacted the Internet Tax Freedom Act (1998) providing a three-year moratorium prohibiting state and local governments from imposing certain taxes on Internet access fees. The Internet Tax Nondiscrimination Act (2001) extended the moratorium to November 1, 2003. Debate continues on how certain taxes should apply to Internet transactions. Existing tax rules were not written with the e-commerce business model in mind, and sometimes online transactions do not fit neatly within existing tax rules, and uncertainty remains. Tax issues also exist in that some policymakers believe that certain Internet transactions should not be taxed so that the Internet and e-commerce will flourish.

CPA firms get involved in the e-commerce taxation debates and issues because of their expertise with tax rules and their obligation to advise clients. The area that has received the most attention involves the application of sales

tax to e-commerce transactions. CPA firms advising businesses setting up e-commerce operations need to be aware of the existing rules governing e-commerce taxation to ensure that their clients have proper procedures in place to collect any tax owed and can structure their e-commerce operations to obtain the best tax planning results. Given the complexity of some of the issues and their often global nature, CPAs will need to stay current on developments in this area so they can properly advise their clients.

FUTURE POTENTIAL—TRENDS AND OPPORTUNITIES

The rapid development of IT has significantly changed the business environment and business models and processes; hence, the accounting profession must respond to the new challenges and take the opportunities to broaden its service spectrum. Because assurance services are critical to all business reporting and the Internet has made continuous reporting possible, CPA firms now have many opportunities to perform continuous audit and assurance. Continuous reporting is real-time reporting, meaning that digitized information becomes available through electronic channels simultaneously with its creation (Elliott, 2002). Many issues are involved with such a practice. Because various types of information often flow to creditors, investors, trading partners, government agencies, and employees, it is vital that the systems provide reliable information (e.g., SysTrust assurance service), that a company maintains its Web sites in a way that the external users of the information can trust it (e.g., WebTrust assurance service), and that the information provided is easy to be downloaded for analysis purposes (i.e, XBRL). Therefore, continuous audit and assurance will be the trend for the accounting profession (both external and internal audit practices).

In addition, the Internet leads to a more global reach of CPA firms, which may cause concern over national or international licensing standards. For this reason, CPA firms may want to encourage more staff to obtain the CISA (Certified Information Systems Auditor) certification because it is recognized internationally. Most important, the business world is moving toward a paperless, or even a virtual, office in which all records are stored on the Web and accessible anywhere and anytime. Because the information is so easily accessed, CPA firms must be especially careful to make their staff aware of all the related legal and regulatory issues, such as privacy and confidentiality of clients' online information, when the firm is using that information for audit or consulting engagements.

Finally, we will likely see CPA firms continue to find innovative ways to use the Internet and e-business opportunities to further expand and enhance their services and enable companies to provide more information and services to their clients.

GLOSSARY

Certified public accountant (CPA) Accountants licensed by a state agency to perform certified financial audits of businesses and other organizations. CPAs typically must have a certain number of university- or college-level courses in accounting and related business subjects and a number of hours of experience. In addition, they must pass a national examination.

Encryption The conversion of data into a secret code for transmission over a public network. The original text, or "plaintext," is converted into a coded equivalent called "ciphertext" via an encryption algorithm. The ciphertext is decoded (decrypted) at the receiving end and turned back into plaintext.

Extensible markup language (XML) An open standard for describing and defining data elements on a Web page and business-to-business documents. It uses a similar tag structure as HTML; however, whereas HTML defines how elements are displayed, XML defines what those elements contain. HTML uses predefined tags, but XML allows tags to be defined by the developer of the page. Thus, virtually any data items, such as products, sales representative's name, and amount due, can be identified, allowing Web pages to function like database records. By providing a common method for identifying data, XML supports business-to-business transactions and is expected to become the dominant format for electronic data interchange.

Electronic data gathering analysis and retrieval (EDGAR) A reporting system that public companies must use to send financial data to the Securities and Exchange Commission. In late 1990s, EDGAR was revamped to accept HTML and PDF files.

Public Key Infrastructure (PKI)

Russ Housley, *Vigil Security, LLC*

INTRODUCTION

As more business transaction occur on the Internet, security services based on cryptography become essential. Public key cryptography plays an important role in providing confidentiality, integrity, authentication, and nonrepudiation. The basic problem with using public key cryptography is determining who holds the corresponding private key. There are two ways to address this problem. In the first approach, the public key user maintains a local database of the public key and identity pairs. This approach is used in secure shell (SSH) and account-based secure payment as defined in ANSI X9.59, but it does not scale to large communities or facilitate ad hoc communications. The second approach does not have these shortcomings. In the second approach, a trusted party issues a *public key certificate,* or simply *certificate,* containing identification information and a public key. The recipient of such a certificate can be confident that the named party has possession of the private key that goes with the public key contained in the certificate. The collection of hardware, software, people, policies, and procedures needed to create, manage, store, distribute, and revoke certificates is called a *public key infrastructure* (PKI).

The certificate may also indicate the applications that it supports. A certificate *issuer,* called a *certification authority* (CA) can specify the supported applications or specify the expected cryptographic operations. For example, the certificate could specify virtual private network (VPN) key management. Alternatively, the certificate issuer might specify that the public key should be used for validating digital signatures.

PKI is not an application in its own right; rather, it is a pervasive substrate. When properly implemented, it can be taken for granted. PKI provides the binding of public keys and identity information, and then applications make use of the public keys to provide security services such as confidentiality, integrity, authentication, and nonrepudiation.

PKI BASICS

The public key certificate contains fields for the subject's identity and public key. The certificate can indicate a company or organization along with a common name. A variety of name forms are supported. Some name forms are abstract, and others are addresses, such as an e-mail address. The certificate also includes two date fields that specify an activation date and an expiration date. The certificate also contains the name of the CA that created the certificate. To clearly identify each certificate that it issues, the CA includes a unique serial number. Finally, the entire contents of the certificate are protected by the CA's digital signature. Figure 1 illustrates Bob's public key certificate.

In Figure 1, the Hawk CA1 issued Bob's public key certificate. The certificate was activated at noon on February 14, 2002, and will expire at noon on February 14, 2003. This certificate has serial number 48. It includes Bob's name and his RSA public key. The Hawk CA1 signed the certificate with it's own private key, using the DSA signature algorithm and the SHA-1 one-way hash function.

The CA's signature ensures that the certificate cannot be undetectably modified. If anyone changes the contents of the signed certificate, it can be easily detected. The signature will not validate with the modified certificate content. If the digital signature does not verify, the contents have been changed or the certificate is a complete forgery. Either way, it will not be trusted.

How can a certificate user determine whether to trust the certificate contents? The certificate cannot indicate whether the subject has died or changed jobs. Similarly, by looking at a credit card, merchant cannot tell whether it has been revoked.

Like business cards, once a certificate is distributed, it is practically impossible to retrieve all of the copies. In fact, the problem is worse for certificates, since they are digital objects, certificates can be easily replicated and redistributed. All copies cannot be recovered if the information in it is no longer current.

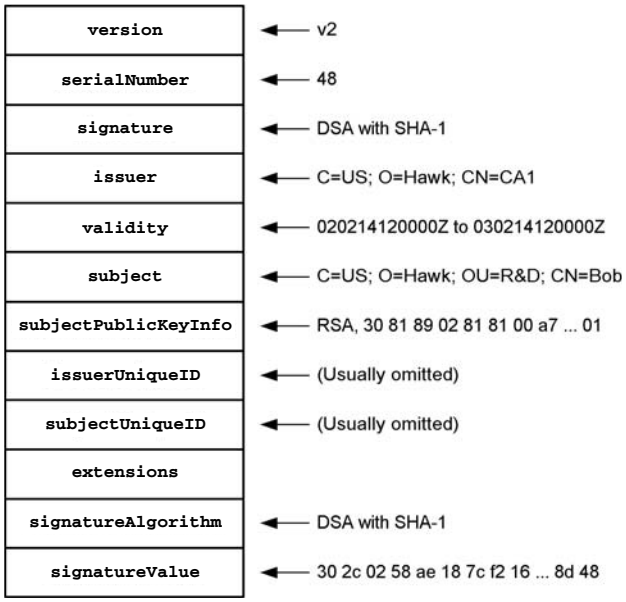

Figure 1: X.509 certificate structure.

The CA's job is to link a public key with a subject's identity in a trustworthy fashion. If the subject notifies the CA that the certificate is no longer correct, then the issuer needs to get that information to anyone who uses the certificate. To determine if the certificate is still trustworthy, the certificate user supplements the unexpired certificate with additional information: either a *certificate revocation list (CRL)* or an *online certificate status protocol (OCSP)* response.

The CRL contains a digitally signed list of serial numbers from unexpired certificates that should not be trusted. The CA generates a CRL regularly and posts it for anyone to obtain. The CA includes the issuance date in the CRL, and usually a date by which an updated CRL will be published. This allows the certificate user to be sure that current information is used. Figure 2 illustrates a CRL that revokes Bob's certificate.

Alice would like to determine the status of Bob's certificate, so she obtains a CRL issued by Hawk CA1. The CRL was issued at 6:00 p.m. on April 15, 2002, and the next issue can be expected 24 hours later. The CRL includes a list of certificate serial numbers for *revoked* certificates.

Alternatively, the OCSP Response provides the revocation status for a single certificate. The certificate user sends a query to a trusted server using the OCSP, suspending acceptance of the certificate in question until the server returns a digitally signed response. In some circumstances, OCSP can provide more timely revocation information than CRLs. More important to many applications, OCSP can also provide additional certificate status information.

One CA cannot reasonably issue certificates to every Internet user. Obviously, there will be more than just one. It is not possible for every Internet user to investigate each CA and determine whether the issuer ought to be trusted. A company might provide certificates to its employees; a business might provide certificates to its customers and business partners; or an Internet user might select a CA

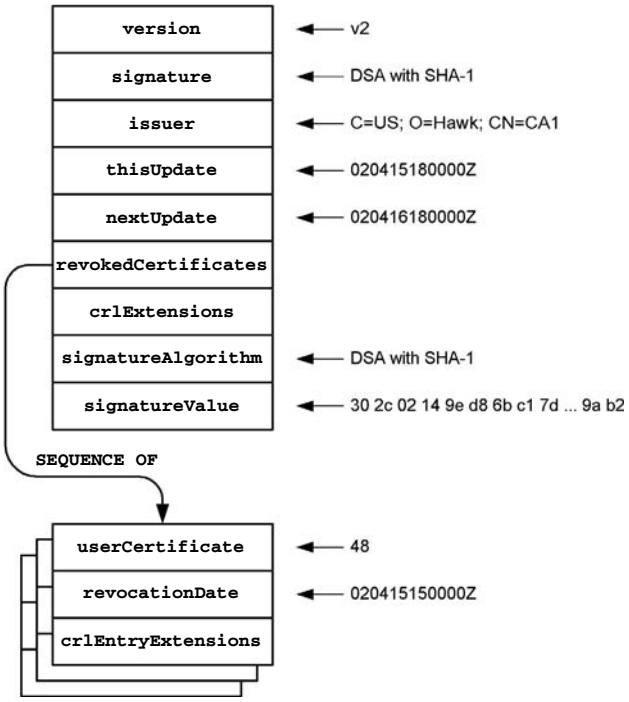

Figure 2: X.509 CRL structure.

to issue their certificate. There are many potential sources of certificate, each satisfying different marketplace needs.

Alice may get a certificate from Hawk CA1. Alice can also trust other CAs that Hawk CA1 trusts. Hawk CA1 indicates this trust by issuing them a certificate. These CAs can indicate trust in other CAs by issuing them certificates. Alice can develop a chain of certificates and automatically decide if certificates from another issuer may be used for the intended purpose. Figure 3 illustrates two

popular PKI construction topologies: the hierarchical PKI and the mesh PKI.

PKI Components and Users

A PKI is often built from three basic functional components: the certification authority (CA), the registration authority (RA), and the repository. A CA is the primary component of the PKI, known by its name and its public key. A CA comprises hardware, software, and the people who operate it. A CA issues certificates, maintains certificate status information and issues CRLs, and publishes certificates and CRLs. A CA must protect the private key or keys used to sign certificates and CRLs, using physical, procedural, and technical controls.

An RA verifies certificate contents prior to certificate issuance, and it may also assume some of the responsibility for certificate revocation decisions. Certificate contents may be verified by information presented to the RA, such as a driver's license. They may also reflect data from a company's human resources department. A CA is likely to work with multiple RAs, because different RAs may be needed for different users groups.

A repository distributes certificates and CRLs. It accepts certificates and CRLs from one or more CAs and makes them available to parties that need them, and it is usually designed to maximize performance and availability. Repositories are often duplicated to maximize availability, increase performance, and add redundancy.

A PKI supports two types of users: certificate holders and relying parties. A certificate holder is the subject of certificate, and it holds the corresponding private key. The CA issues a certificate to the certificate holder. In many circumstances, the certificate holder requests the certificate directly from the CA or through the RA. Certificate holders may need to interact with the repository to obtain their own certificate but do not regularly interact with it. Certificate holders may include their own certificate in transactions.

A relying party uses the public key in a certificate to verify signatures, encrypt data (key transport), or perform key agreement. A relying party identifies one or more trust anchor, verifies signatures on certificates and CRLs, obtains certificates and CRLs from a repository, and constructs and validates certification paths. A relying party regularly interacts with repositories, but it has no interactions with RAs.

PKI ARCHITECTURES

The most basic PKI architecture is a single CA that provides all the certificates and CRLs for a community of users. In this configuration, all users trust the CA that issued their certificate. By definition, new CAs cannot be added to the PKI, and all certificates are user certificates. The users accept only certificates and CRLs issued by their CA. Although the simplest to implement, this architecture does not scale easily to support large or diverse user communities. The single CA PKI presents a single point of failure. Compromise of the CA invalidates the trust point information and all certificates that have been issued in this PKI. Every user in the PKI must be informed about the compromise immediately, or they may establish security based on unreliable information. To reestablish the CA, all certificates must be reissued and the new trust point information must be distributed to all the users. To overcome these deficiencies, two architectures are widely employed: the hierarchical PKI and the mesh PKI. (Recall that Figure 3 illustrates these topologies.)

Hierarchical PKI

The hierarchical PKI is the traditional PKI architecture. All users trust the same central *root CA*. With the exception of the root CA, all of the CAs have a single superior CA. CAs may have subordinate CAs or issue certificates to users or both. A single certificate represents each trust relationship, making certification path construction simple, obvious, and deterministic. The certification paths are usually short. The longest path is equal to the depth of the tree.

Superior CAs may impose restrictions upon the subordinate's actions. These restrictions could be maintained through procedural mechanisms or imposed through the certificates themselves. In the latter case, the CA certificate will contain additional information to describe the restrictions. For example, the Hawk HQ CA could issue a certificate to a subordinate Hawk Legal CA that requires valid certificates to contain a particular prefix in all subject names, which clearly indicates employment in the legal department.

When users are portioned into smaller groups, each served by a different CA in the hierarchical PKI, it is easily handle the compromise of a single CA, as long as it is not the root CA. If a CA is compromised, its superior CA simply revokes its certificate. Once the CA has been reestablished, it issues new certificates to all of its users. The superior issues a new certificate to the CA, containing the new public key, bringing it back into the hierarchy. During the interim, transactions between any two users outside the compromised part of the PKI can proceed. Of course, users in the compromised part of the hierarchy lose all services.

On the other hand, the compromise of the root CA has the same impact as in the single CA architecture. It is critical to inform all the users in the hierarchical PKI that the root CA has been compromised. Until the root CA is reestablished, issues new certificates to its subordinates, and distributes the new trust point information, users cannot use the PKI to establish secure communications. In comparison to the compromise of the single CA, the root CA will have to reissue a much smaller number of certificates to resume operations. The root CA usually operates offline, significantly reducing the likelihood of such a compromise.

Mesh PKI

The mesh PKI architecture is the primary alternative to a hierarchy. Multiple CAs provide PKI services, but the CAs are related through peer-to-peer relationships. Each user trusts a single CA; however, the trusted CA is not the same for all users. Generally, users trust the CA that issued their certificate. CAs issue certificates to each other; a pair of certificates describes their bidirectional trust

relationship. The same constraint mechanisms that were used in the hierarchical PKI may be used to avoid placing unrestrained trust in other CAs.

A new CA can easily be added. The new CA issues a certificate to at least one CA that is already a member of the mesh, who also issues a certificate to the new CA. Path construction is particularly difficult in a mesh PKI; however, it is nondeterministic. Path discovery is more difficult because there are often multiple choices. Some of these choices lead to a valid path, but others result in a useless dead end that does not terminate at a trust anchor. Even worse, it is possible to construct an endless loop of certificates.

Certificates issued to CAs in a mesh PKI are also more complex than the ones usually found in a hierarchical PKI. Because the CAs have peer-to-peer relationships, the certificates contain constraints to control certification paths that will be considered valid. If a CA wishes to limit the trust, it must specify these constraints as certificate extensions in the certificates issued to all of its peers.

Because Mesh PKIs include multiple trust points, they are very resilient. Compromise of a single CA cannot bring down the entire PKI. CAs that issued certificates to the compromised CA simply revoke them, thereby removing the compromised CA from the PKI. Users associated with other CAs will still have a valid trust point and can communicate securely with the remaining users in their PKI. In the best case, the PKI shrinks by a single CA and its associated user community. At worst, the PKI fragments into several smaller PKIs. Recovery from a compromise is simple and straightforward, primarily because it affects fewer users.

Hybrid PKI Architectures

Two approaches are commonly used to join two or more enterprise PKIs: cross-certification and a bridge CA.

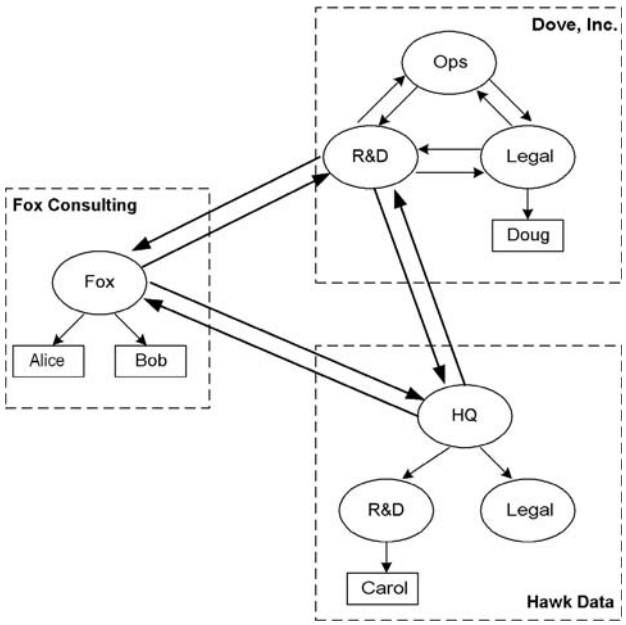

Figure 4: Certification paths with cross certified PKIs.

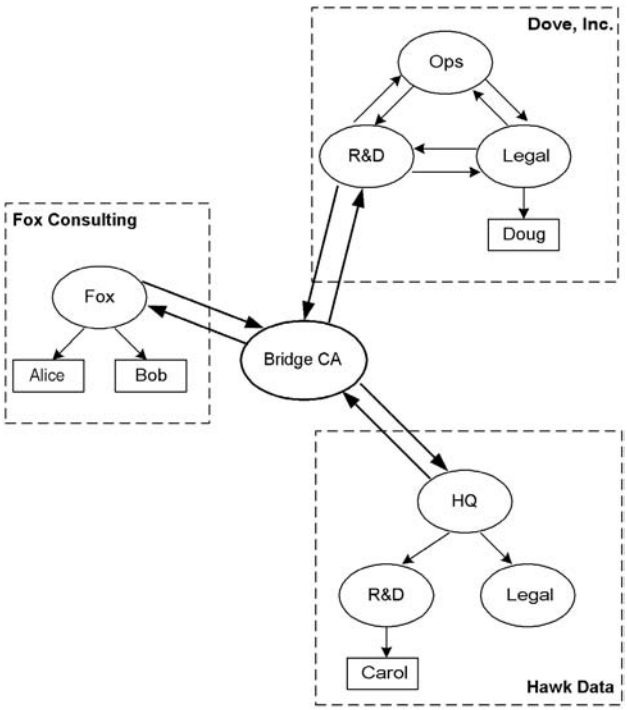

Figure 5: Certification paths with a bridge CA.

Both techniques establish peer-to-peer trust relationships. Figure 4 shows one example of a cross-certified PKI. This architecture is an appropriate solution to establish trust relationships between a few enterprise PKIs. In Figure 4, three peer-to-peer relationships and six CA certificates were required to establish these relationships. This number grows rapidly, however, as the number of enterprise PKIs increases. Cross-certifying n enterprise PKIs requires $(n^2 - n)/2$ peer-to-peer relationships and $(n^2 - n)$ certificates. Establishing these relationships requires a time-consuming review of policies and practices.

Figure 5 shows the same enterprise PKIs establishing trust via a bridge CA. Unlike a mesh CA, the bridge CA does not issue end-entity certificates. Unlike a root CA in a hierarchy, the bridge CA is not intended for use as a trust point. All PKI users consider the bridge CA as an intermediary. The trust relationships between the bridge CA and the principal CAs are all peer-to-peer. It is easy to add new CAs, or entire enterprise PKIs, to a bridge-connected PKI. The change is transparent to the users, because no change in trust points is required. In general, the use of the Bridge CA will require less time to be spent reviewing policies and practices than a comparable Cross-Certified PKI.

Neither cross-certification nor the bridge CA simplified certification path construction or validation. In general, path construction is just as complex as in a mesh PKI; however, path construction can be greatly simplified if CAs are aligned with the name space in which the certificates are issued.

PUBLIC KEY CERTIFICATES

The X.509 public key certificate is named after the document in which it was originally specified: *CCITT Recommendation X.509*. This document, first published

in 1988, specifies the authentication framework for the X.500 Directory. The X.500 Directory requires strong authentication to ensure that only authorized users make modifications. In addition, when the directory contains confidential information, authentication can be used to control directory access.

Over time, the focus shifted from supporting the directory to developing a general-purpose PKI. As a result, two upwardly compatible versions have been published since 1988. Version 2 certificates addressed a single issue: reuse of names. The Version 2 enhancements are rarely used today. Version 3 of the X.509 certificate introduces certificate extensions. Extensions are used when the issuer wishes to include information not supported by the basic certificate fields. All modern PKI implementations generate and process X.509 version 3 (X.509 v3) certificates. The set of extensions used by implementations varies widely.

The Internet Engineering Task Force (IETF) profiled X.509 certificates for the Internet. Like all Internet standards, it is published in a request for comment (RFC) document. The Internet Certificate and CRL Profile, RFC 2459, was published in March 1999. In April 2002, RFC 2459 was replaced by RFC 3280, which identifies optional features of X.509 that are required for the Internet, and it discourages the use of other features.

Subjects and issuers are identified using the distinguished name (DN), a structured type that supports the X.500 hierarchical naming system. The X.500 suite of standards was expected to result in a global directory. This lofty goal required a name form that could be used to create globally unique names. Naming authorities manage their own name spaces, and only that authority assigns names in that space, ensuring collision-free names.

Additional name forms are supported through subject alternative name extension and the issuer alternative name extension. The additional name forms include, but are not limited to, the following:

- Internet domain names (often called DNS names)
- RFC 822 e-mail addresses
- X.400 e-mail addresses
- World Wide Web URLs

CERTIFICATE REVOCATION

Two approaches are used today for certificate status: CRL and OCSP. The basic mechanism for certificate status is the CRL, which is profiled for Internet use in RFC 3280. A CA revokes a certificate by placing the certificate serial number and revocation date on the signed CRL. Certificate users simply search the most recent CRL to determine whether a particular certificate is revoked.

OCSP is specified in RFC 2560, and it enables applications to determine the status of a particular certificate by querying an OCSP responder. A certificate user sends a status request to the OCSP responder, and then the OCSP responder replies with digitally signed certificate status information. The CA can host this service locally, or the CA can delegate this responsibility to an independent OCSP responder.

When using CRLs, the CA name and certificate serial number identify a certificate, but OCSP uses the more complicated certificate identifier. In the absence of a global directory system, it is possible that two CAs could choose the same name. Because an OCSP responder may provide service for multiple CAs, the OCSP responder must be able to distinguish CAs with the same name. Two CAs will not have the same public key, so a hash of the issuer public key is used in addition to the hash of the CA name to identify the issuer.

OCSP is often described as providing revocation information in a more timely fashion than CRLs. An OCSP responder can provide the most up-to-date information it possesses without repository latency. If the OCSP responder is also the CA, the most up-to-date information will be provided. With CRLs, the CA may have additional information that it cannot provide to certificate users. In practice, however, there has been little difference in freshness of the certificate status information provided by an OCSP responder and a CRL.

Most OCSP responders are not CAs. Rather, they are single-purpose machines that handle certificate status requests for a large number of CAs. Typically, these servers obtain their revocation information periodically in the form of CRLs. The information obtained by the requester is no fresher than if they obtained the same CRLs themselves.

The certificate user must place irrevocable trust in the OCSP responder because there is no way for the certificate user to determine if the OCSP responder itself has been revoked. The actions needed to revoke an OCSP responder are similar to the actions needed to remove a trust anchor.

The real utility of OCSP lies in the single-response extension fields. If an application is checking a purchase order signature, the OCSP responder could provide a response stating that the certificate is not revoked and that the signature is acceptable for the stated dollar amount. CRLs cannot provide this additional context-specific functionality.

PKI MANAGEMENT PROTOCOLS

A CA needs to obtain the subscriber's public key, authenticate the subscriber's identity, verify that the subscriber possesses the corresponding private key, and verify any additional subscriber and key information before it signs a certificate. If the certificate contains incorrect information, a certificate user may establish security services with the wrong user or employ the public key for an inappropriate application. A CA must also determine that the status of a certificate has changed before it adds the certificate to the CRL. If the CA adds a valid certificate to the CRL, subscribers are denied service. If the CA fails to add a certificate whose status has changed to the CRL, certificate users will accept the invalid certificate. To meet these requirements, the CA must obtain trustworthy information from PKI participants. *PKI management protocols* are used by CAs to collect the information needed to issue certificates and CRLs. There are several PKI management protocols. Management protocols support two basic types of transactions: *certificate requests* and *revocation requests*.

As noted earlier, a CA needs to obtain trustworthy information before issuing or revoking a certificate. It may obtain this information from three PKI participants: the

prospective certificate holder, a current certificate holder, or a registration authority (RA). The CA has a different relationship with each of these participants.

A prospective certificate holder is essentially unknown to the CA but has requested acceptance into the PKI. The potential subscriber would like the CA to issue a certificate containing a specific identity and public key. The prospective certificate holder can provide this information in an initial certificate request, but the CA cannot determine from the data itself whether the name is appropriate. A CA can cryptographically verify that the requester has possession of the private key, however. For signature keys, the requester can simply digitally sign the request. For key management keys, a challenge-response mechanism may be required.

A certificate holder that possesses a currently valid certificate may request a new certificate. The requested certificate may have a different public key or include new name forms. The CA knows the subscriber's identity; otherwise, it would not have issued the current certificate. The current key pair may be used for authentication, and, as described previously, the CA can also cryptographically verify that the requester possesses the private key. The CA might not trust its subscribers to claim new names, however.

A certificate holder that possesses a currently valid certificate may also request revocation of one of his or her current certificates. The CA should always revoke a certificate upon the request of the certificate holder, so the signed request contains all the information required by the CA. This does not necessarily mean that the CA trusts the subscriber for this information or that the subscriber is telling the truth. If the holder of a private key asserts that it is no longer valid, this request must be honored. If the signed request came from another source, then the private key has been compromised, and the certificate must be revoked anyway.

The RA is empowered by the CA to collect information and verify its correctness. For certificate request operations, the RA may verify the prospective subscriber's identity and their e-mail address or other contact information. For revocation requests, the RA may identify the certificate subject and verify the reason for revocation. The RA is generally a certificate holder as well. RA digital signatures allow the CA to authenticate messages readily from the RA. An RA can review the documentation and determine whether a CA should honor a request.

PKI management transactions must be designed so that the CA obtains reliable transaction information. For some transactions, the CA and the certificate holder can implement the transaction without assistance. These are *two-party transaction models*. In other cases, the transactions leverage an RA to fill in the gaps in the trust relationships between the CA and prospective subscriber. These are *three-party transaction models*. The following is a brief survey of common PKI management protocols.

PKCS #10

Public Key Cryptography Standard (PKCS) #10, Certification Request Syntax Standard, describes a message syntax for certification requests. The certification request consists of a distinguished name (DN), the public key, an optional set of attributes, an algorithm identifier, and a digital signature. The optional attributes were designed to convey attributes for inclusion in the certificate (for example, an e-mail address), to provide the CA with additional information (for example, a postal address), and to establish a *challenge password* for use in a subsequent revocation request. The request is signed by the entity requesting certification using the corresponding private key. This signature is intended to achieve private key proof-of-possession.

PKCS #10 defines the syntax of a single request message, not a full protocol. The contents or format of the response is outside the scope of PKCS #10, although a PKCS #7 message is suggested as one possibility. Almost every PKCS #10 implementation employs PKCS #7 to return the certificate. The syntax and protocol used to request certificate revocation is also unspecified. PKCS #10 must be used with other message formats and protocols to provide functionality of a complete PKI management protocol.

PKCS #10 was not designed to be algorithm independent. The specification assumes the private key may be used to generate a digital signature, as is the case with the RSA algorithm. Proof-of-possession for key agreement algorithms, such as Diffie-Hellman, are outside the scope of PKCS #10. Proof-of-possession can be achieved using optional attributes to convey additional information, however. Despite these limitations, PKCS #10 remains the most widely used certificate request tool.

Certificate Management Protocol

When the IETF PKIX Working Group began development of a protocol for PKI management, they decided not to leverage PKCS #7 and PKCS #10. At the time, RSA Security held the copyright for the PKCS documents, so the IETF could not have change control. In addition, the working group wanted to develop a comprehensive protocol to support a broad variety of models, including RA participation, and implement algorithm-independent proof-of-possession. At the time, it was unclear whether PKCS #7 and #10 were an appropriate starting point to meet these goals.

The PKIX Working Group developed a new protocol defined by the combination of the Certificate Management Protocol (CMP; in RFC 2510), and the Certificate Request Management Framework (CRMF; in RFC 2511). The resulting protocol is comprehensive, can support practically any RA issuance model, and supports algorithm-independent proof-of-possession. The protocol also includes its own cryptographic message protection format, and it supports four transport protocols.

CMP defines seven transaction sequences, employing both request and response messages. These message pairs support three types of certificate requests, a CA certificate request, revocation, and key recovery operations. A proof-of-possession challenge sequence is defined for use in conjunction with the certificate request messages. The complexity of the CMP messages means that different implementations may not support the same combination

of optional fields. As a result, conforming implementations may not interoperate for all possible transactions. Nonetheless, the CMP specification defines the five common transactions in detail. These transactions are mandatory for conforming implementations, and they are specified in sufficient detail to achieve interoperability. Unfortunately, the *revocation request* and *revocation response* is not among these five transactions.

CMP messages are designed to handle multiple requests in a single message. This feature permits a user with two key pairs (one for signature and another for key management) to submit a single request. This feature also permits batch processing by RAs.

Certificate Management Messages over CMS

Over time, the IETF PKIX Working Group grew and became more diverse. Not everyone was comfortable with the direction of the CMP protocol. A group emerged that felt that it was crucial to leverage the installed base of PKCS #7 and PKCS #10. To these vendors, CMP represented a radical departure from a working, deployed protocol. CMP defined too many messages, and the CMP transactions demanded too many roundtrips. In their eyes, the comparative complexity of CMP overwhelmed the new functionality.

The PKIX Working Group fragmented into two camps. Those with a significant investment in CMP pointed out the weaknesses in PKCS #7 and PKCS #10, as well as the historic intellectual property issues. Those with a significant investment in PKCS #7 and PKCS #10 pointed out that a majority of PKIs used the RSA algorithm exclusively and that most PKIs did not involve RAs in protocols directly. When RSA Security decided to relinquish change control for PKCS #7 and PKCS #10 to the IETF S/MIME Working Group, RSA Security also resolved the intellectual property issues.

Eventually, a truce was achieved, and a second protocol emerged. Both protocols share the same certificate request format. The second protocol would use the new Cryptographic Message Syntax (CMS; in RFC 2630) specification to provide cryptographic protection for messages. The Certificate Management Messages over CMS (CMC; in RFC 2797) references PKCS #10 for a basic certificate request format, and CRMF for the more fully featured certificate request format. Furthermore, CMC offers algorithm independence and include support for direct involvement of RAs.

CMC specifies only two complete transactions: the simple enrollment protocol and the full enrollment protocol. These transactions each require two messages. The CA determines which type of certificate request has been received from the content itself. CMC began as a simple structure, but complexity was added to provide all of the necessary security and functionality. CMC control attributes determine the overall control flow. CMC defines 24 control attributes. These control attributes provide many of the features found in the CMP header, such as nonces and transaction identifiers. They are also used to implement proof-of-possession, pass arbitrary data, and indicate which extensions should appear in a certificate.

Simple Certificate Enrollment Protocol

Cisco Systems developed the Simple Certificate Enrollment Protocol (SCEP), and, as such, it is not an open standard like CMP or CMC. SCEP supports the secure issuance of certificates to network devices in a scalable manner, and it makes use of existing technology whenever possible. The existing technology includes the RSA algorithm, the DES algorithm, the PKCS #7 and PKCS #10 message formats, hypertext transfer protocol (HTTP), and LDAP. The protocol supports four transactions: distribution of CA and RA public keys, certificate requests, certificate queries, and CRL queries. The latter two transactions are actually repository functions, but they are included in the SCEP specification. The protocol also supports out-of-band revocation requests by establishing a revocation challenge password during the certificate request.

SCEP requires that end systems obtain three pieces of information as an initial condition: the CA IP (Internet protocol) address or domain name, the CA HTTP script path, and the URL for CRL queries if CRLs will be obtained from a directory. The end system uses an unprotected HTTP Get operation to obtain CA and RA certificates. At this point, the end system must contact the CA operator through out-of-band means and verify the hash of the certificate to ensure the integrity of this operation.

End entities begin the PKI enrollment process by generating their own public/private key pair, then they issue themselves a self-signed certificate. This certificate will be used for both authentication and key management, so the RSA algorithm is used. This provides each entity with a temporary, syntactically correct X.509 certificate. This step is required, because a digital signature protects all messages in the certificate request transaction, or signed and encrypted using PKCS #7, which assumes that a public key certificate is available. PKCS #7 requires an issuer name and serial number to identify the certificate.

POLICIES AND PROCEDURES

The bulk of this chapter focuses on PKI technical mechanisms, but technical mechanisms are insufficient on their own; they must be used in combination with a set of procedures to implement a particular security policy. Two documents describe the policies and procedures associated with a PKI. The first document is known as a *certificate policy* (CP), and the second is called a *certification practices statement* (CPS). These documents share a common format but have different audiences and different goals. RFC 2527, the *Certificate Policy and Certification Practices Framework,* established the recognized format for both a CP and a CPS.

Most PKI users will not refer to the CP or CPS. Users usually obtain the policy information indirectly by processing the certificate policies, policy mapping, and policy constraints extensions. There is a direct relationship between the contents of these extensions and the CP and CPS, however.

The CP is a high-level document that describes a security policy for issuing certificates and maintaining certificate status information. This security policy describes the operation of the CA, as well as the users' responsibilities

for the requesting, using, and handling of certificates and keys. The CP asserts that this security policy shall be implemented from certificate generation until its expiration or revocation. It does not specify how the policy shall be implemented. For example, a CP might state the following: "All subscribers shall be authenticated in person by an RA before a certificate is issued." The CP excludes all operational details, because these may evolve over time. The CP should not identify the physical location of the CA or the products used in the CA. By excluding these details, the CP is a stable and high-level document. Multiple CAs may operate under a single CP. This is often the case when multiple CAs are maintained by a single enterprise, jointly supporting a single community.

Different people will use the CP for different reasons. For example, the CP will be used to guide the development of the CPS for each CA that operates under its provisions. CAs from other enterprise PKIs will review the CP before cross-certification. Auditors and accreditors will use the CP as the basis for their review of CA operations. Application owners will review a CP to determine whether these certificates are appropriate for their application.

The CPS is a highly detailed document that describes how a particular CA implements a specific CP. The CPS identifies the CP and specifies the mechanisms and procedures that are used to achieve the security policy. The CPS asserts that the specified products will be used in combination with the specified procedures. The CPS might state the following: "Users will receive their certificates and smartcards from the RA after presenting the following credentials in person: (a) current driver's license, (b) work identification card, (c) blood sample, and (d) hair sample." A CPS includes sufficient operational details to demonstrate that the CP can be satisfied by this combination of mechanisms and procedures.

Each CPS applies to a single CA. The CPS may be considered the overall operations manual for the CA. Specific portions of the CPS may be extracted to form the *CA Operator's Guide, RA Manual, PKI Users Guide,* or other role-specific documentation. Auditors and accreditors will use the CPS to supplement the CP during their review of CA operations. Note that a CPS does not need to be published. The combination of a CP and the results of an accreditation process should be sufficient for external parties.

RFC 2527 proposes an outline with eight major sections and 185 second- and third-level topics. RFC 2527 established an outline with the following major sections:

Introduction
General Provisions
Identification and Authentication
Operational Requirements
Physical, Procedural, and Personnel Security Controls
Technical Security Controls
Certificate and CRL Profiles
Specification Administration
Privilege Management

Organizations seek improved access control. Public key certificates can be used to authenticate the identity of a user, and this identity can be used as an input to access control decision functions. In many contexts, however, the identity is not the criterion used for access control decisions. The access control decision may depend on role, security clearance, group membership, or ability to pay.

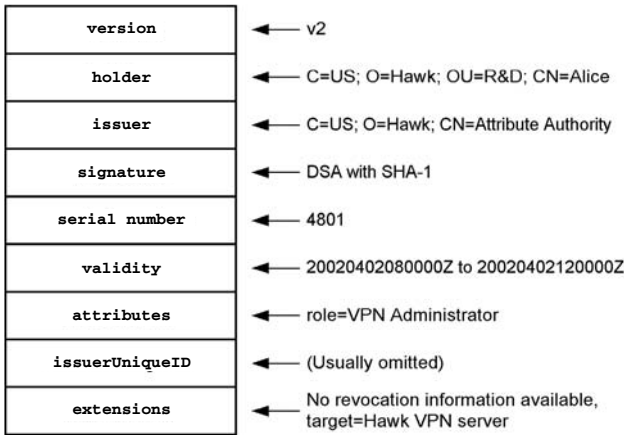

Figure 6: X.509 attribute certificate structure.

Authorization information often has a shorter lifetime than the binding of the subject identity and the public key. Authorization information could be placed in a public key certificate extension; however, this is not usually a good strategy. First, the certificate is likely to be revoked because the authorization information needs to be updated. Revoking and reissuing the public key certificate with updated authorization information can be expensive. Second, the CA that issues public key certificates is not likely to be authoritative for the authorization information. This results in additional steps for the CA to contact the authoritative authorization information source.

The X.509 *attribute certificate* (AC) binds attributes to an *AC holder*. Because the AC does not contain a public key, the AC is used in conjunction with a public key certificate. An access control function may make use of the attributes in an AC, but it is not a replacement for authentication. The public key certificate must first be used to perform authentication, then the AC is used to associate attributes with the authenticated identity.

ACs may also be used in the context of a data origin authentication service and a non-repudiation service. In these contexts, the attributes contained in the AC provide additional information about the signing entity. This information can be used to make sure that the entity is authorized to sign the data. This kind of checking depends either on the context in which the data is exchanged or on the data that has been digitally signed.

Figure 6 illustrates an attribute certificate for Alice. This is a version 2 AC, and the AC holder is Alice. The AC was issued by the Hawk Data *Attribute Authority,* and was signed with DSA and SHA-1. The serial number is 4801, and the AC is valid from 8 a.m. on April 2, 2002, until noon that same day. The attributes indicate that Alice is VPN administrator. The AC extensions indicate that this certificate is targeted toward the Hawk VPN server, and that revocation information is not available for this certificate. ACs often have no revocation information.

ACs may be short- or long-lived. In Figure 6, the AC permits Alice to administer the VPN for 4 hours. As a result of the short validity period, the AC issuer does not need to maintain revocation information. By the time revocation information could be compiled and distributed, the AC would expire. So, with short-lived ACs, revocation information is not distributed. If an AC has a longer life span (for example, weeks or months), then the organizations would need to maintain AC status information.

An AC can be obtained in two ways. The AC holder may provide the AC; this is known as the *push model*. Alternatively, the AC is requested from the AC issuer or a repository; this is known as the *pull model*. A major benefit of the pull model is that it can be implemented without changes to the client or to the communications protocol. The pull model is especially well suited to interdomain communication.

The AC is linked to a public key certificate in one of two ways. The AC holder can contain the issuer and serial number of a particular public key certificate, or the AC holder can contain a subject name. In the first case, the AC is linked to a specific public key certificate. In the second case, the AC is linked to a particular subject, and the AC may be used in conjunction with any public key certificate held by that subject.

FUTURE DEVELOPMENTS

One of the criticisms of PKI is that CRLs can become too large. When this happens, the overhead associated with CRL distribution is unacceptable. *Sliding window delta CRLs* can be used to reduce this overhead. Another criticism of PKI is that certification path construction and validation can be difficult. By delegating these functions to a trusted server, the amount of processing an application needs to perform before it can accept a certificate can be significantly reduced. Sliding window delta CRLs and *delegated path validation* are not widely deployed today, but they are likely to be employed in the future.

Sliding Window Delta CRLs

For PKIs that rely on CRLs, the challenge is to provide the freshest information to certificate users while minimizing network bandwidth consumption. Unfortunately, when PKIs rely on full CRLs, these requirements are in direct conflict. To maximize the freshness, CRLs must be updated frequently. As the time interval between updates shrinks, the probability that a client will find a useful CRL in its cache diminishes. At the extreme, certificate users will download a full CRL for each certificate validation. Most of the information on the CRL is the same, and identical information is transmitted repeatedly, consuming bandwidth without providing any benefit. To minimize the consumption of network bandwidth, CRLs should have reasonably long lifetimes. As the time interval between updates grows, the greater the probability that relying parties will have the appropriate CRL in their cache.

In the simple case, *delta CRLs* and full CRLs are issued together, and the delta CRL lists all the certificates revoked since the last full CRL was issued. A certificate user, who has the previous full CRL, may obtain complete information by obtaining the delta CRL and combining it with the already cached, previous full CRL. The certificate user obtains the freshest information available but consumes a fraction of the bandwidth. If the certificate user does not have the previous full CRL, the full CRL must be downloaded.

A sliding window delta CRL lists all the certificates revoked since an earlier full CRL, perhaps six generations earlier. This delta CRL may be combined with any of the full CRLs from the previous six generations. By repeating some of the revocation information in the delta CRL, there is a greater likelihood that the certificate user will have an acceptable full CRL in the cache, yet the amount of repeated information is small enough to avoid consuming significant bandwidth.

Most of the PKI-enabled applications do not exceed the limitations of full CRLs. As a result, delta CRLs are not widely deployed. Few commercial PKI client implementations process delta CRLs. Fewer CA products can generate sliding window deltas. As PKIs grow, however, the incentive to deploy innovative certificate status will likely grow.

Delegated Path Validation

Some PKI implementers want to offload the entire certification path construction and validation process to a trusted server. A relying party would provide a validation server with an end-entity certificate, one or more trust points, and the initial values for certification path validation, then the path validation server would respond with a message informing the relying party whether the certificate was acceptable. Standard protocols for these services have not yet been developed. This work is currently underway in the IETF PKIX Working Group.

Delegating the certificate validation process to a trusted server has a number of advantages. The certificate user achieves path construction and validation with a single roundtrip protocol, and then the certificate user verifies a single digital signature on the response. The single roundtrip is especially important in bandwidth-limited environments, especially wireless environments. If the certificate user has limited processing power, the reduction in signature verifications is also significant.

Delegating the certificate validation process to a trusted server may also provide performance advantages. If the path validation server has cached the necessary certificates and CRLs, the path validation server may be able to construct and validate a certification path quickly.

These benefits are not free. The path validation server performs all of the security-relevant operations. The path validation server must be secure, because it is the sole trust point for the relying party. In addition, some of the performance enhancements are based on the ability of the server to obtain and cache information. PKIs that rely on OCSP may be counterproductive to this model. In such a case, the path validation server is not likely to hold the required status information. The server will have to retrieve revocation information from the OCSP responder for each certificate in the certification path, mitigating much of the performance gain.

Performance is not the only reason to centralize certification path validation. Some organizations want impose a centralized management discipline with consistent policy enforcement. If applications use the same trusted path validation server, consistent results across the organization are ensured.

GLOSSARY

Attribute authority An entity that is responsible for the issuance of attribute certificates, assigning privileges to the certificate holder.

Attribute certificate A data structure that is digitally signed by an AA that binds attribute values with identification about its holder.

Certificate policy A named set of rules that indicates the applicability of a certificate to a particular community or class of application with common security requirements.

Certificate revocation list (CRL) A digitally signed list of certificate serial numbers associated with a set of certificates that are no longer considered valid by the certificate issuer.

Certification authority An entity that is responsible for the issuance of public key certificates, trusted by one or more certificate users.

Certification practices statement A description of the practices followed by a certification authority in issuing and managing public key certificates.

Public key certificate A data structure that contains a user identity, the user's public key, and other information, digitally signed by the CA.

Online certificate status protocol (OCSP) response A digitally signed response from a trusted server that implements the OCSP that provides status information for a queried certificate.

Public Networks

INTRODUCTION

Networks for the transfer of data between computers, both public and private, are ubiquitous in today's business world. A public network is one that is publicly available to subscribers (Stallings, 2001). It provides service to multiple subscribers and is built and maintained by a public network provider. Internationally, the term "public network" is often applied to networks that are under government control or are a national monopoly. However, a network can also be a privately owned network whose services are sold to the public. Whether the network is under government control or is a privately owned network whose services are sold to the public, businesses access the network by installing an access device at each site and using an access line to the nearest point of presence (POP) of the public network provider (Panko, 2001).

This chapter gives an overview of public network concepts and services and describes the structure of the public switched telephone network (PSTN) system, the technologies used both for access to a public network and within the public network itself, issues related to choosing a public or a private network, and public networks in the Internet and e-commerce environments.

OVERVIEW OF PUBLIC NETWORK CONCEPTS AND SERVICES

Traditionally, companies desiring to connect business computers in different geographic locations have used private networks. That is, they have used point-to-point leased lines between business sites to create their own circuit-switching or packet-switching networks for their data communication requirements (Panko, 2001). Unlike telephone calls, which set up the required capacity as needed, leased lines provide dedicated transmission capacity between sites. These networks are called private networks (Stallings, 2001). By using leased lines, companies have a network capacity that is always available and are offered volume discounts for the bandwidth available on the leased line. An example of a private network is shown in Figure 1.

There are several disadvantages to private networks. Private networks require higher initial costs. The leased line connections must be planned and installed. The switching devices must be provided. And, once a network is operational there are ongoing management and maintenance costs of the networks (Panko, 2001). A public network is an alternative to a private network.

There are advantages to using a public network. A public network does not require a complex network of leased lines and switching devices that the business must plan and install. There is commonly one access line installed per site. Even if a leased line is used to connect to the nearest POP, there are usually less leased lines required. For example, if there are 10 sites using the public network, then there are 10 leased lines. Compare this to a fully meshed private network that requires 45 leased lines. For N locations, $N(N-1)/2$ leased lines are required for a connection to and from each site. Even if not every site is connected to every other site in the private network, but sites are connected through intermediate sites, the number of leased lines for a public versus a private network is generally smaller. Finally, because of competitive pricing, public networks are less expensive than private networks (Stallings, 2001). Figure 2 illustrates an example of a public network.

The global Internet is a network that is publicly accessible worldwide. The Internet is not one single network, but is composed of several networks connected together and communicating with standard Internet technologies (Moody, 2001). Access to the Internet is achieved via an Internet service provider (ISP). The Internet allows a business to have a worldwide presence. Through the use of

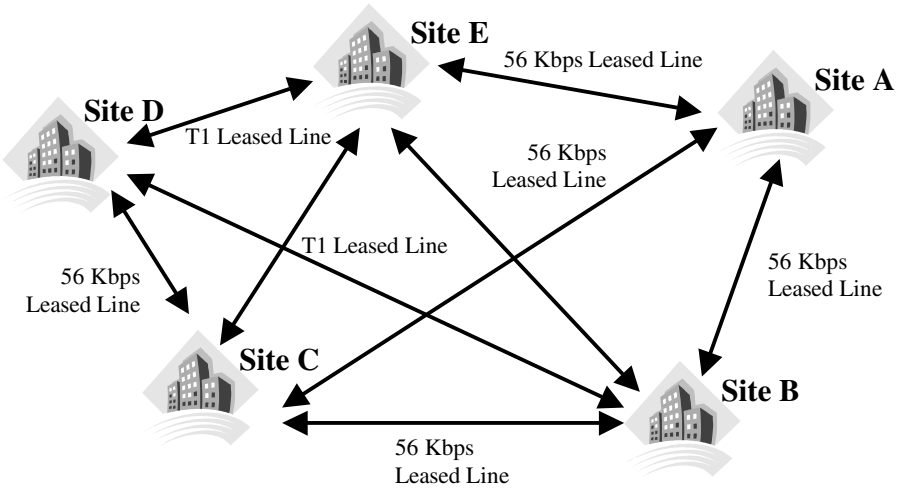

Figure 1: A private switched data network.

E-commerce purchases can be made automatically with software.

A network that transfers data and information only within a single business is called an intranet (Moody, 2001). Intranets use the same technologies as the Internet but access is restricted to employees. They carry corporate information that can range from being routine such as e-mail, manuals, and directories or can be sensitive information such as that of project management and internal purchasing. An intranet can be built using a private or a public network. A private network is naturally an intranet. A business using a public network can ask that the data be restricted to only go to other locations of the same business. Of course, the bandwidth is still being shared with other businesses that use the same public network.

An extranet is a hybrid between the public Internet and the private intranet (Moody, 2001). A portion of the intranet is extended to business partners in a controlled and restricted way. The extranet can be used for project management of projects between partners. Another common and practical use of the extranet is to allow partners access to the stock levels and shipping status. Direct online purchasing of supplies and other applications are made possible through the use of an extranet.

The global Internet can be used to provide an intranet or an extranet by creating a virtual private network (VPN). A VPN is a private network that is deployed over public facilities, but provides the same levels of privacy, security, quality of service, and manageability as private networks (Cisco, 2001).

A VPN can be created when all sites are already connected to the Internet. With a VPN, hosts at different sites communicate across the Internet using either a tunnel mode between local networks, or by using a direct transport communication. However, there are two serious problems that can occur with VPNs since the company no longer has control of the entire data network (Panko, 2001). One problem is the security of the data, because the Internet was not designed to support secure transmission. This problem can be solved through the use of encryption and by using tunnel mode for communication. A second problem is congestion on the Internet. Congestion can

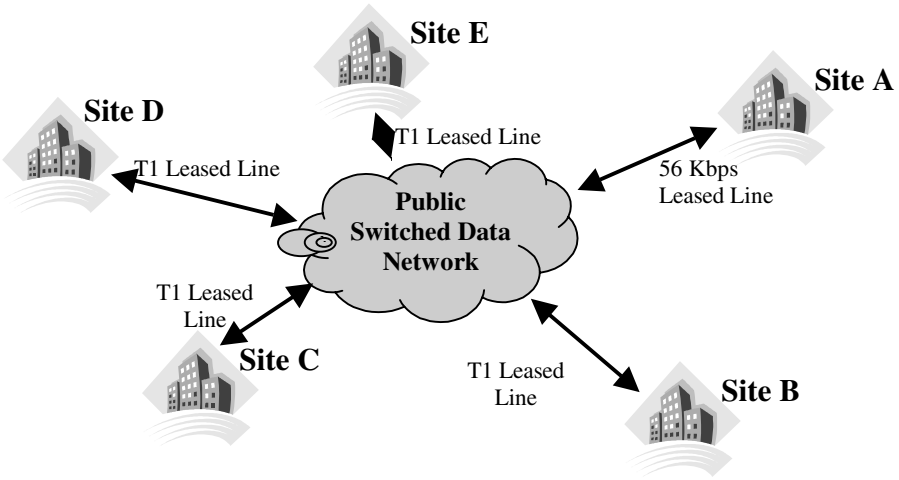

Figure 2: A public switched data network.

cause data to be delayed or even lost. A VPN uses a public network for site-to-site communication and added technology to solve the problems of security and congestion (Panko, 2001).

A public network provider has a value-added network if it owns the packet-switching nodes and leases transmission capacity from an interexchange carrier such as AT&T (Stallings, 2001). It is called a value-added network because the leased lines add value to the packet switching nodes. A network provider that provides a value-added network is sometimes called a value-added carrier. In many cases a public network provider will partner with companies that provide services that require network connectivity such as Web hosting and give discounts to them for using their network. A business which bundles a service with a particular public network provider is called a value-added reseller.

Public network providers often offer services such as Web hosting to subscribers in addition to connectivity between sites. These additional services are called value-added services. These services include asset management, configuration control, fault management, monitoring, Web-based reporting, Web hosting, e-mail services, and content delivery networks.

Asset management is keeping inventory of devices that are connected to the network. As devices are added or taken off the network the asset management system will keep an up-to-date log of the assets. Configuration control is about maintaining and keeping records of the configuration of networked devices. The network provider typically maintains the configuration of the packet switching node that connects each of the subscriber locations to the network. A provider will also monitor devices to detect faults and either fix them or notify the appropriate on-site personnel. This is called fault management. A provider can invest in large network operation centers for monitoring their subscribers' network devices. This includes maintaining a firewall to prevent unwanted users into the network and intrusion detection systems for detecting activity that is consistent with common hacker techniques. With Web-based reporting the provider gives the subscriber reports about the status of their network and a history of its downtime and performance.

One of the most popular value-added services is Web hosting. The provider maintains one or more servers and allocates space on them for the subscriber's Web site. The provider maintains the server and performs backups. Subscribers are given access to their portions of the server to post their Web sites and control their content. An advantage to using this value-added service is that it is likely that the subscriber has other sites that are connected to the same public network. If the server is connected to the same public network, it provides faster response times to the end users.

Medium to large users who have high volumes of content serving a distributed set of users may consider a value-added service called a content delivery network (CDN). A CDN intelligently distributes the content to multiple locations and closer to the end user. By moving the customized content closer to the end user the end user receives faster response times (Allen, 2001). Queries to the main server or group of servers are routed to the location that can best respond to the query. Content is cached at each of the locations and future requests are serviced more quickly because the information traverses fewer links in the network. There are three main advantages to a CDN. First, end users receive faster response times. Second, it relieves congestion on the original server that maintains the master copy of the content. Finally, it reduces the amount of data transmission capacity required on the network since the content is distributed to multiple locations and does not have to come from the original server. Some of the popular CDN providers are Akamai (http://www.akamai.com) and Mirror Image (http://www.mirror-image.com).

STRUCTURE OF THE PUBLIC SWITCHED TELEPHONE NETWORK SYSTEM

The public switched telephone network system is often used to provide the technology that a business uses to access a public network or is the technology of the public or private lines. The structure of the PSTN in the U.S. has evolved from one that was almost entirely controlled by a single company to one that allows competition in a free market. Before January 1, 1984, AT&T (also known as the Bell System) controlled 80% of the PSTN in the U.S. (Bellamy, 2000). A Justice Department antitrust suit filed in 1974 and a private antitrust case by MCI resulted in a breakup of AT&T (Noam, 2001). The suit argued that AT&T used its control of the local operation as an unfair advantage against competing long distance carriers.

On January 1, 1984, AT&T was divided into smaller companies. The breakup involved the divestiture of seven Bell operating companies (BOCs) from AT&T. The seven regional BOCs were known as "Baby Bells" or regional BOCs (RBOCs) and initially carried only regional telephone and mobile service. The network was partitioned into two levels (Bellamy, 2000), and the remaining part of AT&T retained the transport of long distance telephone service.

The U.S. was divided into local access and transport areas (LATAs), which are controlled by local exchange carriers (LECs). LECs can transport telephone calls within a LATA, also called intra-LATA traffic, but are not permitted to transport traffic between different LATAs, also called inter-LATA traffic, even though the same BOC may control both LATAs. The inter-LATA traffic is transported by interexchange carriers (IXCs), commonly known as long distance carriers. Each IXC interfaces at a single point in the LATA called a point of presence. At divestiture, AT&T became an IXC and it opened the door to competition for other companies' long distance service. The major IXCs in the U.S. include AT&T, MCI–WorldCom, and Sprint.

The divestiture decree was supervised by District Judge Harold Greene and known as the modified final judgment (Noam, 2001). LECs had to grant equal access to all IXCs. The service offered by the LECs to the IXCs had to be equal in type, quality, and price (Bellamy, 2000). Also, users could specify their "primary" IXC to transport their long distance and international calls (Noam, 2001). Or,

users could use other IXCs on a call-by-call basis by dialing a prefix.

Another major change in the U.S. PSTN occurred with the 1996 Telecommunications Act that amended the Communications Act of 1934 (Noam, 2001). RBOCs had to comply with a list of tasks before they were permitted to provide long-distance service within their regions. The list permitted competition in the RBOCs regions. It was argued that it was necessary to induce competition in these local markets. RBOCs were required to provide interconnection to new market competitors, unbundle their network, permit competitors to resell their service, and provide users with number portability.

The new local service providers became known as competitive local exchange companies (CLECs) (pronounced "see-lecks") (Noam, 2001). The incumbent LECs became known as ILECs. For a CLEC to be competitive with the ILEC requires that it be able to interconnect with the users cost effectively. Therefore, there came a great struggle between CLECs and ILECs on the issue of collocation since the ILEC had a significant advantage with the existing network. In "physical collocation" a CLEC places its cables and equipment inside the ILEC's central office (CO) to hand off traffic. In another arrangement called "virtual collocation" the physical handoff of the traffic occurs inside or outside the CO, but uses ILEC-owned equipment and must be the economic equivalent of "physical collocation."

It may appear from the previous discussion that the breaking up of the U.S. PSTN is relevant only to the United States but the trend is happening in other parts of the world as well (Noam, 2001). Japan opened its markets to competition. Also, the Europeans have privatized their service. Noam argues that at first a network is not feasible unless supported by outside sources such as governments. As the network grows the average costs decline initially and then rise as a few high-cost users are added. Without regulation the network would not grow beyond a certain point because of the high cost of adding these high-cost users. From a political and societal point of view the network becomes a necessity instead of a convenience and should be offered to everyone. Therefore, the monopolistic breakdown of the network is caused by its own success.

ACCESS AND PUBLIC NETWORK TECHNOLOGIES

To use a public network for data services, a user must access the public network through some network service from the user's computing equipment to the nearest public network node. Factors in selecting a particular service include the cost of the service that is provided and the features, including the transmission speed, that are provided by the technology. Generally, the higher the transmission speed that a technology can support, the more costly the service becomes. Transmission speeds for networks are described in bits per second. Unlike when memory size is described, 1 Kbps is exactly equal to 10^3 bits per second, 1 Mbps is exactly equal to 10^6 bits per second, and 1 Gbps is exactly equal to 10^9 bits per second.

Many technologies are available for access to a public network and for use within the public network. The most inexpensive network access is through a voice-grade modem. A modem is used to convert a digital computer signal to an analog signal that can be sent across ordinary telephone lines. Voice-grade modems can receive data at up to 56 Kbps. In contrast, digital lines that are used to access the network range in transmission speed from 56 Kbps to 10 Gbps. Within the public network a few technologies, including X.25, frame relay, asynchronous transfer mode (ATM), and synchronous optical network (SONET), have become the most commonly used technologies. Table 1 lists the most common technologies along with a comment about usage. Table 1 also compares the transmission speed and the time to download a 10-megabit (1.2 Megabyte) file.

Voice-Grade Modems

A modem is the most inexpensive and easiest to use access technology. The use of modems for data transmission will be substantial for many years to come (Stallings, 2001). Voice-grade modems use a 4-KHz bandwidth on an ordinary telephone line, the same bandwidth that is used for voice signals. Modems can be packaged inside an information product, such as a personal computer. Companies often have modem banks that allow employees to dial-in directly to the company intranet or to access a large computer system.

On March 1, 1993, the International Telecommunications Union (ITU) Telecommunications Standardization Sector (ITU-T) was created as a permanent organ of the ITU, an agency of the United Nations. The charter of the ITU-T is to standardize techniques and operations in telecommunications. Several standard specifications for voice-grade modems have been designated by the ITU-T. Two of the most significant modem specifications are V.32, which is a dial-up modem that transmits at 9600 bps, and V.90, also a dial-up modem. V.90 sends at 33.6 Kbps and receives at 56 Kbps, the highest rates available for voice-grade modems (Stallings, 2001).

Digital Subscriber Lines

A faster service than voice-grade modems that is beginning to be offered by telephone companies is the digital subscriber line (DSL). A widely publicized version of this is asymmetric digital subscriber line (ADSL). ADSL offers high-speed downstream access to the customer site, and a lower speed upstream access from the customer. The ITU-T has developed a standard for low-speed ADSL called G.992.2, or G.Lite. G.Lite specifies downstream speeds of 1.5 Mbps, but sometimes lower downstream speeds are used. Most users find asymmetric speeds to be acceptable, since upstream traffic frequently consists of keystrokes or the transmission of short e-mail messages, whereas downstream traffic may include Web pages, or large amounts of data. In addition to data speed, an advantage of DSL over voice-grade modems is that DSL modems allow voice traffic to be multiplexed onto the telephone wires coming into the customer site. A customer can talk on the telephone at the same time that data are being transferred.

Table 1 Common Network Technologies

Service	Usage Comments	Transmission Speed	Download
Voice-Grade Modem	Modems are inexpensive, telephone rates reasonable for modest connect times	Upload: Up to 33.6 Kbps Download: Up to 56 Kbps	3 min or more
Digital Subscriber Line	More expensive than voice-grade modems, downlink rates higher than uplink	Upload: From 16 Kbps to 640 Kbps Download: From 768 Kbps to 9 Mbps	1.1–13 s
Cable Modems	Download rates depend on the number of simultaneous customers and configuration	Upload: From 64 Kbps to 256 Kbps Download: From 10 Mbps to 30 Mbps	0.3–1 s
Satellite	A cost-effective choice in remote locations	Upload: From 56 Kbps to 256 Kbps Download: From 150 Kbps to 1 Mbps	10–67 s
Integrated Services Digital Network	Charges generally based on duration of call	Basic rate: 128 Kbps, higher rates available	1.3 min
Digital leased lines: 56 Kbps (DS0), T1 (DS1), T3 (DS3), . . .	Most common leased line for high-traffic voice and data; fixed price for a specific capacity	DS0: 56 Kbps T1, DS1: 1.54 Mbps T3, DS3: 44.7 Mbps	56 Kbps: 3 min T1: 6.5 s T3: 0.22 s
SONET	Specification for optical links, highest speed	From 155.52 Mbps to 2.488 Gbps leased	0.004–0.06 s
X.25	Older technology, still in use in public networks	56 Kbps, but can be slower or faster	3 min or more
Frame Relay	Fixed price per month for a specific capacity, widely installed and used	From 16 Kbps to 44.736 Mbps	0.22–625 s
ATM	Universal technology for wide area networking	From 1.544 Mbps to 2.5 Gbps for access	0.004–6.5 s

The telephone company does not have to install any special equipment to use voice-grade modems. However, when the telephone company offers DSL service it has to install digital subscriber line access multiplexers at the end offices. Figure 3 illustrates the equipment used for DSL (Panko, 2001). Because special equipment has to be installed, DSL service is not available in all areas. One factor that determines the availability of ADSL is the distance to the central office. In general, if the distance is greater than 18,000 feet ADSL service is not available. Also, the prices are fluctuating as DSL becomes available in more and more areas.

Cable Modems

Cable modems are a service offered by cable television companies. Often, the cable television or telephone

company operates as both a transmission carrier and a network provider. As with ADSL, the downstream speed of cable modem is much faster than the upstream speed. The upstream speeds are similar to ADSL, but the downstream speeds can be several times faster. However, multiple customers on the same cable line share the capacity. When many customers are accessing the network at the same time the real downstream transmission speed can be much lower. If network traffic is bursty, though, the chances are unlikely that all customers are downloading at exactly the same moment so that sharing does not become as issue until about 100 customers share the same cable service (Panko, 2001).

Satellite

An often cost-effective alternative for network access is the use of satellite technology. This may be particularly true in areas where other wire-based technologies are not yet available. For example, many rural areas do not have the density of potential users that can justify the cost of installation of wire-based technologies such as DSL or cable modems.

Satellites are characterized by the type of orbit they use. The most common type of satellite is the geostationary satellite. These satellites orbit the Earth at about 22,300 miles directly above the equator at exactly the same speed as the Earth's rotation. Because of this, the satellite always appears to be in the same position in the sky and tracking of the satellite by stations on Earth is simplified (Stallings, 2001). The disadvantage of this type of satellite is that the propagation time it takes for the signal to be sent from a transmission station on the Earth to the satellite, and then to be received back on the Earth is about 0.24 s. For large data downloads this is not noticeable since the time overlaps with the time to receive the entire message. However, for interactive computer use or for applications such as telephone calls the time is noticeable and can be annoying. In addition, geostationary satellite signals are not received well in very far northern or southern regions of the Earth.

Two other types of orbits include low- and medium-Earth orbiting satellites. This technology is being proposed for use with mobile terminals and remote locations that need stronger signals and less propagation time. Successful businesses that use this technology are rare. One company currently operating under bankruptcy regulations, Iridium, provides global, mobile satellite voice and data solutions with complete coverage of the Earth through a constellation of 66 low-Earth orbiting satellites (Iridium, 2002).

Large satellite dishes create narrow footprints for transmission, and large dishes are used for point-to-point trunk transmissions. A small dish creates a very large footprint that is suitable for television broadcasts in a large region. Today, very small aperture terminal systems are available and provide a low-cost alternative to expensive point-to-point satellite connections. These stations share satellite transmission capacity for transmission to a hub station (Stallings, 2001).

Satellite access has some advantages over wire-based technologies. The technology is available now for all locations in the United States, whereas DSL and cable modem technologies may not be available in some locations for some time. For the speeds and services available the technology is cost-competitive. However, in order to use satellite, the user must have a clear view of the southern sky. The uploads speeds are modest, so satellite is not suitable for businesses that require high-upload bandwidth for applications such as large upload data transfers or for hosting Web sites. Also, the download bandwidth is shared with all users at the site, and so the technology is not currently suitable for more than five simultaneous users.

At least one company offers packages with two-way, always-on, high-speed Internet access via satellite that is specifically designed to meet the needs of small businesses (StarBand, 2002). StarBand uses a 24-by-36-inch dish and a special modem at the customer's site to connect the user's site to the network. StarBand also serves as a network provider. Fees include an initial equipment fee and a monthly fee for access. Value-added services such as domain registration and networking support for setting up small office networks can be a part of the package.

Integrated Services Digital Network

Many telephone companies offer integrated services digital network (ISDN), a digital service that runs over ordinary telephone lines. As with voice-grade modems the ITU-T has set standards for ISDN. ISDN can be used as an access technology and within a public network. Basic ISDN service includes two "B" channels, each at 64 Kbps, and a "D" channel that is used for signaling. It is possible to use one "B" channel for voice and one for data, but most service providers bond the two "B" channels together to provide a 128 Kbps data rate. Standards for higher rates also exist. Like ADSL, ISDN requires that the telephone company install special equipment at the end office before an ISDN service can be offered. A special ISDN "modem" is used at the customer site.

ISDN is the result of efforts in the early 1980s by the world's telephone companies to design and build a fully digital, circuit-switched telephone system (Tanenbaum, 1996). Because ISDN is circuit-switched, there is never any congestion on the line from the customer to the network service provider. However, since data traffic is generally bursty the user pays for bandwidth that may not be used. ISDN is expensive compared to the modest gain in transmission speed. The customer generally has to pay for the ISDN line to the telephone company and then has to pay an additional fee to a network service provider. The use of ISDN is likely to decline as other higher speed and more economical technologies become available.

Digital Leased Lines

In terms of number of circuits, the most common leased lines are 56 Kbps (Panko, 2001). The transmission capacity of a 56 Kbps is actually 64 Kbps but one bit out of eight is used for signaling, leaving the user with 56 Kbps. A 56 Kbps line is the same as digital signal zero (DS0). The next higher transmission speed is a T1 (DS1), which provides 1.544 Mbps. While a 56 Kbps leased line is relatively inexpensive, the difference in cost and performance between a 56 Kbps and a T1 line is large. Therefore, fractional T1's are also available at 128 Kbps, 256 Kbps, 384 Kbps, and so on. In Europe and other parts of the world

a different digital hierarchy of transmission capacities is used. The standards are defined in the Council of European Postal and Telecommunications authorities (CEPT). The E1 standard operates at 2.048 Mbps and is analogous to the T1 standard. The next step is a T3 (DS3) at 44.7 Mbps and the corresponding CEPT E3 standard operating at 34.4 Mbps. Higher transmission capacities are available using synchronous optical network (SONET) and the synchronous digital hierarchy (SDH) and range from 155.52 Mbps to 10 Gbps.

Digital leased lines can be used to build a company's leased line private network, as shown in Figure 1, or can be used in combination with a public network, as shown in Figure 2. When leased lines are used to access a public network the traffic between several sites must be multiplexed over the single access line. Therefore, it is important to be sure that the leased line is fast enough to support this traffic. For example, if a site has 15 56 Kbps leased lines connected point-to-point with other sites and wants to convert this to a single access line to a public network, then the access line would require at least 840 Kbps of capacity. From Table 1, this would require a T1 line (Panko, 2001).

Synchronous Optical Network

Synchronous optical network defines a hierarchy of standardized digital data rates. A compatible version, Synchronous digital hierarchy has been published by the ITU-T. SONET is intended to provide a specification for high-speed digital transmission over optical fiber.

SONET, or SDH, is the highest speed and most costly digital leased lines. SONET/SDH operates in multiples of 51.84 Mbps. Standards are specified as OCx for SONET, and STMx for the SDH specification. A common SONET/SDH speed is OC3/STM1, at 156 Mbps. Other common rates include 622 Mbps, 2.5 Gbps, and 10 Gbps. SONET technology can be used for access both to the public network and within the public network.

X.25

X.25 was developed during the 1970s for use in public packet switching networks, and this standard was later ratified by the ITU-T (Tanenbaum, 1996). X.25 was very slow, often running at only 9600 bps, but it was fast enough for the text-based transmissions of early networks. Its use is declining, but it is still popular in the U.S. for low-speed applications such as a department store's point-of-sale transaction network. Also, there are many X.25 legacy connections, particularly in Europe and in countries where the telecommunications infrastructure is lagging. X.25 is one of a few standards that have been set by the ITU-T for public switched data networks. Other standards set by the ITU-T for public networks include ISDN, frame relay, and ATM.

Frame Relay

Frame relay is the most popular technology choice within public switched data networks today (Panko, 2001). Its speed range matches the needs of the greatest corporate demand, and it has very competitive pricing. Frame relay can also be used instead of leased lines as an access technology or to connect company private networks. Its low overhead even makes it suitable for interconnecting LANs and high-speed stand-alone systems (Stallings, 2001). Current commercial offerings of frame relay include MCI–WorldCom, which offers frame relay service access speeds from 28.8 Kbps to 45 Mbps (MCI–WorldCom, 2002), and Qwest, which offers frame relay service access speeds from 64 Kbps to 45 Mbps (Qwest, 2002).

Typically, a company accesses a public frame relay network through a leased line. Several frame relay virtual circuits are multiplexed over a single access line to the public network. A virtual circuit is a connection from source to destination and represents an end-to-end path that all packets from the same source to the same destination go through. Virtual circuits simplify forwarding decisions and make the costs of the switches cheaper. A permanent virtual circuit (PVC) is one that is set up manually when a company first subscribes to a public network, and only changes when the site changes. For a large company network, a PVC is established for every pair of sites that would get a leased line in a private leased line network.

The frame relay protocol includes functions for detection of transmission errors and congestion control functions. The frame relay protocol allows users to negotiate a committed information rate (CIR) when a connection is set up. The CIR is the network's commitment to deliver data in the absence of errors, and represents the user's estimate of its "normal" traffic during a busy period. Any traffic sent above the CIR is not guaranteed to arrive, but may arrive if the network has the capacity to deliver it. In addition, a maximum allowable rate is defined, and all traffic above this level is discarded (Frame Relay Forum, 2002).

Pricing for frame relay is usually divided into several different components. First, the company needs a frame relay access device. This is a router that has been modified to allow it to communicate with the frame relay's first switch. Second, the company must lease an access line to the nearest POP of the public network. If the POP is a long distance away then the customer must use expensive, long-distance access lines. The leased line must be fast enough to handle the available bit rate on the line.

At the POP, the leased access line connects to a port on the frame relay switch of the public network. The fee for the port is usually the largest single element in frame relay pricing. To prevent wasting port capacity, the speed of the leased line should be at least as fast as the port speed. There is usually a monthly fee for each PVC and this fee depends on the speed of the PVC. Finally, some vendors build in other fees, such as per-bit traffic charges or fees to set up and tear down switched virtual circuits that are established on a call-by-call basis. Frequently there are substantial initial charges to install the access device, leased line, port connection, or PVC. Figure 4 illustrates the pricing elements in frame relay (Panko, 2001).

Asynchronous Transfer Mode

Asynchronous transfer mode is now viewed to be the universal technology for networking and will likely replace many other current offerings (Stallings, 2001). Just as frame relay allows messages to be divided into many

frames that can be sent across a switched network, ATM uses cell relay. Like frame relay, ATM multiplexes many logical connections over the same physical interface, sending information in fixed size 53-byte cells. ATM can support data, video, voice, and Internet traffic on a single access line.

The use of cells in ATM allows many important features to be defined for a virtual channel. For example, users can negotiate the ratio of cells lost to cells transmitted, cell delay variation and parameters such as the average rate, peak rate, burstiness, and peak duration for a virtual channel (ATM Forum, 2002). The ATM service can use permanent virtual channels for static connections. ATM also allows switched virtual channels to be set up dynamically on a call-by-call basis.

Four classes of ATM service have been defined (Stallings, 2001):

Constant bit rate: The network provider ensures that this rate is available, and the customer is monitored to be sure the rate is not exceeded.

Variable bit rate (VBR): A sustained rate for normal use is defined, and a faster burst rate for occasional use is also defined. The faster rate is guaranteed, but not continuously. The ATM Forum divides VBR into real-time VBR (rt-VBR) and nonreal-time VBR (nrt-VBR) (ATM Forum, 2002). With rt-VBR the application has tight constraints on delay and delay variation, but the rate is allowed to vary according to parameters specified by the user. The nrt-VBR is for applications that are bursty, but do not have tight constraints on delay and delay variation.

Available bit rate (ABR): The user has a guaranteed minimum capacity. When additional capacity is available on the network, the user may burst above this without risk of cell loss.

Unspecified bit rate (UBR): Cells are delivered with best effort, meaning that any cell may be lost. The main difference between UBR and ABR is that ABR provides feedback to the user so that the user can control the amount of data being sent and reduce the risk of loss.

ATM is a high-performance service and is expensive. In the range of speeds where ATM speeds overlap with frame relay, frame relay is more attractive because it is cheaper. However, as customer needs increase, ATM becomes a more attractive option. ATM is widely used within high-speed public networks and by companies that need higher speed private networks. Most ATM public switched data network providers currently offer speeds from 1 Mbps to 156 Mbps, with higher speeds coming. These public networks require access lines ranging from T1 to a SONET OC-3 line. MCI–WorldCom offers ATM access speeds from 1.544 Mbps to 622 Mbps (MCI–WorldCom, 2002). Qwest offers ATM access speeds from 1.544 Mbps to 155 Mbps (Qwest, 2002).

CHOOSING A PRIVATE NETWORK OR A PUBLIC NETWORK PROVIDER

There are several categories to consider when one decides whether to use a private network or a public network. If a public network is chosen, then these same categories can help in choosing a network provider. A survey ISPs conducted in 2001 found that the top three areas that differentiated the best ISPs from the rest were reliability, performance, and low cost (Greenfield, 2001). Subscribers to ISPs in the survey also considered support to be important. In addition, network control is a factor in deciding whether to choose a private network or a public network. Other factors mentioned in the survey include breadth of service, security, installation, repairs, and remote access.

Reliability

Reliability is defined as the amount of time the network service is available. Reliability can be difficult to evaluate because several different things can cause downtime. For example, if a user is trying to transfer data from a server that is down then from the user's point of view the network is down. When a packet switching node or dedicated leased line in a large complex network does fail it affects a large amount of transmission capacity and therefore a large number of users. For example, MCI–WorldCom's frame relay outage in August 1999 lasted eight days and affected 30% of MCI's frame relay customers, perhaps as many as 70,000 users (Orenstein and Ohlson, 1999).

An advantage to using a private network is that the redundancy of the network can be designed according to the business requirements. The major disadvantage is that it requires investment in redundant packet switching nodes and leased lines for fault tolerance, personnel training, disaster recover planning, and testing. These expenses are often overlooked or have less priority when a private network is designed (Snow, 2001). Or once the private network is operational these expenses are considered low priority. Therefore, when there is an outage the business is not prepared for it and its effects are worse than if a disaster recovery plan had been written.

The reliability of a public network has advantages and disadvantages. The advantage of using a public network is that since the cost is spread out over several subscribers added investment in reliability can be cost effective. The disadvantage is that a subscriber is completely dependent on the provider for reliable service. Service level agreements have to be negotiated with clear and strict penalties if the provider does not meet the negotiated reliability. If reliability is of high importance to a business, then they may subscribe to two or more public network providers for added reliability.

Cost and Performance Tradeoffs

The choice between a public and private network includes determining the tradeoffs between the cost and performance of the network. The performance of the network is defined by throughput and delay. The throughput is the actual data speed seen by the user in bits per second. The delay is the maximum end-to-end delay that a packet will incur in the network.

The costs of the network may vary depending on the type and volume of traffic that the network will carry. The type of traffic on a network is classified as being either stream or bursty (Stallings, 2001). Stream traffic is long and relatively constant and therefore more predictable than bursty traffic. An example of stream traffic would be voice traffic or uncompressed video. Bursty traffic is short and sporadic such as computer-to-computer communication in the Internet. Although sporadic, bursty traffic often requires a large transmission capacity for brief periods of time. Many Internet applications such as the Web and e-mail create such bursty traffic. If there are several bursty traffic sources that share a communications link and the volume of the combined traffic is high then the aggregate traffic on the link may be considered stream traffic.

Bursty traffic requires a different type of network than stream traffic. For example, if one file is required to be transferred from an office to a central site once a day then a dial-up connection may be the most feasible. On the other hand, if there is bursty traffic to be transferred among a small number of sites and the aggregate of the bursty sources has a high volume then a private packet switching network would be more efficient. Leased lines are not dependent on volume but have a constant fixed rate for a given transmission capacity and distance. If the percentage of use of the leased line is high enough then the volume discount given by the constant fixed rate can be cost effective. For example, large nationwide contracts can negotiate T1 access lines for $200 a month while users in metropolitan areas can get T1 access for approximately $900 per month (The Yankee Group, 2001). Compare this to $50 per phone time's 24 channels that is $1,200 per month for an equivalent amount of bandwidth.

If there is a moderate volume of bursty traffic to be transferred among a medium to large number of sites then a public network may be a better choice. Since the public network provider has several subscribers, the aggregate volume of traffic is great enough to have high use and therefore is cost effective for the provider. These savings are passed on to subscribers who do not have enough volume of traffic to justify a private network.

The costs for some network technologies can be negotiated with the expected performance in mind. For example, with frame relay, the user chooses the committed information rate in bits per second and committed burst size (Frame Relay Forum, 2002). A frame relay network provider will also specify a maximum end-to-end delay for a frame in their network. These parameters are a part of the pricing for frame relay service.

The price of a network is usually divided up into a fixed cost and a variable cost. The fixed access cost depends on the type of access technology that a user connects to the POP with and the distance the user is from the POP. There may not be a variable cost, but if there is the price is dependent on the volume of traffic. A user may subscribe to a certain data rate from the network for a fixed cost and if the user exceeds the limit, the user is charged for the additional usage.

Support

Support is defined as the quality of a provider's technical and logistical help. In one survey the complaint most cited was the lack of support (Greenfield, 2001). Networks are complex and they do break and fail. A good network provider should be fast to respond and correct problems. A business should consider where the nearest technician would be coming from to service their sites. Service level agreements will define minor and major problems and the type of responses that the network provider will provide.

Control

An organization relies on its network to operate its business (Stallings, 2001). Management requires control of the network to provide efficient and effective service to the organization. There are tradeoffs between a private and public network when considering control. There are

three areas of control that need to be considered: strategic control, growth control, and day-to-day operations.

Strategic control of a network is designing and implementing a network to satisfy the organization's unique requirements. If the organization operates its own private network then it can determine the configuration of the network. But, if the organization uses a public network the organization does not have strategic control over the configuration of the network. The public network provider designs the network for the average subscriber.

Growth control of the network is the ability to expand and make modifications to meet the changing requirements of the organization. It includes adding switching nodes and leased lines, modifying the capacities of the leased lines, and changing the network technology. A private network provides the maximum flexibility for growth control since the organization has complete control over the network. If an organization is a subscriber to a public network it has almost no growth control. All requirements are constrained by the capabilities of the public network.

The other type of control is the day-to-day operation of the network. This includes the ability to handle traffic during peak times, to diagnose problems, and to repair problems quickly. In a private network the organization sets the priorities of the day-to-day operation to fit their business. But, with a private network they also have to hire or develop in-house expertise to maintain the often complex network. Also the organization has to address the reliability of the network by determining where to install redundant packet switching nodes and dedicated leased lines. If an organization is a subscriber to a public network then it is dependent on the public network provider. There are peak traffic times and the public network provider may focus its efforts on the overall health of the network and not on an individual user. On the other hand, the provider can afford more redundancy and hire or develop more in-house expertise because these costs are spread out over several subscribers.

Other Factors

Other factors that are important in choosing a network solution include breadth of service, security, installation, repairs, and remote access. Many network providers offer a wide breadth of value-added services, as previously described. A provider that can provide value-added services such as Web hosting bundled with its network service can have a big advantage. If the server is on the same network that other customers are connected to then performance is better.

Security of a network includes restricting access to information located on corporate servers and preventing malicious activities like denial-of-service attacks that shut down a Web site. A network provider can provide firewalls to restrict activity to sites, VPNs to encrypt and restrict access between sites, and intrusion detection to detect malicious activity.

The installation and repairs category includes the timeliness and quality of an installation. Networks are complex and often require coordination between multiple organizations. For example, in the U.S. if a leased line crosses two different LATAs then at least one local provider and at least one IXC will be required. Also, realistic time schedules are important because a rushed installation usually results in a poor quality installation and long-term problems.

For many businesses remote access is important to be competitive. Remote access permits users in a business to communicate often with e-mail and to access corporate data. Remote access is dependent on the number and location of the network provider's in-dial modem pools. If this is an important part of the business model then a business should look for a provider that has multiple access points in the areas that their employees travel.

PUBLIC NETWORKS IN THE INTERNET AND E-COMMERCE ENVIRONMENTS

Public networks provide a cost-effective solution for small businesses to connect to the Internet and participate in E-commerce because they provide connections to the public Internet through one or more locations. Access to the Internet is restructuring the marketing, sales, management, production, accounting, and personnel management in businesses (Moody, 2001). The Internet provides online up-to-the-minute reports for marketing. Marketing can easily monitor their competitors by accessing the online information and competitors can easily monitor a business. The Internet has had two effects on sales. First, a business can have a worldwide presence. Second, customers are demanding the correct information for deciding which business to buy from. The online purchase is now being handled automatically by software (e-commerce). Members of the sales department can access corporate information over the network while on the road. Management can now have access to more of the organization. They can access information from marketing, sales, production, accounting, and personnel including previous years' sales and regional performance of a product. They can have online meetings and stay in contact with e-mail. Production can receive quicker feedback from the field and have feedback from suppliers about their stock levels. Accounting can pay online and receive up-to-the-minute information. Personnel information such as directories can be provided online and manuals and training material can be placed online.

CONCLUSION

Public networks are an increasingly popular solution for businesses to link multiple sites together to exchange information and to connect to the Internet. Public networks offer several advantages over private networks composed of leased lines, including lower cost for a given performance, value-added services, and fewer requirements of maintaining in-house expertise for network maintenance, support, and similar administrative and management tasks. Public networks do have some disadvantages, including potential variation in performance due to congestion on the public network, and lack of control over day-to-day operations, upgrades, and long-range planning for capacity changes. However, public networks combine

connectivity with value-added services such as Web hosting and CDNs and are a good choice for many businesses.

In the future, only organizations with special requirements in the areas of performance, control, and security will continue to maintain and install private networks. Many organizations with private networks today will migrate their private networks to public networks or use VPNs via their Internet connection. Even organizations that continue to have private networks will have at least one connection to the one global public network called the Internet to participate in activities such as e-mail and E-commerce.

GLOSSARY

Asynchronous transfer mode A network technology, characterized by sending data in fixed size 53-byte cells and offering various levels of service.

Asynchronous digital subscriber line A digital service that uses ordinary telephone lines to connect a customer to a public network. Asynchronous DSL has download speeds that are much faster than the upload speeds.

Content delivery network (CDN) A value-added service that distributes the content to multiple locations and closer to the end user. By sophisticated caching schemes a CDN reduces response times.

Frame relay The most popular technology choice within public switched data networks. Data are divided into frames that are sent on switched networks.

Interexchange carrier A long-distance carrier in the public switched telephone network system.

Internet service provider An organization that provides access to the Internet by providing an Internet address and support of Internet protocols to the subscriber.

Leased line A digital line that provides dedicated transmission capacity between sites.

Local exchange carrier A carrier that controls traffic within a single local access and transport area.

Public network A network that is publicly available to subscribers. A public network can be under government control, operate as a national monopoly, or can be a privately owned network whose services are sold to the public.

Private network A business network composed of point-to-point leased lines between sites.

Public switched telephone network The network that makes up the public telephone system.

Value-added carrier A network provider that provides a value-added network.

Value-added network A network constructed by a network provider that owns the packet-switching nodes and leases transmission capacity to add value to the network.

Value-added reseller A business that provides a service (e.g., Web hosting) that requires network connectivity and sells it for use with a particular public network provider. The network provider often gives discounts to the business for using the network.

Virtual private network A network that uses a collection of technologies applied to the public network to provide the same levels of privacy, security, quality of service, and manageability as private networks.

Radio Frequency and Wireless Communications

Okechukwu C. Ugweje, *The University of Akron*

INTRODUCTION

Radio-frequency (RF) wireless communication systems have been around for many years with applications ranging from garage door openers to satellite communication. The technology has been advancing at an unprecedented rate and its impact is evident in our daily lives. In many parts of the world, wireless communication is the fastest growing area of the communication industry, providing a valuable supplement and alternative to existing wired networks (Cellular Communications Services in the USA, 2003). Based on the number of subscribers to wireless communication products and services, it is now the preferred method of communication (Wireless Communications, Market & Opportunities, 2003). Many systems formerly carried over the wire are now carried over wireless media.

The remarkable success of cellular mobile radio technology has fundamentally changed the way people communicate and conduct business. The wireless revolution has led to a new multi-billion-dollar wireless communications industry. Linking service areas, wireless communication has altered the way business is conducted. For example, with a laptop computer, a wireless modem, and a cellular phone, a business consultant can contact his or her office and clients and conduct business while traveling. While traveling, field service and sales personnel can access corporate databases to check inventory status, prepare up-to-the-minute price and delivery quotes, modify schedule activities, and fulfill orders directly to the factory. Company personnel can use two-way paging services to stay in close contact, even when traditional wired communication services are available. Handheld hybrid phone-computer-fax machines feed information to wireless communication networks, allowing an executive to make decisions while on a leisure outing.

In this chapter, we present a concise summary of the subject of RF and wireless communication. This includes a discussion of the general concepts and definitions of RF wireless communication, various forms and applications of RF wireless communication, and the concepts, properties, and behavior of radio waves. We also summarize existing and emerging technologies for wireless communication. Of particular interest is the cellular mobile radio system, which has become the most widespread RF wireless communication system.

OVERVIEW OF RF WIRELESS COMMUNICATION

Introduction

Wireless or RF communication began at the turn of the 20th century, over 100 years ago, when Marconi

established the first successful and practical radio system. His experiment in 1895 demonstrated the transmission of radio signals a distance of 2 kilometers (Proakis & Salehi, 2002). He conducted additional experiments leading to 1901 when his radiotelegraph system transmitted radio signals across the Atlantic Ocean, from England to Newfoundland, about 1,700 miles away (Mobile Telephone History, 2002). However, only telegraphic codes were transmitted. On December 24, 1906, Reginald Fessenden accomplished the first radio communication of human speech over a distance of 11 miles from Brant Rock, Massachusetts, to ships in the Atlantic Ocean (Mobile Telephone History, 2002). Radio was no longer limited to telegraph codes; it was no longer just a wireless telegraph. This was a remarkable milestone highlighting the beginning of the voice-transmitted age.

In the early years of RF wireless communication, radio broadcasting was the most deployed wireless communication technology. The invention of the vacuum tube and vacuum triode hastened the advancement in radio transmission of voice signals. Radio broadcast by way of amplitude modulation and later frequency modulation (FM) was made possible. Amplitude modulation of the radio frequency was used to carry information until FM was introduced in the late 1930s (Mark & Zhuang, 2003). After FM was introduced, many other RF wireless systems such as television, one- and two-way radio, and radar were introduced between the late 1920s and the mid-1950s. Another milestone was witnessed in the late 1970s, which marked the beginning of the growth in cellular mobile radios and personal communication services. The first successful commercial analog cellular mobile telephone was demonstrated in 1979 (Durgin, 2003). Currently, wireless communication of all kinds abounds in our society.

System Architecture

In RF wireless communication systems, radio waves are used to transfer information between a transmitter (Tx) and a receiver (Rx). RF systems can be classified as either terrestrial-based or space-based systems. Terrestrial-based systems include microwave point-to-point, wireless local area networks, and cellular mobile radio, just to mention a few. Terrestrial microwave systems are limited in distance and line-of-sight (LOS) propagation may be required. Relay towers using carefully aligned directional antennas are often used to provide an unobstructed path over an extended distance. The data signal is processed, up- or down-converted, modulated or demodulated, filtered, and amplified at the transceivers. The transmitted signal propagates through the air and is attenuated by several propagation mechanisms discussed below.

Space-based systems (e.g., the satellite) are similar to terrestrial microwave systems except that signals travel from earth-based ground stations to a satellite (uplink) and a signal is sent back from the satellite to another earth-based ground station (downlink). This achieves a far wider coverage area than the earth-based systems. The satellite system could be in geostationary earth orbit, medium earth orbit, or low earth orbit.

A typical wireless communication system is shown in Figure 1. It consists of a source of information, a hardware subsystem called the transmitter, the channel or means by which the signal travels, another hardware subsystem called the receiver, and a destination of the information (the sink).

The source supplies the information to the transmitter in the form of audio, video, data, or a combination of the three. The Tx and Rx combination is used to convert the signal into a form suitable for transmission and

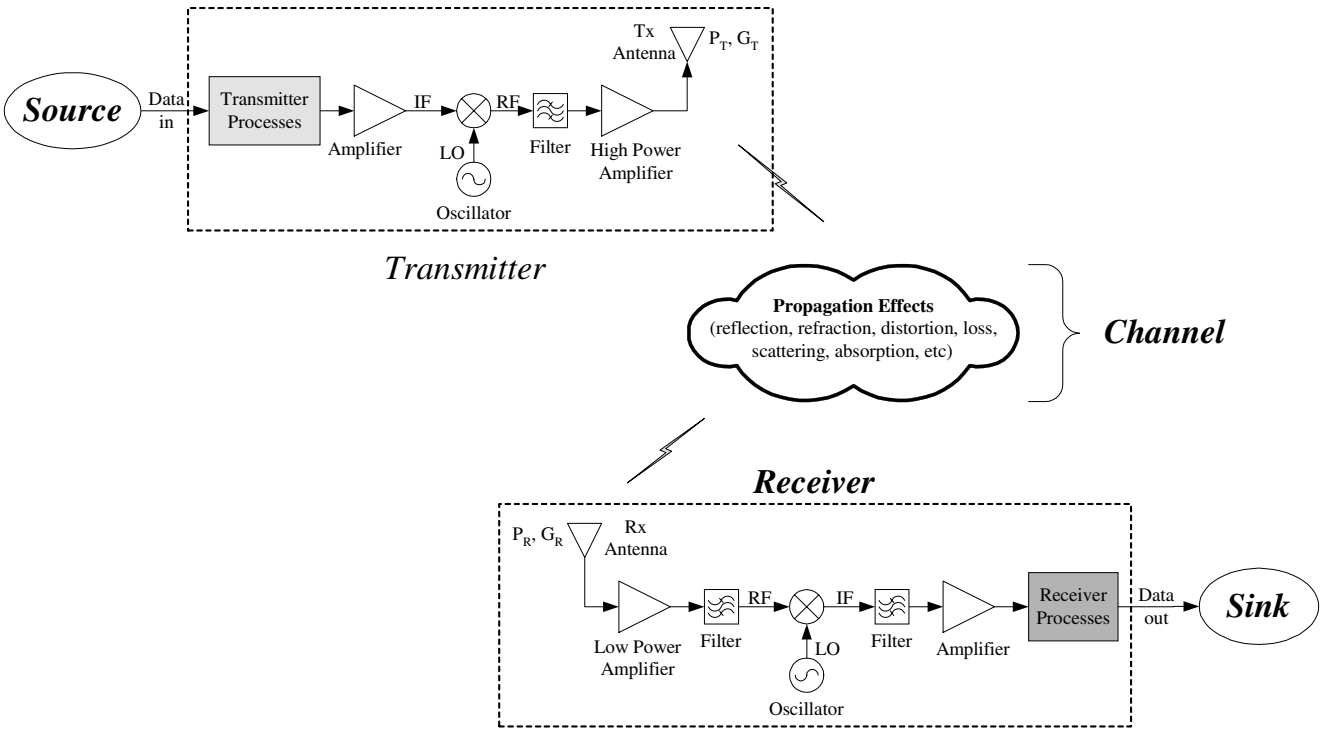

Figure 1: Simplified model of terrestrial-based RF wireless communication systems.

then to convert the signal back to its original form. This is achieved through the process of modulation (or encoding) at the Tx side and demodulation (or decoding) at the Rx side. The channel is the medium by which the signal propagates, such as free space, unshielded twisted pair, coaxial cable, or fiber-optic cable. In wireless communication the channel is free space. Noise and interference is added to the signal in the channel, which causes attenuation, distortion, and eventually error in the received signal.

The transmitter and receiver are very complex systems consisting of many internal components. A block diagram representation of some of the components is shown in Figure 1. Components are denoted as transmitter processes, receiver processes, amplifiers, mixers, local oscillators (LO), filters, and antennas. The transmitter processes represents functions of the transmitter such as modulation, encoding, analog-to-digital conversion, multiplexing, addressing, and routing information. The receiver processes, on the other hand, denote inverse functions such as demodulation, decoding, digital-to-analog conversion, and demultiplexing, as well as addressing and routing information. Effective transmission and reception of radio waves involves processes such as amplification and filtering of the signal at various internal stages, mixing of the desired signal with a local oscillator signal, translating the signal from one frequency to another, and transmission or reception of the RF energy through the antenna. The amplifier is characterized by its gain, noise figure (or output power), and linearity (Weisman, 2003). The gain (in dB) of the amplifier is a measure of how much bigger the output signal is than the input signal. The noise figure (or noise ratio) is a measure of the quality of the receiver system. Mixers are commonly found in the Tx and Rx subsystems and are used to create new frequencies or translate existing frequencies to new ones. They are sometimes called up or down converters. The most common translation of frequency is from intermediate frequency (IF) to RF and vice versa. The mixer performs this function by effectively multiplying two signals at two different frequencies. A signal source that provides one of the inputs to the mixer is the LO. A common type of LO is a voltage-controlled oscillator. The function of the filter is frequency selectivity. Filters select signals based on their frequency components. Regardless of the construction, all filters can be classified as lowpass, highpass, bandpass, or bandstop. These names are descriptive of the function of the filter. For example, a lowpass filter will select signals with low frequency and reject signals with high frequency. A special type of filter commonly used in RF systems is the duplexer. It is used to combine the functions of two filters into one. The duplexer facilitates the use of one antenna for both transmission and reception. The sink or destination can vary as much as the source and type of information.

In the channel, external noise in the form of manmade noise (generated by electrical manmade objects), atmospheric noise, and extraterrestrial noise is introduced. Atmospheric noise is produced by electrical activities of the atmosphere. This type of noise is predominant in the range 0–30 MHz and is inversely proportional to its frequency. Extraterrestrial noise is produced by activities of the cosmos, including the sun.

Radio Spectrum Classification

Radio frequencies or radio waves constitute the portion of the electromagnetic spectrum extending from 30 kHz to 300 GHz. The entire RF spectrum is classified into different bands and ranges, based on propagation properties. Baseband signals or source signals (e.g., audio signals) are in the low-frequency range below 30 kHz. This range of frequencies is classified as very low frequency (VLF), which must be translated into RF before transmission.

Radio waves are also described by their wavelength, λ, as belonging to a particular wavelength range such as shortwave, medium-wave, or millimeter-wave. The higher the frequency, the lower the wavelength, because $\lambda = c/f_c$, where $c = 3.9 \times 10^8$ m/s is the speed of light, and f_c is the carrier frequency. The wavelength is related to the realizable antenna length, L, system bandwidth, B, and other practical system parameters. For example, higher frequency radio waves produce smaller λ, require shorter L, have higher bandwidth efficiency, ρ, are more susceptible to fading, and suffer from atmospheric distortion. The characteristics and applications of radio frequencies are summarized in Table 1.

Within each frequency range, several bands of frequencies can be designated for communication. These bands are commonly identified by either f_c or a letter symbol, as illustrated in Figure 2 (Acosta, 1999; Federal Communications Commission, 1997). For example, in practical applications one could describe an RF system as operating in the C, X, K, or K_A band instead of using the actual frequency numbers. A complete list of the radio-frequency allocation can be found in *Selected U.S. Radio Frequency Allocations and Applications* (2002).

Because of the congestion or unavailability of usable spectrum at the lower frequency bands (below 20 GHz) and the recent demand for multimedia communication at high data-rate capabilities, system designers have directed their attention toward the use of SHF and EHF for communication (Acosta, 1999). Currently, there is a great deal of research on developing RF systems operating at frequencies above 20 GHz (K_A band and above) (National Aeronautics and Space Administration, 1998).

This interest in the EHF band is justified due to its potential benefits, such as the availability of usable spectrum, high data-rate capability, reduced interference, and high achievable gain with narrow beam widths of small antennas (Ippolito, 1989). The drawback, though, is that at these frequencies atmospheric distortion, especially rain attenuation, is very severe (Acosta & Horton, 1998; Xu, Rappaport, Boyle, & Schaffner, 2000). The severity of the meteorological effects increases with increasing frequency. At some frequency bands, the meteorological effects can cause a reduction in signal amplitude, depolarization of the radio wave, and increase in thermal noise (Ippolito, 1989).

Radio Wave Characteristics

When electrical energy in the form of high-frequency voltage or current is applied to an antenna, it is converted to electromagnetic (EM) waves or radio-frequency energy. At the Tx, the antenna converts a time-varying voltage or current into a time-varying propagating EM wave. The resulting EM wave propagates in space away from the

Table 1 Radio-Frequency Band Classification and Characteristics

Frequency Band	Frequency Range	Propagation Characteristics	λ	ρ	L	Typical Use
Very low frequency (VLF)	< 30 kHz	Low attenuation day and night; high atmospheric noise level.	Long	Low	Long	Baseband signals; power line; home control systems; navigation and submarine communication.
Low frequency (LF)	30–300 kHz	Slightly less reliable than VLF; absorption in daytime.				Long-range navigation; marine communication; radio beacons.
Medium frequency (MF)	0.3–3 MHz	Attenuation low at night, high in day; atmospheric noise.				Maritime radio; direction finding; AM broadcasting.
High frequency (HF)	3.0–30 MHz	Omni-directional energy radiation; quality varies with time of day, season, and frequency.				International broadcasting, military communication; long-distance aircraft and shipcommunication.
Very high frequency (VHF)	30–300 MHz	Direct and ground waves; cosmic noise; antenna design and height is critical.				VHF TV; FM broadcast; two-way radio, AM aircraft communication and navigational aids.
Ultra high frequency (UHF)	0.3–3 GHz	LOS; repeaters are used to cover greater distances; cosmic noise.				UHF TV; cellular phone; radar; microwave links; PCS.
Super high frequency (SHF)	3.0–30 GHz	LOS; atmospheric attenuation due to rain (>10 GHz), oxygen and water vapor.				Satellite and radar communication; terrestrial microwave; wireless local loop.

source (the antenna) at the speed of light with the succeeding wave front changing in amplitude as the voltage or current changes in amplitude. Radio waves propagate through space as traveling EM fields proportional to the time-varying voltage or current. The propagating RF energy is composed of an electric field and a magnetic field component. The two fields exist together because a change in the electric field generates a corresponding change in the magnetic field, and vice versa. At the Rx the antenna performs an inverse operation of converting a time-varying propagating EM wave to a time-varying voltage or current.

Polarization of the radio wave is important and is given by the direction of the electric field component. Usually the construction and orientation of the antenna determine the electric field component. Many antennas are linearly polarized, either horizontally or vertically. The magnitude of the power radiated in the direction of propagation can be calculated as the effective isotropic radiated power (EIRP) or effective radiated power. This is the maximum radiated power available from a Tx in the direction of maximum gain for isotropic or directional antennas, respectively. It is a measure of the effectiveness of an antenna in directing the transmitter power in a particular direction (Rappaport, 2002).

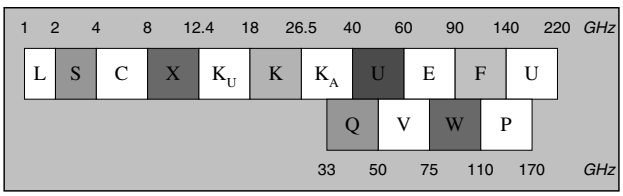

Figure 2: Typical symbol assignment for RF bands.

Forms of Radio Waves

Radio waves propagate in space in various forms. The characteristics of the propagating waves are of interest in many wireless communication systems designs. Propagating radio waves can be classified as direct (or free space), ground (or surface), tropospheric, and ionospheric. These types of waves are illustrated in Figure 3.

Direct waves are the simplest kind of radio waves, in which propagation is in free space without any obstruction. They are projected in a straight LOS between the Tx and Rx. The two-way radio, cellular mobile telephone, and personal communication system seldom have this type of radio wave.

Ground waves are confined to the lower atmosphere or the surface of the earth. A ground wave includes that

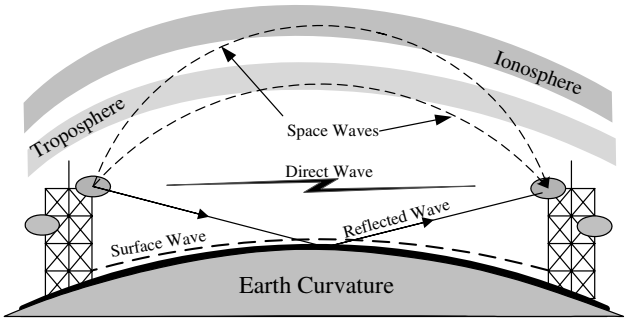

Figure 3: Common types of radio waves in wireless communication systems.

portion of the radio wave directly affected by terrain and objects on the terrain. It is guided along the surface of the earth, reflecting and scattering off buildings, vegetation, hills, mountains, and other irregularities on the earth's surface. These waves propagate outward from the antenna but undergo refraction due to variation in the density of the atmosphere (Garg & Wilkes, 1996). The signal strength decreases as the distance between the Tx and the Rx increases. This wave affects all frequencies in the MF, HF, and VHF ranges, and it is the dominant wave in cellular mobile radio systems. Vertical polarization, the direction of the electric-field component, is best for this type of wave. The polarization is determined by the construction and orientation of the antenna.

Tropospheric and ionospheric waves are commonly referred to as sky waves. They propagate in outer space but can return to earth by reflection or scattering either in the troposphere or in the ionosphere. The tropospheric wave is that portion of the radio wave close to the earth's surface as a result of gradual bending in the lower atmosphere (Garg & Wilkes, 1996). The bending action is due to the changing effective dielectric constant of the atmosphere through which the wave is passing. Its reflective index gradually decreases with height, resulting in a bending path taken by the wave. The troposphere extends about 10 miles above the surface of the earth and applies to waves with wavelength shorter than 10 m; i.e., $\lambda < 10$ m. The ionospheric wave is similar to the tropospheric wave except that it travels farther and the reflection occurs in the ionosphere, 40–400 miles above the earth. This wave is highly reliable for telemetry, tracking, weather forecasting, and tactical military applications. Note that different wavelengths are reflected to dissimilar extents in the troposphere and ionosphere.

Radio-Frequency-Based Systems

Figure 4 shows the different forms of RF-based wireless communication systems, which we have classified into six groups: microwave RF systems, fixed and mobile satellite systems, wireless networks and protocols, personal communication systems, remote sensing systems, and emerging technologies. No distinction is made between the communication layers and protocols in this classification. These systems transmit and receive radio waves tuned to specific bands of frequencies. Microwave is loosely used to describe all radio frequencies between 1 and 40 GHz. This includes the UHF, SHF, and EHF systems. The lower microwave frequencies, i.e., UHF, are most often used for terrestrial-based RF systems, whereas the higher microwave frequencies, i.e., SHF and EHF, are used for satellite communications. A terrestrial microwave system transmits carefully focused beams of radio waves from a transmitting antenna to a receiving antenna. A terrestrial microwave system uses LOS propagation to communicate between the Tx and the Rx with a typical distance of 30 miles between relay towers.

Personal communication services (PCS) are a new generation of wireless-phone technology that introduces a wide range of features and services greater than those available in analog and digital cellular phone systems (International Engineering Consortium, 2003a). It includes any system that provides people with access to information services, such as cellular telephones, home-based systems (cordless telephones, remote control, short-range two-way radio), beepers, pagers, and much more (Goodman, 1997; Rappaport, 2002). PCS provides the user with an all-in-one wireless phone, paging, messaging, and data

service. The most significant segment of this technology is the cellular mobile radio. It is the fastest growing segment of the telecommunications industry. Based on the number of new subscribers worldwide and the number of services, the cellular mobile radio system has evolved as the dominant wireless communication system. Its history dates back many decades, but the modern-day mobile radio became widespread in the 1980s (Rappaport, 2002). The cellular mobile radio system is discussed further below.

Wireless networks and protocols include systems such as wireless local area networks (W-LAN), wireless local loops (WLL), wireless application protocol (WAP), and Bluetooth. These systems are used mainly to provide data communication. W-LAN is an extension to, or an alternative for, a wired LAN. W-LAN provides the functionality of wired LAN, without the physical constraints of the wire itself, combining data connectivity with user mobility (Bing, 2000; Geier, 1999; Wenig, 1996). W-LANs have the potential to support user mobility and constant and unlimited access to information by linking several wireless devices to the wired infrastructure network. In W-LAN, packets of data are converted into radio waves that are sent to other wireless devices or to a wireless access point (AP)–client connection from the wired LAN to the mobile user. The AP can reside at any node on the wired network and acts as a gateway for wireless users' data routed to the wired network. W-LANs require special MAC layer protocols due to the broadcast nature of radio communication (Chen, 1994). A detailed discussion of W-LAN is beyond the scope of this chapter. W-LANs have gained strong popularity lately and are used widely in health care, industry, commerce, warehousing, and academia. An important feature of the W-LAN is that it can be used independent of a wired network. That is, it can be used as a stand-alone network anywhere to link multiple computers together without extending a wired network. W-LAN uses one of the three basic transmission protocols, namely, direct sequence spread spectrum (DSSS), frequency hopping spread spectrum (FHSS), or low-power narrowband. The majority of RF-based W-LANs operate in the industrial, scientific, and medical (ISM) frequency bands, which are located at 902 to 928 MHz, 2.4 to 2.483 GHz, and 5.725 to 5.85 GHz, respectively. The different architectures of W-LAN based on (Agrawal & Zeng, 2003) are summarized in Table 2.

WLL is a system that connects telephone subscribers to the public switched telephone network using radio waves (International Engineering Consortium, 2003b). With WLL, the traditional copper wire-providing link between the subscriber and the local exchange is replaced by a wireless RF network. WLL is advantageous for remote areas where the cost of wire would be prohibitive, i.e., adverse terrain or widely dispersed subscriber areas. With WLL new service providers can quickly deploy wireless networks to rapidly meet the customer's telephony needs. Existing landline operators can extend their networks using WLL. Cellular telephone companies can deliver residential service using WLL without going through the local telephone company.

WAP is an application environment and set of communication protocols (application, session, transaction, security, and transport layers), which allow wireless devices easy access to the Internet and advanced telephony services (Wireless Application Protocol, 2000; Stallings 2002). WAP offers the ability to deliver an unlimited range of mobile services to subscribers, independent of their network, manufacturer, vendor, or terminal. With WAP, mobile subscribers can access information and services from wireless handheld devices. WAP is based on existing

Internet standards such as the Internet protocol (IP), extensible markup language (XML), hypertext markup language (HTML), and the hypertext transfer protocol (HTTP) and is designed to work with all wireless network technology. More information can be obtained from the *WAP Forum* (Wireless Application Protocol, 2000) and in the chapter on WAP in this encyclopedia.

Bluetooth is a wireless technology that makes possible connectivity to the Internet from mobile computers, mobile phones, and portable handheld devices without the need for cable connections. It facilitates fast and secure transmission of both voice and data, without LOS propagation. Some characteristics of Bluetooth technology are summarized in Table 2. Detailed information on Bluetooth can be found in another chapter in this encyclopedia.

Satellite communication is one of the traditional RF wireless communication systems. Signals can be transmitted directly from a ground station (GS) or gateway on earth to a satellite, and back to another GS. Sometimes, the signal can be routed through another satellite (intersatellite) before it is transmitted back to the GS. We can identify a satellite system by how far the satellite is from the earth. The closer the satellite is to the earth, the shorter the time it takes to send signals to the satellite. There are three satellite orbits, namely, low earth orbit (LEO), medium earth orbit (MEO), and geosynchronous earth orbit (GEO).

LEO satellites are closest to the earth, beginning about 100 miles above the surface, and only take a couple of hours to circle the earth. Because LEO systems are orbiting so quickly, multiple satellites are required to provide constant coverage in one location. LEO systems have the capability to receive calls from the earth and pass them to an earth-based switching system in much shorter time than other satellites. However, because of the speed of the satellite, it is frequently necessary to handoff a particular call to a second satellite just rising over the horizon. This is similar to a cellular mobile radio system (discussed below), except that in this case it is the cell site (the satellite) that is moving rather than the user. The lower orbit has the advantage of allowing access to very low-power devices (Printchard, 1993). LEO satellites are used mainly for wireless transfer of electronic mail, pager systems, worldwide mobile telephony, spying, remote sensing, and video conferencing.

GEO satellites circle the earth at a height of 22,300 miles, orbiting at the same rate as the earth rotates so that they appear stationary from the earth's perspective. Most GEO satellites rely on passive bent-pipe architecture so that they receive signals from transceivers on earth, amplify them, and send them back to specific regions on earth. GEO systems are used for a wide array of services including television broadcasts, long-distance telecommunications, and various scientific and military applications. GEO satellites are well suited to transmitting data, but may be undesirable for voice communications because of the long propagation delay. It takes about one-fourth of a second for a signal to travel from a terrestrial GS to the satellite and back. If the receiver GS replies, it takes another one-fourth of a second, resulting in a total of half a second (Printchard, 1993). This is an unacceptably long delay for voice communication. Hence, voice communications are seldom carried via GEO satellites.

MEO satellites can be found between 1,000 and 22,300 miles and are mainly used for global positioning and navigation systems. MEO satellites are not as popular as the LEO or GEO for reasons beyond the scope of this paper.

New wireless or cellular mobile radio technologies are classified under emerging wireless technologies. These are technologies currently under research and development or technologies that are undergoing field tests. In short, these technologies are not widely deployed. These include the third generation (3G) technologies and the forth generation (4G) technologies. The goal of these technologies is to seamlessly integrate a wide variety of communication services such as high-speed data, video, and multimedia traffic as well as voice signals. Some of these technologies can be realized by combining existing technologies. For example, one of the most promising approaches to 3G is to combine a wideband code division multiple access air interface with the fixed network of a global system for mobile communications (GSM). It is expected that these new technologies will increase the performance of the existing wireless systems. These technologies will provide multimedia capability at much higher rates with Internet connectivity.

RADIO WAVE PROPAGATION

Propagation is the process of wave motion, which is very important in the design and operation of RF systems. Because the received signal is always different from the transmitted signal, due to various propagation impairments, and because of the nature of the propagation itself, it is necessary to understand the properties of radio wave propagation. This is most important in telecommunication applications in predicting the transmission characteristics of the channel. When radio waves are radiated from an antenna, propagation is governed by the following mechanisms.

Free Space Propagation

This is the ideal propagation mechanism when the Tx and the Rx have direct LOS and are separated by a distance d between the Tx and the Rx. If P_t is the transmitted power, the received power P_r, a function of distance d, is given by

$$P_r(d) = P_t G_t G_r \frac{\lambda^2}{(4\pi d)^2 L} = P_t A_{et} A_{er} \frac{1}{(\lambda d)^2 L} \qquad (1)$$

where A_e, G, and L are the effective area of antenna, antenna gain, and system loss factor, respectively. The subscripts "t" and "r" refer to the transmitter and receiver respectively. From this relationship, we observe that the received power diminishes at the rate of 20 dB/decade as the distance increases. The product $P_t G_t$ is defined as EIRP, introduced earlier; i.e., $EIRP = P_t G_t$.

Reflection

When a radio wave strikes an object with dimensions very large compared to its wavelength, reflection occurs.

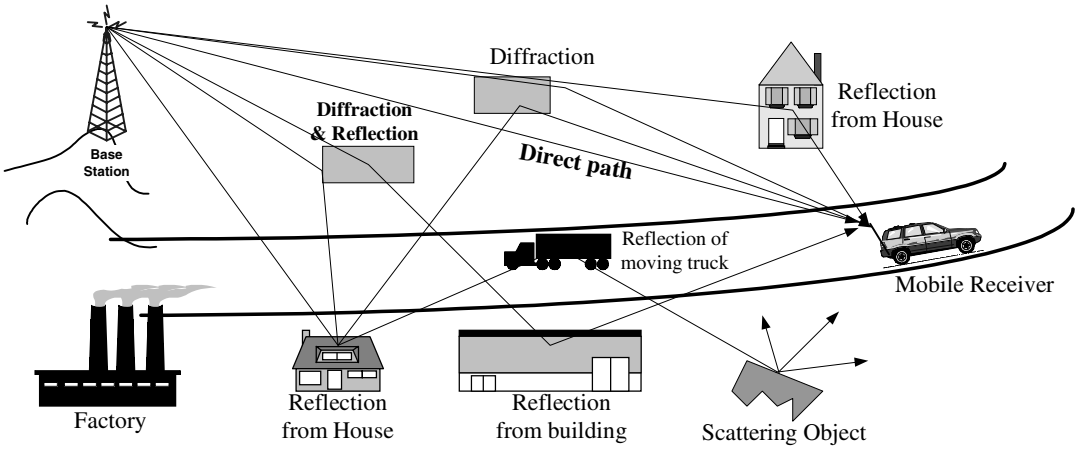

Figure 5: Illustration of reflection, refraction, diffraction, scattering, and absorption.

All radio waves will undergo reflection if the propagation medium undergoes abrupt changes in its physical properties. This is illustrated in Figure 5. The more abrupt the discontinuity, the more pronounced the reflection. Depending on the type of object, the RF energy can be partially reflected, fully reflected, or absorbed. It is possible to compute the amount of reflection from the properties of the two media. This is known as the reflection coefficient, $\Gamma = (\eta_2 - \eta_1)/(\eta_2 + \eta_1)$, where η_1 and η_2 are the intrinsic impedance of the two media. Note that depending on the values of η_1 and η_2, there could be partial reflection, full reflection, or no reflection at all. If the incident object is a good conductor, the wave is totally reflected and the angle of incidence is the same as the angle of reflection.

Refraction

Refraction (see Figure 5) occurs at the boundary between two dielectrics, when the incident wave propagates into another medium at an angle. When radio waves propagate from a medium of one density to a medium of another density, the wave speed changes. This change in speed will cause the wave to bend at the boundary between the two media. The wave will always bend toward the denser medium.

Diffraction

Diffraction of radio waves occurs when the waves encounter some obstruction along their path and tend to propagate around the edges and corners and behind the obstruction. This is illustrated in Figure 5. The height or dimension of the obstruction has to be comparable to the *wavelength* of the transmission. The same obstruction height may produce lower diffraction loss at higher *wavelength* than at lower *wavelength*. The result of this effect is that the object shadows the radio wave. The field strength of the wave decreases as the receiver moves deeper into a shadowed region.

Scattering

Scattering is also illustrated in Figure 5. It is due to small objects and irregularities in the channel, rough incident surfaces, or particles in the atmosphere. When the radio wave encounters objects or particles with dimension smaller than the *wavelength* of the wave, scattering occurs, which causes the signal to spread in all directions.

Interference

Interference can occur when the transmitted radio wave arrives at the same location via two or more paths (multipath). One of the ways this can happen is illustrated in Figure 6. This figure shows three waves arriving at a mobile receiver (the car) after traveling slightly different paths. Due to their phase differences, the radio waves can add either constructively or destructively at the receiver. If the phase shift experienced by the propagating waves

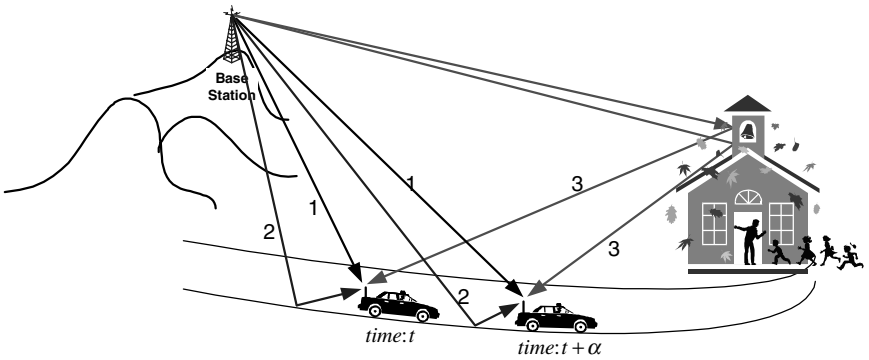

Figure 6: Interference of radio wave.

is time-varying, then it can cause a rapid variation in the received signal, resulting in fading.

Absorption

Absorption describes the process where radio energy penetrates a material or substance and gets converted to heat. Two cases of absorption of radio waves are prevalent. One occurs when radio waves are incident upon a lossy medium and the other is due to atmospheric effects. When the radio wave strikes an object, the incident wave (perpendicular wave) propagates into the lossy medium and the radio energy experiences exponential decay with distance as it travels into the material. The wave either is totally dissipated or will reemerge from the material with a smaller amplitude and continue the propagation. The *skin depth*, δ, is the distance for the field strength to be reduced to 37% of its original value—the energy of the wave is reduced by 0.37. Particles in the atmosphere absorb RF energy. Absorption through the atmosphere also depends on the weather conditions—fair and dry, drizzle, heavy rain, fog, snow, hail, etc. Usually, the absorption of RF energy is ignored below 10 GHz.

Doppler Effect

Doppler shift is the change in frequency due to the difference in path length between two points in space. It is observed whenever there is relative motion between the Tx and the Rx. For a mobile moving with a constant velocity v, the received carrier frequency f_c will be shifted by the amount

$$f_d = f_m \cos\theta = \frac{v\cos\theta}{\lambda} = \frac{v_{eff}}{\lambda} = \frac{v_{eff} f_c}{c} \qquad (2)$$

where θ is the path angle; $f_m = v/\lambda$ is the maximum Doppler frequency f_d, at $\theta = 0°$; and v_{eff} is the effective velocity of the mobile (Garg & Wilkes, 1996). The Doppler shift, bounded by $\pm f_m$, is related to the phase change $\Delta\theta$ caused by the change in path length. Because each component of the received multipath signal arrives from a different direction, each contributes a different value to the Doppler spreading. This effectively increases the bandwidth of the received signal. Depending on the direction of motion and the source, the frequency can be shifted up or down, i.e., $\pm f_m$. The result of this shift is a random phase and frequency modulation of the received RF carrier, which may necessitate the use of differential phase and frequency detection techniques.

The above propagation mechanisms strongly influence system design parameters such as the choice of transmitting and receiving antennas, Tx powers, modulation techniques, and much more. Each of these propagation mechanisms contributes to losses in the RF energy and hence limits system performance. In wireless mobile communications, propagation losses are commonly classified into path loss, shadowing, and multipath fading. These losses are described below.

Path Loss

Path loss (PL) refers to the large-scale envelope fluctuation in the radio propagation environment, which varies with the distance between the Tx and Rx. Because the Rx is located at some distance d from the Tx, a loss factor is used to relate the transmitted power to the received power. For amplitude fading, an increase in d normally results in an increase in PL. Different models have been used to model path loss, but each model obeys the distance propagation law. In free space, with L = 1, PL is expressed as the ratio of the radiated power P_t, to the received power P_r and is given by

$$PL(dB) = 10\log_{10}\frac{P_t}{P_r} = -10\log_{10}\left[\frac{G_t G_r \lambda^2}{(4\pi)^2 d^2}\right] \qquad (3)$$

Shadowing

Due to topographical variations along the transmission path, the signal is diffracted and the average power of the received signal is not constant. Shadowing or large-scale fading refers to slow variations in the local mean of the received signal strength. This variation causes shadowing. The signal is shadowed by obstructions such as buildings and natural terrain, which leads to gradual variations in the mean power of the received signal. The effect is a very slow change in the local mean signal, say P_s. Shadowing is generally modeled by a lognormal distribution, meaning that $s_d = 10\log_{10} P_s$ is normally distributed, with s_d given in dB (Yacoub, 1993). Shadowing is the dominant factor determining signal fading.

Multipath Fading

The collective effect of reflection, refraction, diffraction, and scattering leads to multipath propagation. Due to reflection, refraction, and scattering of radio waves along the channel by manmade structures and natural objects along the path of propagation, the transmitted signal often reaches the receiver by more than one path. This results in the phenomenon known as multipath fading. The signal components arriving from indirect paths and a direct path (if it exists) combine at the receiver to give a distorted version of the transmitted signal. These radio waves are attenuated differently and they arrive with different path gains, time delays, and phases. The resultant signal may vary widely in amplitude and phase depending on the distribution of intensity and relative propagation in time of wave and bandwidth of the transmitted signal. The number of paths may change drastically when the mobile unit changes its position depending on the increase or decrease in the number of intervening obstacles. Unlike shadowing, multipath fading is usually used to describe small-scale fading or rapid fluctuation in the amplitude of a radio signal over a short period of time or over short distances. It is affected by rapid changes in the signal strength over short distances or time intervals and random frequency variations due to varying Doppler shifts on different multipath signals (Rappaport, 2002).

The loss factor associated with multipath fading is usually modeled in the channel impulse response. A transmitted impulse will arrive at the Rx as the sum of several impulses with different magnitudes, delays, and phases. For M multipath, the composite impulse response $h(t,\tau)$

for any given locations of the Tx and Rx is given by

$$h(t, \tau) = \sum_{k=1}^{M} \alpha_k(t)\delta\,(t - \tau_k(t))\, e^{-j\phi_k(t)} \tag{4}$$

where $\alpha_k, (t)$, $\tau_k(t)$, and $\phi_k(t)$ represent the time-varying amplitude, delay, and phase of the kth path signal. This shows that in general, the received signal is a series of time-delayed, phase-shifted, attenuated versions of the transmitted signal. The variables $h(t, \tau)$, $\alpha_k(t)$, $\phi_k(t)$, and $\tau_k(t)$ are also random.

WIRELESS COMMUNICATION TECHNIQUES

Because the wireless channel is not a reliable propagation medium, techniques to achieve reliable and efficient communication are necessary. In mobile channels, for example, the Rx has to constantly track changes in the propagation environment to ensure optimal extraction of the signal of interest. As the receiver moves, the surrounding environment changes, affecting the received signal's amplitude, phase, and delay. The multipath received signals are combined at the antenna either constructively or destructively. During destructive combining the received signal may not be strong enough to produce reliable communication because of the degradation in the signal-to-noise ratio (SNR). It is not uncommon in shadowed signals for the amplitude of the received signal to drop by 30 dB or more within a distance of a fraction of a wavelength (Eng, Kong, & Milstein, 1996). Hence, achieving reliable communication over a wireless channel is a daunting task.

To counter this problem, techniques have been developed for efficient wireless communication. These include spread spectrum, multiple access, diversity, equalization, coding, and related techniques such as multicarrier modulation, orthogonal frequency division multiplexing, multicode and multirate techniques, and multiple input multiple output system, to mention just a few. All these techniques are aimed at increasing the reliability of the channel and the performance of the system. Discussion of some of these techniques is beyond the scope of this paper. However, a summary of the major wireless communication techniques is given below.

Spread Spectrum

Spread spectrum (SS) is a modulation technique where the transmitted bandwidth B_{ss} is much greater than the data bandwidth B_s. The idea is to transform a signal with bandwidth B_s into a noise-like signal of much larger bandwidth B_{ss}. Spreading is usually achieved by modulating the data with a pseudo-random noise (PN) sequence called the "chip" at a rate that is much higher than the data rate. The significance of SS is evident from the capacity equation, given by

$$C = B\log_2(1 + SNR) \tag{5}$$

where C is the channel capacity in bits and B is the bandwidth in hertz. Observe that by increasing the bandwidth B, we may decrease the SNR without decreasing the capacity and, hence, the performance.

The main parameter in SS systems is the processing gain, G_p, defined as

$$G_p = \frac{Spread\ Bandwidth}{Information\ Bandwidth} = \frac{B_{ss}}{B_s} = \frac{T_b}{T_c} \tag{6}$$

where T_b and T_c are the bit period and the chip period, respectively. G_p is sometimes known as the "spreading factor" (Rappaport, 2002). From a system viewpoint, G_p is the performance increase achieved by spreading. It determines the number of users that can be allowed in a system, and hence the amount of multipath reduction effect. It is used to describe the signal fidelity gained at the cost of bandwidth. It is through G_p that increased system performance is achieved without requiring a higher SNR. For SS systems, it is advantageous to have G_p as high as possible, because the greater the G_p, the greater the system's ability to suppress interference. SS techniques are used in cellular mobile telephones, global positioning satellites (GPS), and very-small-aperture satellite terminals. The strength of this system is that when G_p is very large, the system offers great immunity to interference.

There are two major methods of SS modulation, namely direct sequence spread spectrum (DSSS) and frequency hopping spread spectrum (FHSS). In DSSS the frequency of the given signal is spread across a band of frequencies as described above. The spreading algorithm changes in a random fashion that appears to make the spread signal a random noise source. FHSS is the repeated switching of f_c from one band to another during transmission. Radio signals hop from one f_c to another at a specific hopping rate and the sequence appears to be random. In this case, the instantaneous frequency output of the Tx jumps from one value to another based on the pseudo-random input from the code generator. The overall bandwidth required for FHSS is much wider than that required to transmit the same information using only one carrier. However, each f_c and its associated sidebands must stay within a defined bandwidth.

Diversity

Diversity is one of the techniques widely used to increase system performance in wireless communication systems. Diversity combining refers to the system in which two or more closely similar copies of some desired signal are available and experience independent fading. In diversity systems, the received signals from several transmission paths, all carrying the same information with individual statistics, are combined with the hope of improving the SNR of the decision variables used in the detection process. Diversity combining techniques could be based on space (antenna), frequency, angle of arrival, polarization, and time of reception (Eng et al., 1996; Yacoub, 1993). For example, in space diversity the transmitted signal is received via N different antennas with each multipath received through a particular antenna. This can be regarded as communication over N parallel fading channels. Diversity reception is known to improve the reliability of the systems without increasing either the transmitter power

or the channel bandwidth. Regardless of the type of diversity used, the signals must be combined and detected at the receiver. A proper combination of the signal from various branches results in improved performance. The method of combining chosen will affect the receiver performance and complexity. The common combining techniques in wireless communication are maximal ratio combining (MRC), equal gain combining (EGC), and selection diversity (SD). In MRC, the received signals from individual paths are weighted and added in such a way as to emphasize more credible signals and suppress less credible ones (Yacoub, 1993). In EGC, the received signals are equally weighted and then combined without regard to the individual signal strength. In SD, the branch with the best or most desirable signal is selected and the weaker ones are ignored.

Multiple Access

Because the RF spectrum is finite and a limited resource, it is necessary to share the available resources between users. Multiple access techniques are the primary means of sharing the resources in wireless systems. These techniques are multiplexing protocols that allow more than a pair of transceivers to share a common medium, which can be achieved through frequency, time, or code, giving rise to three popular techniques known as frequency division multiple access (FDMA), time division multiple access (TDMA), and code division multiple access (CDMA). In FDMA, the whole spectrum is divided into subbands and the subbands are assigned to individual users on demand. The users use the entire channel for the entire duration of their transmissions. If the transmission path deteriorates, the user is switched to another channel. This access technique is widely used in wireless multiuser systems. Instead of dividing the available frequency as in FDMA, the available time is divided into frames of equal duration in the case of TDMA. Only one user is allowed to either transmit or receive in each time frame. The transmissions from various users are interlaced into cyclic time structure. Instead of using frequencies or time slots, CDMA techniques distinguish between multiple users using digital codes. Each user is assigned a unique PN code sequence, which is uncorrelated with the data. Because the signals are distinguished by codes, many users can share the same bandwidth simultaneously; i.e., signals are transmitted in the same frequency at the same time.

CELLULAR COMMUNICATION

Currently, cellular mobile communication is undoubtedly the most popular RF wireless communication system. In cellular systems, instead of using a single large coverage area with one high-power transceiver (used in traditional mobile systems), the coverage area is divided into small, localized coverage areas called cells. Figure 7 compares the traditional mobile telephone with the cellular telephone structures. Each cell has a base station (BS) or cell site, which in comparison uses much less power. The BS can communicate with mobiles as long as they are within range. To prevent interference, adjacent cells are assigned different portions of the available frequencies. With a certain distance between two cells, the assigned spectrum of a given cell can be reused.

To explain the concept of cellular mobile communication, a summary of the major concepts and techniques is presented below.

Cells

A cell is the basic geographic unit of a cellular system, commonly represented as a hexagon. The term cellular comes from this hexagonal or honeycomb shape of the coverage area. Each cell has a BS transmitting over a cell. Because of constraints imposed by natural terrain and manmade structures, the true shapes of cells are not

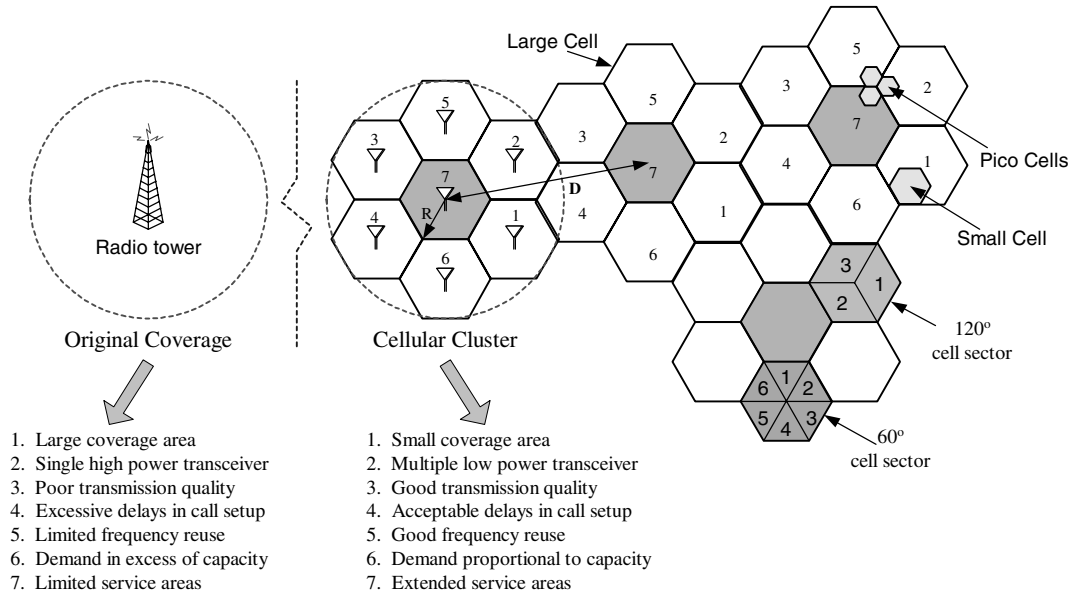

Figure 7: Traditional and cellular mobile radio structure showing frequency reuse, cell splitting and cell sectoring (R = cell radius, D = frequency reuse distance).

hexagons. The coverage area of cells is called the footprint. The BS simultaneously communicates with many mobiles using one channel (pair of frequencies) per mobile. One frequency is for the forward link (BS to the mobile), and the other frequency is for the reverse link (mobile to the BS). Each cell size varies depending on the landscape, subscriber density, and demand within a particular region. Cells can be added to accommodate growth, e.g., creating new cells by overlaying, splitting, or sectoring existing cells. These techniques increase the capacity of the system. Sectoring existing cells and then using directional antennas can also increase capacity.

Clusters

A cluster is a group of cells. No frequencies are reused within a cluster. Figure 7 illustrates a 7-cell cluster, indicated by the dotted circle. Frequency can be reused for all cells numbered 7. Frequencies used in one cell cluster can be reused in another cluster of cells. A larger number of cells per cluster arrangement reduces interference to the system.

Frequency Reuse

Frequency reuse is a technique of allocating channels to cellular systems. Because of the unavailability of spectrum at the cellular band, channel frequencies must be reused. Cells are assigned groups of channels that are completely different from those of neighboring cells. Cells with the same number have the same set of frequencies. If the number of available frequencies is 7, the frequency reuse factor is 1/7, which implies that each cell is using 1/7 of available frequencies (Rappaport, 2002). Frequency reuse introduces interference into the system.

Interference

In cellular mobile communications, there are two types of intrinsic interference, namely, co-channel interference (CCI) and adjacent channel interference (ACI). These interferences are a result of frequency reuse. CCI is the interference between signals having the same frequency (i.e., the reuse frequencies), whereas ACI is the interference between signals having frequencies close together. For example suppose channel 1 has frequencies 825.030 MHz (mobile) and 870.030 MHz (BS) and channel 2 has frequencies 825.060 MHz and 870.060 MHz. Channels 1 and 2 have frequencies close to one another, which will result in ACI. Any other signals having the frequencies of channel 1, 825.030 (mobile) and 870.030 MHz (BS), are co-channel signals and will suffer from co-channel interference. Note that the interference effect is related to the ratio of the reuse distance D and the cell radius R. This is known as the Q-factor Q=D/R and is used to measure the level of CCI. A higher Q value improves transmission quality due to smaller CCI. That is, increasing D improves isolation of RF energy between cells and hence minimizes interference. The ACI is mainly due to imperfect filtering allowing nearby frequencies to leak into the passband of the desired signal (out-of-band interference).

Cell Splitting

Cell splitting is the process of subdividing a congested cell into smaller cells, each with its base station. As the traffic load carried by a large cell reaches capacity, cell splitting is used to increase system capacity. In this way, heavy-traffic regions can be split into as many smaller areas as necessary in order to provide acceptable service levels. Cell splitting decreases R, while leaving Q relatively unchanged. Notice that more cells imply that more cell boundaries will be crossed more often, increasing trunking and handoff. Only those cells that have traffic overloads are candidates for splitting. However, if cells are split in only a part of a system, serious channel assignment problems may result. The difficulty encountered when all the cell sites are not split can be resolved by implementing cell overlay.

Cell Sectoring

Cell sectoring is the process of dividing cells into sectors and replacing a single omni-directional antenna with a directional antenna. Common sectors sizes are 120°, 90°, 60°, and 30°. Cell sectors of 60° and 120° are illustrated in Figure 7. When cells are sectored, R is unchanged, D is reduced, the amount of frequency reuse is increased, and hence capacity is increased. It is observed that the spectral efficiency of the system is enhanced because the frequency can be reused more often.

Handoff

Handoff is the process used to maintain a call in progress when the mobile user moves between cells. Handoff is generally needed in situations where a mobile is at a cell boundary or reaches a gap in signal strength. Because adjacent cells do not use the same frequency, a call must either be dropped or transferred from one radio channel to another when a mobile user crosses the line between adjacent cells. Because dropping the call is unacceptable, the process of handoff is necessary. As the user moves between cells, the transmission is "handed off" between cells in order to maintain seamless service.

EMERGING RF WIRELESS TECHNOLOGIES

The first generation (1G) and second generation (2G) of cellular mobile telephony were intended primarily for voice transmission. This will not be adequate for the new generation of users. With the continued growth of the Internet and World Wide Web, mobile users are continually looking for high-performance wireless Internet technology to enhance their communication capabilities. Although 3G wireless technology has not yet been realized, it promises to enhance users' communication ability, ranging from receiving and sending e-mail to video teleconferencing. The services provided by the generations of wireless technology are summarized in Table 3 (Evolution to 3G/UMTS Service, 2002).

The 3G technologies use wideband code division multiple access (W-CDMA) technology to transfer data over networks. W-CDMA sends data in a digital format over a range of frequencies, which makes the data move faster,

Table 3 Service Differentiation by Wireless Communication Generations

2G	2.5G	3G
Circuit switched	Packet services	Multimedia
Voice	Interactive	High interactivity
Simple message/SMS	Web browsing	Real time road maps

but also uses more bandwidth than digital voice services. W-CDMA is not the only 3G technology; competing technologies include CDMAOne, variants of CDMA2000, which differs technically, but should provide similar services.

CONCLUDING REMARKS

RF and wireless communication systems are being used in diverse areas such as home, military, travel, education, stock trading, package delivery, disaster recovery, and medical emergencies. For example, with wireless technology field employees can connect a portable computer via a wireless network to the area office. Sales professionals can stay in touch with customers about products and services, placed orders, status updates to home offices, and inventory. Airline staff can gather information about ticketing, flight scheduling, and luggage using wireless devices. Public welfare agencies such as police, fire safety, and ambulance services can use wireless devices to relay information. Package delivery companies such as Federal Express, UPS, and DHL have adopted the wireless and mobile computing technology for parcel tracking, as well as emergency drop or pickups of shipments.

Although wireless systems are commonplace in our society, the future of the industry is filled with promises and challenges. Future wireless technologies under consideration include 4G mobile technology, multimedia messaging, and complete convergence via broadband, just to mention a few 4G wireless technology based on ultra-wideband communications will enable the use of low-power, high-bandwidth (100–500 Mbps) networks, supporting devices with sense and radar capabilities. Multimedia messaging will allow pictures and sound to be transmitted along with a text message over the mobile phone. Mobile handsets will support full-color display screens, some with embedded Java capabilities, others with digital cameras built in. It is expected that Bluetooth technology will move from theory and hype to practicality, and issues regarding the security of mobile commerce and information security in general will dissipate.

In this chapter, the topics of RF and wireless communication have been discussed. The concept and general definitions are presented. Within these topics, we have discussed the concept of radio waves as propagating electromagnetic waves, including their characteristics and behavior. It is noted that for wireless and mobile radio systems, it is important to understand distinguishing features of the channel, the properties of the radio wave, and several techniques to enhance the reliability of the channel and increase the performance of the system. Also, a summary of the different forms of wireless communication systems was presented, emphasizing cellular mobile radio, which is currently the most prevalent wireless communication system. Finally, the up-and-coming wireless technologies were enumerated. These are the 3G technologies, which will provide more capabilities to their users.

GLOSSARY

1G, 2G, 3G, 4G 1st, 2nd, 3rd and 4th generation wireless systems.

Amplifier An electronic device used to boost the strength of a signal along a communications channel.

Antenna A device used for receiving or transmitting signals.

Bandwidth The capacity of a transmission channel.

Base station Central radio transmitter/receiver that maintains communications with a mobile radio user.

Bluetooth Short-range wireless protocol allowing mobile devices to share information and applications.

Broadband A classification of the information capacity or bandwidth of a communication channel.

CDMA Code division multiple access.

Cellular Wireless communication technique used in mobile phones.

Channel A radio-frequency assignment made according to the frequency band being used.

Downlink Data transmission from a network to a subscriber.

DSSS Direct sequence spread spectrum.

Duplexer Device for isolating transmitter and receiver signals while permitting a shared channel.

EIRP Effective isotropic radiated power: product of power supplied to an antenna and its gain.

FHSS Frequency hopping spread spectrum.

Frequency Rate of signal oscillation in hertz (one hertz is one cycle per second): the number of times a waveform repeats itself in a second.

GPS Global positioning system—a worldwide radionavigation system.

Ground station The ground equipment needed to receive and/or transmit satellite telecommunications signals, including a dish and other electronics components.

GSM Global system for mobile communications, the mobile phone platform used in Europe and many parts of the world.

Handoff Transfer of wireless call in progress from one site to another without disconnection.

Modulation Process of varying a characteristic of a carrier with an information-bearing signal.

PCS Personal communications services: any of several types of wireless voice and/or data communications systems, typically incorporating digital technology.

Propagation Radiation of electromagnetic waves.

Protocol The rules of order by which a communications network is operated.

PSTN Public switched telephone network: a formal name for the landline telephone network.

Receiver Device on a transmission line that converts a signal to whatever type of signal is needed to complete the transmission.

RF Radio frequency: a radio signal.

Spectrum Range of electromagnetic radio frequencies used in signal transmission.

SS Spread spectrum: a communications technology where a signal is transmitted over a broad range of frequencies and then reassembled when received.

Subscriber A cellular telephone user.

TDMA Time division multiple access: a digital communication technology used by some carriers to provide service.

Transmitter The source or generator of any signal on a transmission medium.

Uplink Data transmission in the direction from the subscriber to the network (back to the provider or Internet provider).

WAP Wireless application protocol: a technology designed to provide users of mobile terminals with limited access to the Internet.

Wavelength Distance between points of corresponding phase in two consecutive cycles of a wave.

WLL Wireless local loop: a wireless system meant to bypass a local landline telephone system.

INTRODUCTION

The diffusion of major new technologies impacts the economy in many ways. Their widespread adoption affects the way things are produced, distributed, and consumed. New technologies influence business organization, market structure, and productivity, among other economic variables. The Internet is no exception. Its convenience, speed, low cost, and versatility are being exploited on a daily basis in ever-changing ways. Industries that have been functioning for decades in a traditional manner, such as real estate, have also become major targets of the transforming power of the Internet.

E-commerce has the capability of transforming the sectoral structure of the economy by creating new industrial sectors or subsectors, by replacing existing, traditional sectors and by changing the mix and range of services provided. Real estate (broadly defined to include builders, brokers, real estate services, and real estate finance and investment) illustrates all the mechanisms through which a traditional industry undergoes rapid transformation under the impact of the Internet. The Internet, including its economic progeny e-commerce, has already influenced the functioning of the real estate industry in direct and indirect ways. It has become a marketing and sales tool that allows a real estate business a greater reach than before. It has affected the location decision—where and how firms do business—which in turn determines the role of firms involved in brokerage, real estate development, investment, and finance. Reductions in transaction costs, coupled with the qualitatively different nature of information dissemination and communications are the primary channels through which the Internet impacts the basic structure and operation of real estate markets. The impact of e-commerce on the provision of real estate services can therefore occur through changes in either the cost or the type of services. That is, e-commerce can do the following:

Reduce the cost of providing traditional real estate services;
Expand the range, form, and content of traditional services; and
Create new value-added services.

THE INTERACTION OF E-COMMERCE AND REAL ESTATE MARKETS

The interaction of e-commerce and real estate markets involves three sets of features. First, there are technological characteristics of the Internet that have an impact on real estate related activity. Second, there are general features of the Internet and e-commerce that make its application to real estate markets especially valuable. Third, there are specific features of real estate markets that benefit in special ways from the use of e-commerce. This section considers these three forms of interaction.

Internet Attributes of Particular Relevance to Real Estate

Together with other sectors of the economy, real estate shares in some of the basic advantages of the Web, such as ease of marketing, communication, and feedback from clients, lowered costs of operations and sales, and convenience of customer service and support. Indeed, because of the dispersed, localized nature of information in real estate, the prospective gains from information dissemination, ease of comparability, and Web links are particularly significant for real estate firms (see Table 1).

Table 1 Internet Characteristics and Real Estate Firms

In addition, the Web possesses three features that are of particular relevance to the real estate industry:

1. **Graphics/visualization capability**: In its most state-of-the-art form, Web sites now allow prospective buyers and renters to take virtual tours of homes, resorts, hotels, and convention centers. Virtual tours are designed with the objective of bringing about a decrease in the number of properties physically visited before the final sale or rental.
2. **Increased geographical reach**: A unique feature of the real estate industry is that real estate is, of course, locationally specific. A physical and local presence, therefore, has generally and traditionally been critical for firms providing services for real estate transactions. E-commerce has the potential to reduce and in some cases even eliminate the need for a local presence. For example, property sales data were previously available primarily in hard copy prior to e-commerce, requiring a local physical presence for access. Large amounts of these data are now in electronic databases, making access independent of location. Not only service providers, but also buyers and sellers of a specific property, can now be represented electronically, without a physical presence. This affects the structural composition of the industry as a whole and impacts individual firms and their organizational makeup. Although the "local" aspect of real estate will perhaps never be whittled away completely, there is no doubt that inquiries about properties can now emanate from far away to a much greater degree than before. This, in turn, potentially increases the market's size and depth, making it more efficient.
3. **Collaborative and interactive features**: The establishment of new kinds of firms in the real estate sector, which deal with development and predevelopment sites, has been made possible by the multilateral, collaborative platform provided by some Web sites. Large, complex projects create logistical and coordination needs of a wide range of professionals, such as architects, engineers and subcontractors who collaborate and interact on a continuous basis. These needs are met by firms that provide Web sites acting as information clearinghouses, and through which all the participants in the project can coordinate their activities and keep abreast of the latest changes in plans, budgets, and blueprints. The Web-attributable features that make this kind of value addition possible are instantaneous comparability, interactive capability, online calculations and communication, and efficient information management.

General Features of E-commerce and Their Relevance for Real Estate Markets

Reductions in transaction costs are the most important general feature of E-commerce for real estate markets. As a closely related matter, new services will emerge where it was previously not cost effective to provide them at all. The two most important economic aspects of e-commerce that lead to reductions in transaction costs are network externalities and economies of scale; see Shapiro and Varian (1999) for a general discussion of Internet economics.

Network Externalities

Network externalities occur when the value of a network to each user rises as the total number of users increases. A telephone network is an example of this demand-side economy of scale. A telephone has limited value if only a small number of people are connected to the phone network. But as the number of people with connections rises, the value of the telephone network to each one increases. While wires physically connect the nodes on a traditional telephone network, there are *virtual networks* as well. Virtual networks, and the related membership group of a *virtual community*, are key mechanisms through which e-commerce creates value for real estate markets.

A good example of the need for a real estate virtual community is the process of selling residential properties in a particular community. Efficiently matching buyers and sellers in such a market is a complicated, but obviously critical, activity. Traditionally, it has required the physical presence of buyers, sellers, and a real estate agent who brings them together. The physical presence of these parties raises the costs in terms of both time and money. E-commerce, however, can readily create a virtual community, in which each potential buyer sorts through the features of the available homes, and then takes a virtual tour of the most promising homes. In this way, e-commerce can eliminate a significant proportion of the search costs.

Another example of a real estate virtual community consists of all the participants in a large-scale commercial

real estate construction project. These participants include developers, architects, city permit inspectors, lenders, investors, workers, material suppliers, to name just a few. For the construction process to proceed smoothly, it is critical that all these participants be aware of what all the other participants are doing on a real-time basis. It is equally clear that high-cost mistakes can readily occur if such communication fails to occur. E-commerce allows the creation of a virtual community in which all these participants are members, and through which instantaneous communication, coordination, and collaboration can occur at very low cost.

Economies of Scale

Database services often exhibit economies of scale since, as the volume of users rises, the fixed cost of creating the database can be spread over a larger number of users. One example of such a database in real estate markets is the set of information that can be distributed to potential homebuyers in a specific community concerning the characteristics of that community, such as schools, parks, and other public services. The delivery of such information can occur through a virtual community, showing that in the application of e-commerce to real estate both network externalities and economies of scale often interact, increasing the benefit of each one.

Specific Interactions of E-commerce with Real Estate Markets

E-commerce is especially valuable for real estate because real estate markets use a great deal of *intermediation resources,* the technical term for the brokers and agents who expedite real estate transactions. Examples include real estate brokers (bringing buyers and sellers together), mortgage brokers (bringing borrowers and lenders together), and insurance agents (bringing insurance companies and their customers together). These intermediaries provide valuable services, which is why real estate market participants are willing to pay their fees. At the same time, the intermediaries are only a means to an end—to complete a real estate transaction—and the market would function better if their services could be provided in a more efficient manner. Underlying the potential of e-commerce to provide such intermediation services in a more efficient manner are the two factors discussed in the previous section, network externalities and economies of scale.

Real estate markets tend to maintain a stock of vacant units, since the matching of demand and supply is always imperfect and takes time. Therefore, the effect of a more efficient process of intermediation between demand and supply is likely to be a reduction in the long-run, natural, vacancy rate. This reduction in the number of vacant units is a social benefit, since it means these resources can now be put to some other use.

REAL ESTATE MEETS THE INTERNET

Real estate firms and related businesses were among the early private sector pioneers of Internet use and have had a fast growing presence on the Web. One example of the real estate sector's presence on the Internet in its pre-World Wide Web incarnation was the real estate classified bulletin board of Prodigy, the online service which had listings for homes and other real estate. Some real estate related Web sites started in 1994. For example, the New York City Real Estate Guide Web site, created in the summer of 1994, was one of the first to offer free access to the latest New York real estate information. By the summer of 1995, the site was receiving more than 100,000 inquiries a month.

By the end of 1995 there were close to 4,000 real estate Web sites. The content of these sites, as well as the mix of real estate related firms on the Web, has changed over time. Initially, quite a few of the sites were residential real estate brokerages and listing guides, but fairly rapidly the list expanded to include commercial and retail listings, mortgage brokers, appraisers, architects, real estate attorneys, developers, construction firms, and suppliers. As investment vehicles for real estate expanded, real estate investment trusts (REITs), publicly held firms, and investment advisors also added Web sites. A particularly high proportion of real estate brokers are taking advantage of Web technology. A survey conducted by Real Estate Broker's Insider in their February 1998 issue confirmed that nearly 95% of the respondents/brokers had a Web site, and that even back then, more than 90% of the housing stock on sale at a given time was listed on the Web.

Existing private sector real estate Web sites can be categorized into three, or possibly four, types, as summarized in Table 2; see also Table 3 for different e-commerce models in real estate, such as business-to-business (B2B) and business-to-consumer (B2C).

The most basic sites provide simple information dissemination. The firm registers a Web site and develops a page giving basic company information, signaling its presence on the Internet. The second stage involves using the Internet as a marketing and customer service tool. From a marketing viewpoint, information dissemination and customer services on the Web can be monitored and analyzed differently from conventional methods. Internet

tools can now provide a firm with data on who accessed the site, which pages were visited most frequently, from where and for how long. This information contributes to improved measures of the results of promotional efforts. The promotional costs associated with the Internet have also been very low. For example, in direct mail marketing, it is generally more expensive to send a one-page color brochure to 5,000 random addresses than it is to add a component to an existing Web site.

The third stage is represented by a full-fledged office/store on the Web with transactions capability. Some firms have even developed a fourth type of Web site that exploits the multilateral coordination and collaborative capability of the Internet. As mentioned earlier, this type of Web site provides a platform that helps in fine-tuning project requirements, forecasting cost overruns, as well as dealing with logistics. This is a qualitatively new kind of economic activity in real estate, and hence a new kind of Web site, whereas the first three stages of Web sites can be seen as evolving sequentially.

E-COMMERCE AND TYPES OF REAL ESTATE FIRMS

Real Estate Brokerage Services: Disintermediation or Reintermediation?

Real estate transactions have relied heavily on intermediaries. Most obviously, brokers use their specialized knowledge to aid buyers and sellers. E-commerce introduces new opportunities, improving the availability of information, reducing transactions costs, and facilitating the searching and matching process. At the same time, e-commerce has reduced barriers to entry and these opportunities may now be available to new entrants to the industry, thus increasing competition.

Consider a specific community in which there are 100 homes for sale and 100 households potentially interested in buying such a home, the potential buyers being scattered across the United States. A key goal of such a real estate market is to match each home with that household for whom the home is the best possible fit. A physical visit of each household to each house, of course, would be prohibitively expensive, requiring 10,000 ($= 100 \times 100$) house visits. Instead, both the buyers and the sellers hire real estate agents, who have special information regarding the particular market, in order to expedite the process of matching buyers and sellers. Of course, the agents must be paid, and their fees can easily represent 6% of the value of the total transaction. Not only is such intermediation costly, but also it may be imperfect, in the sense that the best matches may go unrecognized. E-commerce can provide a substitute for the traditional real estate agent in at least three forms.

First, Web directories and specific Web pages can be created with properties "for sale by owner," allowing such properties to be listed without the resources of a real estate broker. Properties "for sale by owner," of course, existed through newspaper ads even before e-commerce, but e-commerce provides a much more efficient method for allowing potential buyers to "view" the property and ultimately to complete an actual transaction with the seller. So far, however, "for sale by owner" through e-commerce continues to be a relatively small part of most real estate markets.

Second, the information traditionally maintained by real estate brokers can be distributed much more efficiently in an electronic form across all relevant buyers and sellers. The most important example here is an *electronic multiple listing service*. Traditionally, most real estate markets maintained and updated a hard copy describing all properties for sale in that market. This was described as a multiple listing service, since it represented a cooperative effort of the real estate agents in this market. With e-commerce, the multiple listing service becomes a Web page, with a variety of major advantages, including timely updating, versatile database viewing, selection by parameters and much better graphic displays including virtual house tours. The impact is felt in both shorter, more efficient, search processes and in a smaller number of physical visits.

Third, e-mail has emerged as the alternative means of communication between brokers and their clients, substituting for time-consuming and costly face-to-face meetings, faxes, and snail mail. Constant updates and clarifications are now much more conveniently made at times that are individually and separately convenient to both parties, rather than at moments that are simultaneously convenient to them.

It appears, however, that most buyers and sellers of single-family homes continue to need the services of real-life real estate agents and brokers. These services include advice on listing prices for sellers and offer prices for buyers, individual advice on house attributes (location and quality), and referrals to other experts. Interviews with residential brokers suggest that many have chosen to develop a range of additional services, such as Web links to reliable contractors, to appliance vendors, and to local government agencies. The implication is that the Internet and real-life brokers are likely to be complements, not substitutes, over a broad range of home-buying services.

For commercial and industrial brokers in general, the immediate advantages of the Web are few, while the challenges they face appear greater. The residential brokerage system, as mentioned above, already had a database in place with shared listings, making the transition to a Web-based system of sharing information fairly straightforward. The commercial and industrial sectors, in contrast, had not created any basic systems or databases for sharing information. Despite this initial condition, the commercial/industrial brokerage sector is now a major user of the Web and is helping in the creation of a truly national real estate market in properties for sale, lease, or

rent. Individual brokerage companies have complex Web sites that provide information on the local area as well as nationwide markets. New listing services have developed that allow for database searches, both locally and nationally, for suitable buildings or sites. In addition to nationwide databases of properties, a number of firms offer capability for online rental inquiries, as well as online lease agreements.

The potential of electronic multiple listing services raises, of course, the question of competition between traditional real estate agents and the new instruments of e-commerce. This question is considered below.

Real Estate Auctions

Auctions have long been the center of a dilemma in real estate markets. On the one hand, auctions would seem to be highly efficient mechanisms for selling properties, by giving all potential buyers easy and equal access to the bidding process. For example, auctions are commonly used in Australia and New Zealand (see Dotzour, Moorhead, & Winkler, 1998). In the United States, on the other hand, auctions are rarely used and are clearly dominated by the traditional method of "listing" a property with a broker, and then waiting until the broker finds a buyer willing to pay a sufficiently high price to close the deal. What is going on here?

The answer seems to be that, at least in the United States, the traditional physical auction, taking place at a specific location and a specific time, is too constraining in terms of limiting the number of buyers that can actually participate in the bidding process. Thus, with certain exceptions, sellers find that they obtain a higher expected price using the traditional "listing" method. E-commerce, however, provides the potential to resurrect the auction and make it into a key component of many real estate markets. Electronic auctions, relative to physical auctions, have the key advantages that the auction can be left open for a considerable period of time, certainly a week, and possibly a month, and during this time there is no need for participants to be physically present. Other advances in real estate markets that are provided by e-commerce, such as large, automated databases, further enhance the potential for electronic auctions. Nevertheless, as of this writing, electronic real estate auctions have still failed to capture any significant share of the market for real estate transactions.

E-appraisals

Appraisals play an important role in real estate markets, especially as a means for lenders to determine how much money they are willing to lend to the new buyer. In the past, appraisals have often been costly, time-consuming, and inaccurate, significantly raising the costs of carrying out real estate transactions (see Diaz, 1997). E-commerce in the form of automated appraisals has the potential, however, of significantly improving all aspects of the appraisal process. The key factor here is that information on comparable sales is the raw material for appraisals, and this information can be most readily accessed and applied using modern electronic database techniques. Already, there is extensive use of electronic appraisal techniques by government sponsored mortgage agencies such as Fannie Mae and Freddie Mac, and it seems highly likely that these techniques will come to dominate the entire market. This raises the important question, however, whether the new automated services will be provided by new e-commerce firms, or whether traditional appraisal firms will be the providers of these services.

Real Estate Finance

The premium on rapid dissemination of quality information has made finance a very fertile field for Internet usage. The range of real estate finance related Web sites extends from online mortgage firms to those involved in private project financing and equity placements.

Residential Mortgage Lending

Key features of residential mortgage lending that make it suitable for e-commerce enhancements include

a. The need to reference large databases to perform credit checks on the individual and the appraisal on the property;
b. The timely nature of the credit approval process, since the buyer will want authority to proceed with the purchase as soon as possible; and
c. The large menu of choices for mortgage contracts, and the need to update these daily to reflect the most current market conditions.

From the consumer point of view, online mortgage firms provide an efficient entry point in the search for information on mortgages, rates, and fees; see the survey in Mortgage Bankers Association of America (2001). Mortgage lending, however, is highly regulated at the state level in the United States, with the result that a one-size-fits-all lending platform may well run afoul of various state laws. This means that the economies of scale that might be otherwise be available by scaling a single platform to all 50 states will at least be somewhat limited. The issue here is not whether electronic methods will be used in mortgage lending—virtually all lenders now rely on these methods—but rather whether they will simply be efficient tools used by traditional lenders, or whether they will allow the entry of a completely new set of lenders, the so-called "e-lenders."

Commercial Real Estate Finance

The needs of commercial real estate finance are being served by a host of Web sites that are bringing developers, brokers, investors, and lenders together. Developers and sellers of projects and properties make their presentations and solicit offers on these Web sites. The sites involve variations on interactive meetings facilitating free flow of information, and in some cases incorporate due diligence filtering procedures. Mortgage backed securities sites offer data and information on ratings, duration, spreads, delinquency rates, and upcoming offerings. Borrowing from other, more general, finance Web sites, there are now a plethora of sites catering to potential individual investors in REITs and limited partnerships and on speculative property purchases. E-commerce has the potential

to greatly increase efficiency and depth by expanding access to finance from personal networks to a broader set of virtual, anonymous financial markets.

Property Management

Property management companies with large portfolios of apartments need to integrate specialized property management software on the one hand with effective communication with investors, customers, and managers on the other. Both the Internet and its segmented, private version—the intranet—are now being used for to access data and analysis from these applications and then to disseminate the information. At any given time, it is possible to retrieve the latest data regarding revenues, expiring leases, and vacancies. Real-time online tracking and database accessing are made possible by this two-way transfer of processed information.

Project Management/Development and Predevelopment

The complex coordination needs of large projects are now being met by a new generation of Web sites that combine virtual community creation, online collaboration, and support services to create an environment in which the entire process from the design stage to the construction process is streamlined. The scattered activities of subcontractors, architects, engineers, developers and others can now be brought together on a technology platform under the aegis of an Internet firm in order to facilitate quick changes in blueprints, fine tuning of work in progress, and resolving supply bottlenecks. Some developers, construction firms, and contractors have their own specific, project-linked, intranets to manage their supply-chain issues. Some predevelopment oriented Web sites have developed online technology platforms for studying cost metrics, design parameters, and feasibility analysis. Digital storage of project data and information, accessible databases/blueprints, online updating/fine tuning, supply management, and project planning capabilities result in new kinds of value creation in real estate.

Relocation Services

The United States has an extraordinarily high internal mobility, with more than 20 million people moving each year. A number of Internet-based relocation services firms have appeared offering complete relocation packages (packing, shipping, trucking, etc.), with links to moving companies, listings for the destination point, short-term rentals, and other relevant information about the destination city. Some sites also come with a range of excellent tips and checklists, with both "before move" and "after move" versions. For corporate customers there are modules for cost comparisons, as well as absorption data, vacancy rates, and office, retail, or industrial spaces available.

Title and Other Property Insurance

Insurance plays an important role in all real estate transactions, since both investors and lenders will desire protection against physical risks (such as fire) and the risks of an invalid title (title insurance). Many activities of an insurance company—actuarial, claims, and billing—are highly data and informative intensive. So it is not surprising that insurance firms are taking significant advantage of Internet capabilities in managing their back offices. Furthermore, the Internet is increasingly being used to market insurance, based on the ability of firms to offer policies based on the information that the consumer provides, and for consumers to carry out comparison shopping. Title insurance is a particularly interesting example, since records pertaining to property ownership are now becoming available online. The computerization of these records together with the advent of the Internet is allowing title insurers to expand to serve national markets.

INTERNET USE: THE EXPERIENCE OF REAL ESTATE FIRMS AND CONSUMERS

The Fisher Center for Real Estate and Urban Economics at the University of California, Berkeley, carried out a limited survey of a sample of 60 leading real estate related firms in the United States and California. [The sample consisted of those firms that were members of the Advisory Board of the Fisher Center for Real Estate and Urban Economics at the University of California, Berkeley. These firms cover a wide range of real estate activities and are among the largest in the industry. See Bardhan, Jaffee, & Kroll (2000).] The survey showed that over four-fifths had Web sites by March 1999, with about one-third having already established their sites by the end of 1996 and another third with sites inaugurated in 1998 or early 1999. Brokers, lenders, financial services firms, law firms, and residential developers were among the early adopters. Commercial developers, consultants and advisors, lenders, REITs, and investment firms were among the later adopters. Those without sites were more likely to be privately held firms with a relatively narrow base of activity.

Most firms with Web sites used their site to provide information about the company and to market services. Some marketed property from their site (either as individual pieces or as part of a REIT), providing detailed information on the characteristics of buildings available, surrounding communities, and other related data. Other Web site uses included employee recruiting, providing information for members or investors, and disseminating related information on topics such as regulations or real estate markets (see Figure 1). It should be noted, however, that both the survey mentioned above and one from Georgia Institute of Technology mentioned later will become outdated in a field that is changing as rapidly as e-commerce.

From the point of view of real estate firms, a key feature of the Internet is to create initial leads that are later followed by transactions. Real estate businesses use the Internet initially for marketing and communication, and later additionally for customer support and service.

Web sites frequently lead to contacts that are then nurtured through telephone and person-to-person meetings. For residential real estate, Web activity from the point of view of the consumer includes residential searches,

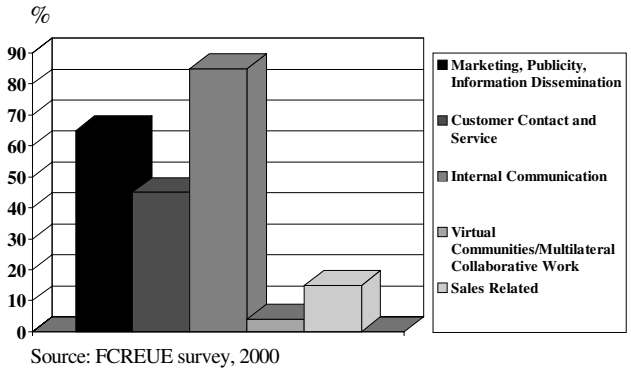

Figure 1: Web use by real estate businesses.

other housing information, and pricing comparisons (both on houses and mortgages), with follow-up contact with brokers. A significant volume of real estate related transactions is seen in the hospitality industry (making reservations for hotels and vacation homes), and to some extent in online mortgage applications (see Table 4 for how consumers and businesses use the Web in real estate transactions).

Surveys carried out by the Graphics Visualization and Usability Center (GVU) at the College of Computing, Georgia Institute of Technology, help us to understand the demographic and other determinants of people who access real estate sites. GVU has been carrying out these online surveys on growth and trends in Internet usage since 1994, and they cover issues of demographics, usage patterns, attitudes, social standing, commercial usage and occupation, among others. The authors have carried out an analysis based on GVUs downloadable raw data of the tenth survey carried out in 1998; see http://www.gvu.gatech.edu/user_surveys/.

Of the range of variables covered in the survey, the variable "Real Estate Access" is of particular relevance. These data were used to estimate a probit equation. Responses involving accessing of real estate sites at any frequency were coded as 1 and not having ever accessed any site as 0. This became the dependent variable. The explanatory variables are education (college and above = 1), gender (male = 1), age (below 30 = 1), and usage pattern variables that were coded in a similar way.

The results of the probit estimation are shown in Table 5 as marginal effects, or transformed probit coefficients. The probability of accessing real estate Web sites increases with college education (4%), youth (< 35 years; 7.5%), household income (> $75,000; 3.8%), and decreases if the Web surfer is male (6%). The probability also increases if Web usage is with the purpose of looking for product information (6%) and for shopping on the Internet (10%). Since the sample has some selection issues, the results can be considered only indicative. Perhaps the coefficient on the age variable is the somewhat surprising, but since the survey did not differentiate between accessing real estate Web sites for purposes of renting, researching, or with a view to purchasing, it is possible that young renters were a sizeable part of the sample. Of the total sample of 3,206 respondents, more than a third (1,226) had accessed real estate Web sites.

CONCLUDING REMARKS: THE EMERGING STRUCTURE OF NEW E-COMMERCE REAL ESTATE MARKETS

Impact on Real Estate Firms

The interaction of traditional real estate markets with e-commerce is having an impact on both real estate firms and on real estate markets. For existing firms, a major adjustment is to incorporate the Internet directly in their operations. At the same time, a new generation of firms is entering the market, some providing traditional services with e-commerce techniques and others providing new services of value in the marketplace.

Table 4 A Real Estate-Oriented View of the Web

Point of View of Real Estate Business	Point of View of Real Estate Consumer
• Marketing/Publicity • Customer Service • Direct, Instantaneous Feedback & Communication • Customer Support • Online Sales	• Product Information Research • Price and Attributes Comparison Communication • Ease & Convenience of Ordering, Payment, Delivery and After-Sales Service

A key question is whether new services will be provided primarily by new, specialized, e-commerce firms, or by already existing firms in the industry. Generally speaking, new e-commerce firms will have better information regarding the new electronic techniques, while the existing firms will have a comparative advantage in information regarding the real estate market itself. The "winners" will be those firms, new or existing, that can combine both areas of competence to create value-added service products for the real estate industry. In this respect, the adjustment of the real estate industry to the Internet is similar to that of established firms in many other economic sectors.

In the areas of real estate brokerage and real estate lending, it appears that traditional firms are likely to continue to dominate the real estate service markets. In the real estate brokerage area, control of new real estate listings and multiple listing services by traditional firms should allow these firms to continue to dominate the market. In the real estate lending area, automated techniques were rapidly adopted by most existing lenders, thus taking the initiative from new e-commerce entrants. In both cases, however, the traditional firms will have to continue to innovate and adopt new electronic techniques to sustain their dominance.

In the areas of real estate appraisals and construction project management, in contrast, new e-commerce firms may well dominate. In the case of real estate appraisals, the existing industry may be too slow to adopt the new electronic techniques, and thus ultimately may lose their market share. An important factor here is that the existing industry consists largely of very small firms, often just individuals for whom it is not feasible to adopt the new techniques. In the case of construction project management, basically a whole new service area is being developed, so by its nature it requires new firms.

There is also the question whether the adoption of e-commerce techniques in real estate service markets will create incentives for mergers across service lines, creating multiline service providers. For example, is the merger of real estate brokers, lenders, and insurers into single mega-sized firms likely? E-commerce can provide incentives for such mergers as a result of the network externalities and economies of scale discussed earlier. Specifically, e-commerce techniques may provide an important means to bundle and cross sell real estate services. On the other hand, regulatory prohibitions are the main reason that existing real estate service providers have not already merged in order to bundle and cross sell their services. Thus, the creation of highly integrated e-commerce real estate service firms would require a significant change in the regulatory environment, something unlikely to happen rapidly.

Impact on Real Estate Markets

Decreasing transaction costs and relatively low barriers to entry have increased competition in some sectors of the industry. Costs have been lowered by shortening the transaction cycle and by precise market targeting, in addition to the savings in information dissemination. A major open issue is whether the Internet and e-commerce will have a significant overall impact on the demand for various types of real estate (see Table 6). There is some mixed evidence on the impact of e-commerce on retail real estate markets. Schlauch and Laposa (2001) reported that retailers who incorporate online operations into their overall real estate strategy manage to lower somewhat their real estate related costs. At the same time, new electronic retailers—that is, retailers who conduct business purely over the Internet—are increasing the demand for warehouse space.

Table 6 Potential Effect of Internet and E-commerce on Real Estate By Type

Category of Real Estate	Through Type of Internet Related Activity
Office	Telecommuting
Residential	Telecommuting
Warehouse	E-commerce
Retail	E-commerce
Hotels/Resorts	Online Reservations

In the long run, the fast growth of electronic retailers and the slower growth of traditional retailers may create a shift in real estate demand from traditional retail space toward warehouses. There might also be a net contraction in total real estate demand, since the electronic retailers will likely require less space per dollar of sales. In the short run, however, the total demand for real estate may actually expand, since traditional retailers may contract very slowly, while the new electronic retailers are expanding very rapidly.

Whatever the details, the fundamental point is that the real estate markets will be most influenced by those firms that can create value at the intersection of real estate and Internet technology.

GLOSSARY

Agent, real estate Another term for real estate broker.

Appraisal, real estate Estimation of market value of a property or home as concluded by a third party, usually a licensed professional.

Broker, real estate An entity or person who brings together potential buyers and sellers of real estate and generally charges a fee for the services. In most states, real estate brokers must pass exams to be licensed. Brokers may also act as intermediaries in leasing transactions.

Commercial real estate Real estate properties used for commercial purposes, including office buildings, shopping malls, and hospitals, among others.

Development, real estate The process of transforming vacant or underused land into residential or commercial real estate.

Economies of scale Situation in which the average production costs fall the greater the volume produced.

For sale by owner Properties that are listed for sale by the owner, without the use of a real estate broker.

Intermediary, real estate A firm or individual who provides valuable services to enable or facilitate a real estate transaction.

Mortgage A financial instrument that is used to borrow funds to enable the purchase of real estate. The property is used as collateral, whereupon a lien is placed on it as security for repayment of the debt.

Mortgage Backed Securities (MBS) A security containing a large number (pool) of individual mortgages. When investors purchase one unit of the MBS, they receive a prorated interest in the pool.

Multiple listing service A service generally organized by local real estate brokers, which gathers all of the local property listings into a single place so that purchasers may review all available properties from one source.

Network externalities The quality of a network that its value to each user rises as the total number of users increases.

Real estate Land and the structures built on the land. The structures may be either for residential housing or for commercial uses.

Real estate investment trusts Publicly traded companies that hold a portfolio of real estate properties, similar to a mutual fund, but which hold properties, not common stocks.

Residential real estate Real estate, which is used for housing, including single family, multifamily (apartments), condominium, and cooperative formats.

Transactions costs, real estate The costs of carrying out a real estate transaction, including fees for appraisers, brokers, and other intermediaries.

Virtual community and virtual network A group of individuals with a common association or activity but connected only through the Internet.

Virtual tours An Internet method that provides the visual experience of "walking" through a property.

Research on the Internet

Paul S. Piper, *Western Washington University*

INTRODUCTION

Whether one is searching for inexpensive airline tickets, or looking for information on corpus collosum bisection, the Internet is an invaluable resource. Studies indicate that students, both graduate and undergraduate, are using the Internet for research in unprecedented numbers and in some disciplines more frequently than any conventional resources (Davis & Cohen, 2001; Davis, 2002). Faculty, scholars and other researchers are not far behind (Zhang, 2001). The Nintendo generation is consistently more acculturated to using online resources than previous generations, and one can expect this trend to continue into the foreseeable future. How did we get here?

In July of 1945 Vannevar Bush, Director of the Office of Scientific Research and Development, published an article in *The Atlantic* entitled "As We May Think" (Bush, 1945). In this article, Bush envisioned a research tool that would link researchers globally, place the contents of libraries at a researcher's fingertips, and monitor what pathways of research each researcher utilized, so that pathways could be easily replicated. The research tool was dubbed the Memex. An interface of software, system and hardware, the Memex was conceptualized exclusively to accelerate and enhance research. Today, the Internet is rapidly actualizing the conceptual Memex. Within the past 20 years the Internet has radically altered the way research is conducted in nearly every area of academia, commerce, and society.

The Internet was initially created to enable computers at universities and government facilities to share files, thus enabling computer scientists and researchers to exchange and disseminate data and information over great distances. The initial experiment, dependent on the creation of packet switching, by the ARPAnet project, achieved initial success on Labor Day weekend, 1969. Since then, the primary Internet developments have been rapid and, with the exception of electronic mail (e-mail) and entertainment applications, primarily research driven.

By 1971 there were 23 hosts connected: all universities, government research facilities, developmental companies (such as BBN), and independent research facilities. By 1973, the Internet was international, with a host computer at the University College of London, England. From there on, the growth has been quite literally explosive.

The development of research enabling and enhancing software for the Internet has followed suit. In 1971 Ray Tomlinson invented a piece of software that may represent the most common Internet use today—e-mail. Within months, Lawrence Roberts, the chief scientist at ARPA, wrote the first e-mail management program, enabling the development of electronic lists (such as LISTSERV), which have become a critical component of scholarly communication and research. 1974 heralded the creation of Telenet, the first commercial packet data service, which opened the door for file transfer between any computers on the network.

Early Internet researchers, primarily academics, used these applications to share and disseminate information, data sets, and manuscripts. Unlike snail (postal) mail or fax, information could be instantly disseminated to all the members of an online community of scholars, and

feedback was potentially instantaneous. Also unlike fax or snail mail, data were instantly computer useable.

Virtual space arose in 1979 with the creation of multiuser dialog software, originally created for gaming interests, and USENET. USENET and bulletin board systems (BBSs) represented a quantum leap in Internet popularity and information sharing. The 1980s saw the growth of networks dedicated to various research groupings, such as NFSNET and BITNET. Internet relay chat was developed in 1988.

Until HYTELNET (the first Internet directory) and Archie (the first Internet search engine) were released in 1989, researchers were dependent on their own haphazard exploration, the word of colleagues, and information posted on mailing lists and newsgroups to identify Internet content. Networks, and network nodes (computers on the network), were extremely limited and regulated. There was little or no open access for outside users. Furthermore, users needed to be relatively skillful at using the UNIX operating language to extract content from the Internet. Archie changed forever the way content was accessed on the Internet.

The advent of Gopher software in 1991, and its search software, Veronica and Jughead, in 1992, completed the conceptual shift of the Internet from a series of nodes on a network to a collection of databases, virtual libraries, and document delivery systems. Searches could be executed and relevant information returned, printed, or downloaded. Search results were low-cost, increasingly global, and instantaneous. In 1992, the number of Internet hosts increased to exceed 1,000,000 in 40 countries.

At this time there was little commercial content or traffic on the Internet, and it was essentially a playground for online searchers and researchers. The Internet Hunt, an online game where a player located the answers to questions in the most efficient way, gained enormous popularity. The Internet was inadvertently creating a culture of searchers.

The World Wide Web (WWW), created in 1992, remained relatively obscure until the creation of the Mosaic browser in 1993. During this year, the growth of Gopher was 997%; the growth of the WWW was 341,634% (Zakon, 2001). While the Lynx browser (a graphicless browser) enjoyed brief success, and is still used faithfully by some, it has for all practical purposes disappeared. Netscape followed on the heels of Mosaic, and researchers have seldom looked back.

On a different front, Project Gutenberg, begun in 1971 by Michael Hart at the University of Illinois, began hosting entire books (classics and older texts) in the public domain in ASCII text format. These texts could be read and searched online, or downloaded. Hart's philosophy was based not on that of a lending library, but on what he termed "replicator technology." Replicator technology advanced the theory that every digital file possessed infinite possibilities for replication. Project Gutenberg also launched the phrase "e-texts." Gutenberg, and similar projects, such as Net Library, has enormous value for researchers and scholars because they allow full-text online searching of manuscripts.

Within academic research, academic journals are the most critical medium for reporting and tracking research. The Internet offered not only another medium for dissemination, but also an opportunity to incorporate other e-text features, such as hyperlinks, into the journals. By 1994 there were over 40 electronic journals on the Internet (Roes, 1995).

In 1994 the first true WWW directory, Yahoo!, was created by David Filo and Jerry Yang at Stanford University. During the same year, the first WWW search engine, Lycos, was invented at Carnegie-Mellon University. There is no way the import of these two inventions can be overestimated.

As the Internet has grown to several billion pages, so has its usability as a research tool. Of particular note is the Internet's value to developing nations (Warren, 1995). Information access and storage is problematic in developing nations, with the adverse factors of climate, space, economics, and censorship impacting text-based collections. The Internet, with its plethora of free information, is viewed as a literal godsend, allowing information to flow relatively unfettered from the information rich to the information poor.

DIRECTORIES

Internet directories represent an attempt to organize Internet content, and are invaluable for conducting research on the Internet. While directories are often referred to as search engines, they are an entirely separate endeavor, and they often incorporate search engine software in their enterprise. Directories range from a simple list of hypertext links related by subject, to an extensive and highly detailed taxonomic organization of subject categories such as The Open Directory Project.

While directories vary greatly as to design, scope, and purpose, there are several qualities that they share. Directories are typically created by people, so there is at least some degree of human judgment that influences the selection of Internet sites included. This gives them, potentially, an inherent authority, but in some cases can also bias them. Directories are organized according to particular, and often unique, schema. And directories often feature site descriptions, annotations, and/or evaluations. On the negative side, directories are limited, sometimes severely, in scope and content. Since sites are typically reviewed by people, and annotations or brief descriptions created, directories are labor-intensive, and this naturally limits their size. For the same reasons directories are extremely difficult to keep up-to-date. Given these constraints, however, directories created by academics or other subject authorities are a critical resource for researchers.

The first online, hypertext directory on the Internet was HYTELNET, a worldwide directory of telnet sites on the Internet compiled in 1991 by Peter Scott of the University of Saskatchewan. The directory was multidimensional, and featured library catalogs, databases, bibliographies, BBSs, government sites, and a number of other resources. Its major flaw was the alphabetical organization, which created lengthy, unwieldy lists. Furthermore, content was often impossible to deduce from the nomenclature. These faults aside, however, HYTELNET represented a major breakthrough in accessing Internet information. One of its greatest assets was the list of links to library catalogs

from every continent. Complete with log-in instructions, this access was the first time researchers could access libraries across time and space and examine holdings.

The next major development in directories was the creation of Yahoo!. Yahoo! was conceived as a personal map of the Internet, highlighting sites useful to Filo and Yang's Ph.D. research, as well as Web sites of personal interest. The magnitude of content eventually necessitated a division into categories, and subsequently subcategories. Yahoo! celebrated its first million-hit day in the fall of 1994, and a new era of locating content on the WWW had successfully germinated.

The number of Internet directories has continued to multiply, even as their scope divides. Directories with vertical subject emphasis have emerged, often hosted by academic societies, libraries, universities and research facilities. These directories are extremely valuable for research purposes. As directories propagated, metadirectories, or directories of directories, materialized. These are exceedingly useful tools for locating directories that index narrow and obscure subject areas. A search for a subject combined with the phrase "Internet directory" (for example, herpetology and "Internet directory") in a good search engine will often yield valuable results.

While most large, general directories such as Yahoo! or The Open Directory Project represent the compilation of numerous contributors, there are a great number of personal directories that are exceedingly useful for researchers. These vary in size from a short list of related links to an extensive directory such as Alan Liu's Voice of the Shuttle, a humanities directory hosted by the University of California, Santa Barbara.

Rings

Rings, although a different entity, share some characteristics with Internet directories. Rings exploit the interconnectivity of the Web by linking sites within a particular specialization. Rings consist of member sites which all have a stake in the authority and credibility of the entire Ring.

While the creation and maintenance of early rings, such as EUROPa, were left to the participants, commercial software and servers now offer ring creators and participants the luxury of HTML templates, scripting language, and automatic updates. Some of these commercial services, such as Yahoo! Rings and WebRing, offer directories of the thousands of Rings using their software or servers. Although rings are particularly popular in the areas of sports, recreation, entertainment, and other areas of popular culture, the serious researcher should not neglect this resource, since they often contain sites that are otherwise unavailable. Some Ring sites require registration to use, while others allow casual users to browse freely.

Weblogs or Blogs

Web logs, or blogs, are a recent hybridization of personal directories, electronic newsletters, clipping services, and alert services. Blogs are collections of links to Internet information in specific areas that the author feels are useful and important. Typically authored by one person, blogs vary highly in content, scope, and purpose. They are often idiosyncratic and represent strong opinions and passions. They are updated frequently and often feature brief annotations. Some blogs offer search capabilities. Directories of blogs exist on many of the major Internet directories.

SEARCH ENGINES

Before a user can effectively utilize Internet information, he or she needs to know that the information exists. The most widely used tools for locating information on the Internet are commonly called search engines. The name is somewhat of a misnomer, however. What Internet users commonly refer to as a search engine is actually an information retrieval system (Liddy, 2001). A search engine typically consists of several components: a document locator, a document processor, a query processor, a search and match processor, and a relevancy ranking delivery system.

Pre-WWW Search Engines

The pre-WWW search engines were rudimentary products based on early database applications, but unlike database software, they were dealing with a chaotic, often disconnected collection of data, information, and files in varied formats. The primary problems for researchers with the rudimentary search tools, Archie, Jughead, and Veronica (which searched Gophers), and wide area information servers (WAIS) were three-fold. File names or Gopher menu headings, the primary search field, often had nothing to do with content. There were many discrete networks and no one tool searched all. And each had different commands and handled information differently. WAIS deserves special mention because it was the first full-text Internet search tool.

Gopher was fated by the fact that its creation was virtually simultaneous to the creation and release of the World Wide Web by Tim Berners-Lee at CERN in 1991. While the WWW floundered until the creation of a decent browser, Mosaic in 1993, use of the Web grew 341,634% and Gopher 997% over the next year, and Gopher, Veronica, and Jughead faded into relative obscurity.

WWW Search Engines

With the advent of the WWW and capable Web browsers, Internet search engines began to actualize the capabilities of what researchers had come to expect when using commercial database services. The evolution of these information retrieval systems has been extremely vigorous.

The primary characteristic of WWW search engines is that they typically search the full text of the documents they have indexed. Full text searching had existed on the Internet before these applications but it suddenly became the status quo. This represented a departure in technique for many researchers, who were accustomed to authority language such as descriptors and subject headings.

Web search engines obtain their index content in several ways, but the most prominent is by using bots, spiders, crawlers, or other intelligent agents. These automated agents utilize hyperlinks to "travel" the expanse of the Web, and identify and index Web content. Most search engine providers have numerous crawlers working

in concert. Providers also rely on content that is submitted by content creators. Even today, none of the most sophisticated Web search engines come close to indexing all Web content. There are several reasons for this that will be discussed later in this section. Once the content is identified, the document processing component identifies the elements that require indexing, removes stopwords, performs stemming (identifies the root of a word for truncation searching), and stores the indexed terms in an inverted file. The program then weights the terms, typically by weighting the term's position within the document's fields, the number of occurrences of the term, and other components. This component differs between search engines, and leads, in part, to different result lists and/or differing position of results when the same search is submitted to several search engines. Different search engines also process varying amounts of information from each site, with some concentrating on the first few pages, others indexing the entire documents. This is why it is critical for serious researchers to use more than one search engine. When all these processes have been completed, the results are stored in an index, or searchable database.

Components of a successful search consist of the user's query, and how that query is constructed and processed. Competent researchers successfully strategize their search by teasing out key words, synonyms, and names and exploiting the advanced features of the search software (fields, truncation, domain, and phrase searching), which differ from engine to engine.

Internet search engines are unique with regard to what search options they offer users and how they process a search query. Search options include using natural language, Boolean operators, truncation, proximity operators; and/or searching by phrase, field, file type, language, case, URL, or "links to URL." They typically do not include authority vocabulary (descriptors and subject headings), although some software allows for metatag field searches. The lack of consistent authority language is still a major obstacle to increasing relevance, but the range of content and content providers on the Internet makes authority control virtually impossible.

Search engines also vary considerably in how they create relevancy rankings for search results. The most common methods include how often the term or terms occur; in what proximity they occur; in what fields they occur; and how many links exist to a Web page. In addition, it is becoming more common to charge money for search return placement. This procedure, called "paid placement," guarantees those willing to pay placement within the top results. Paid placement is seen as a detriment to fair relevancy, but typically involves commercial (dot-com) sites which often do not factor highly in research. The more upright search engines either segregate paid results or do not accept paid placement.

How results are displayed also varies considerably, with relevancy-ranked annotated lists the most common search outcome. Some newer search engines employ artificial intelligence programs to process requests and display results as related topics, subcategories, and alternative topics (for example, a search for "Dolphins" might return the categories "Marine Mammals," "Whales and Dolphins," and "Miami Dolphins"). Users can then modify their original search based on the most accurate category. While search engines of this nature are designed primarily for novice searchers, the categories and concepts returned can prove valuable by offering the researcher additional or related terminology.

General search engines are considered horizontal search tools, in that they search across all subject areas. Specialized search engines are vertical search tools and address a researcher's need to explore in depth a particular subject area. They have evolved rapidly and exist for numerous subjects. A search on a general search engine for specialized engines, for example ("search engine" geology), will generally give researchers the tool they desire, as will directories of search engines such as Beaucoup or Search Engine Colossus.

Meta-search engines are search engines that have no database or inverted file of their own, but run a query simultaneously against a set of independent Internet search engines. Some meta-search engines allow the user to configure which engines are searched, while others operate with default settings. These tools can prove extremely useful for obscure topics because they cover so much ground. Their major drawbacks are that meta-search engines cannot handle customized searches well, due to the vagaries of how individual engines handle a search, and some of them fail to remove duplicates. Their software continues to improve, however, and some of the new generation engines are proving extremely useful for a wide range of needs.

In addition to search engines, a number of commercial products exist which add value to results in terms of organization, categorization, storage, and note integration.

Virtually all fee-based professional journal indexes and databases now have Web interfaces. These can often be readily accessed through local libraries. Many of these databases index Web sites as well as journal articles. Versions of government-funded databases such as Medline, Agricola, and ERIC are free of charge to all users and offer excellent user interfaces. There are also some terrific databases such as Ingenta and Scirus that offer document delivery options at a cost, but offer searching and bibliographic information free of charge.

Ask an Expert Services

These are typically commercial services that are modeled after a library reference service, but actually have their precursors in BBSs such as EasyNet. A user is connected with an "expert" in the chosen field, who then provides research assistance. While these services are generally free, some do cost. And while they can prove useful, their primary drawback is their lack of screening "experts."

Maximizing Search Engine Effectiveness

The difference in all areas of search engine performance is truly staggering. For this reason, an effective researcher needs to consistently use and master several search engines, exploiting their differences. It is critical to explore help pages, use advanced search options, and practice repeatedly. Keeping current on search engine developments is also critical, since this technology changes daily. For

this purpose, academic and trade journals, newsletters, and various online publications dedicated to this technology are invaluable.

Document Code

Advances in HTML code, such as extensible markup language (XML), enhance machine-readable structure within the document itself, thus augmenting search precision. XML, an extension of SGML, is a structural ordering system which defines a range of discreet document sections. XML enables generic SGML to be served, received, and processed on the Web similar to HTML, thus making available a number of discrete document sections or fields that are not currently available in standard HTML. The potential growth of XML holds great promise for researchers dissatisfied with the lack of precision in the structure of standard HTML documents.

The Invisible Web

The Invisible Web refers to information on the Internet that has value but is not typically indexed by search engines. There are two general categories of material that go undetected.

The first category consists of information not detected by the various crawlers and spiders search engines use to index Internet content. This lack of detection is occasionally due to Web pages that possess no external hyperlinks. Pages of this type are considered disconnected. If a crawler cannot get into the content, it cannot index it, and since most crawlers rely on hyperlinks as their conduit, if there are no links in, crawlers cannot find them.

Site depth also accounts for invisibility. Some search engines do not index entire documents, but specify a certain percentage or number of pages they do index. Others only index pages to a certain level, which means that information several levels below the home page may not be indexed. Information on site coverage is characteristically found in the "About" information on a search engine site, and it is well worth investigating when evaluating search engines for research potential.

Further information can remain hidden from search engines because it contains content that cannot be interpreted by a crawler. Among the thousands of file types on the Web, there is only a handful that crawlers capably identify. Some crawlers are more adept than others, and a few search engines allow the user to specify file type, retrieving file types with extensions such as doc, pdf, ppt, gif, jpg, mpg, aud, and others.

Other obstructions to crawler technology are online forms. Forms act like gates that need to be entered before content becomes available. Crawler technology is coevolving and will soon be capable of passing through at least some forms.

Dynamically generated pages are yet another impediment for crawlers, since these are pages created by scripting language in response to a database query, form, or other user interaction. These vary dependent on the user request, and it is impossible to index them all. The best a crawler can do is index the interface gate, which may be adequate if enough terminology is provided by the page author.

There are also many specialized databases of journal articles, reports, newsletters, corporate and organizational information, and so forth, whose content is hidden from crawlers. To search these databases effectively, one needs to identify the database and search it independently. An Internet search engine will not return Medline or ERIC results. These remain invisible to crawlers.

The other primary category of invisible information is hidden information. Hidden information is not detected by crawlers because the author or webmaster desires it so. Webmasters use different methods of blocking access to sites (Sherman & Price, 2001). Blocking protocols, such as the robots exclusion protocol (which creates a list on the server of files not to be crawled), or "noindex" metatags will keep many crawlers out. Passwords are a more effective method of thwarting crawlers and keeping information private.

INTERNET COMMUNICATION

Electronic Mail

Electronic mail was originally created as a convenience or entertainment but quickly became a vital component of the research process, giving researcher's global access to people and information instantly. A major breakthrough occurred when it was discovered that the transmission of documents, graphics, presentations, and other files was possible by attaching them to e-mail messages. This quickly became an invaluable tool for researchers who were jointly writing and editing. In addition, e-mail grew in popularity as an alert service for articles, publications, products, conferences, and other events of interest to scholars and researchers.

Mailing Lists and Newsgroups

An evolution of e-mail that has become de rigueur for many researchers is that of mailing lists and newsgroups. Mailing lists employ software that disseminates or makes available information, commentaries, and questions simultaneously to all subscribers of the list. The first mail list designed specifically for research, THEORYNET, originated at the University of Wisconsin in 1977. In these, and all other mailing lists on ARPAnet and the early BITNET, human intervention was required to add subscribers to the list and distribute the e-mail. By 1985, BITNET had replaced ARPAnet as the academic and research network. Their mail list, called LISTSERV, was also person-moderated, and experienced enormous delays in both subscriptions and mail delivery.

LISTSERV software, invented in 1986, automated this process. Through automation mailing lists have flourished. Catalist, the primary directory of LISTSERVs, listed 210,949 at the time of this writing. While the term LISTSERV has become genericized to represent any similar software or group, there are numerous other push mailing list technologies, such as (Majordomo or Gnu) in existence, and other directories that index them.

LISTSERVs can be moderated or unmoderated. Moderated lists are mailing lists that employ a human editor to filter submitted messages before they are distributed. Unmoderated lists disseminate to all members without

human intervention, although most software is now capable of some filtering. Unmoderated mailing lists tend to be larger and function more quickly. LISTSERVs can also be public or private. Public lists have open enrollment, while private lists require members to meet specific membership criteria, such as enrollment in a professional organization, employment or enrollment at a specific institution, or designated academic or professional status.

Newsgroups are similar to mailing lists in that they sort and distribute mail according to subject specialties, but they utilize pull technology, which requires users to access a server to read messages, rather than receive them as e-mail. Newsgroups generally thread, or group their messages, into topics, giving users the option to choose which discussions, within a general topic, to interact with. Newsgroups have become a major component of online instruction.

USENET is the largest news group on the Internet to date. USENET was originally created in 1979 by graduate computer science students at Duke University and the University of North Carolina as an alternative to the ARPAnet, which many students and researchers contended was too restrictive. USENET evolved into hundreds of subject groups, arranged hierarchically. Examples are alt (alternative), humanities (fine art, literature, and philosophy), sci (the sciences), and soc (sociology and social concerns). USENET groups evolved into one of the most vibrant areas of intellectual, cultural, and recreational discourse on the Internet. They have recently been subsumed by a commercial search engine, but remain fully functional, and searchable, including the archives. They contain a plethora of extremely unique information, but some care should be exercised since identity and informational claims are not verified. Even with these limitations, USENET represents one of the most underused research tools on the Internet. There are currently many other mail and newsgroups, many of them managed by commercial interests.

Bulletin Board Systems

Bulletin board systems are computer systems used as information centers and forums for particular interest groups or locations, and as such had limited, though unique usability. BBSs typically required individual dial-up access and faded out as the Internet developed. It could be argued that portals represent an analogous conceptual approach.

Chat Rooms and MUDS

Multiuser dungeons (MUDs) were inaugurated at England's Essex University in 1979 for the purpose of allowing multiple users to create imaginary worlds and play fantasy games. Along with their successor MOOs (object-oriented MUDs), these virtual spaces have enormous potential as brainstorming and discussion venues. They are currently underused for this purpose.

Online Conferences

Online, or virtual conferences, are online versions of a physical conference, capitalizing on the unique features of a Web environment. Online conferences may utilize a combination of virtual space (MUDs and MOOs) and other real-time chat technologies; online video and audio feed; white board technology; e-mail and mailing lists; online reports, articles, and supplementary documents; and related hyperlinks. Since virtual conferences typically model academic conferences, virtual conference attendees register, often paying money, choose a conference track or tracks, and read, listen to, or watch the conference presentations and any supplemental material provided. The track participants typically join a mail list or partake in chat sessions, which mirror conference discussion and networking, a key element of conferences. Presenters are generally available via e-mail for questions and discussion as well. Conference products include bibliographies and proceedings, as well as electronic updates.

While there are numerous criticisms of online conferences, there are many advantages. There is no travel involved, thus allowing underprivileged participants and those with time constraints to participate; the cost is minimal; materials can be read and presentations attended in a flexible manner and over long periods of time; hyperlink technology provides a plethora of supplemental materials; and e-mail connectivity allows interactivity with participants and presenters, many of whom are essentially off limits at nonvirtual conferences.

LIBRARIES AND THE INTERNET

Providing research access and assistance is one of the essential functions of libraries. With the advent of the Internet, there has been much discussion as to how useful libraries remain. The fact is, however, that libraries have embraced the Internet since its origin and are reliant on it for operation. They are extremely proactive in the development of research-based Internet applications and services, and remain critical in assisting in almost all aspects of Internet use and evaluation.

Academic libraries, often affiliated with the early ARPAnet partners, established an early presence on the Internet by hosting their catalogs online. Since these academic libraries were among the most prestigious in the world, this sudden, global sharing of collections enabled researchers to locate rare or previously unknown materials and expanded the scope and depth of their research enormously. As the Internet developed with the WWW, libraries migrated to the Web as the primary medium for catalog delivery and other services.

The technological development of online catalogs over the Internet led to cooperative or union catalogs. MELVYL, a union catalog comprising all the University of California schools, began development in 1977. HYTELNET was the first Internet software to provide access to global library catalogs. Libdex is a contemporary Web-based directory and search engine for libraries on the WWW.

Libraries without Walls

The concept that the materials contained within the physical structure of a library no longer limited the library's collection first surfaced in the mid-1980s. Access to library

catalogs from anywhere in the world accelerated the development of interlibrary loan, or the ability to borrow materials from other libraries. Access was suddenly on equal footing with ownership. Electronic access in concert with interlibrary loan expanded the concept of the library far beyond its physical space.

Online Computer Library Center, Research Libraries Information Network, and other similar services provide Internet networks that share copy cataloging, allowing catalog updates instantly on a global scale, and global access to collections, thus greatly accelerating the speed and precision of interlibrary loan.

Current access to databases, directories, full-text books and journals, and other digital collections has continued to expand the concept of the library without walls.

Librarians and the Internet

It is safe to say that librarians continue to perceive the Internet as a double-edged sword. The primary complaints are a lack of content quality and quality control, a lack of organization, and the labile nature of much Internet material, which frustrates attempts to catalog and retrieve it. Another fear, often unstated, is that the overwhelming popularity of the Internet could, at least partially, replace libraries and librarians. On the other hand, libraries embrace the Internet as a medium for hosting collections and databases; for exchanging books and other materials; for creating authoritative directories and portals; for doing reference; and for a host of other uses. Librarians are also key teachers of Internet literacy. Rather than diminishing the need, the Internet has in reality created an increased need for librarians and other information professionals.

Internet Reference Service

The ability to answer reference queries at a distance has always been an important component of library service and has proved invaluable to research. Distance reference queries were initially communicated by letter, telephone, and fax. E-mail gives librarians a tool for answering queries and/or sending research strategies without constraints of time and locale. This service has become instrumental for distance learning.

A new development in e-mail reference service is the development of consortia that share and disseminate requests, often automatically. Internet users submit a request form whose databased fields are linked to another database of subject experts. Based on the topic, the request is sent to a librarian (who may reside in an entirely different locale) with expertise in that field. The most comprehensive example of this service at this time is the Collaborative Digital Reference Service hosted by the Library of Congress and piloted in the year 2000. This service is global and provides professional reference service to researchers 24 hours a day, via an international digital network of libraries and related institutions.

Some libraries have experimented with real-time interactive video reference over the WWW. Dependent upon compatible systems and webcams, this technology has not developed quickly, but there is optimism for future applications.

Cataloging the WWW

Librarians and professional researchers, as well as commercial enterprises, have been struggling with methods of cataloging the Internet. In many ways the task is fruitless, since millions of pages of information are added daily, and a significant fraction of those disappear or change location. Still, this has not curtailed efforts.

There are two primary approaches in the library world. The first is selective cataloging, and this is commonly practiced by libraries of all type. It consists of cataloging Internet information that fits selection criteria, such as quality, authority, longevity, uniqueness, and so forth. Information of this type is identified by individual bibliographers and selectors, as well as cooperatively. The second approach is to somehow identify Internet resources by subject headings or other authority languages.

Online Cooperative Library Center (OCLC) is exploring both of these approaches. The Dublin Core/Metadata Initiative calls for the development of interoperable online metadata standards, analogous to Library of Congress subject headings that support a broad range of purposes and business models. The resulting descriptors would be inserted into the metatag field of a Web document, hopefully yielding a much higher degree of search precision.

While the Dublin Core project addresses code-based content, OCLC is also mainstreaming a project called CORC. CORC is an attempt to create a shared database of librarian-selected and cataloged Internet sites. CORC uses an on-the-fly cataloging process, pulling data automatically from HTML fields. Membership in the CORC collaborative enables the member libraries to access all CORC Internet records. CORC members will have access to an ever-increasing number of stable, superior Web documents and information. Users of these libraries will reap the benefits.

ELECTRONIC JOURNALS

The linchpin of academic research has, and continues to be, academic journals, although there are signs this foundation is eroding slightly due to economic concerns. In addition, traditional academic journals are losing their current awareness function to mailing lists, electronic journals, electronic alert services, and other Internet-based services.

What we currently know as electronic journals evolved out of projects such as ADONIS, which replicated text-based journals by placing article images on CD-ROM. Full-text databases on CD-ROM were also precursors. The first electronic journals on the Internet began appearing in the late 1980s, and soon after several directories appeared. The largest of these was sponsored by the Association of Research Libraries and featured the LISTSERV NEWJOUR-L as an alert for new additions. Dubbed the Directory of Electronic Journals, Newsletters and Academic Discussion Lists, the directory contained 440 entries by April 1994. These early journals were accessed in a variety of ways including e-mail/USENET, Gopher, FTP, WAIS, and WWW, with ASCII being the primary format (Roes, 1995).

The increasing popularity of the WWW as a medium for accessing and disseminating information has created

a profusion of Web-based electronic journals, as well as other publications such as newsletters, newspapers, magazines, books, and hybrids. While many of these are electronic versions of print versions, some are unique to the Web. Regardless, there are considerable advantages to the Web format which include quicker peer-review; electronic preprints; full-text searching; no article size limitation; quicker delivery time; open access; exploitation of hyperlinks to connect to other related articles, authors, or supplemental material; the inclusion of multimedia and other graphic, auditory, or database file components into an article; links with online discussions, surveys, and other interactive components; and "spaceless" archival storage. While the migration of prestigious academic journals to WWW format has been more cautious than originally anticipated, there are currently very few academic journals that do not offer some type of Web presence. Even many text-only journals are commonly using the Web as a source of supplemental material.

Many specialized electronic journals are now available for table of contents browsing, and in some cases key word searching of article titles and abstracts. Some large publisher aggregates now offer search features similar to journal databases, free of charge.

EVALUATION OF INTERNET CONTENT

Faulty information on the Internet is, and will plausibly always be, a major problem. The fact that nearly anyone can publish on the Internet creates both an environment of exhilarating freedom, and one that lacks any overall quality control. The filtering and editing traditionally furnished by content providers is now largely in the hands of the Internet user. Superimposed on the particularities of individual sites is a major structural misconception. In traditional venues for the exchange of information, there is a frame or package that reflects content. This frame creates reader or viewer expectations of content. A popular magazine, for example, creates the expectation of content that differs radically from that of an academic journal. The same can be said of newspapers, radio, and television. For example, some radio talk shows are liberal, others conservative; some television stations feature primarily comedy, others old films, and so forth. Readers, listeners, and viewers are either immediately aware, or quickly become aware of these differences. With the Internet, however, the package, for example, a list of results from a search (which is roughly analogous to a table of contents) may contain content that differs fundamentally with regard to quality and orientation. Wise Internet use, or Internet literacy, can be achieved by following some fairly common-sense guidelines.

Authority and Bias

Innate within the information contained in any publication is its authoritative credibility. It is no different on the Internet. Information hosted by the National Library of Medicine or the Louvre has a credibility that may be lacking from a personal Web page. A personal Web page constructed by an acknowledged authority in the field has a credibility that a personal Web page constructed by a high school student does not have. Furthermore, even though we recognize that all information is on some level biased, the degree of bias varies considerably between information hosted by NASA and that hosted by a racist group.

URL Clues

One quick way of evaluating quality is by examining domain names, which, although not fool-proof, can provide clues. Generally speaking, government (dot-gov) sites are accountable to the public for information hosted on their sites, which makes them relatively reliable and unbiased. The information on organizational (dot-org) sites is susceptible to the viewpoint and bias of the organization, which can affect both the veracity and slant of the information. Information hosted by commercial (dot-com) sites is most problematic. Generally speaking, commercial sites are out to sell a product and will not host information that undermines that purpose. It is recommended that one obtain corresponding verification if using facts and figures obtained from commercial sites. The primary exceptions are fee-based sites such as indexes and databases and electronic newspapers, magazines, journals, and books, which are generally as reliable as their print counterparts. Sites bearing the dot-edu or educational domain are fairly reliable, but personal philosophies typically go unedited. One can generally find solid, credible information from departmental or research-oriented pages.

There is growing confusion and blurring of domain names, particularly dot-org and dot-com, with a number of for-profit endeavors opting for dot-org domains. In addition a number of new domains (dot-name, dot-museum, and dot-info) are appearing, which in addition to country domain codes muddy the water considerably. Still, the domain name is a good starting place.

Another URL clue is the tilde (~), which often signifies a personal page hosted by an Internet service provider or a company, organization, or institution. As such, the authority and bias of the host is not applicable, since personal sites are not always reviewed for content by the hosting organization. When critiquing the quality of a personal page, reflect first on the standing and authority of the page's author.

URLs can be checked at a variety of domain lookup sites to verify author, contact information, and so forth, and this can provide users with important clues as to the intention of the site's creator. I suspect that site author names and site names can be searched on search engines and journal or newspaper databases, occasionally turning up exposes and countering or verifying information. USENET searches can also turn up interesting results.

Audience

The bias and quality of information correlates to the intended audience of the information. Information that preaches to the saved is not the same as information that seeks new converts. Serious Internet researchers, unless they are investigating popular culture, will typically seek information that is addressed to subject authorities, rather than information addressed to the general public.

Currency

Maintaining a Web presence is an ongoing task, and there are numerous Web sites that went up with a bang three years ago and have not been updated since. The very best sites will tell you up front when they were created and when they were updated. Individual articles, reports, or bits of information may also have dates. The current research is not necessarily the best, but it is necessary to know if it is current or not before that judgment can be made.

Coverage

The extensiveness of coverage is another quality to scrutinize when evaluating an Internet resource. Bias will often be reflected in the error of omission rather than the inclusion of erroneous information. This is often true of commercial (dot-com) and organizational (dot-org) sites that want the user to see it their way. Providing a contrast of perspectives would be counterproductive to their purpose.

Language

Always subject a new or dubious site to a quick semantic analysis. Is the language excessively descriptive, comic, inflammatory, or hyperbolic? Such language tends to represent bias or opinion. In addition, be wary of unsubstantiated claims, for example "*The Harvard Law Review* claims. . ." without identifying information describing volume, issue, date, or page numbers.

Page Structure

There are different philosophies in Web design, and these vary depending on the target audience; hence it is difficult to definitively advance one mode of design over another. However, any design that impedes access is not desirable. Information is only useful if it is available. Excessively busy or chaotic Web sites, sites that are poorly organized, and sites whose design features (color, layout, frames, tables, graphics, animation, Flash, and other multimedia devices) interfere with navigating the site and succeed in obfuscating the information they are purportedly trying to promote. There are also page designs that will attempt to lead researchers to certain information and away from clues to intent.

Links

The "About Us" or related links often provide definitive information about the mission, philosophy, perspectives, and goals of a Web site host. Even spoof and spurious sites can often be exposed this way. Examine e-mail links and related links for clues. The quality and destination of links can often inform one as to the quality of a Web site's content. Numerous broken links can indicate the site has not been updated recently or is ill-maintained.

Source Code

Viewing the source code of a Web page is often less revealing than it once was due to the increased use of Perl, Javascript, ASP, and other scripting languages. Web page creators can now, utilizing scripting language, direct spiders to one page, and browsers to another, thus allowing search engines to classify a site by different terms and concepts than the page the user sees. The growing invisibility of the page source will no doubt continue to increase. It can still be extremely insightful to view source code. An examination of the page title, the metatag field, filenames for linked pages and graphics, and comments can often reveal the true intention of a page.

Misinformation

There is copious information on the Internet that is patently false, some of it by blameless error, some of it by spurious intent (Piper, 2000). Spurious information is problematic because the creators of the information desire to deceive, either for monetary gain or support of a political ideology or other personal rationale.

Counterfeit Web sites and/or credentials are the most common manifestations of spurious information. Counterfeit Web sites mirror the appearance of an authentic site but contain false information. A deviation of direct counterfeit is an authentic site that has been cracked (hacked) and legitimate information is replaced with false, or disinformation. The armed conflicts in the Middle East and the former Yugoslavia have germinated hacking of this nature. Investors have also been victimized by spurious Web pages that counterfeit authentic investment news, such as the fake Bloomberg's page touting the acquisition of ParGain in April 1999.

E-mail fraud, which is an electronic extension of mail fraud and targets specific audiences often using Internet mailing lists, is also a major problem. As might be expected, the elderly are often victims, and the content is often health or financially oriented. E-mail and mail list information is particularly subject to fraudulent claims, and identities can be easily counterfeited. If doubted, these should be verified by legitimate sources.

Spoofs

Spoofs are deliberate parodies, often of existing sites or topics. They are often political in nature, but they can be for instructional or recreational purposes as well. While spoof sites vary considerably with regard to professionalism, intent, and scope, they are generally open about their intentions. Their purpose is most often to parody perceived exaggerations or errors in the original information.

The most common way that parody or spoof pages deceive a legitimate researcher is when underlying pages on a spoof site are returned by a search engine without reference to a home page. These decontextualized pages, often featuring only a fake report or article, are lacking the disclaimers that often accompany the home page and can be misleading even to experienced researchers.

Alternative Views

The Internet provides a more direct mirror of social norms, ideas, and prejudices than any previous medium in history (National Council of Civil Liberties, 1999). This results in an unprecedented array of published alternatives

to status quo or mainstream cultural values and "truths." These alternatives can be viewed as fertile terrain for researchers, or they can be viewed as erroneous information. It is often a personal and subjective call. The prudent method of dealing with alternative information is to unearth and attempt to understand the bias or point of view projecting it and compare and contrast it with authorized findings and beliefs.

Help

There are numerous organizations that track spurious information on the Internet. The Computer Incident Advisory Capability, a site hosted by the U.S. federal government, is a good place to start, and there are numerous other organizations such as Snopes that are excellent in tracking Internet frauds and hoaxes.

CONCLUSION

The condition of global research has evolved significantly due to the Internet. There is no area of research that has gone untouched. Researchers can write, edit, and share papers and reports electronically; read and interact with journals, books, other texts, and media online; examine the holdings of millions of libraries, research facilities, museums, and political entities; perform relatively sophisticated searches on billions of documents; and do all of this, and much more, in real time and from nearly anywhere in the world.

Furthermore, the Internet has made available to researchers information that is impossible to obtain elsewhere, material that is accessible without extensive (or any) cost, and material that represents a wider variety of opinion and cultural concern than is obtainable via any other medium. While writing this chapter, the entire Abraham Lincoln Papers' collection was uploaded at the Library of Congress' American Memory site, fully searchable. And this is just one of millions of comparable items that became available during these few short months.

While it is tempting to wax on about future developments for researchers, it is futile to deal in particulars. At least some of the copyright issues which currently block large amounts of information from appearing on the Internet will be settled; bandwidth will increase enabling new formats and faster transmission; interactivity and intelligent interfaces will further evolve; search engines will become "smarter;" information will become standardized and easier to catalog; and the overall amount of information, particularly from developing nations, will continue to increase at astronomical rates. On the other hand, barring any massive global governmental interventions, information on the Internet will remain relatively uncensored and extremely varied, making it crucial for users to become literate in evaluating content.

GLOSSARY

Internet directories Hyperlinked lists of Internet sites organized by subject, typically selected by an information professional, and often annotated and evaluated.

Rings Internet sites that are related by subject and linked together. Rings often require membership, and self-select for quality.

Internet search engines Software that identifies Web content, organizes and indexes it, searches it, and displays results based on relevance.

Invisible Web Those files on the Internet that are not easily detected by search engines.

Return on Investment Analysis for E-business Projects

Mark Jeffery, *Northwestern University*

INTRODUCTION

As the late 1990s came to a close, many companies had invested heavily in Internet, e-business, and information technology. As the technology bubble burst in 2000 many executives were asking, "Where is the return on investment?" When capital to invest is scarce new e-business and information technology (IT) projects must show a good return on investment (ROI) in order to be funded. This chapter will give the reader the key concepts necessary to understand and calculate ROI for e-business and IT projects. In addition, the limitations of calculating ROI, best practices for incorporating uncertainty and risk into ROI analysis, and the role ROI plays in synchronizing IT investments with corporate strategy will be discussed.

What is ROI? One conceptual definition is that ROI is a project's net output (cost savings and/or new revenue that results from a project less the total project costs), divided by the project's total inputs (total costs), and expressed as a percentage. The inputs are all of the project costs such as hardware, software, programmers' time, external consultants, and training. Therefore if a project has an ROI of 100%, from this definition the cash benefits out of the project will be twice as great as the original investment. (In the section Review of Basic Finance we will discuss how this definition of ROI, although qualitatively correct, does not accurately include the time value of money, and we will give a more accurate definition based upon internal rate of return [IRR].)

Should a manager invest a company's money in an e-business project if it has a projected ROI of 100%? There are many factors one should consider when making an investment decision. These factors include, but are not limited to those listed below:

The assumptions underlying the costs of the project.

The assumptions underlying the potential benefits.

The ability to measure and quantify the costs and benefits.

The risk that the project will not be completed on time and on budget and will not deliver the expected business benefits.

The strategic context of the firm; that is, does the project fit with the corporate strategy?

The IT context of the project: that is, does the project align with the IT objectives of the firm, and how does it fit within the portfolio of all IT investments made by the firm?

As discussed in the section Review of Basic Finance, the simple definition of ROI given above is not rigorous enough for good investment decision-making. In addition, the assumptions underlying the model and risks associated with the IT project are key drivers of uncertainty in any ROI analysis. Awareness of these uncertainties and the impact of risks on ROI can significantly improve the likelihood of successful investment decisions.

The return on investment for corporate information technology investments has been the subject of considerable research in the last decade. (For reviews, see Brynjolfsson & Hitt, 1998; Dehning & Richardson, 2002; and Strassmann, 1990.) The most recent research suggests that investing in IT does on average produce significant returns (Brynjolfsson & Hitt, 1996). See the next section, The Information Paradox, for a discussion of this research.

Jeffery and Leliveld (2002) surveyed CIOs of the Fortune 1000 and e-Business 500 companies: Of the 130 CIO respondents, 59% reported that their firms regularly calculated the ROI of IT projects prior to making an investment decision, and 45% of respondents reported that ROI was an essential component of the decision-making process. ROI is therefore an important component of

the information technology investment decisions made in many large companies.

However, an interesting observation is that only 25% of companies responding to the survey actually measured the realized ROI after a project was complete. ROI analysis is therefore primarily used to justify an investment decision before the investment is made. Performing post-project analysis provides valuable feedback to the investment decision process to verify the validity of the original ROI analysis, and the feedback improves ROI calculations in the future. Feedback also enables the weeding out of underperforming projects. Full life-cycle ROI analysis translates into better information to make better decisions, which in turn should impact the returns for the total corporate IT portfolio of investments.

The total IT investments made by a firm can be thought of as a portfolio, similar to a financial portfolio of stocks and options. Each IT investment will have a different risk and return (ROI) and, because capital is limited, selecting the optimal portfolio is a challenging management decision for any firm. The methodology for choosing and managing an optimal IT portfolio is called IT portfolio management. This process often includes the use of scorecards so that executive managers can rate projects on multiple dimensions and ultimately rank projects in relative order of importance to the firm. A typical scorecard will include several categories that help quantify the value of a project to the business and the risk of the project. Note that ROI is typically only one category on the scorecard and that several other factors may have equal or greater importance. In the Executive Insights section at the end of this chapter, an example of the IT portfolio management process at Kraft Foods and its score card used to rank e-business and IT projects are discussed.

In the following section we will briefly review the research literature on returns on investment for information technology and the related information paradox. The third section, Review of Basic Finance, is an introduction to the key finance concepts necessary to calculate ROI. Using these concepts, the ROI for a case example is calculated in the section Calculating ROI for an e-Business Project, and a template is given that is applicable to any ROI calculation. Uncertainty in assumptions and risk are important considerations, and the section Uncertainty, Risk, and ROI shows how to include these factors in the ROI analysis. Specific risk factors for e-business projects that may impact the ROI are also discussed. This section shows how sensitivity analysis and Monte Carlo methods can be applied to ROI models; these are two powerful tools for understanding the range of possible ROI outcomes based upon the cost and revenue assumptions and the risks in the project. The last section, Executive Insights, gives some tools for oversight of technology investment decisions—specifically, questions to ask when reviewing an ROI analysis and how ROI fits within an information technology portfolio management framework for optimal IT investment decisions are discussed.

THE INFORMATION PARADOX

The question of how investment in information technology impacts corporate productivity has been debated for almost a decade (for reviews, see Brynjolfsson & Hitt, 1998; Dehning & Richardson, 2002; and Strassmann, 1990). Productivity is defined similarly to ROI in the introduction—it is the amount of output produced per unit of input—and although easy to define, it can be very difficult to measure for a firm (Brynjolfsson & Hitt, 1998). This difficulty in measurement is similar to the challenges of measuring ROI for information technology and e-business projects. The output of a firm should include not just the number of products produced, or the number of software modules completed, but also the value created to customers such as product quality, timeliness, customization, convenience, variety, and other intangibles.

One would expect that the productivity of the overall economy should increase over time, and this is indeed the case for the manufacturing sector, where the outputs are relatively easy to measure—see Figure 1a. This productivity increase is not due to working harder—because

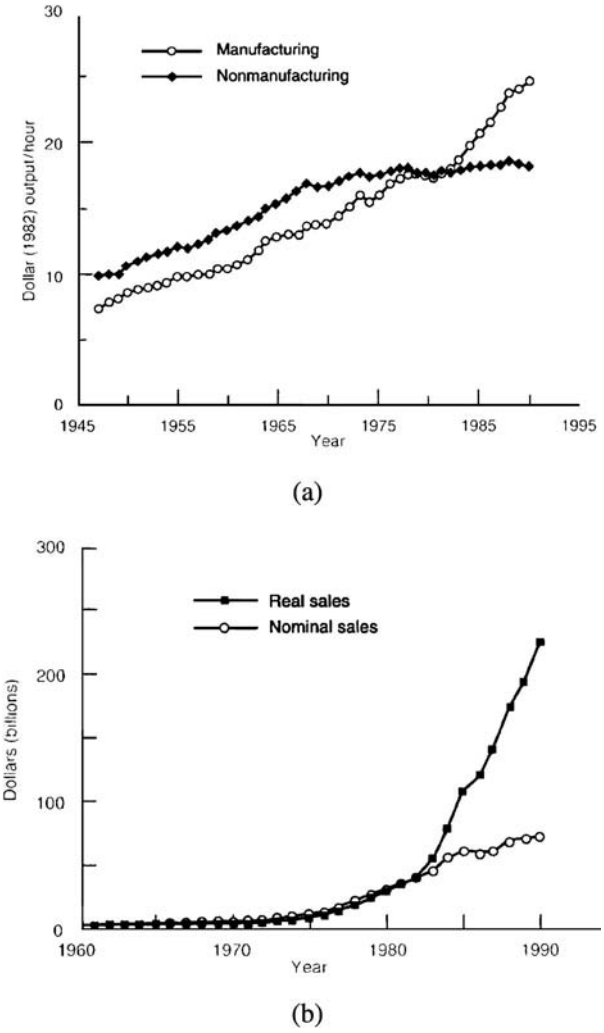

Figure 1: (a) Average productivity for the manufacturing and service sectors. (b) Purchases of computers not including inflation (nominal sales) and sales adjusted for inflation and price deflation due to Moore's law (real sales). although working harder may increase labor output, it also increases labor input. True productivity increases derive from working smarter, and this usually happens by adopting new production techniques and technologies.

The greatest increases in productivity have historically been associated with "general-purpose technologies." Examples are the steam engine and the electric motor. These inventions were applied in a variety of ways to revolutionize production processes. One would expect that computers and the Internet, because they are also general-purpose technologies, should dramatically increase productivity.

However, data in the late 1980s and early 1990s suggested that the average productivity of the U.S. economy in the nonmanufacturing or service sector, which is a primary user of computers and IT, had been constant from 1970 to 1990—see Figure 1a. During this same time frame corporate investments in computers had increased dramatically, so that by 1990 investments in computer hardware averaged 10% of a company's durable equipment purchases. Furthermore, following Moore's law, the number of transistors on a computer chip doubles approximately every 18 months and the speed of computers doubles every 2 years. Hence the "real" computing power purchased by firms increased by more than two orders of magnitude from 1970 to 1990. The apparent inconsistency of IT spending and productivity was termed the *productivity paradox,* and the conventional wisdom of the late 1980s was that there was no correlation between investment in IT and productivity. If the productivity paradox is true, it suggests that firms should not invest in IT because it does not create good ROI.

The problem with this conclusion is that it is based upon aggregate data averages of the entire U.S. economy. These data are averages that measure productivity in terms of the number of products produced. So as long as the number of products increases for the same level of input, the productivity increases. For computers, this accounting works well if they are used to cut costs, but it does not work if they are used to transform business processes or create intangible value. Brynjolfson and Hitt (1998) use the example of the automated teller machine (ATM) and the banking industry. ATMs reduce the number of checks banks process, so by some measures, investing in ATM IT infrastructure actually decreases productivity. The increase in convenience of ATMs goes unaccounted for in traditional productivity metrics. For managers, IT can look like a bad investment when they can easily calculate the costs of the IT investments but have difficulty quantifying the benefits.

In the mid- to late 1990s several research studies were undertaken on new data sets that included individual data on thousands of companies (see, for example, Brynjolfsson & Hitt, 1996; Dewan & Min, 1997; and Malone, 1997). These data enabled researchers to find a significantly better way to measure firm performance. Across all of these research studies there is a consistent finding that IT has a positive and significant impact on firm output, contradicting the productivity paradox. However, these studies also show that there is a significant variation in the magnitude of this payoff among firms.

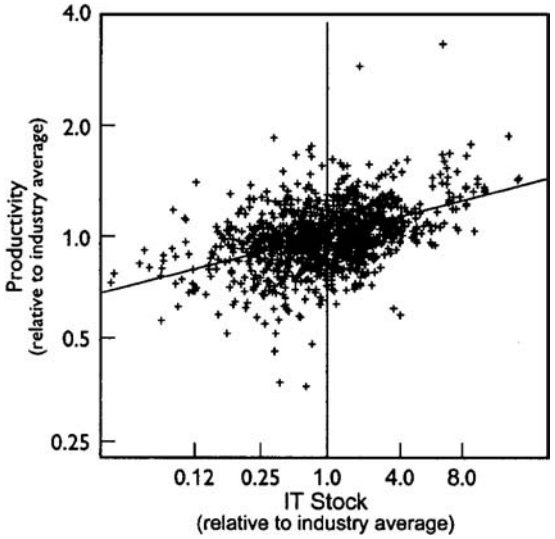

Figure 2: Productivity as a function of IT Stock (total firm IT related expenditures) for a sample of 1,300 individual firms. Source: Brynjolfsson and Hitt (1998). © 1998 ACM, Inc. Reprinted by permission.

Figure 2 is a plot of the variation in productivity and IT investments across 1,300 firms (Brynjolfsson & Hitt, 1998). The horizontal axis (labeled "IT Stock") is the total IT inputs of the firm. The vertical axis is the productivity, defined as the firm outputs divided by a weighted sum of the inputs. Both productivity and IT input are centered at the industry average. The best-fit line is clearly upward-sloping, indicating the positive correlation between IT spending and productivity at the firm level. However, the striking feature of these data is the wide variation of returns. Some companies spend more than the industry average on IT and have less productivity, whereas others spend less and have greater productivity.

The large variations in returns on IT are well known by many corporate executives. For every amazing IT success story such as Dell, Cisco, or WalMart there are many failed or out-of-control IT projects (Davenport, 1998). As examples of these failures, a Gartner survey of executives found that 55% of customer relationship management (CRM) projects do not produce results, and a Bain consulting survey of 451 senior executives found that one in five reported that the CRM system not only failed to deliver profitable growth but also actually damaged longstanding customer relationships (Rigby, Reichfeld, & Schefter, 2002).

The wide variation of returns in Figure 2 is indicative of the fact that there is more to productivity than just investment in information technology. Other factors are just as important—the ability of the firm to exploit organizational change and how the IT investment fits in the context of the firm's strategy in a given industry. Research suggests that there is on average a time lag, of order one to three years, before the benefits of a large IT investment significantly impact a firm's productivity (Brynjolfsson & Hitt, 1998).

In summary, research studies of the late 1980s and early 1990s suggested that there was no correlation between IT investments and firm productivity; this was

called the *information paradox*. However, studies in the mid-1990s based upon firm-level data from thousands of companies all suggest that there is a significant payoff from IT investments, contradicting the information paradox. However, these payoffs are contingent on a firm's ability to effectively adapt through organizational change to the new technology, and on a firm's ability to effectively manage the overall portfolio of IT investments. These results suggest that investing in IT is on average a positive ROI activity, but the benefits of IT investments are difficult to measure and risk factors can significantly impact the actual ROI realized.

REVIEW OF BASIC FINANCE

In this section we review the basic finance necessary to calculate ROI. The key concepts are the time value of money and internal rate of return (IRR). For a complete introduction to corporate finance see Brealey and Myers (1996). In the following section, a general framework is given for ROI analysis, and the ROI is calculated for a case example e-business project. The reader should note that ROI analysis for e-business investments and IT is in principle no different from ROI analysis for other firm investments such as plant and equipment, research and development, and marketing projects. All use the same financial tools and metrics and follow the general framework discussed in the next section.

The Time Value of Money

As an example, consider two e-business investments. Assume that both projects cost the same, but the first (Project 1) will have new revenue or cost-saving benefits of \$5 million (M) each year for the next five years, and the second (Project 2) will have benefits of \$11 M at the end of the first and second years, and nothing after that. If we only have enough capital to fund one project, which of these e-business projects is worth the most cash benefit today?

We might argue that the first investment's cash flows are worth \$5 M times five years, which is \$25 M, and the second project's payouts are \$11 M times two years, or \$22 M. From a purely financial perspective, assuming all other factors are equal, we would conclude by this reasoning that we should invest in the first project instead of the second. However, intuitively we know that \$1 today is worth more than \$1 in the future—this is the "time value of money." The dollar today is worth more because it can be invested immediately to start earning interest. So just adding the cash flows ignores the fact that \$5 M received today has more value than \$5 M received five years from now.

The correct approach is to discount the cash flows. That is, \$1 received in one year is actually worth $\$1/(1+r)$ today, where r is called the discount rate and is the annual interest rate investors demand for receiving a later payment. In this example, if r is 10%, a dollar received in one year is worth $\$1/1.1 = 91$ cents today. Similarly, cash received two years from now should be discounted by $(1+r)^2$, so that the dollar received two years in the future is worth $\$1/(1.1)^2 = 83$ cents today.

This argument can be generalized to a series of cash flows $A_1, A_2, A_3, \ldots, A_n$ received in time periods 1, 2, 3, ..., n. The value of these cash flows today is calculated from the discounted sum

$$PV = A_1/(1+r) + A_2/(1+r)^2 + A_3/(1+r)^3 + \cdots + A_n/(1+r)^n. \quad (1)$$

where n is the number of time periods and PV is called the present value of the cash flows. Discounting a series of cash flows is mathematically equivalent to weighting cash received in the near term more than cash received further in the future. The effect of inflation is generally ignored in the cash flows, so that $A_1, A_2, A_3 \ldots, A_n$ are given in today's prices. Inflation can be included in the present value calculation by adding an inflation factor to the discount rate. This is particularly important in economies that have high inflation rates. For a complete discussion of how to incorporate inflation see Brealey and Myers (1996).

In general, the series in Equation (1) can easily be calculated using the built-in present value function in personal computer spreadsheet software (such as Microsoft Excel) or using a financial calculator. For the special case when the cash flow is the same for each period ($A_n = A$), such as in a bank loan, the sum can be calculated in closed form:

$$PV = \sum_{k=1}^{n} \frac{A}{(1+r)^k} = A\left[\frac{1}{r} - \frac{1}{r(1+r)^n}\right]. \quad (2)$$

Returning to our original example, the present value of the two cash flows is calculated in Figure 3a assuming $r = 10\%$. In this example, PV(Project 1) = \$19 M and PV(Project 2) = \$19.1 M, so the expected cash benefits of the second project actually have more value today in present value terms than the first project. If the projects cost the same to execute, and this cost is less than \$19 M, a manager should prefer to invest in Project 2.

In order to compare projects that have different costs (investment amounts), it is useful to subtract the initial investment costs I from the present value, thus obtaining the net present value (NPV):

$$NPV = PV - I. \quad (3)$$

If the costs of the project are spread out over multiple time periods, then I is the present value of these costs. Hence from Equation (1), Equation (3) is equivalent to

$$NPV = -C_0 + \frac{(A_1 - C_1)}{(1+r)} + \frac{(A_2 - C_2)}{(1+r)^2} + \frac{(A_3 - C_3)}{(1+r)^3} + \cdots + \frac{(A_n - C_n)}{(1+r)^n}, \quad (4)$$

where the costs of the project $C_0, C_1, C_2, C_3, \ldots, C_n$ have been subtracted from the cash benefits $A_1, A_2, A_3, \ldots, A_n$ in the corresponding time periods 1, 2, 3, ..., n.

When making investment decisions, one always strives to invest in positive NPV projects. If the NPV of a project is negative, this means that the initial investment is greater than the present value of the expected cash flows. Investments in projects with negative $NPVs$ should not be

made, because they do not add value to the firm and actually extract value.

Returning to our example, assume that the initial cost of Project 1 is \$9 M and the initial cost of Project 2 is \$10 M. From Figure 3b the *NPV*(Project 1) = \$10 M and *NPV*(Project 2) = \$9.1 M. Hence both projects have positive *NPV*, and should add value to the firm. However, if capital is limited (or rationed) one must select investments that have the most "bang for the buck." In other words, one must select projects that have the greatest returns for a given dollar of investment. A useful ratio capturing this idea is called the profitability index:

$$\textit{Profitability Index} = \frac{\textit{Net Present Value}}{\textit{Investment}}. \qquad (5)$$

For our example in Figure 3b, the profitability indices are 1.11 and 0.91 for Project 1 and Project 2, respectively, and *NPV*(Project 1) = \$10 M > *NPV*(Project 2) = \$9.1 M. Because the profitability index is greater for Project 1 than Project 2, if the funding decision is based purely upon financial metrics Project 1 is the preferred investment.

The present value and net present value clearly depend upon the discount rate. What discount rate should we use for an e-business investment? The discount rate used for investments in a specific firm is defined by the expected return of the combined debt and equity of the firm for a given industry. This discount rate is called the weighted average cost of capital (WACC) of the firm. Calculating the WACC for a firm is beyond the scope of this chapter; the interested reader is referred to Brealey and Myers (1996). However, as a rule of thumb, discount rates typically range from 10% to 25%, and a WACC of 15% or more is common in the technology industry. The Chief Financial Officer's (CFO's) office in a large company will usually calculate the WACC for use in investment decisions.

The discount rate is related to the risk of an investment so that firms in high-risk industries (such as technology) have higher WACCs—these companies in turn have higher expected returns in the stock market. Due to this risk–return relationship, the discount rate for more risky technology project investments is sometimes increased relative to that for less risky investments when *NPV* is calculated. A potential issue with this approach is that the discount rates chosen for riskier projects can be somewhat arbitrary. Arbitrarily increasing the discount rate adds additional uncertainty into the *NPV* calculation and may reduce one's objectivity in comparing projects. A better approach for technology investment decision-making incorporating project risk, and other factors such as the business value of the project, is discussed in the Executive Insights section.

The CFO's office will often compare investments based upon *NPV*, because this makes possible objective comparison and selection of the most profitable investments. The CFO is most likely managing a large portfolio of investments, and the power of the *NPV* approach is that is takes the guesswork out of financial decision making by placing all investments on a common footing. One limitation of *NPV* is that it does not take into account management flexibility to defer decisions into the future. The value of this management flexibility, or option value, is discussed in the Executive Insights section.

ROI, Internal Rate of Return (IRR), and Payback Period

Return on investment was defined in the Introduction as

$$ROI = \frac{Project\ Outputs - Project\ Inputs}{Project\ Inputs} \times 100\%. \quad (6)$$

where the project outputs are all of the benefits of the project quantified in terms of cost savings and revenue generation, and the project inputs are all of the costs of the project. The major problem with this definition is that it does not include the time value of money.

Specifically, ROI, defined by Equation (6), is rather vague, because a 100% ROI realized one year from today is more valuable than a 100% ROI realized in five years. In addition, the costs of the project may vary over time, with ongoing maintenance and professional services support. The benefits of the project may also vary over time, so that the cash flows are different in each time period. Equation (6) is therefore not a convenient way to compare projects when the inputs and outputs vary with time, and it is also not useful for comparing projects that will run over different periods of time. Due to these deficiencies, one typically uses internal rate of return (*IRR*) (Brealey & Myers, 1996). For good management decisions the ROI defined rather loosely in Equation (6) should translate in practice into calculating the IRR of a project's cash flow.

What exactly is IRR? The IRR is the compounded annual rate of return the project is expected to generate and is related to the *NPV* of the project, defined in Equations (3) and (4). The IRR is the discount rate at which the *NPV* of the project is zero. That is, the IRR is the discount rate where the cash benefits and costs exactly cancel. From this definition, the internal rate of return is calculated by solving for IRR in

$$NPV = -C_0 + \frac{(A_1 - C_1)}{(1 + IRR)} + \frac{(A_2 - C_2)}{(1 + IRR)^2} + \frac{(A_3 - C_3)}{(1 + IRR)^3} + \cdots + \frac{(A_n - C_n)}{(1 + IRR)^n} = 0 \quad (7)$$

where $A_1, A_2, A_3, \ldots, A_n$ are the positive cash benefits and $C_0, C_1, C_2, C_3, \ldots, C_n$ are the costs of the project in each time period 0, 1, 2, 3,..., n. In practice one most often uses spreadsheet software, or a financial calculator, and the built in *IRR* and *NPV* functions for calculations.

How do we make financial management decisions using *IRR*? When the *IRR* is greater than the project discount rate, or WACC, we should consider accepting the project—this is equivalent to a positive *NPV* project. When the *IRR* is less than the WACC the project should be rejected, because investing in the project will reduce the value of the firm. The tenet of basic finance theory is that all projects that have positive *NPV*, or *IRR* > WACC, should be funded. This is based upon the assumption that the firm has unlimited capital and, because positive *NPV* projects have an *IRR* better than the WACC of the firm, accepting these projects will increase shareholder value. As discussed in the previous subsection, however, in practice capital is limited (or rationed) and managers must make decisions based upon limited resources. The profitability index, Equation (5), can be used to calculate which projects have the greatest return per investment dollar. Hence positive *NPV* (or good *IRR*) is only one factor to consider in a technology investment decision.

Another concept that is a useful tool when combined with *IRR* and *NPV* is that of payback period. The payback period, or payback, is the time it takes for the project to recoup the initial investment. The payback period is calculated by cumulatively summing the net cash flows (projected revenues and cost savings less costs) of a project. When the sign of the cumulative sum of the net cash flows changes from negative to positive the project has "paid back" the initial investment. (For an ROI analysis where a new project is compared to a base case, without the project, the payback should actually be calculated from the incremental cash flows. See the case example in the following section.)

The payback period for a typical e-business project can be in the range of six months to two years, depending upon the type of project. It is unusual for an e-business project to have a payback period longer than two years. In making investment decisions, projects that have good *IRR* and the shortest payback periods are most often selected.

This section on introductory finance did not include tax or depreciation in the *IRR* analysis. The reader should note that the financial metrics *PV*, *NPV*, and *IRR* calculated with and without tax and depreciation can be very different. Tax and depreciation are important factors and are incorporated into the case example discussed in the following section.

In summary, return on investment analysis for technology projects is the process of calculating the *IRR* for a project. The calculation of *IRR* is based upon sound financial theory and is related to the *NPV* of the project. *NPV* and *IRR* are equivalent ways of incorporating the time value of money into financial investment decisions. In the following section these concepts are applied to an example e-business project and a template is given that is applicable to any technology *IRR* calculation.

CALCULATING ROI FOR AN E-BUSINESS PROJECT

The overall process of calculating *IRR* for a new project business case is straightforward. The first step is to calculate the base case revenue and costs expected in the future if the business continues as it is now. The next step is to calculate the net cash flows with the new proposed project; this includes total revenue, potential cost savings, and all

costs of the project. Finally, the base case cash flows are subtracted from the projected cash flows with the new project. The results of these subtractions are called the incremental cash flows for the project. The *IRR* is then calculated from these incremental cash flows. An equivalent approach is to calculate the additional benefits of the project directly to obtain the incremental cash flows. For complex business models, however, separating out the additional benefits when there are multiple variables can be more difficult than calculating the total cash flows with the new project and then subtracting the base case.

As discussed in the previous section, if the *IRR* calculated from the incremental cash flows is greater than the project discount rate, or WACC, the project should be considered for funding—this is equivalent to a positive *NPV* project. The challenge is to accurately incorporate the business drivers in the base case and all of the project costs, potential cost savings, and potential revenue benefits in the new project's cash flows.

In order to put the ROI calculation process in context, and to discuss some of the important details, it is useful to walk through an example. This section discusses a case example of ROI analysis applied to a Web portal e-business project. The Web portal in this example is a Web site with a product catalog, and customers can buy products and transact orders using the portal. The Web portal front end acts as a customer interface and, for a large firm, is typically connected internally to the firm's back-end IT systems, such as an enterprise resource planning (ERP) system, and other enterprise systems, such as customer relationship management (CRM) software.

The particular example discussed in this section is for a midsize electronics manufacturing company with global sales and operations. The example has been simplified to illustrate the main features of ROI analysis, and all numbers have been changed for confidentiality reasons. The cost and revenue numbers in this example are therefore for illustrative purposes only. The objective of this case example is to illustrate the general process and the important mechanics for calculating ROI rather than the exact costs and benefits of a Web portal project. For a detailed discussion and analysis of ROI for a Web portal e-business initiative and for an example of management of a Web portal development project see the two case studies in the references (Jeffery, et al., 2002a; Jeffery, et al., 2002b).

Base Case

The first step in setting up any ROI analysis is to understand the base business case. That is, what are the primary costs and revenues expected if the firm continues operations and does not implement a new e-business solution? Answering this question should focus on the major costs and revenue drivers that the new technology project is expected to impact. The process of understanding the existing business is called business discovery.

A best practice of business discovery is to understand the cost and revenue drivers in a particular business process and then benchmark against competitors in the industry. For example, if the average transaction cost for order processing in a firm is $35 per order, and the industry average is $10 per order, there is clearly an opportunity for improvement. Similarly, if the industry average take-rate (fraction of customers who accept a marketing offer) is 3% and a firm has a take-rate of 1%, there is an opportunity for improvement.

If e-business or other information technology is used by competitors to achieve cost or revenue improvements, benchmarking data provide estimates of the improvements that might be expected if a similar solution were applied to existing processes within a firm. Benchmarking data for IT are provided by several consulting groups. Because consulting services are most often the source of benchmarking data, one must be cautious that these data are accurate and applicable.

Understanding the key business drivers, and which factors can improve business performance, is essential and can have important bottom-line implications. For example, a major U.S. general retailer with over $40 billion in revenues used a Teradata enterprise data warehouse (EDW) combined with analytic CRM software to improve the target marketing of 250,000 catalogs mailed to customers each year. This initiative resulted in 1% improvement in the number of trips to stores generated among mailed customers, 5% improvement in the average purchase dollars per trip, and 2% improvement in gross margin, as the products featured in the advertisements for specific customer segments captured sales without reliance on "off-price" promotions. The initiative ultimately resulted in an increase in mailer revenue of $215 M per year, and the catalog targeting project alone with the new EDW and CRM technology had an *NPV* exceeding $40 M.

For the case example discussed in this chapter we can assume that the business discovery yielded a set of assumptions that are summarized in Figure 4. Specifically, the revenue and cost drivers are assumed to be the sales transactions to 1,700 customers and the transaction costs for processing these orders, respectively. The average sales revenue per order is $258, the average cost of goods sold (COGS) is 70% of each order, and the transaction cost

using phone and fax averages $30 per transaction. In the next year (Year 1) the company anticipates 141,000 total transactions through existing channels and without a Web portal. Multiplying the average revenue per order by the number of transactions, and subtracting COGS and transaction cost, one can calculate the net income in Year 1. If the tax rate is 35%, the net Year 1 after-tax free cash flow is expected to be $4.3 M.

Cash flows projected into additional future years can be estimated by multiplying the Year 1 numbers by anticipated annual growth rate factors. One must make assumptions based upon the expected increase in sales and costs for the next few years. As part of the business discovery, these assumptions may be based on data for the firm's performance in the past. For simplicity in the present example we can assume that the firm is in a mature industry and anticipates 3% growth in the total number of transactions, assuming the Web portal imitative is not implemented. The base case three-year future (also called pro forma) cash flows derived from these assumptions are given in Figure 5a.

Note that this base case is simplified for this example and in practice may be much more complicated. For example, the revenue may come from multiple market segments with different transaction costs, and the number of transactions may be very large. See the references (Jeffery et al., 2002a ; Sweeney, et al., 2002a; Sweeney et al., 2002b) for examples of market segmentation and business discovery for complex ROI analysis.

Incorporating the E-business Project

The Web portal case example has two primary business objectives: (1) enable self-service order entry by customers, thus reducing costs, and (2) enable access into a broader market for customers, potentially increasing revenues. In addition to these business goals, the Web portal has strategic value, because in the electronic components manufacturing industry a Web portal is becoming a requirement for conducting business.

The costs of a project are often the easiest component of the IRR analysis to quantify. These costs may include items such as hardware, software, license fees, programmers' time, professional services (consulting), project management, hosting fees, outsourced contractors, and ongoing operating expenses. IT managers strive to keep the total cost of ownership of new products and systems at a minimum.

Minimizing total cost of ownership is related to the build vs. buy decision for a new IT or e-business project. This is because custom-built applications can have high total cost of ownership over their useful life. A useful rule of thumb is that if less than 10% custom modification to a packaged enterprise application is necessary then it is generally cheaper to buy than build. Greater than 10% custom modification puts the cost of building vs. buying about even, because new version releases of the packaged software will require continual custom modifications.

Web portal technology was novel in the mid-1990s, but by 2001 several vendors were offering stable solutions. Hence, for this case example the best approach is most likely to integrate commercial off-the-shelf packaged applications with the firm's existing enterprise software systems. The major costs will most likely be integration with existing systems and infrastructure to support high availability (24/7 operation with little or no down time) across multiple geographic markets. The cost of outsourcing the system, versus keeping it in-house, may also be considered. Detailed costing and a work breakdown structure would be completed for the final project plan. Cost estimates can also be obtained from similar projects that have been completed in the past.

For the purpose of this example we assume the project cost is $5 M, with ongoing costs of $1 M in each year. The ongoing costs include maintenance, upgrades, license fees, and professional services. To help facilitate the second business goal the Web portal initiative must include a marketing campaign in target markets. For simplicity in this example, these marketing costs are assumed to be included in the ongoing costs of the project. In practice the marketing plan would contain detailed costing and would most likely be broken out into a separate line item in the cash flow statement.

The primary anticipated benefits, or outputs, of the Web-portal initiative are reduced transaction costs and increased revenue generation. The cost savings occur because phone and fax orders for this company average $30 per order, and electronic processing is anticipated to cost $3 per order. The revenue generation benefit is expected to come from the Web portal's ability to have a global reach, so that with targeted marketing more customers can access the firm's products without increasing the size of the sales force. Other benefits of this initiative include fewer errors in processing transactions, reduced time to process orders, improved information on customers, and improved customer satisfaction, because customers can place orders 24/7 and have access to up-to-date product data.

Accurately quantifying all of the benefits of an e-business or IT system is the most challenging part of any ROI analysis. In practice one can often quantify the major hard cost savings. Revenue growth is more difficult to estimate and must come from market research, industry data, and past experience. It is often not possible to quantify soft benefits such as customer satisfaction and strategic advantage. The analysis therefore typically includes cost savings and revenue generation that can be estimated, and unquantifiable soft benefits are not included. This means that the ROI calculated will potentially be less than the realized ROI including soft benefits. One must then subjectively consider the project's soft benefits and how important they are to the firm. An ROI analysis is only as good as the assumptions that go into the analysis. The best practices for incorporating assumptions into an ROI model are discussed in the following section.

The details of the financial analysis calculation including the Web portal are described as follows. See Figure 4 for the assumptions and Figure 5b for the complete cash flow statement. Please note that what is most important in this chapter is the structure of the overall analysis, not the specific details.

For the case example, the average transaction cost is the easiest benefit to quantify and is straightforward to calculate. For all of the transactions processed, 50% of the

customers are assumed to use the Web portal and 50% are assumed to use fax and phone methods of ordering. The average total transaction cost is the weighted average of the number of transactions expected using the new Web-portal system (assumed to be 50% of total transactions) multiplied by the transaction cost of $3 for each electronic transaction and $30 for each phone and fax order: $0.5 \times (\$3 + \$30) = \$16.50$ per order. With a larger fraction of customers using the e-business system, the average transaction cost per order decreases significantly from $30.

For this case example, we assume that with the new portal, market penetration will increase and that there will be an initial jump in the number of total transactions

in Year 1 as the global customer base is enabled to do online transactions. With a 14% increase in transactions in Year 1 and a 10% yearly growth in the total number of transactions driven by the marketing campaign in Years 2 and 3, the effective growth in gross revenues is 13.3% per year. Because it costs only $3 to process an order using the Internet, in addition to revenue growth there is also a substantial cost savings of $2 M due to the reduced average transaction cost to process an order.

Figure 5b incorporates the revenue and cost savings of the new Web portal initiative into a pro forma cash flow statement. The upfront and ongoing costs of the new initiative are also included. The revenue generation is incorporated in the increased number of transactions, and the cost savings are encapsulated in the total order processing cost line of the cash flow statement Figure 5b. For the calculation of net income we subtract out the depreciation of the project, assuming a three-year straight line schedule.

In the United States, for tax reasons new IT projects cannot be expensed in the year they are capitalized. The hardware, software, and professional service costs must be depreciated using a five-year MACRS (modified accelerated cost recovery schedule). This is an accelerated depreciation schedule described in Stickney and Weil (2000). Although the accounting books may use MACRS, depreciation for ROI analysis is most often incorporated using three- or five-year straight line depreciation. Straight line is a conservative compromise, because it weights the expense equally in each year, whereas accelerated depreciation weights the capital expense more in the first few years than in the last. Once the system is operational, ongoing costs such as maintenance and professional service support can be expensed when they occur.

Off balance sheet and lease financing options are usually not incorporated into the cash flow statements for the ROI analysis with a new project. For capital budgeting, the base case and the case with the new project should be objectively compared, independent of how the project is financed. Leasing and off balance sheet financing can artificially improve the ROI, because the cost of the project is spread over time by the lease payments. A more conservative estimate is to assume the costs of the project are incurred up front, or at the same time as the costs are anticipated to actually occur. Once the project is accepted for funding the best method of financing should be chosen.

To calculate the free cash flow with the new project, the last step is to add back the depreciation expense to the net income after tax. The depreciation expense was included in the calculation of net income in order to correctly include the tax advantage of this expense. However, for the final free cash flows the total depreciation is added back to the net income, because depreciation is not a "real" expense that actually impacts the cash flows, other than for tax reasons.

Incremental Cash Flows and IRR

Once the pro forma base case and new-project free cash flows have been calculated, the calculation of IRR is straightforward. The base case cash flows are subtracted from the cash flows with the new Web project; these are the incremental cash flows. See Figure 5c. The incremental cash flows are the net positive or negative cash in each time period that occurs in addition to the base case. The *IRR* is calculated from these incremental cash flows.

Using spreadsheet software, the *NPV* and *IRR* of the project are calculated by applying Equations (3) and (7), respectively, to the incremental cash flows. For the parameters given in this example, the NPV is $941,000 and the IRR is 22%, with a $5 M initial investment. Assuming the assumptions are correct, the IRR being greater than the firm's discount rate (WACC) suggests that this is a project the firm should consider funding.

Another factor to consider is the payback period. The payback for this project is calculated in Figure 5c from the incremental cash flows and occurs early in the third year (the beginning of the third month). The payback is anticipated to be just over two-years, which is potentially a little long, so one possibility is to consider adjusting the total project expenses to enable earlier payback.

The reader should note that if the major project expenses occur up front, and the net cash flows in later time periods are increasing and positive, the IRR will increase if the time period of the analysis is extended. For this case example, if the assumptions were extended into Years 4 and 5, the five-year IRR would be 46%, compared to 22% IRR for three years. This is because we have extended the time over which the cash benefits can be included in the calculation from three years to five, for the same up-front implementation cost.

Because the Web portal projects may produce benefits over a long time period into the future, an important question is, "What time period should be taken for a particular IRR calculation?" The time period for the analysis should match the time period used to calculate IRRs for similar investments in the firm. Often the one-, two-, and three-year IRR numbers are calculated for an investment decision, and depending upon the firm, management decides which one to use for comparisons with other projects. For the Web portal project example, 36 months was chosen as the length of time for the analysis. For e-business projects IRRs for time periods longer than three years are usually not considered when projects are compared, even though the project may have benefits in additional years.

Note that the 22% *IRR* calculated in this example does not include additional benefits such as: fewer errors in processing transactions, reduced time to process orders, improved information on customers, and improved customer satisfaction because customers can place orders 24/7 and have access to up-to-date product data. One can attempt to quantify these benefits and include them in the model; however, soft benefits such as improved customer satisfaction and better information are extremely difficult to accurately quantify. The approach most often used is to realize that the calculated *IRR* does not include these benefits, and hence the actual *IRR* of the project should be somewhat higher.

In addition, the case example does not include the strategic value of the initiative. Specifically, the Web portal may be a "table stake"—an investment that is required to stay in business in a particular industry. Hence, even if the *IRR* is less than the hurdle rate for the company, management must invest in the project, or risk losing market share to competitors who have the technology.

The complete ROI analysis for the case example e-business project is summarized in Figures 5a–5d. This spreadsheet can be used as a basic template and starting point for any technology ROI calculation.

UNCERTAINTY, RISK, AND ROI

As with any ROI analysis, the three-year IRR calculated at 22% in Figure 5c is only as good as the assumptions that are the foundation for the model. In this section we discuss how the assumptions and potential risk impacts of the project are essential factors to examine so that the ROI analysis supports the best possible management decision. The major uncertainties will come from the business assumptions and the risks of the technology project. We first focus on major uncertainties, business risks, and sensitivity analysis, and then on specific risks related to the technology. How to interpret ROI results and incorporate uncertainty and risk into the ROI analysis is also discussed.

Uncertainty

For the case example described in this chapter we know one thing for sure: the 22% *IRR* calculated in Figure 5c will not be the actual *IRR* obtained by the project. How do we know this? There are many assumptions that went into the simple analytic model, and there are risks that may impact the project. It is therefore practically impossible that the assumptions will indeed be exactly correct. The important realization is that the ROI analysis of Figure 5 is only a point estimate. Management decisions based upon this single estimate will not be as informed as decisions based upon a range of possible outcomes.

In creating the ROI analysis, there are several important questions to ask, such as: What are the major assumptions in the model? Does the model capture the essential drivers uncovered in the business discovery? What are the ranges of possible outcomes for each major assumption?

For complex problems, a simple yet effective method is to estimate the best, the worst, and the most likely case for each of the major assumptions. Market research, the business discovery, industry experience, and project management experience should be used to define a reasonable range of possible outcomes. The expected value of the *IRR* can then be estimated from (Project Management Book of Knowledge [PMBOK], 2003)

$$\text{Expected Value} = \frac{\text{Best Case} + 4 \times \text{Most Likely Case} + \text{Worst Case}}{6}. \quad (8)$$

Equation (8) is equivalent to weighting the best and worst cases individually by the probability .167 and the expected case by the probability .67 (the probabilities for approximately plus or minus one standard deviation for a normal distribution). If similar projects have been undertaken in the past, it may be possible to assign empirical probabilities to the best, worst, and most likely cases.

The best and worst case ROI numbers are just as important for the management decision as the expected value. The expected value is a point estimate of the most likely outcome, and the worst case *IRR* is an indicator of the downside risk of the project. Even with a good potential upside, funding a project that has a large downside risk of a very low or negative ROI can be questionable. If there is a wide variation of the best and worst case IRRs from the expected value, this is an indicator that there is significant risk in the project.

Equation (8) is a simple estimating tool to define the expected value of the ROI given a range of possible outcomes and is used in project management (PMBOK, 2003) to estimate the expected value of the cost and time for an IT project. Spreadsheet software enables sensitivity analysis of ROI models. This is a powerful and more sophisticated tool to help understand which parameters in a model are most important, and how these parameters interact.

Sensitivity Analysis

For the case example, the major assumptions in Figure 5 are the following:

The increased transactions as a result of the Web portal and the marketing campaign.

The fraction of existing customers who will migrate to use the Web portal over time.

The reduced transaction cost with the Web portal.

The cost of the project.

Two of these assumptions are particularly aggressive. First, we assume that when the Web portal becomes active 50% of the existing customer base will use the portal for transactions in the first year. The large number of users migrating to the system is the driver for the large cost savings. In practice the 50% migration may take longer than one year.

The second major assumption is that the number of transactions will jump by 20,000 in the first year, as a result of the global reach of the new Web portal, and that these transactions will then grow at a rate of 10% per year. This new revenue will not be possible without a significant and coordinated marketing campaign. Hence, this revenue generation assumption must be benchmarked against market research data and the experience of the marketing team.

Spreadsheet software (such as Microsoft Excel) enables one to dynamically change one or two variables in a model simultaneously and calculate the corresponding *IRR*. This analysis is surprisingly easy to do and provides a visual picture of the dependencies in any model. Figure 6a is the table of *IRR* output calculated by varying the total cost savings and the revenue generation. The "Auto Formatting" function enables color-coding of cells—gray was chosen for *IRR*s less than the hurdle rate of 12%, white for *IRR* greater than 12%. The gray cells correspond to cost saving and revenue generation amounts that would not be acceptable (negative *NPV*). The boundary, where the cells change from gray to white, is the minimum cost saving and revenue generation necessary so that the *IRR* approximately equals the hurdle rate ($NPV = 0$). These tables can be used as a tool to review the ranges of *IRR* in the context of the best, worst, and average cases expected for each input parameter.

Figure 6: Case example of sensitivity analysis of the ROI model: (a) Cost savings versus revenues, and (b) percentage of customers shifting to the new Internet channel versus Year 1 transaction lift due to the Web portal initiative. Gray cells have IRR less than the 12% hurdle rate for the firm.

Figure 6b calculates the *IRR* as a function of two key drivers in the model: the number of new transactions and the fraction of customers using the new Web-portal channel. The boundary clearly shows the importance of migrating customers to the new channel to reduce transaction costs. Sensitivity analysis using the built-in functions in spreadsheet software (such as the Table function in Microsoft Excel) is a powerful tool to analyze the dependencies between variables in any ROI model.

Project and Technology Risks

A theme for this chapter is that the business drivers, rather than the specific technology, are often most important for any ROI analysis. However, risks of a technology implementation project can also have a significant impact on ROI. As discussed in the section on the productivity paradox, the majority of large IT projects fail to deliver on time and on budget (see Davenport, 1998; Rigby et al., 2002). The technology implementation project enters into the ROI analysis through the cost of the project and delays in realizing the revenue benefits, so that risk events often increase the cost and time of the project, decreasing the overall ROI. Risks for Internet projects and strategies to mitigate these risks are discussed in another chapter. Here we focus on specific risks that may impact the overall ROI of an e-business or IT project.

Keil and co-workers (Keil, Cule, Lyytinen, & Schmidt, 1998) conducted a research study of three panels of expert technology project managers in Finland, Hong Kong, and the United States. The three panels listed the common risk factors for any technology project in order of importance; see Figure 7.

What is so surprising about the list in Figure 7 is that managers across continents and in very different cultures perceive the same major project risks in order of importance. It is also interesting to note that technology is mentioned only once in this list—"Introduction of new technology" is third from the bottom.

1. Lack of top management commitment to the project
2. Failure to gain user commitment
3. Misunderstanding the requirements
4. Lack of adequate user involvement
5. Failure to manage user expectations
6. Changing scope/objectives
7. Lack of required knowledge/skills in the project personnel
8. Lack of frozen requirements
9. Introduction of new technology
10. Insufficient/inappropriate staffing
11. Conflict between user departments

Figure 7: Risk factors identified by three independent panels of technology project managers listed in order of importance. Adapted from Keil et al. (1998).

In the early and mid-1990s Internet technology was new and many new Internet technology projects of that time period were "bleeding edge." These new Internet solutions were much more complex than previous IT systems. In addition, the Internet mania and infusion of vast amounts of venture capital pushed product development to "Internet time" in order to grab market share (Iansiti & MacCormack, 1999). These time pressures resulted in buggy code releases, and beta versions abounded. ROI for such new technology projects where costs and benefits were relatively unknown, was very difficult to define.

However, in 2003 and beyond, with Internet technology entering the mainstream and distributed architectures becoming more the norm than the exception, practically all technology investments are required to demonstrate a good ROI. Fairly good and systematic cost estimates for e-business systems are available today. The business benefits of these systems, although still difficult to quantify, are easier to estimate than when the technology was first introduced.

From Figure 7, the primary project risk factors are therefore not technological but organizational. For example, the top two risks in the list Figure 7 are "lack of top management commitment" and "failure to gain user commitment." These risk factors involve the people who will support and use the project and are risk factors that a project manger has little or no control over. Organizational issues are an essential consideration for the success of any technology project. Figure 7 is a simple tool one can use to assess the major risks of a project that may impact the ROI. If any of these risk factors are present, they should be included at least qualitatively in the management decision. In addition, a risk management strategy can be invaluable for planning contingencies for mitigating various risk events (Karolak, 1996).

Monte Carlo Analysis Applied to ROI

Sensitivity analysis using spreadsheet software is a useful tool for visualizing the interrelationships between parameters in an ROI model. However, this method has the limitation that one can vary at most two parameters simultaneously. Even for the relatively simple model given as a case example in this chapter, several parameters combine to give the ROI. The variation of multiple parameters simultaneously can be included using Monte Carlo methods.

The idea of a Monte Carlo simulation is to generate a set of random numbers for key variables in the model. The random numbers for a specific variable are defined by a statistical distribution. Similarly to defining the best, worst, and expected case for each input parameter in a sensitivity analysis, the shape of the distribution and spread (mean and standard deviation) are best defined by the management team. Past experience, market research, and the judgment of the management team are all factors to consider when defining the statistics of the input variables.

The random numbers are then put into the analysis spreadsheet and the output (the *IRR* and *NPV*) is calculated. A new set of random numbers is then generated based upon the statistical functions defined for each input variable, and the output is recalculated. If this process is repeated a large number of times statistics can be generated on the output of the model. Intuitively, one Monte Carlo cycle is a possible outcome of the model with one particular set of variations in the inputs. By running thousands of cycles, one is effectively averaging what might happen for thousands of identical projects given many different variations of input parameters.

Relatively low-cost packaged software is available that can perform Monte Carlo simulations in spreadsheet software (Crystal Ball 2003, Palisade @Risk 2003). This software is easy to use—the user selects specific cells and specifies distribution functions for the variables. The software then varies the values of the cells with random numbers. The output, in this case the IRR or NPV, is automatically calculated for a large number of cycles and statistics of the possible outcomes are generated.

Figure 8 is an example of the Monte Carlo output for the case example of Figure 5. The project cost, increase in number of transactions, and percentage of users migrating to the Web channel were varied simultaneously. The distribution functions chosen for the inputs were all normal distributions with standard deviations $1 M, 15,000, and 25%, respectively. The average IRR, or expected value, is 22%, with standard deviation 17.5%.

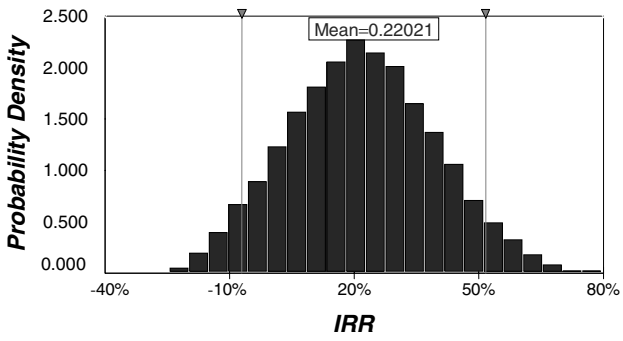

Figure 8: Distribution of three-year IRR calculated from 10,000 Monte Carlo iterations.

The Monte Carlo analysis shows that the model has considerable spread in the *IRR* with these parameters. Specifically, there is a 28% probability that the project will have an *IRR* less than the hurdle rate for the company. Given this information, the management team can consider whether they will fund the project as is, kill the project, or revise the scope and assumptions to reduce the downside risk.

EXECUTIVE INSIGHTS

This chapter has developed the tools necessary for calculating ROI for an e-business or IT project. This section provides a "big picture" framework for how ROI is used for technology investment decisions and what questions to ask when reviewing an ROI analysis. We also look "beyond ROI" at trends for the future.

The Important Questions to Ask When Reviewing an ROI Analysis

This chapter has discussed the major issues concerning ROI analysis and factors to consider in developing an analytic financial model for technology projects. The following set of questions summarizes the issues that were discussed. These questions may be useful to consider when reviewing an ROI analysis:

1. What are the main assumptions in the model?
2. Was there a business discovery to define the assumptions?
3. Are all the major uncertainties and risks adequately accounted for?
4. Are the assumptions realistic and are they expressed as a range of possible inputs?
5. Is the calculated IRR expressed as a range with an expected value and approximate probabilities?
6. Is there a sensitivity analysis and how is it interpreted?
7. What is the downside risk (worst case) and is there a plan to mitigate this risk?
8. Will the project have senior management and end user support, are the requirements well defined, and will an experienced project manager run the project?
9. What is the strategic value of the project to the firm in addition to the benefits incorporated in the model?
10. How important are other factors, such as soft benefits, that were not included in the analysis?
11. Does the project contain any option value that should be factored into the decision?

As described in detail in the section Risk, Uncertainty, and ROI, the analysis is only as good as the underlying assumptions. The first four questions are designed to probe if the assumptions incorporate the important issues, how they were obtained, and if the uncertainty in the assumptions is understood. Assumptions are critical to the validity of the ROI model. An effective method is for the management team to collectively define the assumptions based upon their experience and market research. If the assumptions are all based upon conservative estimates, and the management team collectively agrees on the assumptions, the ROI analysis is ultimately more convincing.

Questions 5 through 7 probe if the range of possible outcomes is understood and if there is a plan to deal with the worst case. Question 8 asks if the primary organizational risks have been thought through. In addition to Question 8 the list in Figure 7 can be used as a checklist for additional potential risks that may impact the project and Karolak (1996) gives a complete software project risk management checklist. Finally, questions 9 through 11 probe for additional value that may not have been captured in the ROI analysis and that should be considered for the funding decision.

The last question, 11, is concerned with the potential option value of the project—from the survey of Fortune 1000 CIOs 20% of respondents report that they qualitatively consider option value in funding IT projects (Jeffery & Leliveld, 2002). What is the option value of a technology project? An e-business or IT project has option value if, as a result of the project, the firm has the opportunity to implement additional projects in the future, and these projects would not have been possible without the initial project investment. Option value can be an important component of added value and is especially important for infrastructure investments.

For example, an enterprise data warehouse (EDW) is a very large IT infrastructure investment that, from a cost containment perspective, may be difficult to justify. However, once this infrastructure is put in place, the firm can leverage it for a variety of potential applications: Analytic CRM, improved supply chain management (SCM), and improved demand chain management (DCM) are a few of these applications. Hence, implementing the EDW is equivalent to buying options for CRM, improved SCM, improved DCM, and a variety of other strategic initiatives. Analytic methods exist for calculating financial option values and these methods have been applied to technology projects (McGrath & MacMillan, 2000). Qualitatively at least, the option value of a technology project should be considered when making an investment decision.

A Framework for Synchronizing E-business Investments With Corporate Strategy

A major challenge for executive managers is how to decide which new e-business and IT projects to fund. This is a complex decision, because for a large firm the annual IT budget may be several hundred million dollars or more and often there can be many new projects that must be considered for investment. For example in the 1990s a major worldwide banking institution, which was representative of other industry leaders, had an annual IT budget of $1.3 billion and had over 800 projects running simultaneously.

The process of managing the portfolio of technology investments of a firm is called IT portfolio management. This process is similar to managing other portfolios in the firm such as financial assets, new products, and marketing initiatives. IT portfolio management includes important factors such as the strategy of the firm and the risk and return of investments. This idea is not new and was first discussed by McFarlan (1981).

- Define the firm-wide strategic intent and business objectives
- Understand the strategic context of the firm. This context defines the focus of the technology investments
  - *Corporate strategy: operational excellence, customer focus, innovation*
  - *IT focus: Cost reduction, defined by strategy, strategy enabler*
- Develop e-business and IT objectives matched to the corporate strategic objectives
- Develop an appropriate portfolio of e-business and IT investments to support the strategic business objectives
  - *Make risk and return (ROI) tradeoffs on investments*
- Update as necessary
  - *Requires a continual dialogue of cross functional executives and technology managers*

Figure 9: Linking strategy to IT portfolio investments: a framework for managing IT by business objectives. Adapted from Weill and Broadbent (1998).

As discussed in the Introduction and throughout this chapter, ROI analysis is only one component of a technology investment decision. A general framework for investing in technology is given in Figure 9. This top-down approach (Weill & Broadbent, 1998; Weill, Mani, & Broadbent, 2002) starts with executive managers defining the strategic objectives of the firm. From the corporate strategy the key business objectives are defined. For example, these objectives may include increasing revenues in core markets, growing revenue in specific new markets, or cutting costs internally.

When defining the strategic initiatives, it is important to understand the strategic context of the firm within a given industry. The major focuses of corporate strategy can be grouped approximately into three categories: operational excellence, customer focus, or innovation. Treacy and Wiersema (1997) conducted a research study of thousands of firms and found that market-leading firms were often exceptional in one or two of these three categories, but none were exceptional in all three. One example is Dell Computer: Dell excels at operational excellence and customer service, but does not produce particularly innovative products. Another example is IDEO, a design company that has won countless awards for product innovation focused on what customers need.

In 2000 and beyond, the line between the three focuses of operational excellence, customer focus, and innovation is blurring. Increasingly, all firms must exhibit some level of customer focus excellence to remain competitive. However, understanding the core drivers of a firm's business is an essential first step to ensure that investment dollars are optimally allocated. The goal is to synchronize e-business and IT investments with the corporate strategy. The IT objectives for the firm must support the key business objectives (KBOs) derived from the corporate strategy in order to optimize the value of the portfolio of IT investments. Synchronization of IT with corporate strategy is simply not possible if the KBOs are not well defined.

Once the key IT objectives have been defined, the next step in the process in Figure 9 is to select an optimal portfolio of projects. This can be a challenging task, because often capital is limited and there may be many potential projects that could be funded. How do we select an optimal portfolio of e-business and IT investments? A rigorous IT portfolio management selection process can help capture the value of the project to the business and the risk of the project.

Kaplan and Norton (1992) have pioneered the use of scorecards to rate business performance. Scorecards are a powerful tool to objectively rank technology projects against one another. As an example, Figure 10 is the scorecard used by Kraft Foods to rank IT and e-business projects. Note that there are two dimensions of the scorecard: "Business Value Criteria" or value to the business, and "Likelihood of Success Criteria" or ability to succeed. Ability to succeed is related to the risk of the project. Also note that ROI, labeled as financial return, is just one component of the total score.

The categories on the scorecard and the category weights were defined by the Kraft Foods executive management team. A detailed grading rubric was developed

Likelihood of Success Criteria		Wt.	Score	**Business Value Criteria**		Wt.	Score
Technical Standards	X1:	10%		Financial Return	Y1:	30%

so that each category could be objectively scored, and an independent review committee evaluated all projects and ensured consistency in scoring. All projects were then ranked by the business value criteria total score, and a line was drawn that corresponded to the total IT budget. The projects were also plotted on the portfolio application model matrix, Figure 11. The portfolio application model makes possible a schematic of the risk and return profiles for all of the IT projects. Based upon this information, the executive management team at Kraft Foods, which included the CFO and business unit sponsors, discussed which projects to fund and which to reject. The discussion enabled the CIO to increase the IT budget, with the CFO's approval, in order to fund additional projects that had high value to the business.

As a general example, if a KBO for a firm is to cut costs, a corresponding IT objective may be to increase electronic transaction processing. On the scorecard, projects that support electronic transactions will be weighted more than projects that do not. New e-business projects such as e-procurement are therefore more likely to be selected for funding through the IT portfolio management selection process. An e-procurement system may also be considered to have a relatively high ability to succeed, or equivalently a low risk.

Projects plotted on the matrix in Figure 11 fall into four categories. Projects in the upper right have high value to the business and ability to succeed. These projects should be funded. Small and medium-sized e-business projects such as e-procurement and customer self-service portals may fall into this category, and are often "low-hanging fruit," projects that will yield quick payback. Projects in the lower left corner have low value to the firm and have high risk—these projects clearly should not be funded.

Projects on the upper left in Figure 11 have high value to the company but are difficult to execute. Example projects may be ERP, CRM, or EDW and large strategic e-business initiatives. These projects may well be drivers for the long-term competitive advantage of the firm. Risk is clearly an issue with these projects, and a risk management plan can potentially significantly improve the ability-to-succeed score. In order to reduce the risk for a large project, the project may be broken into components or phases that each have a high ability to succeed. Projects that fall into the lower right corner in Figure 11 have low perceived value, but have a high ability to succeed. IT executives may choose to selectively fund projects in this category because they can be easy wins for the IT team.

A potential issue is that infrastructure investments may often be categorized as having low value to the business by non-IT business executives. The low value-to-the-business score may be due to the value not being accurately captured on the score card. Infrastructure is an important platform for future projects and may have significant option value. However, without a specific category for option value an infrastructure investment may receive a low value-to-the-business rating as perceived by executive managers. Future IT initiatives often depend on an infrastructure being in place. Therefore, for infrastructure projects the option value and future dependencies can be important considerations for the funding decision.

The IT portfolio management process gives executive managers a framework for optimal investment decision-making. Implementing this framework in practice gives managers objective information that can be used to make informed management decisions. Ultimately the management decision is made based upon executives' experience and must weigh subjective issues that are not quantified by the process. In addition, executives should also consider the dependencies between projects and the optimal order for execution. Kraft Foods exemplifies how a cross-functional executive team discussed the available information and reached consensus on the funding decision.

Finally, to effectively synchronize strategy and IT investments the IT portfolio management process must be ongoing. Many firms in mature industries have fixed annual IT budget cycles, so that the IT portfolio management process is implemented for the funding decisions of each cycle. However, in order to optimize the return from IT investment dollars, firms in dynamically evolving industries should implement quarterly or more frequent IT portfolio reviews.

Beyond ROI: Trends for the Future

Following the bursting of the Internet bubble in 2000, the technology industry is undergoing a shakeout and consolidation, which may last several years. As we look forward in this environment, optimizing investments in e-business and information technology is increasing in importance as companies struggle to maintain competitive advantage. Calculating ROI is important for informed management decisions. However, as we have discussed, ROI is only one component of the decision-making process.

The method of calculating ROI for an e-business or IT project is in principle no different from the method for calculating ROI for a new manufacturing plant, marketing plan, or research and development project. However, e-business and IT projects can be incredibly complex, so that estimates and generalities that are good enough for a manufacturing project can potentially destroy an IT project if any element goes wrong. Building the ROI model on sound assumptions and developing a risk management strategy can therefore significantly impact the actual ROI realized for IT projects.

A trend for the future will be that firms will increasingly implement more sophisticated IT portfolio management processes and will incorporate ROI into these processes. Furthermore, we have discussed ROI in the context of new project selection. In order to maximize IT value one must realize that ROI analysis is an important on-going process. That is, the ROI of projects should be measured after the project is complete. This after action review enables feedback to the entire IT portfolio management process, and the firm can then calculate the realized ROI of the entire IT portfolio.

Similarly to a financial portfolio, it does not make sense to invest in a mutual fund or stock that is losing money year after year. E-business and IT projects are no different, and measuring the ROI of existing IT projects enables executives to weed out underperforming investments.

Some complex strategic e-business initiatives may have high cost, high risk, and huge potential payoffs. For these projects a management strategy is to break the project down into phases, where each phases is defined by ROI. Once a phase is complete it should demonstrate good ROI before the next phase is funded. This approach reduces the risk of the e-business investment and makes the project "self-funding," because new revenue or cost savings can fund the next phase of the initiative.

During the roaring 1990s, Internet and e-business initiatives were viewed as too complex, or too innovative, for management investment decisions to be made using ROI. As we move into the next phase of the technology revolution powered by the microprocessor and networking technologies, e-business initiatives will be scrutinized and evaluated on the same basis as all other firm investments. IT management teams must therefore embrace the financial management techniques of ROI analysis and portfolio management that are used widely in other functional areas of the firm.

GLOSSARY

COGS Cost of goods sold, equal to the beginning inventory plus the cost of goods purchased or manufactured minus the ending inventory. These costs are expensed because the firm sold the units.

DCF Discounted cash flow, equal to future cash flows divided by discount rate factors to obtain present value.

Depreciation The portion of an investment that can be deducted from taxable income. It is also the reduction in book market value of an asset.

Discount rate The rate used to calculate the present value of future cash flows.

Hurdle rate The minimum acceptable rate of return on a project.

Information technology portfolio management A methodology for managing information technology investments as a portfolio with different risks and returns. The process often involves using scorecards to rate projects on multiple dimensions, such as the alignment of the project with the strategic business objectives of the firm and the ability of the project to succeed.

IRR Internal rate of return, the discount rate at which the net present value of an investment is zero.

ITPM Information technology portfolio management.

MACRS Modified accelerated cost recovery system, the accepted U.S. income tax accelerated depreciation method since 1986.

NPV Net present value, a project's net contribution to wealth—present value minus initial investment.

Payback The payback period of an investment, or the time taken to recoup the original investment with the new revenue and/or cost savings from the project.

PV Present value, the discounted value of future cash flows.

Real option A deferred business decision that is irreversible once made and whose eventual outcome is contingent upon the future evolution of the business environment.

Risk free rate The expected return for making a safe investment, usually equivalent to the rate of return from government bonds.

ROI Return on investment, a generic term for the value of a project relative to the investment required. In practice the ROI for a project is calculated as the IRR for the project.

Table stake A technology investment that is necessary in order to remain competitive in a particular industry.

Time value of money The idea that cost savings or revenue received today is more valuable than the same cost savings or revenue received some time in the future.

WACC Weighted average cost of capital, the expected return on a portfolio of all the firm's securities. Used as the hurdle rate for capital investment.

Risk Management in Internet-Based Software Projects

Roy C. Schmidt, *Bradley University*

INTRODUCTION

Despite the success stories in the literature, it remains a sad statistic that too many software development projects end in failure. At least a quarter of all software projects are cancelled outright, and it is likely that 75% of all large systems projects are dysfunctional because the systems produced do not meet specifications or are simply not used. The average software project runs over its budget by 50% (Gibbs, 1994; Lyytinen & Hirschheim, 1987; van Genutchen, 1991; Walkerden & Jeffrey, 1997). It is common knowledge that software projects are risky, and thus there has been an intense search for appropriate managerial action to counteract software project risk.

One approach that has gained popularity in recent years is the use of the Internet as a vehicle for communication among project team members (Benett, 1998; Collaborative Strategies, 2000). By improving communications and facilitating work flow management, Internet-based project management seeks to reduce some elements of risk. A thriving industry of support and management of Internet-based projects has grown up in just five years. One such company is Reinvent Communications (formerly USWeb), which not only supports Internet collaboration but also uses its own tools to provide its support (Bumbo & Coleman, 2000). At this point, it is too early to tell if this new management approach has had any impact on project success, but the new approach may be displacing some risk factors with new ones, thus creating new opportunities for failure (Ash, 1998).

A more traditional method for reducing failure in software projects is the concept of software project risk management. Advocates of software project risk management claim that by identifying and analyzing threats to success, action can be taken to reduce the chance of failure. In this chapter, the traditional risk management approach is extended to include the new Internet-based project management environment.

Risk management is a two-stage process: assessing the risk and taking action to control risk. The first stage, risk assessment, consists of three steps: (a) identification of risk factors, (b) estimation of the likelihood for each risk factor to occur and potential damage from the risk, and (c) an evaluation of total risk exposure (Charette, 1989). So the first step toward control of software project risk is an understanding of the exact nature of risk factors.

WHAT IS RISK?

The concept of risk is not clear to most practicing managers. Much like the problems the average person has understanding Bayesian statistics, the word "risk" usually conjures up an image of negative outcomes. A "risky" project is seen as one that is likely to fail. A risk factor is seen as an opportunity to fail. This view of risk overlooks the true nature of the beast.

Risk as an Element of Decision Theory

The following explanation is highly simplified but sufficient for the purpose of this chapter. For a complete treatment of decision theory and risk, see the collection of essays by Arrow (1965).

Decision theory describes the decision-making process as a choice of actions leading to a specific outcome. A small number of actions lead to outcomes that are favorable, a few to those that are unfavorable, but the vast majority lead to outcomes that are unclear. Assuming that the clearly favorable outcomes are too small to be attractive, the unclear alternatives present the decision maker with risky opportunities.

For each of the risky alternatives, there is some probability of a favorable outcome. For example, a given alternative may have 15% chance of success (a favorable outcome) and thus an 85% chance of failure. How would this alternative compare with another that has 99% chance of success? To make this evaluation, one also needs to know the magnitude of the outcome.

Suppose that the first alternative, if successful, would net $1 million in profit but a failure would mean the loss of $50,000 invested in the alternative. The second alternative would net $500,000 profit, but failure would lead to a loss of $3 million. Although the second alternative seems unattractive because of the magnitude of the loss and the smaller profit, it is actually the better choice. To compare the alternatives, both the probability of the outcome and

its magnitude must be accounted for. The product of the magnitude and probability is called *expected outcome*. The first alternative promises a positive expected outcome of $150,000 ($1 million × 15%), or a negative expected outcome of $42,500 ($50,000 × 85%). The second alternative could lead to a positive expected outcome of $495,000 or a negative expected outcome of only $30,000. So despite appearances, the second alternative is less risky.

For this reason, risk is evaluated based on the product of the magnitude of an outcome and its probability of occurrence. A risk factor is any event that embodies risk. Risky alternatives have both positive and negative expected outcomes, and both must be considered when evaluating the risk. This approach to evaluating software project risk is strongly advocated by Charette (1989). Surprisingly, practicing managers often overlook these facts.

Risk as Viewed by Practicing Managers

There are two important biases affecting risk evaluation that have been observed among practicing managers. First, managers act as if they are evaluating only the magnitude of a loss, without considering the probability of the loss. Their focus is on the loss, not the potential gain, because risk carries a negative connotation to them. As a result, their ranking of alternatives is often out of line with expected outcomes (March & Shapira, 1987).

Second, managers do not attend to all potential risks. Regardless of magnitude or expected outcome, if a risk factor appears to be outside their direct control, managers assign them to a category that might be called "Acts of God." They make no attempt to ameliorate these risk factors, even if the expected outcome could be shutdown of a project (Schmidt, Keil, Lyytinen, & Cule, 2001).

Information Technology (IT) Project Risk

IT project risk factors have been defined as any factors that could affect the success of IT projects (Schmidt et al., 2001). Numerous studies have sought to catalog IT project risk factors. A thorough review of risk factors and a ranking of the most important risk factors are presented by Keil, Cule, Lyytinen, and Schmidt (1998) and Schmidt et al. (2001). All 53 of the risk factors discussed in these two papers apply to both traditional IT projects and Internet-based projects. There are significant differences between them, however. As a result, additional risk factors are associated with those differences. In the following section, some of those additional risk factors are examined.

INTERNET-BASED PROJECT RISKS

In recent years, the management of software projects, as well as other types of projects, has met with a new venue, the Internet. By taking advantage of the flexible, ubiquitous communications afforded by the Internet, project managers have been able to extend team membership to analysts and programmers who would not have worked on the project because of distance and time factors. Using groupware (both integrated commercial packages and stand-alone tools), Internet-based project teams can become larger, with more diverse interests and talents. Workflow management software allows project managers to track tasks and monitor team member contributions. Whether these new tools are better than traditional techniques is not well established. Even teams that share the same geographic location are attempting to benefit from the new Internet-based project management tools through the use of intranets (Benett, 1998).

How Internet-Based Projects Differ From Other IT Projects

Geographic dispersion of team members and the locus of project management are just two of the important risk factors affecting Internet-based projects. Project managers must also deal with the problem of being separated from their users, both geographically and temporally, which complicates the process of verifying work and seeking advice. Outsourced projects are likely to become Internet-based for convenience of the outsourcing company and the contractors. Even the software to support Internet-based project management might be outsourced from firms like iVenturi, a joint venture between Dow Chemical and Accenture (Gilbert, 2000). With such outsourced project management applications, the user interface of the support software becomes an important issue as well. Finally, security of project data is in jeopardy both during transmission and in storage at dispersed sites.

Locus of Project Management

An important decision that must be made at the outset of an Internet-based project is the physical location of the project manager. From the standpoint of the project manager, preference would be given to remaining in his or her current location. In the case of outsourced projects, however, the project manager might be a significant distance from the client, greatly complicating coordination during the project. The client might prefer that the project manager be located close to them, but then the manager would be separated from the bulk of the project team members, again causing coordination and supervision problems.

Even in the case of in-house projects, the project manager and team members may be working at different locations. The emphasis is on fast development, so geographic separation demands reliable, fast communications. Ken van Heel, a business manager in Dow Chemical's e-business group says, "Everyone's trying to get products to market faster. They need fast communication about hitting milestones and resolving problems" (Gilbert, 2000, 159).

Detached Users

When the project manager and team are geographically separated from the users, the gulf between them is even wider than that experienced in traditional software development projects. It becomes much more difficult to involve users in the regular decisions that must be made in the course of development, both in design and in coding. To use project support software or groupware for this purpose requires user training, adding upfront time and cost to the project. Users are also less likely to devote full attention to project team requests because of their lack of physical presence and the pressures of their day-to-day jobs.

Outsourced Development

Many of the problems that accompany outsourced development have already been addressed in traditional software project risk management (Schmidt et al., 2001). When the primary means of coordination and workflow management is through the Internet, however, a special burden is placed on the outsourcing firm to keep track of the contractor. Much as the users lose touch with the project, management is less likely to attend to project oversight—out of sight, out of mind. The first hint of problems with the project will inevitably have to come from the project manager, who might be reluctant to communicate these problems without the specific approval of contractor management.

The only alternative to this scenario is for client management to receive training in the use of the project support software and to use the software on a regular basis to track project activity. This should lead to a "shadow" project manager within the client organization. This alternative introduces more complications, such as the irritant of "being watched" and the possibility of conflict between the contract project manager and the overseer.

User Interface

The user interface of any software is one of the most important design considerations. Because of the special needs of Internet-based project management, practically all software supporting the project comes from vendors not associated with the users or the developers. Thus, the user interface of the project support software is not specifically designed for their purposes. Practically all firms offering such software, including iVenturi, Agile, Oracle, and SAP, are designing "one size fits all" products (Gilbert, 2000). With a widening user base, including the client users, client management, project manager, and project team members, the special needs of each type of user are less likely to be met in the user interface. This could lead to confusion, frustration, and less than perfect communication.

Security

Considering the vehicle for communication, geographic dispersion, and affiliation of stakeholders, Internet-based projects are especially vulnerable to security problems. Every use of coordination software exposes sensitive project data to compromise. Although high-level encryption is supported by modern Web browsers, not all project management software and groupware support such data protection. E-mail is also often sent unencrypted, so that routine communications among team members or between the team and users might not receive any protection at all.

With geographic dispersion of team members, the number of locations where sensitive data is stored is much greater than with traditional projects. Paper files, computer files, diagrams, audio and video recordings, software simulations and prototypes, screen images, and so forth are likely to be generated to facilitate communication among developers and between the developers and users. With the additional storage locations, the job of managing security of project data becomes complicated.

If the project is outsourced, the project participants belong to different organizations. The affiliation of those holding project data can get in the way of effective security management, from the standpoint of both physical surveillance and the enforcement of security policies. Attention to security issues can vary significantly from one organization to the next, so client management and the project manager might not agree on proper procedures and policies.

Sources of Risk

As a first step in formulating strategies to deal with risks, it is important to understand the sources of risk (Schmidt et al., 2001). There are two reasons for this. First, by recognizing the source of a risk, the project manager can take action directed at the source to improve the chance of a positive outcome, much as a doctor treats an infection rather than the fever that is a symptom of the infection. Second, some risk sources are perceived by managers to be beyond their control, which leads them to inactive management of the associated risks. By understanding the sources, project managers can take special care to attend to risks they might otherwise overlook.

Users

One factor that can plague Internet-based projects is lack of trust on the part of the users. Because the development team has only a virtual presence, users never develop the kind of relationship and the level of trust that is achievable when the team and the users are located together. The physical separation of users from the team also contributes to inadequate user involvement, historically one of the more serious risks to project success (Barki, Rivard, & Talbot, 1993; Schmidt et al., 2001). Because users do not have convenient access to the assembled team, roles and responsibilities can become muddled, leading to a further decline in user involvement. This is the phenomenon called "the detached user." There is also a strong possibility that users will develop expectations that are not in line with the expectations of the project team. Delivering software that does not match user expectations is another frequent cause of project failure (Schmidt et al., 2001).

General Management

The same lack of trust that can arise among users can also be found in general management. Poor professional relationships can lead to poor coordination of project activities or disinterest in the success of the project (Ash, 1998). The geographic and temporal separation of project team, users, and management also makes it difficult to maintain control over project dependencies with any external agents involved in the project.

As sponsor of the project, general management plays a special role in project success. The most important risk factor in software development projects is top management commitment to the project (Keil et al., 1998). If general management staff members lose focus of their stake in the project, their commitment becomes questionable.

Environment

Because project participants are not meeting face-to-face as in traditional projects, cues that might reveal to them

any changes in the business or political environment will be missed. For example, a change in upper-level leadership might result in changes in business strategy or organizational culture. The project as originally designed might not support the new strategic direction. The project also might continue along lines that are no longer politically acceptable. Even worse, the delivered system is at risk of poor alignment with the organizational culture, so when it is delivered it might not be used.

Technology

Technological risk is not new to software project management. Half of Boehm's (1989) top 10 risks were related to technology. But over the years, as reliability of computing technology and sophistication of the user interface have increased, the perception of risk associated with technology has decreased dramatically (Schmidt et al., 2001). In Internet-based projects, however, there is an increased risk associated with the use of technology to support the actual development process. Most of the technology designed to support Internet-based project management is less than three years old. Although there have been many studies of the use of groupware to support system development, using this technology across organizations in complex projects is not well understood. The majority of project managers have only limited experience and training with the new software and are only just beginning to understand the organizational dynamics of Internet-based projects.

Project Management

A different kind of project manager might be required for Internet-based projects. Internet-based projects tend to be more complex and under increased time pressure (Gilbert, 2000; Highsmith, 2000). Complexity arises not in the software development tasks, but in the coordination of activities with geographically and temporally dispersed team members, client management, and users. Time pressure arises through two phenomena. First, the users expect faster development because the use of Internet technology appears speedier than other means of communication. This is actually an unrealistic expectation (Ash, 1998). Rapidly communicating a requirement does not mean that the code satisfying the requirement will be written faster. Second, the startup time for an Internet-based project is longer because of the need for a period of training and orientation in use of the supporting software before actual work can proceed. So team members are under pressure to perform at a rate beyond their capability.

The Internet-based project is not just a traditional project on steroids. Because of the different ways of handling relationships with users and client management, the different supporting software, and the different way of managing the workflow, the skills demanded of the project manager are radically altered from those of traditional projects. Adequate techniques for managing Internet-based projects have not been developed or taught, and new methodologies especially designed for Internet-based projects are still being tested. Project management still has the potential to be a significant source of risks.

Project Team

If the project manager is not well prepared, how can the project team be prepared? Changes in personnel or staffing levels can have a wrenching effect on traditional projects. With Internet-based projects, such changes are more difficult to handle because the team members are often in different locales. Thus, bringing a new team member up to speed on the project is difficult. Also, because team members outside the organization are utilized, key personnel support resources may be difficult to access or nonexistent. Team members can become disheartened or disgruntled.

Because the project team is often pulled together using members at a distance from each other, their interpersonal relationships are tenuous at best. They lack the cohesiveness of a team that works together with daily "face time." Also, because they are remote from the project manager, there is an increased risk that other duties and activities may draw part of their time or attention, slowing project execution (Ash, 1998).

STRATEGIES FOR RISK MANAGEMENT

As mentioned in the introduction to this chapter, risk management is divided into two stages: assessing risk and controlling risk. The most difficult step in the first stage is identifying the risks that pertain to the project at hand. Historically, two methods have been favored for this task. The checklist method makes use of a list of potential risks. The brainstorming method relies on interactive input from experienced project managers and team members.

Once the appropriate risks have been identified, the project manager must take these risks into account when making project plans. Countermeasures should be devised in advance to minimize the damage of a negative outcome or to take advantage of a favorable outcome in the event one of the anticipated risks is triggered by events. The choice of countermeasures depends on an understanding of the risks in terms of a general classification. By recognizing the type of risk to be dealt with, specific strategies can be chosen that target the source of the risk. There are two principle means of countering risk. First, the manager may plan a project in such a way as to minimize the occurrence of certain risks. Second, when such planning is not possible, the manager might prepare specific actions to be taken in the event that a particular risk is triggered. Another approach might be to seek ways to hedge against particular risks that cannot be resolved by action (Kumar, 2002). For more complicated eventualities, the manager might develop scenarios that help the team understand what to do in the event certain circumstances occur (Ahn & Skudlark, 2002).

Recognizing Risks

To identify the risks associated with a particular project, the project manager must first be able to recognize risks. That is, the manager needs to know what the typical risks are. Each of the methods for risk identification has strengths and weaknesses in this regard. When choosing a method, the manager must take these strengths and

weaknesses into account. In this chapter, the two most popular methods are described. Charette (1989) describes other methods that might be used.

The Checklist

When managers lack a sufficiently broad experience with project management, they do not fully trust their own recognition of potential risks. In such case, a checklist of potential risks is essential. The checklist is useful for experienced managers as well, because it serves as a memory aid. Checklists are often compiled from "lessons learned" gleaned from analysis at project closeout. One problem with such checklists is cultural blindness to issues that may threaten a project. Schmidt et al. (2001) suggested that a more comprehensive checklist can help overcome cultural biases that may hinder the recognition of key risks.

There are two problems with the checklist approach. First, such a list may not be complete. Second, some risks on the list may have been overcome by events, making the list outdated. In the first case, the manager might overlook important risk factors, and in the second case the manager might spend valuable time preparing for a contingency that is not a risk at all.

For some years, Boehm's (1989) top 10 list was used as a starting point for risk analysis. By the mid-1990s, several independently compiled checklists were available. An examination of those checklists combined produces 33 distinct risk factors. A study that unified and expanded the existing checklists presented a list of 53 risk factors (Schmidt et al., 2001). Table 1 lists the 11 software project risks deemed most important by the international panel of experienced project managers polled in that study. Considering the currency of this unified list, it is not likely to suffer from the second weakness discussed here, but this list was compiled based on the experiences of project managers with traditional software projects. For that reason, it suffers from incompleteness when considering Internet-based project risk.

Table 1 Top Eleven Risks

RANK	RISKS
1	Lack of top management commitment to the project
2	Failure to gain user commitment
2	Misunderstanding the requirements
4	Lack of adequate user involvement
5	Lack of required knowledge or skills in project personnel
6	Lack of frozen requirements
7	Changing scope or objectives
8	Introduction of new technology
9	Failure to manage end user expectations

The discussion of Internet-based project risks in the preceding section suggests several new risks that should be added to any checklist a project manager might use. It also suggests that the likelihood of some previously known risks' occurrence should be increased. There is no guarantee that all eventualities have been taken into account, however. The project manager needs more than just a checklist to prepare for risk management.

Brainstorming

The other major approach to risk identification is brainstorming. This method allows for the recognition of new and unusual risks that might be uniquely associated with a given project. Groupware provides an electronic forum in which brainstorming can be conducted across a wide group of participants regardless of their geographic or temporal separation. Special tools are available for capturing, classifying, and winnowing suggested risks to obtain as comprehensive a list as possible.

This method relies completely on the combined experience of the participants in the brainstorming session. If the participants lack sufficient experience, it is not likely that they will have encountered all the common risk factors, let alone less common risks that might apply to the project at hand. This is especially true for Internet-based projects, because most project managers have not had any experience with this form of project management, and even the seasoned Internet managers' expertise cannot compare with the long experience of traditional project managers.

General Principles

Thus, it is not likely that a single method of risk identification will suffice for any given project. The recommended approach is to supplement the checklist with a brainstorming session to identify potential risks not found on the checklist. The evaluation period immediately after brainstorming can help identify listed risk factors that are not pertinent as well.

After identifying the risks, the project manager must evaluate each risk in terms of its likely impact on the project, as well as the likelihood of its occurrence. This evaluation should be done in coordination with all the stakeholders in the project. These stakeholders will have a better appreciation of the expected outcomes for some risk factors. For others, the project manager should review the records of past projects of a similar nature in the organization. With this information in hand, the manager can assess the relative expected outcomes of the various risks. Once this is done, the more serious threats to the project will have been identified. Next, the manager will be ready to consider countermeasures for these risks and prioritization of action based on the relative expected outcomes.

Planning for Risk Countermeasures

Controlling risks is not a simple matter. Most managers would like to manage risks through elimination of the risk. This can be done by removing or countering any factors that might threaten the project. An examination of the lists of risk factors given by Schmidt et al. (2001) and found

in the previous section of this chapter reveals that these risks cannot be controlled in this manner. For example, the project manager cannot secure a 100% guarantee that all of the team members will stay with the project through completion. Even iron-clad contracts cannot counteract sickness, injury, or death.

Most managers take a rather simple approach to risk planning. They consider risks in three general categories: those that come from a source within their control, those that are beyond their control, and those that are a shared responsibility (Schmidt et al., 2001). Their behavior toward each category is based on their desire to manage the expected outcome of the risk down to zero. For factors beyond their control, managers are apt to take no action whatsoever (March & Shapira, 1987). For those within their control, managers have confidence in their ability to handle each risk effectively. Managers spend most of their time and effort on the risk factors that have a source that is a shared responsibility. This categorization of risks suffers from one serious flaw: It does not consider the probability of the occurrence of a given risk.

For example, the project manager would probably view the exit of a team member from the project as a factor beyond his or her control. Even though managers spend considerable effort on retention of team personnel, little or no effort would be expended to prepare for the eventuality that a team member would leave. Turnover in the IT field is high, however: In IT projects it runs to nearly 30% (Keil et al., 1998). Considering the budgetary and political impact of a serious delay in project completion, the expected outcome of a team member's exit is high. In their survey of American managers, Schmidt et al. (2001) found that this risk factor did not even make the list of risk factors to be ranked for potential action.

The manager must be aware of such biases and prepare plans accordingly. An important technique in this regard is to use a classification scheme that is free of bias. Once properly classified, the manager can choose the appropriate strategies for dealing with each class of risks.

Classifying Risks

There are numerous ways of classifying risks. One simple method is to look at the sources of the risks. Schmidt et al. (2001) identified 14 risk sources and sorted their 53 risk factors according to these sources. Dealing with risks in this manner immediately suggests some actions that can be taken to control the sources of the risks. It also provides the manager with an indication of where to direct action.

Keil et al. (1998) suggested a four-quadrant approach to classifying risks (Figure 1). They use two dimensions, the level of expected outcome and the level of control the manager has over the source of the risk, to map a 2×2 grid. Each quadrant of the grid then suggests some general approaches to controlling the risks associated with the quadrant.

Cule et al. (2000) took a similar approach but further suggested that appropriate coping behavior for the four quadrants should be effective for any risks in those quadrants. In such case, it would not be necessary to identify and assess every individual risk. By treating each class of risks rather than individual risks, the risk management process is greatly simplified.

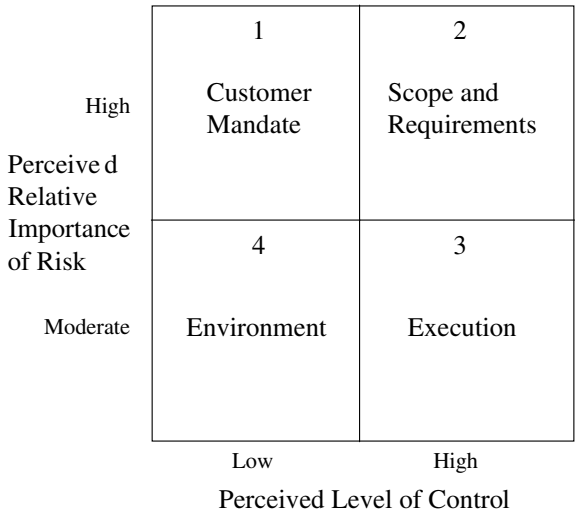

Figure 1: Risk Classification Framework. From Keil, et al. (1998). ©1998 ACM, Inc. Reprinted by permission.

Regardless of the approach taken to cope with risk, the classification of risk factors into four quadrants has considerable merit. It is obvious that no project manager could possibly attend to 53 or more risks, and it is doubtful that full attention could be paid to 14 sources of risks. Although a few large projects have used risk mitigation teams to cope with large numbers of risk factors, the vast majority of projects are too small to afford such an approach. By grouping the sources according to the scheme devised by Keil et al. (1998), the project manager can devise coherent strategies to counter the more serious risks facing the project.

It is important to understand that a specific risk factor might be assigned to a different quadrant from project to project, depending on its expected outcome and the assignment of authority. Consequently, the coping strategy chosen will shift from case to case for the same risk factor.

Choosing Appropriate Strategies

The highest priority group of risks to consider is risk factors that have a large negative expected outcome and are outside the direct control of the project manager. For example, if users and general managers develop a lack of trust in the project team, they may reject the team's work, leading to project cancellation or significant, costly delays. Coping strategies for such risks require relationship management, trust-building, and political skills (Keil et al., 1998). Because this is a high-threat category of risks, project managers must be prepared to take on these responsibilities.

But beyond the nature of these skills, the project manager must choose a specifically targeted approach to mitigate the anticipated risk. In the case of detached users and management, more rigorous scheduling and intensive performance tracking for reviews are necessary. A detailed communication plan should be in place to help mitigate this risk.

The remaining risk factors with a large negative expected outcome are directly under the control of the project manager. These risks largely can be controlled by

the project manager but do require skillful interfacing with the user or customer. Effective processes for managing change and ambiguity are needed. The real danger associated with risks in this category is that project managers may overestimate their own abilities or fail to realize their own limitations in dealing with the risks. With Internet-based projects, the lack of experience among project managers is a serious problem. If project managers assume the same practices they have used for traditional projects will suffice, it is likely that some of these risk factors will not be treated properly.

For risks that have a small negative expected outcome and fall under the direct control of the project manager, more routine project management techniques would be appropriate. The emphasis should be on internal and external reviews with the aim of keeping a project "on track." Considering the low threat these risks hold for the project, it would be more likely for the manager to try to treat these risks with a blanket approach as advocated by Cule et al. (2000). Direct attention to each of these risks would be disproportionate to their relative importance to the project.

The final class of risks includes those over which the project manager has little or no control and also have a small negative expected outcome. The primary problem with this class of risks is that because they are not viewed as being terribly important, the project manager is less likely to expend any political capital in getting anyone else to attend to the risks. Sometimes the small negative expected outcome is due to the low likelihood of occurrence of a risk. If such a risk has a large magnitude, then when it hits a project, its effects can be significant and dangerous. It is extremely difficult to plan for these risks. Because of their rare occurrence, there is a dearth of experience in dealing with them and it is impractical to engage in elaborate preventive measures to mitigate the risks. Contingency planning, including concepts and tactics associated with disaster planning, is the most sensible strategy for dealing with this class of risks. Scenario building is another approach for developing plans to deal with these risks should they occur (Phelps, Chan, & Kapsalis, 2001).

CONCLUSION

In this chapter, the possibility of new risks associated with Internet-based project management was explored. Existing knowledge about software project risk was summarized, and the concept was extended to cover specific situations typical of Internet-based projects. Four important concepts were emphasized. First, all risks can be traced to a source, and action taken to manage risks should be directed at the sources of risk. Second, identification of project risks is a key process in risk management. A hybrid approach using checklists of known risks combined with brainstorming to adjust the list to a specific project provides the best approach to identifying risks. Third, rather than classify risks according to source, the risks can be classified using a 2×2 grid that compares level of expected outcome with degree of control over the outcomes. Fourth, project managers can manage most risks with some simple coping behaviors. Some risks (those that pose the most serious threats to the project), however, require specific, targeted treatment.

GLOSSARY

Expected outcome The product of the magnitude of an outcome and the probability of its occurrence.

Groupware Software specifically designed to support group interaction, including brainstorming, collaborative work, and consensus building.

Internet-based project Any project that is principally or wholly managed through the use of Internet tools, rather than through face-to-face interaction.

Risk An event with an uncertain outcome.

Risk factor Any factor that could affect the outcome of a risk.

Workflow management The active oversight and direction of a series of tasks by any group of actors working in concert toward a common goal.

Rule-Based and Expert Systems

Robert J. Schalkoff, *Clemson University*

INTRODUCTION

One of the most widely used models of knowledge representation and manipulation is the production system. Rule-based systems may be thought of as a subclass of production systems. Production systems are conceptually simple and, when implemented as shells in "canned" form, may be developed with a minimum of specialized programming. Examples of such system shells are OPS5, CLIPS, and Corvid (see "OSHA Compliance Monitoring and Advising" later in the chapter).

The term "expert system," although seemingly a catchall in current jargon, is used to indicate a subset of production systems that are restricted to specific task domains. Many expert systems (ESs) are implemented using the rule-based paradigm, in which knowledge is encoded in "if–then" form.

The explosive growth of the Internet has created a large application environment for rule-based expert systems. Many of these systems are packaged inside so-called intelligent agents. Applications include recommender systems for e-commerce, online portfolio selection, network monitoring, and expert advisors for OSHA (U.S. Occupational Safety and Health Administration) compliance monitoring. In addition, there are efforts to standardize the communication of business-related rules across the Web. These are described more fully in Selected Internet Applications at the end of the chapter.

THE PRODUCTION SYSTEM PARADIGM AND RULE-BASED SYSTEMS (RBS)

Overview

Figure 1 shows a somewhat simplistic and generic rule-based production system (Schalkoff, 1990) consisting of the following:

1. A database of information or knowledge (e.g., facts).
2. A set of productions (e.g., rules) that modify the existing database and whose applicability is conditioned on the current database.
3. A control mechanism or rule interpreter that determines the applicability of the rules in the context of the current database and selects the most appropriate rule(s) through a process known as conflict resolution.

Productions in production systems are specified by a set of condition–action pairs. Specification of conditions in the form of "if" statements and actions via "then" yields the familiar rule-based system representation. Production systems may also be thought of as a subset of pattern directed systems, systems in which production applications are driven by input (or initial) data patterns. Production system operation is based on a "production cycle" of searching for applicable rules, selecting a particular applicable rule, using (firing) the rule, and repeating the cycle. Firing of a rule usually results in some modification (e.g., addition or deletion of facts) of the current database.

Rule-based systems provide a natural means to express situation–action heuristics in problem solving. They are also a natural means to express observed human behavior. Thus, a rule-based paradigm is a natural choice for expert system implementation. Rule-based expert systems are typically based on if–then (implication)–based representations of knowledge obtained from expert query and applied in narrowly defined problem domains.

Following is an example of a rule from the DENDRAL (Lindsay, Buchanan, Feigenbaum, & Lederberg, 1980) expert system. DENDRAL is one of the oldest ES, having been developed in 1964 (in the programming language LISP). A typical production in DENDRAL (Harmon/King, 1985) is the following:

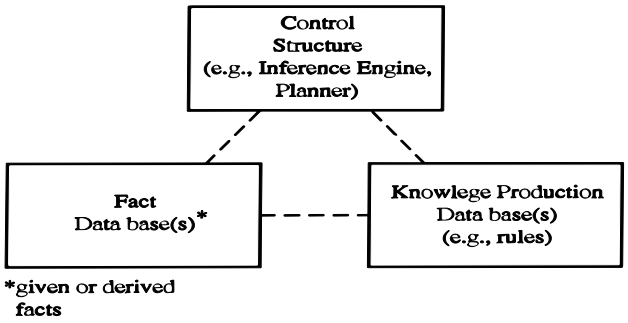

Figure 1: Basic production system architecture.

If
the molecule spectrum has two peaks at masses
$x1$ and $x2$ such that
$x1 + x2 = M + 28$ AND
$x1 - 28$ is a "high" peak AND
$x2 - 28$ is a "high" peak AND
at least one of the $x1$ or $x2$ is high,
Then
The molecule contains a ketone group.

Another sample rule, taken from the online technical support example in the "Web-Based Technical Support" section is this:

if "symptom" = "Label Designer hangs on converting
databases dialog"
and ("BackTrack Version" <= "4.10")
and "second edition" = "yes"
and (operating_system = "Windows 98 Second Edition"
or operating_system = "Windows 98")
then problem = "Win 98se"

Figure 2 shows a more realistic rule-based system architecture, which takes into account practical concerns such as user interfacing and structuring and partitioning of the fact and rule databases.

Features of Rule-Based Production Systems

Advantages

Characteristic of systems employing productions in rule form are the following generally positive features:

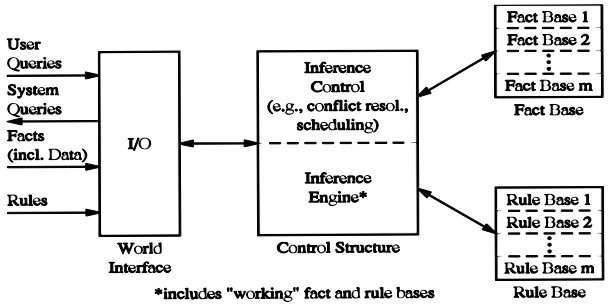

Figure 2: More complete rule-based production system structure. Includes structured rule and facts databases and user interface.

1. Expressibility (rules allow the expression of knowledge in a form understood by human experts and at the same time sufficiently quantitative for symbolic manipulation by the machine).
2. Ease of modification of the database (facts and or rules may be added or removed); in addition, the development and implementation of systems that are highly modular (e.g., see Figure 2) is straightforward.
3. Ease of exploring the current knowledge base contained in the system (i.e., the encoding of information is in a readable form).
4. Flexibility of processing (the inference mechanism(s) may be chosen to suit the problem).
5. Ease in following the inference mechanism (the order in which rules were employed may be recorded and traced for an "explanation" of the system's conclusions).
6. Standardization in terms of a knowledge representation and inference approach.
7. Availability of off-the-shelf software for implementation.

Disadvantages

Disadvantages of productions in rule form include the following:

1. Inability to predict system behavior for a given problem. (This characterizes many AI computations.) In other words, there may be many solutions, no solution or a unique solution, and the only way to establish this is via IE search.
2. Inability to force a specific production sequence compared with imperative programming. (Note some expert system shells allow manipulation of inference engine parameters to accomplish this.)
3. Lack of suitability for all applications.
4. Lack of ability to implement directly "deep reasoning" and "common sense." Note that this is a general representational issue, not an inherent shortcoming of the rule-based production system paradigm.

THEORETICAL AND COMPUTATIONAL ASPECTS OF RULE-BASED SYSTEMS

The Logical Basis of Rule-Based Inference

Generation of new facts or verication of a goal fact set in a rule-based production system proceeds by linking the "then" parts of rules to the "if" parts of other rules and proceeding until the goal statement is proven to be true or no new facts may be produced. This process is called chaining and is accomplished under the control of the inference engine (IE).

Consider a simplistic rule of the (abstract) form:

$$\text{If } p \text{ then } q,$$

where p is denoted the rule antecedent and q is denoted the consequent. More formally, p and q are statements in logic, connected by implication (the symbol $\rightarrow$ denotes the implication connective), and this is normally written

as

$$p \rightarrow q. \tag{1}$$

Modus ponens (MP) is one logical basis for chaining and is based on the axiom

$$\{(p \cap (p \rightarrow q)) \rightarrow q\} = T. \tag{2}$$

Thus, given a rule (which itself is assumed to be TRUE) of the form $p \rightarrow q$, to prove $q(= T)$, we must verify $p(= T)$ in the database. Typically, Equation 2 is shown with the following notation:

$$\begin{array}{r} p \\ \underline{p \rightarrow q} \\ q \end{array} \tag{3}$$

Rules typically involve variables to enable a more general representation. For example, a rule indicating "X is the grandparent of C" in the form of Equation 1 might look like this:

$$[(\text{parent } XY) \cap (\text{parent } YZ)] \rightarrow (\text{grandparent } XZ). \tag{4}$$

In this example, notice the use of variables that appear multiple times (i.e., are shared) in the antecedent (i.e., variable Y) and those that are shared across the antecedent and consequent (i.e., variables X and Z). Assignment of a value to a variable is called binding. Given a database of clauses of the form (parent tom sally) and so on, it is necessary to find a consistent set of bindings for variables X, Y, and Z to use the rule in Equation 4. Such a set of bindings is called a unifying substitution. When rules involve variables, as in the preceding example, MP is revised as follows:

$$\begin{array}{rl} p^1 & \text{(statement(s) without variables)} \\ p \rightarrow q & \text{(rule with variables)} \\ \dfrac{(\exists\theta)(p^1 = p\theta)}{q^1 = q\theta} & \text{(unifying substitution).} \end{array} \tag{5}$$

THE CONCEPT OF CHAINING AND INFERENCE DIRECTIONS

Chaining is an important concept in the implementation of a rule-based system. It is typical that the consequents of some rules are the antecedents to others (using unifying substitutions, where necessary). These links form potential "chains," which are logical links or paths through the system rulebase. A forward chaining (or antecedent-driven) production system attempts to form chains from the initial fact base to a database containing the goal. A backward or consequent-driven paradigm attempts to form (conditionally) chains backward from a goal database to the initial facts database. Hybrid strategies involve both forward and backward chaining. Whether a production system is implemented through a forward, backward, or hybrid chaining paradigm, the IE searches for one or more paths through the problem state space and may therefore explore a large number of redundant or unsuccessful paths in the process. A good IE design uses all available a priori information (such as properties of commutativity and decomposability, if applicable), to avoid needless or unproductive searching.

Potential Complexities in Chaining

Referring to Equation 2, rule-based inference becomes complicated in a number of realistic situations, including the following:

1. There exist many rules to choose from, that is, the database contains multiple rules of the form

$$\begin{array}{lll} p_1 & \rightarrow q & (= T) \\ p_2 & \rightarrow q & (= T) \\ & & \vdots \\ p_n & \rightarrow q & (= T). \end{array} \tag{6}$$

   Thus, we have the initial problem of choosing a rule.
2. The antecedent p in a rule is not a simple statement, but a compound expression in logic, for example,

$$p = p_1 \cap p_2 \cap p_3 \ldots \cap p_n. \tag{7}$$

   Thus, it is necessary for the IE to verify $p_1 \cap p_2 \cap p_3 \ldots \cap p_n$.
3. Assuming (shared) variables are involved, there are multiple bindings that would satisfy all antecedents in the structure of the antecedent in Equation 7.

All of these circumstances may occur in realistic problems.

THE INFERENCE ENGINE (IE)

The heart of a rule-based production system is a database (facts and rules) and the corresponding inference mechanism or inference "engine" that manipulates this database. As noted, the inference engine (IE) is responsible for

1. Selection of relevant rules (or sets of rules), which may pertain to a specific reasoning scenario that the control mechanism determines should be focused on.
2. Determining the suitability of a given rule, using the criteria listed here, given the current database.
3. Execution or firing of the rule(s) and subsequent modification of the database.
4. Determination if the overall goal has been satisfied.

In practice, the control strategies used to implement conflict resolution (rule selection) are diverse. They may range from tests as simple as "fire the first rule found to be applicable" to "fire the rule that (according to some heuristic) gets the system closest to the desired goal state."

It is entirely possible for the IE to be formed from a production system in which meta-rules (rules about rules) are used to guide the selection of production system rules.

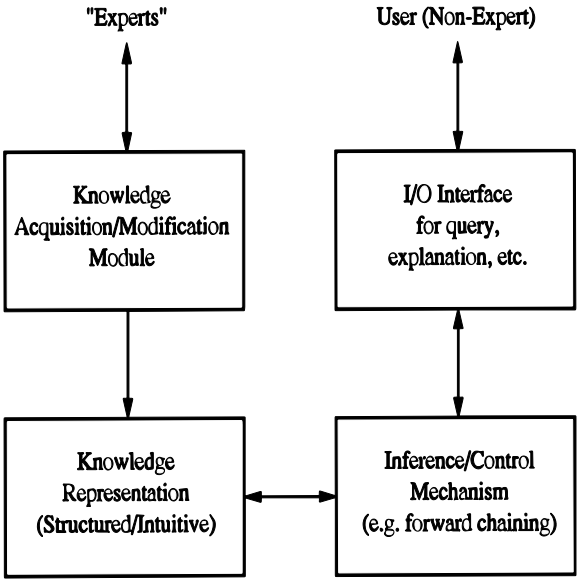

Figure 3: Overall expert system structure indicating both development phase (knowledge engineering) as well as system interface to nonexpert.

Although perhaps enabling a more sophisticated rule selection mechanism, this approach necessitates the design of another meta-rule-based IE.

RULE-BASED EXPERT SYSTEMS DEVELOPMENT

The term "expert system," although seemingly a catchall, is used to indicate subset of production systems that are restricted to specific task domains: Expert systems are programs that attempt to emulate the behavior of human experts, usually confined to a specific field. Expert system shells and knowledge acquisition systems have been developed using disparate approaches to knowledge representation and manipulation as well as user interfacing. A sample ES structure is shown in Figure 3.

The following are typical attributes of an ES:

1. Knowledge is usually represented in declarative form to enable easy reading and modification. Most ESs use if–then structures for representation; thus, rule-based ESs predominate.
2. There is usually a clear structure to the knowledge representation (this excludes neural expert systems).
3. There is a clear distinction between the knowledge representation and the control or manipulation mechanism.
4. A significant user I/O (input/output) interface is provided to allow query, advice, explanation, and interaction with the ES.
5. A user knowledge acquisition or knowledge modification module is often provided for extension of the ES.

The Appeal of Expert Systems

The development of ES is motivated by a number of factors, including the following:

1. Expert-level knowledge is a scarce and expensive resource.
2. ESs make expert behavior available to a large audience. This is especially true of those implemented using the Internet.
3. The integration of the expertise of several experts may lead to ESs that outperform any single expert.
4. ESs are not motivated to call in sick, leave a company for better working conditions, or demand huge salaries (although their development and maintenance costs are often substantial).

The potential for expert systems is enormous. Declining development costs have led to numerous efforts in developing both small, easily modified ES, as well as large systems. The quantification coding of human insight, compassion, motivation, guessing ability, and learning capabilities is still an elusive goal, however. Often the ES design process requires a minimum of new technology and a large amount of engineering judgment.

Expert System Examples

Many ESs have been developed and are currently in operation. An early example of a commercially successful systems is XCON from Digital Equipment, which configured computer systems. XCON was written in OPS5, a rule-based programming language. Other historically significant examples include MYCIN (Buchanan & Shortliffe, 1984) and CADUCEUS, used for medical diagnosis, and PROSPECTOR, which guided geological prospecting. When PROSPECTOR found a molybdenum deposit worth $100 million (U.S.), this application gained respect.

Expert System Challenges and Limitations

One might expect the performance of expert systems, which could tirelessly and exhaustively consider every possibility associated with a problem, to outperform humans in a spectrum of applications. This is currently not the case. ES developers have discovered that knowledge acquisition can be slow, expensive, and iterative. Furthermore, systems tend to be "brittle" in the sense that slight modifications in the application lead to unacceptable deviations in ES performance. It is not incidental that a human spends approximately 12 years past the age of 5 (or so) in formal schooling. Notwithstanding the possible lack of efficiency in this process, a significant amount of both information and experience (which is perhaps not as easily quantifiable) is gained over this time interval. In addition, most perceived experts have a considerable amount of additional informal and formal education past this point. Thus, we should not be surprised at even the practical difficulty of representing expert behavior.

Expert System Development

The first questions an expert system developer must ask are the following: Are bona fide experts available whose performance is significantly better than that of amateurs? Can their expertise be automated? and Does it make practical and economic sense to develop an ES?

The development of expert systems proceeds with the consulting of an expert (or group of experts) with the aim of developing a manipulable knowledge base. This is often referred to as knowledge engineering (KE). The first phase of the process consists of the formation of a database of domain specific knowledge. In the expert interrogation process, the formulation of "good" questions is paramount. Fortunately, experts often articulate problem-solving methodologies in terms of if–then structures. Moreover, an expert may volunteer rationalizations of the resulting rules (i.e., "I conclude this because . . . "). This type of explanatory production is also desirable.

The development of an expert system is almost always an iterative task, involving the cycle of expert query, database formation development of the inference strategy, verification of system performance, and so on. The gap between the concept of an ES and a finished, delivered product may be enormous. The necessary application-specific selection of a reasoning structure, interviewing of experts, development of a prototype, refinement, user training, and documentation may take several years.

One of the most important aspects of ES development is verification of system operation. A set of test cases is developed and used by both the ES and the human experts. When responses differ, modifications to the system and perhaps additional expert consultation are required.

The ability of an ES to provide the user with an explanation is also important. An expert system response such as "patient has disease x" is probably insufficient, even if correct, because no explanation of the inference process is provided. An explanation may be as simple as indicating the sequence of rules used or as complicated as indicating all possible inference paths considered and the logic that leads to the most appropriate response or conclusion.

Reasoning With Uncertainty

Unfortunately, knowledge may seldom be put into the rule-based if–then form without some concern for concepts such as impreciseness, ambiguity, and uncertainty. Although several techniques (e.g., fuzzy systems) are treated more fully elsewhere, the incorporation of measures of uncertainty in the representation as well as the inference (manipulation) strategy leads to more realistic ES implementations. A number of significant research efforts have attempted to incorporate uncertainty in inference techniques. These are the following:

1. Numerical approaches, which attempt to associate a quantitative measure of confidence (or certainty) with the truth value of facts. This includes fuzzy set and probabilistic approaches. For example, "certainty factors" have been used to quantify uncertainty in expert reasoning. In the expert system MYCIN, a confidence scale of [−1,1] was used to represent the range of confidence associated with a particular fact or assertion (conclusion). A value of −1 indicates total lack of confidence (i.e., complete confidence the assertion is FALSE), whereas a measure of 1 represents complete certainty the assertion is TRUE. If, after exhausting all search possibilities, the cumulative confidence measure associated with a hypothesis is in the interval [−0.2, 0.2], the hypothesis is regarded as unconfirmed. Of course, this is an empirically determined range that is subject to modification or alternate interpretation in a particular application.
2. Symbolic approaches incorporate uncertainty but in a less numerically quantitative manner. Examples are linguistic extensions to the connectives of classical logic that allow statements using "perhaps," "may be," and so on. An example rule is the following:

```
If  symptom is believed to be spots,
then  diagnosis may be measles.
```

3. Another approach is the use of multivalued logic (Bolc & Borowik, 1992).

Rule-Based Expert Systems and Intelligent Agents

The notion of agents brings together a number of technologies and research areas, including artificial intelligence, software engineering, robotics, and distributed computing. Agents are a powerful, natural metaphor for conceptualizing, designing, and implementing many complex, distributed applications. A quantitative definition is "an agent is an encapsulated computer system that is situated in some environment, and that is capable of flexible, autonomous action on behalf of its user (or owner) in that environment in order to meet prespecified design objectives."

The Internet is arguably one of the most complex, changing, and unpredictable environments with which software designers must deal work. At the same time, Internet applications are arguably one of the most important areas from both technical and economic perspectives. The Internet may offer one of the best opportunities for the agent paradigm.

The current trend is that of multiple agents; a multiagent system is one that consists of a number of agents that interact with each another as well as the environment. Characteristics of an agent include the following:

1. An agent is a problem-solving entity with well-defined boundaries and interfaces.
2. An agent is embedded in a particular environment.
3. An agent is designed to achieve specific objectives.
4. An agent is autonomous.
5. An agent is flexible and displays (context-dependent) problem-solving behavior. In other words, the agent is reactive.

One connection between agents and expert and rule-based systems is straightforward: Expert or intelligent agents may be implemented using a rule-based paradigm. Sample applications are shown in Katz (2002) and Grosof (1995).

SELECTED INTERNET APPLICATIONS

Web-Based Technical Support

Numerous examples of Internet-based technical support exist. Software companies, in particular, observed early on that many product technical support issues revolve around problems that recur. Web-based technical support for these problems provides a number of benefits for both the company and its customers. For example, a certain percentage of customer support issues may be solved autonomously. The customer gets a quick resolution of the problem, and technical support resources are conserved for the more challenging problems. In addition, autonomous Web-based technical support serves as a filter for human technical support. When a customer does not get a resolution to the problem using the online expert system, human technical support may be invoked. An additional benefit is that preliminary problem information has already been acquired by the autonomous system and thus the duration required for the session is shortened. Finally, the autonomous system may gather all the data from many Web-based support sessions and thus provide a comprehensive database of previously encountered problems and corresponding solutions.

An example of this approach is Strandware, which develops bar-code label design and data collection software for industrial and business tracking applications (http://www.strandware.com/). (A sample rule was shown earlier.) The rule-based automated technical support system is implemented using Amzi's WebLS product. WebLS is a simple ES tool, designed specifically for deploying expert systems on the Web.

When the customer initiates a support session, he or she is asked for information regarding the product and problem. The system uses this initial information to filter the rules that might apply and gathers additional information as needed in its search for a problem resolution. A sample screen is shown in Figure 4.

The Strandware ES is composed of questions, rules, and answers. An initial goal starts the system searching through the rules. The antecedents of some rules in this system are facts with values that can be obtained by querying the user. The following are two such facts related to diagnosing a 16-bit ODBC (open database connectivity) problem:

```
question("second edition", [
     prompt = $Is it Second
        Edition or have you
               installed the Y2K
                 update?<BR>$,
     ask =yes_no,
     askAfter = ["symptom"]
]).
question("BackTrack Version", [
     prompt = $What version of
       BackTrack are you
               running?<BR>$,
     ask = field,
     askAfter = ['symptom']
]).
```

Details of the Strandware system are provided at http://www.amzi.com/customers/strandware.htm and in Hicks (2000).

Electronic Commerce: Recommender Systems

E-commerce provides many opportunities for advanced automation, including gathering and using information on potential customers, buying trends, and product purchases. This information may be used to suggest future purchases to previous customers. A knowledge-based recommender system (KBRS) generates purchase recommendations by consulting a product information knowledge base and then reasoning what products will best satisfy perceived user requirements (Burke, 1999). One technique for building a recommender system is a knowledge-based approach called the PersonalLogic system. This system helps users make decisions on wide range of product choices. The system first acquires user requirements in a particular product domain (e.g., automobiles) and then consults its knowledge base to find suitable items that satisfy the users' requirements. An automobile shopper could provide requirements such as automobile type, size, features, and price range, and the system would then search its knowledge base for automobiles that best satisfy these requirements.

Online Portfolio Selection

PORSEL (PORtfolio SELector) (Zargham & Mohammad, 1999) is a system for analysis and selection of stocks. PORSEL allows for fundamental analysis and uses an expert system. PORSEL is a Web-based client–server system, with the stock analysis programs and an associated information database residing on the server. The Web allows remote access to the system.

PORSEL uses a fuzzy rule-based system to perform fundamental analysis. Fundamental analysis primarily uses information about a company to predict future movements of the company's stock. This is the approach articulated by a number of famous investors, thus a large body of knowledge is available for use in creating rules. Most rules are derived from well-known rules, such as Graham's rule:

> If a stock has a price-to-earnings ratio of less than 40% of the stock's highest price-to-earnings ratio over the past 5 years, then the stock's rating is good.

PORSEL has shown excellent performance when compared with the Standard and Poor's 500. Sample results are shown in Table 1. (Note that these results represent retrospective, not prospective, performance.) Here, all shares were purchased at the beginning of the year, held for the entire year, and sold at the year's end. PORSEL then selected 20 new stocks for the the next year. "Equal proportion" means that the same amount was invested in each of the selected stocks, whereas "Variable proportion" indicates that PORSEL also optimized the relative amount invested in each selected stock.

Table 1 Sample PORSEL Performance

YEAR	EQUAL PROPORTION	VARIABLE PROPORTION	S&P 500 INDEX
1989	55.5	58.8	31.49
1990	73.06	89.5	−3.17
1991	109.3	226.5	30.55
1992	29.1	−4.0	7.67
1993	567.4	573.5	9.99
1994	38.1	44.4	−1.50
Average	145.41	164.78	12.5

S&P = Standard and Poor.

Network Monitoring

ExperNet (Vlahavas, 2002) is a multiagent system for monitoring computer networks, detecting problems, and diagnosing the source of problems. Each agent in the system is responsible for managing a portion of the network (e.g., a single agent manages each subnet). Using multiple agents has many advantages, including fault tolerance and a reduction in the amount of monitoring information transmitted over the network.

Each agent has a modular structure. The "Device" knowledge base system comprises the expert system shell in which rules are implemented. Device is implemented on top of CS-Prolog II. CS-Prolog II uses an extension of HNMS network management software, called HNMS+, to acquire information about the network. The system also uses a computer monitoring program called BigBrother to gather information about the computer to which the agent is attached. This information is used to infer information about the network's performance. Device provides many interesting features, such as support for multiple rule types (deductive, production, and event-driven rules) and object orientation.

OSHA Compliance Monitoring and Advising

OSHA compliance monitoring, for many companies, is a complex, time-consuming, and important issue. Rather than providing a static database, OSHA, using the Corvid ES development tools from EXSYS (http://www.exsys.com/exsys.html), developed eTools for this purpose. These tools are available at http://www.osha.gov/dts/osta/oshasoft/. According to OSHA,

> eTools are "stand-alone," interactive, Web-based training tools on occupational safety and health topics. They are highly illustrated and utilize graphical menus as well as expert system modules. These modules enable the user to answer questions, and receive reliable advice on how OSHA regulations apply to their work site.

Corvid allows the development of interactive experts that deliver individualized decision-making knowledge from a Web page or as stand-alone systems. The Exsys CORVID developer interface provides two ways to view the underlying system logic through Logic Blocks and individual rules. The Rule View window shows the full text of each rule in English, making the rule simple to read and interpret. A wide range of interfaces and controls are available for how questions are asked of the system user and for integration with other software.

CORVID Logic Blocks may be integrated with forward or backward chaining. Furthermore, Logic Blocks are built and maintained in a visual development environment. The underlying knowledge representation in the block is an if–then rule.

CommonRules

Although not strictly a simple ES, the IBM CommonRules framework is highly related to both e-commerce and rule-based systems. In 1999, IBM developed an application called CommonRules 1.0: Business Rules for E-Commerce. Its goal was to make a program available that would allow businesses to communicate their "business policy rules about pricing, promotions, customer service provisions for refunds and cancellation, ordering lead time, and other contractual terms & conditions, to a customer application/agent." An overview may be found at http://www.research.ibm.com/rules/commonrules-overview.html. According to IBM,

> CommonRules 3.1 is a rule-based framework for developing rule-based applications with emphasis on maximum separation of business logic and data, conflict handling, and interoperability of rules.
>
> . . . it provides a platform that enables the rapid development of rule-based applications through its situated rule engine via dynamic and real-time connection with business objects. CommonRules can be integrated with existing applications at a specific point of interest, or it can be used to create applications composed only of rules. (IBM Common Rules, n.d.)

Each business involved in e-commerce probably implements its own set of rules, implemented using many different languages. Because these representations are different, communicating business policy to customers or other businesses becomes challenging. The purpose of CommonRules is to eliminate this difficulty by using a semantically rich rule language called CLP (Courteous Logic Program). CLP incorporates many rule sets and a rule-based computational model. XML (extensible markup language) is the string format used for CLP, which makes it a natural format for the Web.

CommonRules 1.0 was developed in Java and runs on the user's computer. It accesses the Internet when invoked. When the user wishes to look at a seller's available business rules, the user downloads these rules and runs them through CommonRules to output a file with a set of user-readable rules. This eliminates the customer's needing to have the same rule representation of the seller to view its business policies. The current version of CommonRules is 3.0 and can be found at http://alphaworks.ibm.com/aw.nsf/download/commonrules.

CONCLUSION

Many internet applications may be enhanced with the perception of intelligent behavior. This "intelligent" enhancement may be achieved using a rule-based or agent-based computational paradigm. Examples include e-commerce, diagnosis, and compliance monitoring.

GLOSSARY

Agent Encapsulated and task-focused software structure.
Antecedent The "if" part of a rule.
Certainty factor One method to incorporate uncertainty in the inference process.
Conflict resolution Process of choosing which rule or rules to use in the inference process.
Consequent The "then" part of a rule.
Expert system Software intended to emulate human expertise.
Heuristics "Rules of thumb" intended, but not guaranteed, to aid in the solution of a problem.
Inference engine Production system controlling software.
Knowledge representation The paradigm chosen to encode knowledge (e.g., rules and facts).
Modus ponens A logical basis for rule-based inference.
Multivalued logic A logical system with more than two truth values.
Production (rule-based) system A conceptual and computational paradigm useful for building intelligent and expert systems.
Recommender system Software that tracks previous purchases and extrapolates to future recommendations.
Rule If–Then structure used to represent expertise or knowledge.

Secure Electronic Transactions (SET)

Mark S. Merkow, *E-commerce Guide*

INTRODUCTION TO SECURE ELECTRONIC TRANSACTIONS (SET)

Credit card theft on the Internet has reached epidemic proportions, and everyone who handles credit card numbers and expiration dates clearly needs to understand that the handling is akin to *toxic chemical handling* and mandates the utmost of care and diligence. The risks of theft and misuse of credit card data by thieves and nefarious users who target the databases and systems that store and maintain the data are too great to ignore or treat casually.

Daily reports of security breaches, extortion, identity theft, and general havoc continue to dog e-commerce and drive away large proportions of the buying public. To partially answer these concerns, the banking associations—Visa and Mastercard—jointly issued Secure Electronic Transactions (SET) as a specification to implement the business services needed for worldwide processing of credit, debit, and charge card transactions over open channels like the Internet.

SET opens the doors to e-commerce but comes with a steep price both in time and in dollars to implement. SET is complex—so complex that possible future use of the banking standard remains an open question. Unlike most other efforts aimed at secure e-commerce, SET mandates the involvement of all its participants—buyers, suppliers, card processors, and back-end bank system operators. SET compliance requires onerous efforts on everyone's part. In 2002, many industry observers and experts would say that SET is dead with the selling public still satisfied to use secure sockets layer (SSL), but perhaps SET is only hibernating, awaiting an elusive market catalyst.

Background

Early in the 1990s, banks were refusing to accept or process charges originating on the Internet and required merchants who wanted to sell their merchandise online to use existing infrastructures (dial-up, etc.) for charge authorizations; point-of-sale transactions, phoned-in requests for charge authorizations, and follow-on batch processing activities. These banks, led by pressures on two sides—merchants and consumers—began pressuring the Visa and MasterCard Associations to develop secure standards for using credit cards over any insecure channel, such as the Internet.

Visa and Microsoft responded with one standard they released in September 1995. The *Secure Transaction Technology* (STT) specification was posted to the Visa Web site for download by interested parties. At the same time, Microsoft announced that it would develop STT implementation tools for Windows 95 and Windows NT that could be licensed by developers. Tools for other desktop platforms would be developed by Spyglass Technology, which was behind what is known in 2002 as Microsoft's Internet Explorer software.

Meanwhile, MasterCard and its allies, Netscape, IBM, Cybercash, and GTE (now Baltimore Technologies), had developed the *Secure Electronic Payment Protocol* (SEPP) as a proposed specification and posted it to the

MasterCard Web site for a public comment period. MasterCard had hoped that SEPP could be in use for Internet transactions as early as April 1996.

Incompatible Payment Card Standards

STT and SEPP generated such heated debate and finger pointing between the two opposing factions that the entire industry was at odds. Both sides claimed their standards were defined with "openness in mind" and was designed in cooperation with the Internet standards-setting bodies, the W3 Consortium, the Internet Engineering Task Force (IETF), CommerceNet, and the Financial Services Technology Consortium.

Industry and financial services observers at the time believed that STT and SEPP were similar, yet different enough to render them incompatible. This meant that separate implementation efforts were required, and all parties desiring to support Visa and MasterCard products needed separate processing systems to meet the unique requirements of each protocol.

Not So Different After All

In fact, STT and SEPP both attempted to achieve the same objectives, but did so from different directions. These objectives included

Changing Internet-based credit card transactions from the risky *card-not-present* scenario (such as mail order/telephone order transactions) to the less risky *card-present* situation (such as retail shopping and eateries) to reduce the chances of fraud and increase the potential to lower the fees that merchants must pay for maintaining merchant accounts.

Requiring all parties in a transaction (customer, merchant, credit card processor, or bank) to possess digital certificates that establish their identities and their authority to conduct transactions.

Requiring that public-key certification agencies (Certificate Authorities) manage the certificate distribution processes on behalf of the card associations or member banks.

Using industry-standard public-key cryptography techniques, as developed by Ron Rivest, Adi Shamir, and Leonard Adelman (RSA Data Security).

Encrypting only credit card numbers and transactional data rather than encrypting the entire browser and shopping sessions.

Concealing credit card data from all merchants to prevent merchant-initiated fraud and reduce the risk of operating a merchant commerce server.

Enabling use of *any* type of credit card product, regardless of issuer. The card associations however, reserved the right to specify that only *their* protocols be permitted for transactions with their cards.

By the end of 1995, banks that issued both Visa and MasterCard were up in arms against the attempt to force two separate standards that accomplished the same task. The banks persisted and finally forced Visa and MasterCard to work together on a *single* standard, because supporting two separate ones appeared unachievable.

In February 1996, an announcement rocked the Internet community:

> Visa & MasterCard Combine Secure Specifications for Card Transactions on the Internet Into One Standard.

SET Consortium Established

According to the agreement, Visa and MasterCard, along with GTE, IBM, Microsoft, Netscape Communications Corp., SAIC, Terisa Systems, Verisign, and RSA Data Security formed the SET Consortium. Its goal was to resolve the differences and conflicts between STT and SEPP and develop a new unified standard.

The development of SET arose not so much from a spirit of mutual cooperation as from the intervention of major banks that saw the industry giants, Visa and MasterCard, heading in separate, nonintersecting directions. Obviously, for any pragmatic solution to the problems of electronic commerce, a single, standard approach, both flexible and platform-independent, was needed.

SET is designed to eliminate most problems of credit card usage and data management on the Internet, adding the following elements:

Message authentication to assure entities involved in a credit card transaction that they are dealing with whom they think they are dealing

Data integrity to prevent spoofed messages

Confidentiality to prevent eavesdropping

The first version of SET, based on the work of the SET Consortium, was released to software developers in draft form on June 24, 1996. The draft release, embodied in three separate electronic books, was intended to be used for testing and to elicit comments from outside experts. These books contained preliminary specifications sufficient for developers to build components that would "bolt on" to existing cardholder browsers, merchant commerce servers, and financial institution credit authorization systems. SET Version 0.0 appeared as follows:

Book 1—The business description containing background information and processing flows. It was intended as a primer on software that interfaces with payment systems and employs public-key cryptography.

Book 2—The programmer's guide containing the technical specifications for the protocol, intended for use by software developers who wished to build cardholder and merchant software components.

Book 3—The formal protocol definition, intended for use by cryptographers analyzing SET's security aspects, writers producing programming guides for toolkits or components, and system programmers developing cryptographic and messaging primitives. The formal protocol is cast in Abstract Syntax Notation (ASN.1).

With the initial release, SET Version 0.0 was placed under change control with a January 1997 deadline for enhancement requests to Version 1.0, and March 1997 for proposed corrections to the testing version. On April 21,

1997, SET Version 0.2 was released to the public, containing requests for enhancements that satisfied the additional needs of non-Visa/MasterCard issuers, such as American Express, Japan Credit Bank (JCB), and Novus/Discover.

On May 31, 1997, SET Version 1.0 was released to the public.

Complying with the SET Standard

Because SET is an open and neutral protocol, in theory it is possible to purchase any implementation from anyone who offers it without concern for proprietary ingredients. To turn this theory into a reality, independent testing is required to ensure compliance as defined by the specification.

SET Version 1.0 was the baseline standard that developers used to build their systems, knowing that later versions will most certainly supersede it. As SET versions evolved, software needed to be tested and retested for compliance with the new standards.

Developer interpretation of the specification was at the root of the problem. For SET to ever succeed, it needed a single, unambiguous understanding among developers that eliminated the possibility of proprietary implementations of SET. That is one of the major tasks of Secure Electronic Transaction, LLP, or SETCo.

Compliance Testing and Certification

SETCo operates under the sponsorship of the card associations, but is independent of them. They assume the responsibility for SET's development, maintenance, evolution, and market acceptance, and they regulate the use of the SETmark for products that successfully pass a rigorous compliance testing program. SETCo also maintains a dispute resolution board that decides how to best handle disputes or questions regarding an implementation. The SET Compliance Administrator (SCA) serves the administrative functions for SETCo, evaluating test results submitted by software developers and maintaining SET testing tool suites.

Upon signing SETCo's Master License Agreement and paying the fees, developers are given testing tools and scripts. These testing tools run through various permutations of SET messages, monitor, and log the results, and assist in identifying noncompliance (if it occurs). Once a developer is satisfied that its product is compliant, it sends the test results back to SETCo for verification. After SETCo is satisfied, it permits the developer to use the SETmark on its software. Each compliant software component of SET will bear its own SETmark, attesting that the component itself passed the battery of tests. The SETmark, however, does not ensure that the component will work properly with other counterpart SET components build by other developers. SETCo does not offer end-to-end testing services, nor does SETCo offer interoperability testing services.

Baseline vs. Derivative Systems

SETCo established rules separating the products that must be tested and certified from the ones that need not be. Each unrelated operating system implementation is considered a baseline product and must undergo full testing with submission of test results to SETCo. Derivative products are adaptations of baseline products intended for use on similar operating systems. An example of a derivative is a port from Solaris to AIX. The derivative must be documented for SETCo's purposes, and testing is strongly encouraged, but test results need not be submitted and no additional fees are charged. Developers decide which products they consider the baselines and which ones the derivatives.

In addition to the initial testing of the baseline version, SETCo requires developers to retest their products every 6 months. In the re-evaluation process, retesting is performed using the latest testing scripts, with the results resubmitted to SETCo for evaluation. If recertification is not performed, the developer risks losing the use of the SETmark. Periodically, SETCo may decide to audit completed software compliance tests. Reasons for these audits include random selection to assure conformance and reports from the field indicating suspected failures or compromises of security. To remain in the compliance-testing program, developers must pay an annual fee to continue licensing SETCo's services.

Whereas SETCo oversees the testing that ensures direct compliance of distinct components, the interoperability testing between components and between products from different companies remains the domain of SET developers, who take on the work themselves.

Vendor Interoperability Testing

Recognizing that interoperability is a critical hurdle, most SET developers agreed that their products must be tested for interoperability before they were introduced into the marketplace. Therefore, IBM and VeriFone produced the "Interoperability Reference Guide for SET Version 1.0," based on IBM and VeriFone's experiences culled from the testing they performed. The document describes test scenarios, assumptions in use, configurations for environments, and other related information. RSA Data Security Inc. also developed interoperability documentation to assist developers. The SET 1.0 Interoperability Test Plan defines a certificate infrastructure, data, and business scenarios that vendors may use to test their applications among themselves.

CREDIT CARD PROCESSING AND CORRESPONDING SET PHASES

To the uninitiated, credit card processing may appear straightforward and simple, but the complexity involved is hidden under the covers. To help understand SET within the context of its intended use, the following is a quick explanation of who is involved and what happens when a credit card charge is made and the goods are delivered.

Roles in Card Processing

A cardholder is the user of a credit card that was applied for and received from an Issuer Bank.

A merchant is an accepting destination for a credit card charge

An acquiring bank manages merchant relationships and accepts charge receipts from merchants as deposits into Merchant Accounts.

A card association (e.g., Visa and Mastercard) dictates the conditions under which its branded cards may be used and provides the network and processing to permit the three primary constituents (cardholder, merchant, and acquiring bank) to transact business.

Basic Credit Card Schemes

There are two major approaches to credit card schemes—closed loops and open loops. In a closed loop system, the issuer and the acquirer are the same organization—they manage both the cardholder and merchant relationships. Examples of closed loop systems include Discover (Novus), American Express, Japan Credit Bank (JCB), and Diner's Club (operated by Citibank). In an open loop system, the issuer of a credit card may or may not be the same as the acquiring bank. Because the Visa and Mastercard networks consist of well over 20,000 banks worldwide, there are a tremendous number of possible combinations (4×10^8) of issued cards and acquirer processors for any given charge transaction. For example, a cardholder holding a Visa card issued by Bank A may shop at a merchant who has a merchant account at Bank B. As the charge card is swiped on the merchant's point of sale (POS) terminal, a charge request is initiated and sent to Bank B (the acquiring bank), which places a charge authorization request on VisaNet. The Visa network then routes the request to Bank A to determine account status and sufficiency of credit for approving a new charge to the account. The response to this authorization request is an authorization response, containing an approve or decline status, along with a code for the merchant to use when the sale is completed (goods are shipped) and the merchant is ready to settle the charges.

SET provides the specifications for *request–response message pairs* that permits the parties involved to use open networks like the Internet to perform the same work that previously was performed using the private networks that the banks mandated for moving credit card information around. These message pairs offer the same business services that the private-network POS system offers, without the cost of dedicated network links and maintenance.

SET message pairs correspond to the following business services used for credit card processing:

Inquiry into charge transaction status

Payment processing

Authorization reversal when customers change their minds

Capture reversal when goods are returned for credit

Credit issuance when goods are returned for credit

Batch administration to settle charges and clear transactions

Certificate issuance for all entities

Certificate inquiries on pending certificate requests or status information

Error handling

SET Digital Certificate Management

SET certificate management and processing are in addition to any other transaction-based processing that takes occurs. The purpose of such processing is to ensure that certificates are current, are accurate, and are always ready for use when needed. SET cardholder certificates are constructed to mimic both the physical piece of plastic and the signature on the back of it. Merchant certificates ensure the transaction acquirer and the cardholders that they are dealing with a legitimate operator who is contractually obligated to the brand to remain honest. Charge processors and merchants are ensured that they are dealing with cardholders who have legitimate rights to use a brand product. Both merchants and cardholders are ensured that their transactions are seen and processed only by those charge processors who have legitimate rights to see and process them.

In some cases, a SET payment gateway is needed to validate SET digital certificates and preprocess authorization, capture, and settlement work. Payment gateways are operated by companies that perform the charge processing duties for merchants and banks. The terms *acquirer payment gateway* and *payment gateway* are synonyms. One example of a card processor in the U.S. is First Data Corporation in Omaha.

Because an SET merchant server takes the place of POS terminals, it needs to perform all the work POS terminals do, and then some. One significant benefit of using the Internet, rather than private networks and dial-up lines, is its flexible nature, which makes it possible to communicate freely. With Internet connections, it is possible to avoid some third-party work (with a resultant saving of their fees) by connecting directly to acquiring banks or card company payment gateways.

SET in Action During Charge Processing

SET is implemented as pairs of request and response messages that are enciphered using strong cryptography before being placed onto the public Internet to hide their contents to all but those intended to receive and process them.

In person, it is easy to check for a matching signature on a card or to ask a person for an ID. On the Internet, it is virtually impossible. Authentication thus can only occur through cryptography. SET uses a robust set of digital certificates to accomplish the identification and authentication activity. Each participant in a SET transaction requires a specific certificate or set of certificates that not only uniquely identify them, but also attest to their privileges as holders of payment cards or merchant accounts.

Before any transaction can take place, everyone involved needs one or more SET digital certificates. Without now looking specifically at how they are obtained, assume that the digital certificate issuance process has already occurred and everyone is prepared. Call this Phase 0.

Phase 0: All SET Software and Requisite Digital Certificates in Place

A cardholder of a Bank A credit card possesses a corresponding cardholder digital certificate and has installed the SET E-wallet software to operate with their Web browser. A merchant with an account at Bank B has installed the SET Merchant POS System and installed the requisite merchant digital certificates to enable it to operate. Bank B's payment gateway is up and running with

a payment gateway digital certificate for each credit card brand that it services.

Phase 1: The Shopping Experience

A cardholder visits a merchant's site, browses through the online catalog, and makes decisions about which goods to purchase for delivery.

Phase 2: Item Selections

As the cardholder selects goods to purchase, he or she adds the goods to the shopping cart that the merchant server uses, and the system dynamically tallies up the sale.

Phase 3: Check Out

Just as a shopper pushes his shopping cart to the cash register, the merchant server responds in kind when the cardholder proceeds to "Check Out." The shopping cart program adds up the costs of the items in it, adds sales tax, computes delivery and handling fees, and presents a list of selected items and the total back to the customer. When the cardholder is satisfied with the order, he or she proceeds to the payment selection phase.

Phase 4: Form of Payment Selection

With order totals still displayed on the screen, the consumer is given a choice of payment options. Assume the cardholder has selected a SET-enrolled Visa Card as the form of payment. *SET is now initiated*.

Phase 5: Payment Initiation Processing

By virtue of selecting a SET-enabled Visa payment, the merchant server sends a special message to the cardholder's browser, telling the e-wallet to *wake up*. This wakeup message tells the e-wallet to prompt the consumer to enter a secret password to unlock the wallet. The wakeup message also initiates the first SET payment processing message pair, called the Payment Initialization Request, which is generated and sent back to the merchant SET POS software (a component of the merchant server cash register functions). With a successful payment initialization response, the e-wallet then creates a SET purchase request message. This message has two components—a purchase order piece and a payment instructions piece. The merchant POS software can only read the purchase order. The payment instructions, containing information about the cardholder's Visa account, can only be deciphered and processed by the acquiring bank systems.

Phase 6: Payment Authorization Request

Along with the payment instructions, the merchant's SET POS software prepares a SET authorization request message intended for Bank B's payment gateway. The message contains the details about the amount of sale, the merchant account requesting it, and the previously created payment instructions component that the cardholder e-wallet software generated in Phase 5. When the authorization request is deciphered, the payment gateway creates a standard authorization request and places it on the bank's back-end private interchange network, which locates the cardholder's account at Bank A. With an approval code from Bank A to proceed with the sale, the payment gateway responds with a SET authorization response that tells the merchant's POS software to complete the sale. The

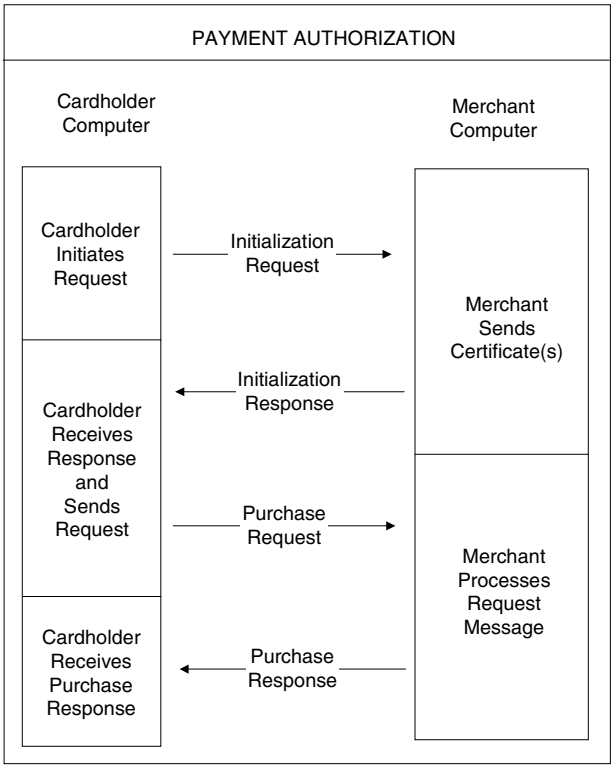

Figure 1: SET payment authorization flow between cardholder and merchant.

POS system then creates a purchase response message intended for the cardholder's e-wallet to confirm the sale and produce an electronic version of a receipt or record of charge.

Phase 7: Delivery of Goods

When the merchant POS system notifies the merchant's back office that a new order is ready for shipment, a shipping record is prepared and the merchant's POS system is informed of the business event via a data entry form.

Phase 8: Capture and Settlement

With the successful authorization code from Phase 6, the merchant's SET POS software received a capture record (SET calls these tokens). With the sale completed and the goods delivered, the POS software can initiate a capture request to finalize the sale with Bank B's payment gateway system. With each capture response, the settlement file grows, awaiting the merchant's decision to deposit these receipts into his or her merchant account at Bank B in exchange for funds transfer. Settlement file or batch processing is also carried-out via the Internet using SET's batch administration message pairs, designed specifically for those purposes.

See Figures 1 and 2 for illustrations of the flow for a SET payment authorization request/response message. Figure 1 illustrates the flow between cardholder and the merchant. Figure 2 illustrates the flow between the merchant and the payment gateway.

Although SET's actual processing work is identical to the work initiated via a POS terminal operating on a private network, SET makes it possible to use the Internet through its cryptography and message-passing

mechanisms. It turns the *public* Internet into a *private* network that protects every SET message pair.

SET uses two forms of messages that relate to requests for and responses to processing between the cardholder and the merchant, and between the merchant and the acquirer payment cateway. There is never a direct link between the cardholder and the payment gateway—the merchant always serves as the message broker between the two parties.

Digital Certificates for SET

Digital certificates represent identity for all SET participants by binding a person's identity to a pair of electronic encryption keys that are later used to encrypt or sign digital information. A digital certificate helps to verify someone's electronically transmitted claim that he or she is who he or she claims to be and has the right to use the encryption keys. SET digital certificates prevent people from using stolen or fraudulent keys to impersonate other people. Used in conjunction with encryption, digital certificates provide a more complete security mechanism than simple ID and password mechanisms and SSL protections. The contents of a generic digital certificate may include the following:

Owner's public key.
Owner's name.
Expiration date of the public key.
Name of the certificate issuer.
Serial number of the certificate.
Digital signature over the entire certificate created by the certificate issuer (CA).

The most widely accepted format for digital certificates is defined by the CCITT X.509 international standard; thus, such certificates can be read or written by any application complying with X.509. SET's version of digital certificates is a special "flavor" designed exclusively for credit cards. SET *extends* the X.509 standard for e-commerce to permit its international presence without concern for export controls on encryption products or services.

See Figure 3 for a representation of a basic X.509 digital certificate.

Certifying SET Participants

SET mandates that all users obtain salient key-pairs in a secure manner that is impervious to attacks. Because the cracking of keys requires inordinate time and effort, would-be thieves typically will strike at the management and maintenance systems that store keys, rather than through cryptanalysis of the keys themselves.

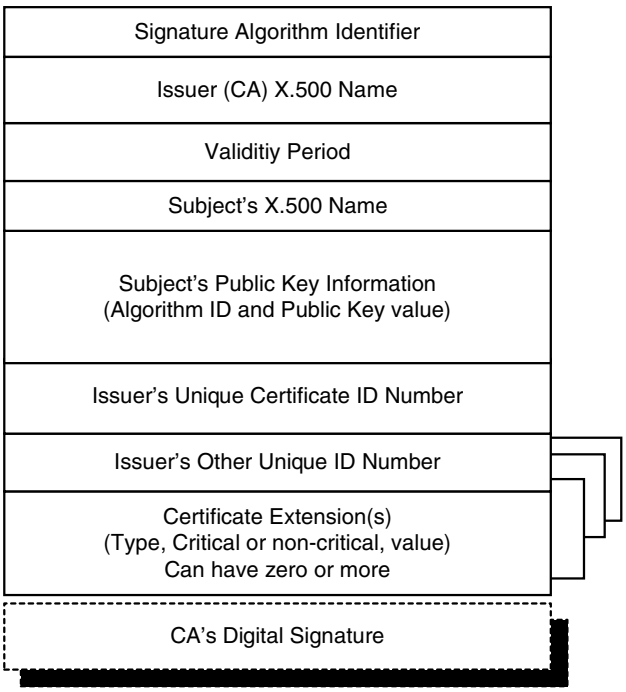

Figure 3: A basic X.509 digital certificate.

Table 1 Certificate Types Summary

Certificate Types	Digital Signature	Key Encryption	Certificate and CRL Signing

Payment Gateway	X	X	
Cardholder Certificate Authority	X	X	X
Merchant Certificate Authority	X	X	X
Payment Gateway Certificate Authority	X	X	X
Brand Geo-Political Certificate Authority	X		X

Root Certificate Authority			X

Digital certificates can aid in the effort to keep private keys secure while aiding in the dissemination of the related public keys (which together form the key pair). If a private key is disclosed (either by cryptanalysis or by theft), that fact needs to be shared so that the recipients of messages signed with the stolen key know to reject or disregard them. The mechanism that X.509 dictates and SET uses to determine if a private key has been compromised and reported is called the Certificate Revocation List, or CRL.

SET digital certificates attest to the binding of an end entity's public key to the end entity itself. Suppose Charles presents his payment instructions using his Visa Platinum Card from Bank A. When a merchant receives his message and subsequently forwards it for processing, both the merchant and the payment gateway can verify Charles' claim that the message and the certificate are his and no one else's. Because the private key tied to the Visa brand certificate was used to sign Charles' credit-card-based certificate, and Charles' message can only be decrypted using Charles' public key from the certificate, two things must be true; the message must have come from Charles, and upon successful certificate validation within the Visa brand tree of trust, the certificate must have been signed by the Visa brand certificate and no other.

In their basic forms, digital certificates contain the private-key holder's public key (half of the keypair), his or her name, the certificate's expiration date, a serial number, the name of the authority that issued the certificate, the policies under which certificate use is permissible, and any other information the issuer deems vital or useful. Most important, it contains the digital signature of the issuer. SET Certificates follow the ITU Recommendation X.509 for Version 3 certificates.

Summary of Certificate Types

SET's public key certificate hierarchy, or tree of trust, is an arrangement of certificate authorities (CAs) that implements the needs of each SET participant brand (Visa, Mastercard, etc.). These CAs hang off a root CA, operated by SETCo, which operates as SET's managing authority. The possible certificate types that may be present in the tree are summarized in Table 1.

SET APPEARS ON THE MARKET

With the release of Version 0.2 in 1997, developers began exploring how SET might be developed as a suite of products that covered the entire span of relationships mandated by SET. By 1998, new SET-compliant products appeared, such as the following:

Cardholder E-wallets

Integrated SET merchant POS systems and e-commerce systems

Payment gateway software for acquiring banks and card processors

Cardholder E-wallets

The first e-wallets appearing on the scene as SET-compliant immediately created an untenable situation for banks and cardholders. Banks do not tend to be very good at distributing software and software updates to millions of users. This fact, coupled with consumer skepticism of e-commerce as it existed in 1997 and the size of e-wallet download files, which ran up to 10MB downloaded over dial-up connections, led to downright uninterest and anger from cardholders.

Merchant POS Servers

The first suites of products intended to satisfy merchant requirements for SET could only be touched by those with the greatest patience and deepest pockets. Implementation would mean tens or hundreds of thousands of dollars in new hardware and software purchases in order to meet the stringent requirements for security. Banks did little to offer incentives to merchants to build SET compatibility into e-commerce, and at the same time, SSL-based security of credit card data over the Internet was thought *good enough*. Merchant uninterest in SET soon followed.

Payment Gateway Systems

A few pioneering banks began to develop their own payment gateway interfaces for SET, and SET pilot testing with willing merchants or simulated e-commerce systems using employees of the banks began to reveal problems in implementation and compatibility of implementations across software developers.

In the United States, NationsBank of Charlotte, North Carolina conducted the bank's first SET transaction in early 1998, demonstrating *some* interoperability between SET software providers. NationsBank worked closely with IBM, MasterCard, GlobeSet, and GTE to create a system for purchase of items from the MasterCard Emporium, an initial Web site built by the association to help consumers make small initial purchases and overcome their fears of shopping electronically.

Interoperability actually turned out to be more elusive than anyone had originally thought. For example, if an IBM CommercePOINT e-wallet failed to send properly formatted and decipherable messages to a GlobeSet POS system or vice versa, the IBM product would lock out customers or payment processors except for those who used the same software—creating an intolerable situation. Although any given SET suite may have worked flawlessly across all its own components, it was of no use if did not also work with components from other SET software developers. The situation was similar to the problem of a Web site owner insisting that visitors use one brand of browser to the exclusion of all other browsers. Merchants will never be certain which e-wallets shoppers use, nor can they know which payment gateway software their Acquirer bank uses.

By the middle of 1999, it looked like implementing SET—without adequate incentives from the issuers—was leading to a train wreck, and by 2000, several of the software providers for SET systems had sold off their assets and closed their doors forever.

With the ongoing pilot testing of SET Version 1.0, banks were finding that their consumers were experiencing agony and resentment when asked to deal with bank-branded electronic wallets. Banks were erroneously hoping their customers could perform these tasks:

Select SET-compliant e-wallets

Download them

Install them correctly on their PCs

Acquire the digital certificates for each credit card they wanted to use on-line

Always use SET for shopping and refuse to shop with merchants who were not SET-compliant.

Between the excessive downloading times for the huge e-wallet files (6MB+), encrypted transmissions that caused bandwidth-sapping operations, and unacceptable waiting times while transactions completed their processing, the testing banks and SET developers were forced to consider alternative software distribution approaches. Complicating the problems further, testing banks and SET developers assumed that merchants (and their webmasters) would become experts in banking systems for payment card processing. Initial implementations of POS components required near-ideal secure hosting environments, robust cryptographic processing facilities, and full understanding of banking and bank internetworks. As it turned out, only merchants with colossal patience could begin to meet these requirements.

Industry Attempts to Assuage SET User Concerns

GlobeSet, out of Austin, Texas, was the first to introduce the GlobeSet ServerPOS as an alternative to the GlobeSet POS System for merchant commerce servers. With ServerPOS, the merchant's acquiring bank or card service provider operates the POS component on its premises with a merchant storefront adapter that resides on the merchant's commerce server.

ServerPOS used a multiprotocol approach, supporting both SET and SSL, to encompass all online merchants with whom the acquiring bank had forged relationships. On the consumer front, GlobeSet also offered ServerWallet, using a similar scheme. With the GlobeSet ServerWallet, card issuer banks bear the responsibility for managing the SET consumer digital certificates (and public keys), transaction data related to purchases made with their cards, and the other SET-related security data. Consumers needed only to download a thin-client component (45 Kbytes in size) to start the communications with ServerWallet at the bank when a SET transaction was initiated.

Trials of ServerWallet began in July 1998 and continued throughout the summer. The service model for SET appeared as a bright moment for the future of SET, but unfortunately, little interest in the service model was garnered, either, and the assets of GlobeSet were sold off in 2000.

Further interest in testing or hopes of ever rolling out SET in the U.S. had completely waned by 2000. Interest internationally, where credit card fraud very much remained a threat to the banking industry, continued to expand and several applications of SET made it into the news.

International Field Trials of SET

EasySET was one implementation of SET from the Spanish bank Banesto. EasySET was designed to answer many of the criticisms of "classical SET" by lightening the weight of consumer wallets and centralizing the complex processing of the point of sale (POS) system and the acquirer payment gateway system into a service model implementation, hosted at Banesto. This service model approach to SET takes the processing load off the merchant r-commerce systems and offers the advantages of improved transaction security and faster processing.

EasySET

Banesto's involvement with SET began in 1996 with a pilot project using the Banesto Virtual@Cash card. By mid-1997, the first Spanish SET transaction was run, and in 1999 the SET Facil, or EasySET project was launched.

The EasySET wallet supported SET transactions for Eurocard Mastercard and Visa cards issued by Banesto. The wallet was a free download to Banesto's customer using a "click-and-go" interface that enabled a 1-step download for SET cardholder certificates.

When customers used a SET-enabled credit card for payment, the EasySET POS system and payment gateway went to work at the Banesto site. Because the heavy-lifting work needed by the wallet is housed and maintained on Banesto's system, any upgrades needed to the software are made completely transparent to users. Additionally, the SafeLayer wallet supported the Electronic Commerce Markup Language (ECML) to speed up checkout processing though autofill features on merchant Web forms. Banesto also offered for free the CiberTienda shopping cart system and Virtual POS as open source downloads under the GNU public license.

In compliance with the SET specification, the EasySET systems offers the full complement of the SET messaging protocol to keep credit card information from falling into the wrong hands. It also supports the uses of SSL where SET is unavailable on cardholder registered cards. Cardholders need only download and install the SafeLayer wallet (around 500 Kbytes) and register their cards for SET enablement. Merchants download and install the Banesto Virtual POS along with the CiberTienda shopping system or within their existing e-commerce software. Multiple merchants can share the same POS software, provided that each merchant obtains and manages unique pairs of SET digital certificates needed to conduct transactions and settlement steps.

Banesto serves as the merchant CA and cardholder CA. As of mid-2002, EasySET is still in use in Spain.

Dutch Trials

I-Pay with SET was the first widespread commercial implementation of SET in the Netherlands, through Interpay Nederland B.V. in conjunction with Dutch banks offering debit or giro accounts using Maestro and Eurocard/Mastercard credit card accounts.

I-Pay offered Dutch merchants the security of SET with the additional benefit of accepting cross-border transactions from non-Dutch customers. I-Pay payments are processed within the I-Pay wallet when a customer selects either his or her Maestro account (debit) or his or her Eurocard/Mastercard (credit) as the form of payment. The I-Pay wallet prompts the user to enter a password to unlock the wallet, checks the balance on the account or the open-to-buy amount, and then challenges the user to prove legitimate ownership of the account. This step occurs in one of two ways: either a SmartCard protected by a PIN is required or a bank-supplied digital token is used to generate a one-time password once the correct secret is entered by the buyer. Two-factor authentication (what one has plus what one knows) of the buyer is sufficient proof for the banks that honor I-Pay with SET so that completed payments are irreversible, helping merchants gain confidence in debit and credit card payments via the Internet.

Merchant Web servers must run a piece of software called the Digital Till Point of Sale (POS) system to communicate with both I-Pay wallet and I-Pay payment acquirers. To accept I-Pay payments, merchants must also enter into connection agreements with Maestro for debit or giro accounts and with Eurocard/Mastercard for credit card transactions. As a merchant bank, Interpay Nederland B.V. offers both types of accounts to Dutch companies.

Struggles to Keep SET Pertinent

Suggestions for differing mechanisms to implement SET continue to crop up, including one called merchant-originated SET, or MOSET. The approach with MOSET eliminates cardholder certificates and reuses many of the traditional payment system processes with SET messages passing between the merchant POS and the acquirer, whereas the cardholder uses SSL to communicate with the merchant. Other proposed changes to SET for Version 2.0 attempted to address some of the concerns with SET Version 1.0 and add some new features, including these:

Japanese payment option (JPO) to support extended character sets,

Merchant-originated authorizations,

Online personal ID (PIN) extensions, and

CVV2/CVC2 extensions to accommodate the new Visa card fraud prevention schemes.

Other enhancements to SET that were planned included these:

Support for chip cards (smart cards);

An architecture to support debit cards with SET; and

Chip electronic commerce (CEC) to add SET messaging to the Europay, Mastercard, and Visa (EMV) specifications for chip-card payments on EMV-compatible terminals. CEC was designed as an extension to EMV (prevalent in POS systems in Europe and South America) for use on the Internet.

SET Version 2.0 never saw the light of day.

By the middle of 2002, SET had completely failed to catch on in the U.S. and it continues to languish in international markets, even as it struggles. In Spain, the Netherlands, and Finland, SET appears to have gained some traction, as dozens of merchants are SET-compliant, and the market appears to be growing.

LESSONS LEARNED AND NEW DIRECTIONS IN SECURE ONLINE PAYMENTS

The card associations eventually arrived at the realization that SET would not succeed in the U.S., and took what they learned from the experience, and went back to the drawing board. In the fall of 2001, Visa emerged with a new specification to support secure online credit card payments, called Verified by Visa, or VbV. VbV is based on the 3D-Secure payer authentication protocol, designed to authenticate cardholder identities—in real time—at the

point of purchase prior to accepting the card as payment. Meantime, Mastercard emerged in early 2002 with its own standard for Mastercard-branded products, called Secure Payments Application, or SPA.

Verified by Visa

To implement VbV, merchants are only required to install Visa-supplied software to activate a cardholder interface that challenges cardholders for passwords or asks them to insert their Visa smart cards into smart card readers and enter PINs.

Cardholders register for Verified by Visa with their participating issuer banks and can use the service when shopping at merchants that are enrolled for Verified by Visa through their merchant acquirer banks.

Verified by Visa works with traditional magnetic-strip cards using a password to identify the cardholder and also with Visa smart cards using cryptographic processing on the chip that can only be activated with the correct entry of a PIN at the time of purchase. Issuer banks must be enrolled in Verified by Visa for cardholders to use the service; otherwise the credit card payment is processed as a traditional card-not-present transaction.

The overall objectives of Verified by Visa are to improve the security of e-commerce payment transactions and to improve both cardholder and merchant confidence in Internet purchases, as well as to reduce disputes and fraudulent activity related to the use of Visa payment cards.

Components Within Verified by Visa

Verified by Visa consists of the following components that support cardholder enrollments with issuer banks and cardholder authentication to determine payment authorization:

Merchant Commerce Server: Hardware and software to support online transactions and facilitate communication between the merchant application and the merchant's acquirer bank.

Merchant Software: Software integrated into the merchant's e-commerce environment that enables merchants to participate in the Verified by Visa service.

Validation Server: Software that verifies issuer identity on digitally signed authentication responses sent to the merchant. Merchants integrate this software into their commerce server software.

Directory Server: Identifies participating Verified by Visa Issuers and cardholders and routes authentication dialog between merchants and the appropriate issuer access control server. This server is operated by Visa.

Transaction Manager Server: Stores transactions in the transaction manager database for which authentication was performed. The database is used to verify authenticated transactions and to provide additional information during the dispute process. This server is operated by Visa.

Visa Integrated Processing (VIP) Systems: Provides authorization, clearing, and settlement services through VisaNet for Visa members.

Issuer Access Control Server (IACS): Stores information about enrolled cardholder accounts and account access information in the account holder file (AHF). The server validates cardholder participation in the service and provides a digitally signed authentication response data to merchants. The IACS is operated by the issuer, processor, or Visa, on behalf of the issuer.

Issuer Enrollment Server: A server that manages cardholder enrollment by presenting a series of questions to be answered by the cardholder and verified by the issuer. The enrollment server is operated by the issuer, its processor, or Visa on behalf of the issuer.

Payer Authentication Processing

The seven steps below follow a transaction from initiation to completion using Verified by Visa:

Step 1. The Cardholder Makes a Purchase After merchandise selection through traditional online shopping steps, the cardholder proceeds to checkout. At checkout, the cardholder may complete the requested information in any variety of ways, including self-entered, an electronic wallet, merchant one-click, or other checkout capabilities. After the purchase information is entered, the cardholder selects the "buy" button. This activates the merchant plug-in to determine if the Visa card account participates in Verified by Visa.

Step 2. The Merchant Starts the Authentication Process The merchant plug-in identifies the account number and queries the Visa directory server to determine if the card account is enrolled in Verified by Visa. If the account number does not participate, the merchant plug-in returns the transaction to the merchant's commerce server and the merchant proceeds with a standard authorization request. If the account number participates in Verified by Visa, the Web site address of the issuer access control server is returned to the merchant plug-in.

Step 3. The Issuer Access Control Server Takes Control For participating cardholders, the merchant plug-in sends an authentication request to the issuer via the cardholder's browser. The issuer access control server displays a pop-up screen to the cardholder displaying information for that purchase and prompts the cardholder to enter his or her password. The cardholder enters the password and the issuer server verifies it. A cardholder is given a maximum of three attempts for password entry. If the cardholder is unable to correctly enter his/her password, the cardholder is prompted with the hint that was established during enrollment. The cardholder is given one last chance to enter the correct response. If answered correctly, the transaction continues as if the password was entered correctly. If answered incorrectly, an authentication failed response is returned to the merchant. If the cardholder has a smart Visa card, the issuer server also prompts for insertion of the chip card in the reader to initiate a dialogue with the chip. The smart Visa card generates a cryptogram that is sent to the issuer access control server along with the related transaction data used to generate the cryptogram. The server validates the cryptogram and determines if the

card authentication passes or fails. The card authentication results in information that is formatted into the response message.

After the password and/or smart Visa card is verified, the issuer access control server determines whether the cardholder authentication has passed or failed and formats an authentication response. The issuer server also sends a copy of the authentication response message to the authentication history server. All attempted authentication transaction responses (passed, failed, and not available) are transmitted and stored in the authentication history database.

Step 4. The Merchant Processes the Authorization Upon receiving the authentication response, the merchant plug-in verifies that the authorization response message is from a valid participating issuer. If it is verified and the issuer's authentication response contains a "passed" result, the cardholder is deemed "authenticated." The merchant plug-in returns the authentication response message to the merchant storefront software. If the merchant receives a "failed" authentication response from the issuer server, the merchant should request another form of payment from the shopper. Merchants are not permitted to submit failed authenticated purchases for authorization.

Step 5. The Merchant Acquirer Processes the Authorization The acquirer receives the authorization request from the merchant. The Verified by Visa data fields are mapped into existing VisaNet fields.

Step 6. VisaNet Verifies the Authentication and Processes the Authorization The VisaNet integrated payments (V.I.P.) system receives the authorization request containing the authentication data from the acquirer. These transactions are processed as standard service electronic commerce transactions.

Step 7. The Issuer Authorizes Internet Purchase The issuer's authorization center receives the request with authentication data and processes the transaction.

By mid-2002, Verified by Visa was implemented at a number of major online merchants and offered to the cardholders of Bank of America, First USA, and Bank One.

Secure Payment Application (SPA)

VbV is not without its critics. Mastercard claims that the VbV service adds processing times to transactions, takes customers off the merchant Web site, and adds complexity to integration woes, and have initially pledged not to support it. Instead, the SPA solution is Mastercard's answer to the card-not-present transaction problem. SPA relies on Mastercard's universal cardholder authentication field (UCAF) infrastructure to improve online security of payment transactions and reduce chargebacks for fraudulent transactions. SPA consists of these elements:

Issuer-provided SPA-enabled e-wallet,
SPA/UCAF value generation,
Cardholder authentication,
Merchant collection, presentation, and processing of SPA/UCAF data,
Acquirer acceptance and processing of SPA/UCAF data,
Banknet support to carry SPA/UCAF data, and
Authorization support of SPA/UCAF.

Universal Cardholder Authentication Field (UCAF)

UCAF is a 32-byte field with a variable data structure that is useful to support any number of authentication approaches to cardholder identities, including these:

SPA,
Biometrics,
Digital certificates,
Smartcards, and
Mobile and pervasive devices.

The flow for SPA processing follows:

Phase 0: Cardholders visit their credit card issuer Web sites, register their cards with SPA, establish passwords or PINs, and download and install SPA-enabled e-wallets.

Transaction Flow: Upon checkout, all traditional data are still collected (name, shipping address, billing address, etc.) whether they are filled in by the cardholder, entered via a wallet, or already stored by the merchant. The data are then posted to a Web page that the SPA-enabled wallet can access.

Once the SPA-wallet retrieves the data, it generates a payment authentication request and sends it to the issuer's wallet server.

Upon receipt of the data from the SPA-wallet, the issuer's wallet server challenges the identity of the cardholder using any method selected by the issuer (entry of password or PIN, insertion of smart card, etc.). If the challenge is met with a successful response from the cardholder, the wallet server generates a transaction-specific authentication token and sends it back to the SPA-wallet. This token is referred to as the SPA/UCAF.

The cardholder's wallet then populates the merchant's payment page with payment card details, optionally with the Mastercard card validation check value (CVC2), and with the SPA/UCAF token within a hidden field. The page is then posted back to the merchant Web server.

Once the merchant server receives the data, it formats an authorization request to the acquirer and sends along the SPA/UCAF token as a new attribute in the request.

The authorization request is then placed on Banknet and routed to the issuer bank for a response.

When the authorization request is received, the issuer bank validates that the SPA/UCAF is authentic and has not been previously used with a different transaction; it then issues an approval or declines the request based on the state of the underlying payment card. The response is then returned through the networks back to the merchant server for further processing of the sale.

SPA is intended to offer the digital equivalent of a physical cardholder signature on a record of charge, and bring

the Holy Grail of card-present transactions to the Internet. By the end of 2002, Mastercard International agreed to also support the 3D Secure Payer Authentication protocol and put an end to inter-association card acceptance problems.

Surrogate Credit Card Numbers

Still another approach that some issuer banks have adopted is called surrogate card numbers and appear in forms like Private Payments from American Express. With a surrogate card number, a shopper visits his or her issuer bank Web site and requests a "disposable" card number for one-time use at a merchant. The issuer bank keeps track of the real card number when it processes the authorization request and settlement records but conceals the number from the merchant site. Even in the event the merchant site is hacked and the tables of credit card numbers are copied, these surrogate payment card numbers would be rejected on a second authorization request and treated as fraudulent.

Although VbV, SPA, and surrogate payments may appear as evidence that the card associations cannot agree on a single secure payment system, implementing these approaches is easier than implementing SET could ever be. Vendors are offering systems and services in the marketplace to accommodate issuer banks and merchants with remotely hosted Web services applications and low-cost processing and overhead to support VbV, SPA, and surrogate card numbers. Software is available in the 2002 marketplace and is written to hide the various implementation details from the issuer banks and from the merchants to prevent the need for multiple systems to accomplish the same work. Clearly these moves are a step in the right direction.

CONCLUSION

Even as the SET specification continues to collect dust on the bookshelves of so many developers and bankers, SET's legacy is peppered with plenty of lessons to learn and mistakes to avoid. Still, SET is revolutionary, and over time, its resurrection in some form or another may materialize to finally bring an end to the intolerable state of Internet credit card fraud.

GLOSSARY

Abstract Syntax Notation One (ASN.1) A standard, flexible method that (a) describes data structures for representing, encoding, transmitting, and decoding data, (b) provides a set of formal rules for describing the structure of objects independent of machine-specific encoding techniques, (c) is a formal network-management transmission control protocol/Internet protocol (TCP/IP) language that uses human-readable notation and a compact, encoded representation of the same information used in communications protocols, and (d) is a precise, formal notation that removes ambiguities.

Acquiring bank A bank that does business with merchants who wish to accept credit cards. Merchants are given accounts to deposit the value of batch's card sales. The banks acquire batches of sales slips from any issuer bank cards and credit their value to the merchants' accounts.

Authorization A process whereby transactions are approved or declined by card issuers. Successful charge authorizations reduce the amount of available credit on a credit card but do not actually charge the customer or move money to the seller. Authorizations can be performed via telephone, POS terminal, or the Internet.

Batch settlement A process whereby accumulated credit card transactions are submitted for final settlement with a merchant's acquirer bank. Batches can be submitted for processing throughout the day or they can continue to grow until their value is sufficiently large and worthwhile to process.

Bolt-on application A "helper" or plug-in application program that extends the functionality of another program. SET is bolted onto existing merchant commerce servers and consumer Web browsers to provide POS functionality and e-wallet functionality, respectively.

Brand certificate authorities Trusted parties that serve a payment card brand (e.g., Visa, MasterCard) in performing the services needed for SET brand digital certificate management.

Branded payment cards Credit or charge cards that bear a company brand name (e.g., Visa, MasterCard, American Express).

Card associations Consist of operating banks that support franchises for particular payment card brands (e.g., Visa) and establish the by-laws that frame the uses of the franchise and the products within it.

Card issuer A bank or payment card company that issues branded cards to its customers.

Card-not-present transactions These are said to occur where the physical plastic card is not present for the merchant to see. These transactions are considered riskier than card-present transactions and typically occur with mail order/telephone order (MOTO) and Internet purchasing.

Cardholder A user (typically a consumer) of a credit or charge card issued by an issuer bank.

Certificate authorities Trusted parties who operate on the behalf of the SET Consortium (SETCo) and payment card brands to manage the distribution and currency of SET digital certificates.

Certificate revocation list (CRL) A mechanism that certificate authorities use to ensure that revoked certificates are not used in transactions. CRLs contain revoked certificate serial numbers, their date of revocation, the date the CRL was generated, its expiration date, the issuer name, and the serial number of the CA certificate used to sign the original certificate.

Certification The process of attesting to a person or entity's proof of identity and is performed prior to the issuance of a signed (notarized) certificate bearing the entity's public key.

Clearing A process of exchanging transaction details between a merchant bank (acquirer bank) and an issuer bank. Clearing posts charges to cardholder accounts and reconciles the merchant's batch of settlement records.

Closed loops Processing arrangements where a single company or bank owns both the cardholder relationship and the merchant relationship. American Express and Discover (Novus) are examples of closed-loop systems.

Credits Transactions that return money to a cardholder when goods are returned to a merchant for restocking or for defective products.

Data Encryption Standard (DES) SET's default symmetric key encryption algorithm, defined by Federal Information Processing Standard (FIPS) 46–2 and published by the National Institute of Standards and Technology (NIST).

Digital certificates Used to bind a person's identity to his orher public key and are generated by a trusted party (certificate authority).

Digital signatures Created using public–private key (PPK) cryptography and message digests (hashes of a message). Once a message digest is computed for a message, encrypted using the sender's private key, and appended to the original message, the result is called the digital signature for the message and proves that the message was sent by the claimed sender and that it was not altered en-route to the receiver.

Discount rates Paid by a merchant to a merchant bank as a privilege fee for using its credit card processing services. Fees are based on the value of each transaction and typically range from 1% up to 5%, depending on a number of factors, including charge volumes, risk models, size of the business, methods of submission, and merchant bank policies.

Electronic wallets (e-wallets) The cardholder's component for SET, which implements the protocol necessary from the cardholder end of a transaction and is used to help acquire and manage cardholder digital certificates.

Hashes A computation that reduces a large domain of possible values into a smaller range of values. Hash values and message digests are created using hashing functions. SET uses the secure hashing algorithm (SHA-1) as the default for hashing operations.

Interchanges Used to exchange information and money between the banks connected to it. The credit card interchange systems are managed by Visa and MasterCard to standardize data exchanges use across the globe.

Interchange fees Amounts charged to a acquirer bank by an issuer bank to compensate for the time the issuer bank needs to wait for payment between settlement time and actual receipt of bill payment from a customer.

Issuer banks Banks that extend credit to their customers (cardholders) through bank card accounts. These banks enter into contractual agreements (franchises) with Visa or MasterCard to issue their respective products.

Merchants Any business operation that accepts payment cards for goods or services. Merchants establish the privilege of accepting payment cards through relationships with acquiring (merchant) banks.

Merchant SET POS system A "bolt-on" application for merchant commerce servers that carries out the work necessary for online payment-card acceptance using the rules and messages defined by SET.

Open loops Contrasted to closed loops in that merchant and cardholder relationships are maintained by separate banks, but transactions with payment cards can still take place.

Out of band activities Activities that are performed outside the definition of the SET specification. For example, the exchange of order-detail information is conducted out of band to SET.

Payment gateway A front-end processor for acquirer authorization and settlement systems that translates SET messages to and from standard bank financial processing record formats.

Point-of-sale (POS) Refers to the technology (devices and systems) that carries out the work of authorizing and settling payment card charges wherever goods and services are exchanged.

Private keys The half of a key pair that are retained on the computer that generated the key pair as described by industry best practices. Private keys are used to encrypt and/or digitally sign messages that can be verified as legitimate if the associated public key is able to decrypt them.

Processing fees Charged to acquirer banks and merchants for the privilege of using the interchange network or for using merchant account services. Typically, processing fees are built into the discount rates.

Public keys The half of a key pair shared with message recipients to use in sending encrypted messages back to the private key holder. Typically available as part of an entity's certificate. In fact, authentication of entities is typically done via a message exchange between a client and an entity based on the ability to use the entity's public key to decrypt a message or digital signature with the corresponding private key held in secret by the entity.

Root certificate The topmost level in a tree of trust that is used to sign subordinate certificates. The SET root certificate is used in signing the brand certificates and is an activity performed by SETCo.

Root key authority A managing organization responsible for the generation, maintenance, and distribution of root certificates. For SET, SETCo is that managing body.

Secure hash algorithm (SHA-1) Used for hashing all data under SET. It is defined by Federal Information Processing Standards 180–1.

SETMark Visible proof of successful SET certification of vendor software, providing consumers with confidence that they are transacting using bona-fide SET.

Settlement A process that occurs when an acquiring bank exchanges financial information for funds from an issuer bank.

Third-party processors Companies that enter into contractual agreements with issuer and scquirer banks to process authorizations and settlement operations on their behalf. See charge processor.

Tree of trust Documents the hierarchy established for SET to manage the issuance, maintenance, and currency of SET digital certificates.

X.509 An industry standard to define the most widely accepted format for digital certificates, as specified by the CCITT. SET's version of X.509 digital certificates are a special "flavor" designed exclusively for payment cards.

E-COMMERCE AND SECURE COMMUNICATION CHANNELS

Overview

This chapter provides an overview of how the SSL protocol and its variant the TLS protocol are used to establish and operate a secure communication channel. It is assumed that the readers of this chapter are nontechnical in their academic background. As a result some space will be spent in explaining the background concepts necessary for a full understanding of SSL and TLS. If the reader requires more technical detail, Boncella (2000) is suggested.

This chapter has five major sections. First is a discussion of the need for and history of secure channels for e-commerce. Second is an overview of the internetworking concepts necessary to appreciate the details of SSL and TLS protocols. Third is a brief review of cryptographic concepts used in SSL and TLS. Fourth is a detailed exposition of SSL and TLS. And finally is a discussion of SSL and TLS protocol's status in e-commerce—its strengths and weakness, and possible alternatives.

Definition of E-commerce

E-commerce may be defined as the use of electronic or optical transmission media to carry out the exchange of goods and services. E-commerce in particular and e-business in general rely on electronic or optical communication in order to exchange information required to conduct business.

In an e-commerce transaction both the user and the provider of the service have expectations regarding the security of the transaction.

The user's expectation is that the service to be provided is legitimate, safe, and private: legitimate in the sense that the providers of the service are who they say they are; safe in the sense that the services or information being provided will not contain computer viruses or content that will allow the user's computer system to be used for malicious purposes; and finally, private in the sense that the provider of the requested information or services will not record or distribute any information the user may have sent to the provider in order to request information or services.

The server's expectation is that the requestor of the information or service is legitimate and responsible: legitimate in the sense the user has been accurately identified; responsible in that the user will not attempt to access restricted documents, crash the server, or use the server computing system as means of gaining illegal access to another computer system.

Both the server and the user have an expectation that their communications will be free from eavesdropping and reliable—meaning that their transmissions will not be modified by a third party.

The purpose of Web security for e-commerce is to meet the security expectations of users and providers. To that end, Web security is concerned with client-side security, server-side security, and secure transmission of information.

Client-side security is concerned with the techniques and practices that protect a user's privacy and the integrity of the user's computing system. The purpose of client security is to prevent malicious destruction of a user's computer systems, e.g., by a virus that might format a user's fixed disk drive, and to prevent unauthorized of use of a user's private information, e.g., use of a user's credit card number for fraudulent purposes.

Server-side security is concerned with the techniques and practices that protect the Web server software and its associated hardware from break-ins, Web site vandalism, and denial-of-service attacks. The purpose of

server-side security is to prevent modification of a Web site's contents, to prevent use of the server's hardware, software, or databases for malicious purposes, and to ensure reasonable access to a Web site's services (i.e., to avoid or minimize denial-of-service attacks).

Secure transmission is concerned with the techniques and practices that will guarantee protection from eavesdropping and intentional message modification. The purpose of these security measures is to maintain the confidentiality and integrity of user and server information as it is exchanged through the communication channel. This chapter focuses on a solution to the requirement for a secure channel.

Secure Channels

The Internet can be used for electronic communication. Those who use the Internet for this purpose, on occasion, have the need for that communication to be secure. Secure communication can be ensured by the use of a secure channel. A secure channel will provide three things for the user: authentication of those involved in the communication, confidentiality of the information exchanged in a communication, and integrity of the information exchanged in the communication.

SSL and its variant TLS are protocols that can be used to establish and use a secure communication channel between two applications exchanging information. For example, a secure channel may be required between a user's Web browser and the Web server the user has accessed. The paradigm example is the transfer of the user's credit card information to a Web site for payment of an online purchase. Another example would be an employee using the Web to send his or her check routing information to her employer for use in a direct deposit payroll request.

History of Secure Channels—SSLv1 to v3, PCT, TLS, STLP, and WTLS

Secure Sockets Layer (SSL) is a computer networking protocol that provides authentication of, confidentiality of, and integrity of information exchanged by means of a computer network.

Netscape Communications designed SSL in 1994 when it realized that users of its browser needed secure communications. SSL Version 1 was used internally by Netscape and proved unsatisfactory for use in its browsers. SSL Version 2 was developed and incorporated into Netscape Navigator versions 1.0 through 2.X. This SSLv2 had weaknesses (Stein, 1998) that required a new version of SSL. During that time—1995—Microsoft was developing PCT, Private Communications Technology, in response to the weaknesses of SSLv2. In response, Netscape developed SSL version 3, solving the weakness of SSLv2 and adding a number of features not found in PCT.

In May 1996 the Internet Engineering Task Force (IETF) authorized the Transport Layer Security (TLS) working group to standardize a SSL-type protocol. The strategy was to combine Netscape's and Microsoft's approaches to securing channels. At this time, Microsoft developed its Secure Transport Layer Protocol, which was a modification of SSLv3 and added support for UDP (datagrams) in addition to TCP support.

In 2002 the WAP Forum (wireless access protocol) adopted and adapted TLS for use in secure wireless communications with its release of WAP 2.0 Protocol Stack. This protocol provides for end-to-end security over wireless or combined wireless/wired connections (WAP Forum, 2002; Boncella, 2002).

An in-depth understanding of secure channels in general and SSL and TLS in particular requires familiarity with two sets of concepts. The first is how the client/server computing paradigm is implemented using the TCP/IP protocols. The second set of concepts deals with cryptography. In particular one needs to be familiar with the concepts of encryption, both symmetric and asymmetric (public key encryption), key sharing, message digests, and certification authorities.

The first set of concepts, clients/servers using TCP/IP, is discussed in the following section, and the cryptography concepts are reviewed following TCP/IP discussion. These cryptography concepts are discussed in detail in another chapter.

INTERNETWORKING CONCEPTS NECESSARY FOR E-COMMERCE

Clients and Servers

The World Wide Web (WWW or Web) is implemented by means of interconnection of networks of computer systems. This interconnection provides information and services to users of the Web. Computer systems in this interconnection of networks that provide services and information to users of computer systems are called Web servers. Computer systems that request services and information use software called Web browsers. The communication channel between the Web browser (client) and Web server (server) may be provided by an Internet service provider (ISP) that allows access to the communication channel for both the server and client. The communication of the client with a server follows a request/response paradigm. The client, via the communication channel, makes a request to a server and the server responds to that request via a communication channel.

The Web may be viewed as a two-way network composed of three components:

clients
servers
communication path connecting the servers and clients.

The devices that implement requests and services both are called hosts because these devices are "hosts" to the processes (computer programs) that implement the requests and services.

Communication Paths

The communication path between a server and a client can be classified in three ways:

an internet
an intranet
or an extranet.

An internet is an interconnection of networks of computers. However, the Internet (with an upper case I) refers to a specific set of interconnected computer networks that allows public access.

An intranet is a set of interconnected computer networks belonging to an organization and is accessible only by the organization's employees or members. Access to an intranet is controlled.

An extranet uses the Internet to connect private computer networks or intranets. The networks connected together may be owned by one organization or several. At some point, communication between hosts in an extranet will use a communication path that allows public access.

For a request or response message to travel through a communication path, an agreed-upon method for message creation and transmission is used. This method is referred to as a protocol. The de facto protocol of the Internet is the TCP/IP protocol. An understanding of the client/server request/response paradigm requires an overview of the TCP/IP protocol. The TCP/IP protocol can best be understood in terms of the open system interconnection (OSI) model for data communication.

The OSI Model and TCP/IP

The open system interconnection model defined by the International Standards Organization (ISO) is a seven-layer model that specifies how a message is to be constructed in order for it to be delivered through a computer network communication channel. This model is idealized. In practice, few communication protocols follow this design. Figure 1 provides a general description of each layer of the model. The sender of the message, either a request or a response message, provides input to the application layer.

The application layer processes sender input and converts it to output to be used as input for the presentation layer. The presentation layer, in turn, processes this input to provide output to the session layer, which uses that output as input, and so on, until what emerges from the physical layer is a signal that can be transmitted through the communication channel to the intended receiver of the message. The receiver's physical layer processes the signal to provide output to its data link layer, which uses that output as input and processes it to provide output to the receiver's network layer, and so on, until that message is accepted by the receiver.

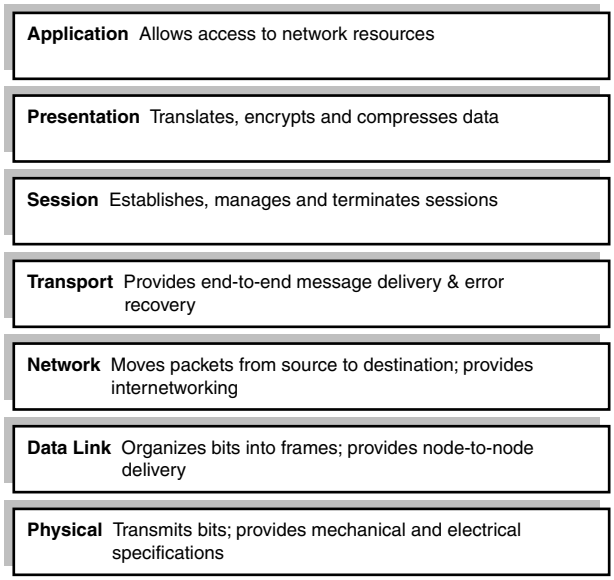

Figure 1: OSI model.

This process is depicted in Figure 2. Figure 2 also illustrates the signal (message) being relayed through the communication channel by means of intermediate nodes. An intermediate node is a host that provides a specific service whose purpose is to route a signal (message) efficiently to its intended destination.

Figure 3 depicts the TCP/IP protocol on the OSI model. (TCP/IP is an abbreviation for transmission control protocol/Internet protocol). For our purposes the TCP/IP protocol is made up of four layers. What follows is a brief overview of the TCP/IP protocol. For an introduction to the details of TCP/IP consult Forouzan (2000).

The application layer contains a number of applications that a user may use as client processes to request a service from a host. The client processes are said to run on a local host. In most cases, the requested service will be provided by a remote host. In many cases there will be a similarly named application on the remote host that will provide the service. For example, the user may open a Web browser and request HTTP (hypertext transfer protocol) service from a remote host in order to copy an HTML (hypertext markup language) formatted file into the user's Web browser. If the receiving host provides HTTP service, it will have a process running, often named HTTPD, that will provide a response to the client's request. Note that users need to specify the host by some naming method and the service they desire from that host. This is taken care of by the use of a universal resource locator (URL) (e.g., http://www.washburn.edu). The Application Layer produces a message that will be processed by the transport layer.

The client's request will pass through the local host's transport layer. The responsibility of the transport layer is to establish a connection with the process on the remote host that will provide the requested service. This client-process-to-server-process connection is implemented by means of port numbers. A port number is used to identify a process (program in execution) uniquely. Unique identification is necessary because local hosts and remote hosts may be involved in a number of simultaneous request/response transactions. The hosts' local operating systems, in concert with the TCP/IP protocol concept of port numbers, can keep track of which of several responses corresponds to the correct client process request on that local host and which request corresponds to the correct service on the remote host.

The transport layer will cut the message into units that are suitable for network transport. In addition to the port numbers, the transport layer adds information that will allow the message to be reconstructed in the receiver's transport layer. Other information is added to these units that allows flow control and error correction. The output from the transport layer is called a segment. The segment is composed of the data unit and a header containing

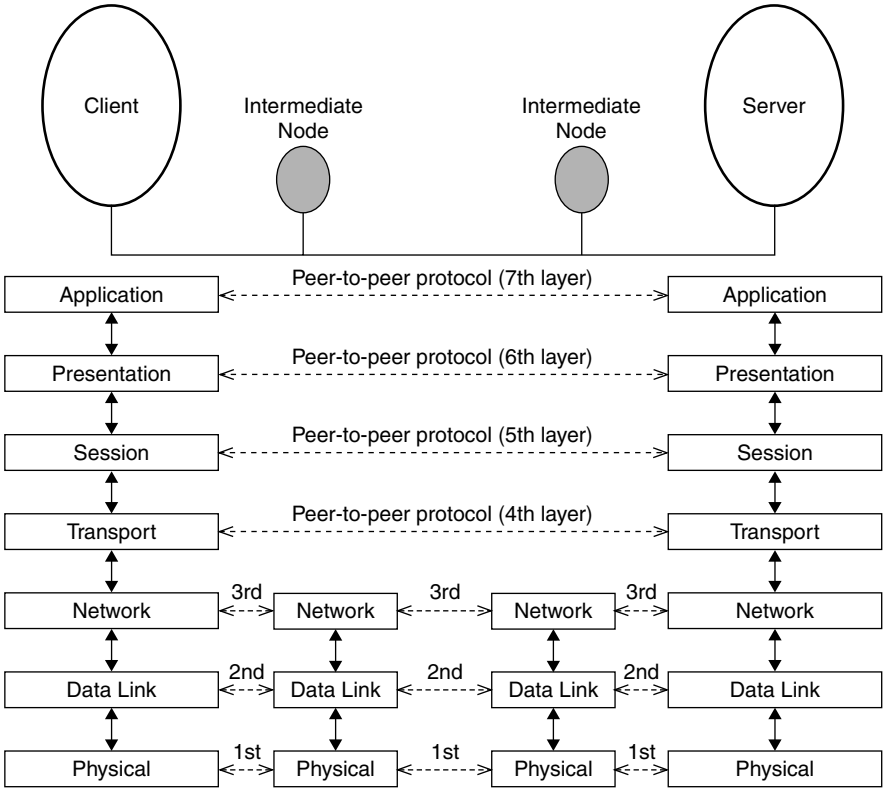

Figure 2: Messaging delivery using OSI model.

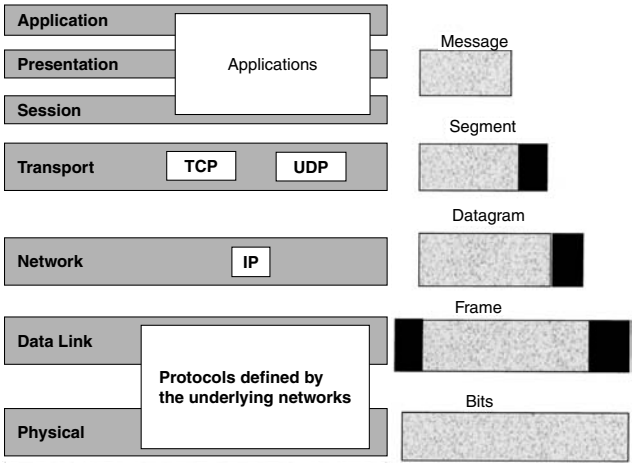

Figure 4: TCP/IP message delivery.

the information described above. Figure 4 shows this process.

The output of the transportation layer—a segment—is sent to the network or IP layer. The responsibilities of the IP layer include providing the Internet or IP address of the source (requesting) host and destination (response) host of the segment. One important part of the IP address is a specification of the network to which the host is attached. Depending on the underlying physical network, the segments may need to be fragmented into smaller data units. The information from the segment header is duplicated in each of these fragments as well as that the header information provide by the network or IP layer. The output of the IP layer is called a datagram.

The datagram is passed to the lowest layer, where the physical addresses associated with the source and destination hosts' IP addresses are added. The physical address of a host uniquely identifies the host on a network. It corresponds to a unique number of the network interface card (NIC) installed in the host. An example is the 48-bit long Ethernet address provided by the manufacturer of an Ethernet card. When the TCP/IP protocol is installed on a host, that host's physical address is associated with an IP address. The physical address allows a particular host to be independent of an IP address.

To understand Web security and e-commerce, we need to be aware of three concepts associated with the TCP/IP protocol. These are

port address
IP addresses
physical addresses.

These ideas allow the request/response message to be exchanged by the intended processes (as specified by port numbers). Those processes are running on hosts attached to the intended networks (as specified by the IP addresses) and, finally, running on the intended hosts (as specified by physical addresses). Figure 5 depicts these address assignments and the layers responsible for their assignments.

CRYPTOGRAPHIC CONCEPTS USED IN SSL AND TLS

Encryption

Encryption is the process of converting plaintext (readable text) into ciphertext (unreadable text). Decryption is the process of converting ciphertext into plaintext. Usually this is done by means of a publicly known algorithm and a shared key. Encryption is vital in providing message confidentiality, client/server authentication, and message integrity. There are two methods of encryption: symmetric or private-key and asymmetric or public-key. Each method of encryption has its particular use. Symmetric encryption is used for encryption of the messages exchanged between a client and a server, whereas asymmetric encryption will be used to exchange the common keys used by clients and servers in their symmetric encryption process. Asymmetric encryption may also be used for the encryption of messages.

Symmetric Encryption

There are two main types of symmetric encryption: stream ciphers and block ciphers. Stream ciphers combine one byte of the key with one byte of the plaintext to create the ciphertext in a byte-after-byte process. Block ciphers process plaintext in blocks of bytes, generally 8 or 16 bytes in length, into blocks of ciphertext

RC4 is a widely used stream cipher. There are a number of block ciphers. Among them are DES, 3DES, and RC2. AES is another block cipher that is an improvement to DES. The specifics of these ciphers are discussed elsewhere in this volume.

Asymmetric Encryption

In asymmetric encryption a pair of keys, a public key and a private key, are used to carry out the encryption process. If the private key is used to create the ciphertext then only the corresponding public key can be used to decrypt that ciphertext and vice versa. Asymmetric (or public-key) encryption can be used for key sharing and digital signatures.

Key Sharing

There are two means to carry out key sharing. One is "key exchange" where one side of the message exchange pair generates a symmetric key and encrypts it with the public key of the private/public key pair of the other side. The other technique of key sharing is "key agreement." In this technique each side of the message exchange pair cooperate to generate the same key that will be used for symmetric encryption. The RSA public key algorithm can be used for the key exchange technique. The Diffie–Hellman public algorithm can be used for the key agreement technique. The details of these algorithms are discussed elsewhere in this text.

Digital Signatures

Digital signatures are used for nonrepudiation. Public-key algorithms can be used for digital signatures. RSA is a means of providing a digital signature by the sender encrypting a known pass phase with his or her private key; only the corresponding public key will decrypt the ciphertext of the pass phrase to the correct plaintext. The digital signature algorithm (DSS) is another algorithm that can be used for this purpose.

Message Digest Algorithms

Message digest algorithms are used to generate a "digest" of a message. A message digest algorithm computes a value based on the message content. The same algorithm and message content will generate the same value. If a shared secret key in included with the message before the digest is computed then when the digest is computed the result is a message authentication code (MAC). If the client and server are sharing this secret key and know each other's message digest algorithms then they can verify the integrity of the message exchange.

Two commonly used message digest algorithms are MD5, which computes a 16-byte value (128 bits), and SHA-1, which computes a 20-byte value (160 bits).

Certification Authorities

A certification authority (CA) is a trusted third party that is responsible for the distribution of the public key of a public/private key pair. The CA does this by issuing (and revoking) public key certificates. A standard for these certificates is X.509v3. This standard defines the fields contained in the certificate. This is a widely accepted standard and is used by most CAs.

SSL ARCHITECTURE

Overview

SSL is composed of four protocols. Three of the four, SSL Handshake Protocol, SSL Change Cipher Spec Protocol, and SSL Alert Protocol, are used to set up and manage secure communication channels. The remaining protocol, the SSL Record Protocol, provides the security service required by applications. The SSL lies between the application layer and the TCP layer of the TCP/IP protocols. This architecture is represented in Figure 6.

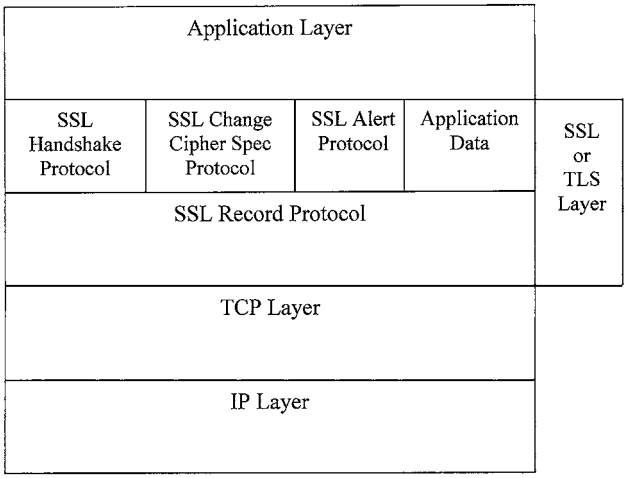

Figure 6: SSL layers within TCP/IP.

Once a secure channel has been established the SSL takes messages to be transmitted, fragments the message into manageable blocks, optionally compresses the data, applies a message authentication code (MAC), encrypts, prefixes the SSL record header, and sends the result to the TCP layer. Ultimately these data blocks are received and the data are decrypted, verified, decompressed, reassembled in the receiver's SSL layer, and then delivered to higher level clients.

The technical details of these protocols are discussed in a number of places. The primary document is the Web page http://wp.netscape.com/eng/ssl3/ssl-toc.html.

There are a number of excellent secondary sources that provide more background information as well as the specifications of the protocols. The interested reader is directed to Rescorla (2001) and Stallings (2000). The protocols used to establish a secure channel give SSL its flexibility for client/server communication.

SSL is flexible in the choice of which symmetric encryption, message digest, and authentication algorithms can be used. When an SSL client makes contact with an SSL server, they agree upon the strongest encryption methods they have in common. Also, SSL provides built-in data compression. Data compression must be done before encryption.

When an SSL connection is established, browser-to-server and server-to-browser communications are encrypted. Encryption includes

URL of requested document
Contents of the document
Contents of browser forms
Cookies sent from browser to server
Cookies sent from server to browser
Contents of HTTP header, but *not* particular browser to particular server.

In particular, socket addresses—IP address and port number—are not encrypted; however, a proxy server can be used if this type of privacy is required.

Connection Process

The connection process is shown in Figure 7. To establish an SSL connection, the client (browser) opens a connection to a server port. The browser sends a "client hello" message—Step 1. A client hello message contains the version number of SSL the browser uses, the ciphers and data compression methods it supports, and a random number to be used as input to the key generation process.

The server responds with a "server hello" message—Step 2. The server hello message contains a session ID and the chosen versions for ciphers and data compression methods the client and server have in common. The server sends its digital certificate—Step 3—which is used to authenticate the server to the client and contains the server's public key. Optionally, the server may request a client's certificate—Step 4. If requested, the client will send its certificate of authentication—Step 5. If the client has no certificate, then connection failure results. Assuming a successful connection, the client sends a

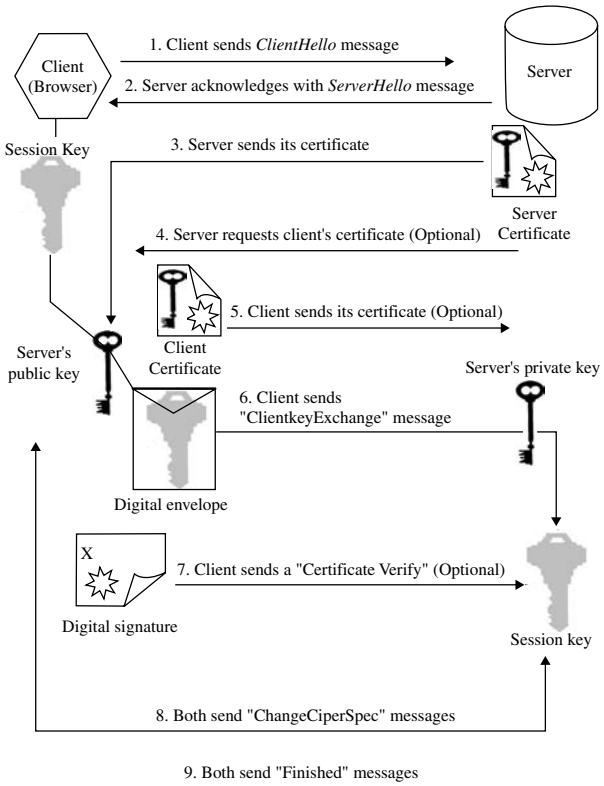

Figure 7: SSL connection process.

"ClientKeyExchange" message—Step 6. This message is a digital envelope created using the server's public key and contains the session key chosen by the client. Optionally, if client authentication is used, the client will send a certificate verify message—Step 7. The server and client send a "ChangeCipherSpec" message—Step 8—indicating they are ready to begin encrypted transmission. The client and server send finished messages to each other—Step 9. The finished messages are MACs of their entire conversation up to this point. (Note: a MAC, message authentication code, is a key-dependent one-way hash function. It has the same properties as the one-way hash functions called message digests but they have a key. Only someone with the identical key can verify the hash value derived from the message.) Accordingly, if the MACs match, then messages were exchanged without interference and, hence, the connection is legitimate.

Once the secure channel is established, application-level data can be transmitted between the client and server using the SSL Record Protocol.

Record Protocol

The SSL Record Protocol provides two of the three essential requirements for secure transmission of data: confidentiality and message integrity. Confidentiality is provided by symmetric encryption that uses the shared session key exchanged between the client and server during the handshake protocol. This handshake protocol also defines a shared secret key that can be used to create a message authentication code (MAC), which can be used

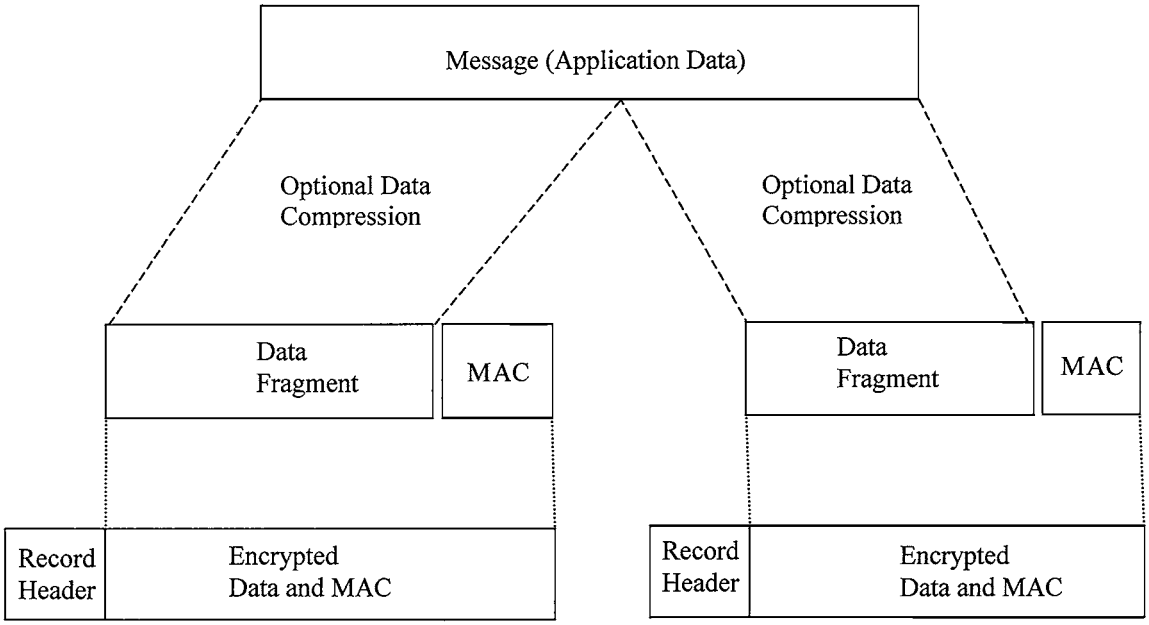

Figure 8: SSL connection process.

to ensure message integrity. The third requirement, authentication, is provided by the handshake protocol in its requirement of at least a server's certificate.

The record protocol processes a message by first breaking the message into fragments of equal fixed size, padding the last fragment as needed. The next step is optional compression of each fragment. Once the compression is completed, a MAC is computed for each fragment and appended to the fragment. The result is then encrypted using the key and algorithm agreed upon by the client and server. An SSL record header is appended. Then this segment is passed to the TCP layer for processing. The received data are processed by the receiving protocol in the reverse process: data are decrypted, verified by means of the MAC, and decompressed if necessary, the fragments are reassembled, and the result is then passed on to the destination application. This process is depicted in Figure 8.

TLS—Transport Layer Security

TLS is an IETF attempt to specify an Internet standard version for SSL. The current proposed standard for TLS is defined in RFC 2246 (2002).

The proposed TLS standard is very similar to SSLv3. The TLS record format is identical to the SSL record format. There are a few differences between SSL and TLS. Some of these are how MAC computations are carried out, how pseudorandom functions are used, including additional alert codes and client certificate types, and how certificate_verification and finished message are carried out. The details of these differences are discussed in Stallings (2000).

SSL and TLS Protocols: Details

The preceding sections provide an overview of how a secure channel is set up and used. A better understanding of this process is obtained when a detailed examination of this process is presented. It is informative to work through each step of Figure 7 and detail how the protocols work to set up the secure channel. The following is an adaptation of information that may be found in specification documents for SSL (Netscape Communications, 1996, 1998).

Handshake Protocol

Of the four protocol that make up SSL and TLS, the handshake protocol is the most critical. This protocol is responsible for setting up the connection. It uses a sequence of messages that allows the client and server to authenticate each other and agree upon encryption and MAC algorithms and their associated keys.

The format of the handshake protocol is simple and is depicted in Figure 9 below. The type field of the handshake protocol indicates one of 10 messages listed in Table 1 below. Length is the length of the message in bytes. Content is the parameters associated with the message type (cf. Table 1).

Step 1 of Figure 7 is the *ClientHello* message. Its parameters are

version The version of the SSL protocol by which the client wishes to communicate during this session. This should be the most recent version supported by the client.

random A client-generated random structure. This is a value 32 bytes long. The first four bytes are the time

of day the message was generated and the remaining 28 bytes are created using a secure random number generator. This 32-byte value will be used as one of the inputs to the key generation procedure. The time stamp (first four bytes) prevents a possible man-in-the-middle attack.

session_id The ID of a session the client wishes to use for this connection. This parameter will be *empty* if no session_id is available or the client wishes to generate new security parameters.

cipher_suites A list of the cryptographic options supported by the client, sorted descending preferences. If the session_id field is not *empty* (implying a session resumption request) this vector must include at least the cipher_suite from that session.

compression_methods A list of the compression methods supported by the client, sorted by client preference. If the session_id field is not *empty* (implying a session resumption request) this vector must include at least the compression method from that session. All implementations must support a. null compression method (i.e., no data compression is used).

After sending the ***ClientHello*** message, the client waits for a ***ServerHello*** message. Any other handshake message returned by the server except for a ***HelloRequest*** is treated as a fatal error.

Step 2 is the ***ServerHello*** message. The server processes the ***ClientHello*** message and responds with either a handshake_failure ***alert*** or a ***ServerHello*** message. The *ServerHello* message parameters are

server_version This field will contain the lower of that suggested by the client in the C*lientHello* message and the highest supported by the server.

random This structure is generated by the server and *must* be different from (and independent of) the *ClientHello* random structure.

session_id This is the identity of the session corresponding to this connection. If the *ClientHello* message session_id parameter was nonempty, the server will look in its session cache for a match. If a match is found and the server is willing to establish the new connection using the specified session state, the server will respond with the same value as was supplied by the client. This indicates a *resumed* session and dictates that the parties *must* proceed directly to the *finished* messages. Otherwise this field will contain a different value identifying the new session. The server may return an *empty* session_id to indicate that the session will not be cached and therefore cannot be resumed.

cipher_suite The single cipher suite selected by the server from the list in the ***ClientHello*** message cipher_suites parameter. For *resumed* sessions this field is the value from the state of the session being resumed.

compression_method The single compression algorithm selected by the server from the list in the *ClientHello* message compression_methods parameter. For *resumed* sessions this field is the value from the resumed session state.

Step 3 is the *Certificate* message. If the server is to be authenticated (which is generally the case), the server sends its certificate immediately following the S*erverHello* message. The certificate type must be appropriate for the selected cipher suite's key exchange algorithm, and is generally an X.509.v3 certificate. The same message type is also used for the client's response to a server's *CertificateRequest* message.

If the server has no certificate or if a key exchange technique other than RSA or fixed Diffie–Hellman is used the server will send *ServerKeyExchange* message. In this case the parameters for this message will contain the values appropriate for the key exchange technique, see (Stallings, 2000) for these details.

In **Step 4** (optional), a nonanonymous server can optionally request a certificate from the client, if appropriate for the selected cipher suite. The *CertificateRequest* massage has two parameters. These are

types A list of the types of certificates requested, sorted in order of the server's preference.

authorities A list of the distinguished names of acceptable certificate authorities.

After **Step 3** (or optional **Step 4**) the server will send a *ServerHelloDone* message to indicate that the server has sent all the handshake messages necessary for the server hello phase. After sending this message the server will wait for a client response. When the client receives the *ServerHelloDone* message the client will determine the validity of the server's certificate and the acceptability of the *ServerHello* message parameters. If the parameters and certificate are valid then the client will one or two messages.

Step 5 (optional) is the *Certificate* message. This is the first message the client can send after receiving a *ServerHelloDone* message. This message is only sent if the server requests a certificate. If no suitable certificate is available, the client should send a *NoCertificate* alert instead. This error is only a warning, however the server

may respond with a *FatalHandshakeFailure* alert if client authentication is required.

Step 6 is the *ClientKeyExchange* message. The content of the message will be based on the type of key exchange negotiated during the first phase of the handshaking process. The key exchange method is determined by the cipher suite selected and server certificate type. For example if the client and server agree upon the RSA key exchange method then the client generates a 48-byte *premaster_secret* and encrypts it with the public key from the server's certificate or uses the temporary public key from the server's *ServerKeyExchange* message.

If the server has requested a client certificate and it requires verification then the client will send a *CertificateVerify* message to provide explicit verification of its client certificate.

In **Step 8** the client sends a *ChangeCipherSpec* message that indicates the client has switched to the negotiated cipher suit. All subsequent messages will be sent using those encryption algorithms and appropriate keys. It should be noted that the *ChangeCipherSpec* message is a separate protocol and not part of the Handshake protocol. The purpose of this is to make SSL and TLS more efficient. The *ChangeCipherSpec* message consists of only one byte.

In **Step 9** the client sends the handshake message *Finish*. The message is a concatenation of two message digest values. Each value is computed using a different message digest algorithm—MD5 and SHA—on the same data. The data are the master secret (see below) and the set of handshake messages sent up to this point.

In response to these two client messages the server sends its version of the *ChangeCipherSpec* and a *Finished* message computer using that same data as the client. If this *Finished* message value differs from the *Finished* message value sent by the client then this indicates that the handshake has been modified and secure channel my not be setup. When the client receives the *finish* message from the server it does a comparison with its locally computed *finish* message value. If they match then all is well; otherwise the secure channel may not be established.

Cipher Suites and Master Secrets

There are two more concepts that need to be presented to complete this discussion. In Step 1 above the client sends a list of cipher suites to the server that the client is able to use. In Step 6 the client sends a pre_master_secret that will be used to compute the master secret. This master secret is then used to compute the key_block. This key_block is used to derive the keys that will be used with the algorithms specified in the cipher suites. The details of each of these need to presented.

Cipher Suites

A cipher suite is a list of key exchange techniques and cryptographic algorithms supported by the client and server. The **cipher_suite** parameter of the *ClientHello* message provides a set of key exchange techniques, server authentication algorithms, bulk encryption algorithms, and message digest algorithms the client can support. The client lists these sets in order of the client's preference. For example, one of the entries of this set may be

TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA

In this example the key exchange technique is DHE, where DHE denotes ephemeral Diffie–Hellman. The Diffie–Hellman parameters are signed by a DSS or RSA certificate, which has been signed by the certificate authority (CA). The signing algorithm used is specified after the DHE parameter. In this case the signing algorithm is the RSA (Rivest, Shamir, Adelman) algorithm.

The bulk encryption and message digest algorithms follow the WITH delimiter. In this the bulk encryption is performed by 3DES_EDE_CBC, where 3DES_EDE_CBD denotes 3DES encryption using the encrypt–decrypt–encrypt mode in the cipher block chaining mode, and the message digest algorithm is SHA, where SHA denotes the secure hash algorithm.

Master Secret

The master secret creation is the vital component in setting up the secure channel. The master secret is used to compute the key_block. Once the key_block computed it is partitioned into six keys that are used by the client and server in their communications. The computation of the key_block is as follows.

The *ClientKeyExchange* message provides the server with the pre_master_secret. The client and server use this 48-byte value along with the *ClientHello* random parameter value and *ServerHello* random parameter value (they both have copies of these) to create a hash value by using the MD5 and SHA algorithms in the same sequence on this common set of values. They will both compute the identical hash value. This value is the master secret that is shared (computed) by both. A similar process is used to compute the key_block but instead of using the pre_master_secret in the computation the master_secret is used. This results in a key_block that is "shared," computed independently but to the same value, by the client and server.

The size of the key_block is determined by the cipher specifications. These specifications give the number of bytes required for the bulk encryption keys (i.e., one for the client to use and one for the server to use), MAC keys, and if necessary initialization vector keys. Initialization vectors (IV) are necessary if a bulk encryption algorithm will be using the cipher block chaining mode.

This "shared" key_block is partitioned in the same sequence by the client and server. The first set of bytes are used in the client MAC secret, the next set are used for the server MAC secret, the next set are used for the client bulk encryption key, the next set for the server bulk encryption key, the next set of bytes for the client initialization vector, and finally the last set of bytes will be used as the server's initialization vector.

STATUS OF SSL

SSLv3 and TLS 1.0 and Commercial Use

SSL and TLS are primarily used to protect Web traffic that is using HTTP. In order for this to occur both the client and the server need to be SSL- and/or TLS-enabled.

Table 2 Web Servers that Support the SSL Protocol

Package	Creator	Obtain From
OpenSSL	OpenSSL Development Team	www.oepnssl.org
Apache mod_ssl (requires OpenSSL)	Apache Software Foundation	www.apache.org
Microsoft IIS	Microsoft Corporation	Bundled with WINNT, WIN2000 and WINXP
Netscape Enterprise and Suitspot	Netscape Communications	www.netscape.com
Covalent SSL (SSL Acclerator)	Covalent Technologies, Inc.	www.covalent.net
Apache Stronghold (commercial Apache)	C2Net	www.c2.net

The Web browsers Netscape Navigator and Microsoft Internet Explorer support SSL and TLS. These browsers allow the user to configure how SSL and/or TLS will be used. In Netscape Navigator 6.0 the user may consult the Security Preferences panel and open the SSL option under the Privacy and Security selection. In Internet Explorer the user may consult the Security entry in the Advanced Tab on the Internet Options selection in the drop down menu item for Tools. An interesting option in both browsers is the choice of whether or not to save the downloaded page to the local cache. The downloaded page is no longer encrypted and if it is saved to local storage it will be in plain text. If the local machine is compromised or stolen (e.g., a laptop) that document is now readable by all.

When a secure channel has been established these browsers will inform the user by means of a small padlock icon at the bottom of the browser. This indicates the page was downloaded using SSL or TLS. The URL of the web page indicates if SSL is required on the part of the web browser. A URL that begins with HTTPS indicates that SSL should be used by the browser.

A number of Web servers support SSL and TSL. A sample of such programs is displayed in Table 2.

The details of what is required to install and set up an SSL/TLS web server can be found in a number of places. For a detailed overview the reader is directed to Garfinkel & Spafford (2002) and Stein (1998). For a technical discussion of what is required the reader should consult Rescorla (2001).

Advantages and Disadvantages of and Alternatives to SSL/TLS

SSL and TLS provide server authentication, encryption of messages, and message integrity. Their design has several advantages, disadvantages, and alternatives.

Advantages

An important advantage of both SSL and TLS is they provide a generic solution to establishing and using a secure channel. This solution lies between the Application layer and TCP layer of the TCP/IP protocol suit. This implies that any protocol that can be carried over TCP (e.g., ftp, nntp) can be guaranteed security using SSL or TLS.

Another advantage is that SSL and TLS's design is publicly available. Because of this a large number of SSL and TLS implementations are available both as freeware and as commercial products. Further, these implementations are designed as APIs that are similar to networking APIs. In a C/C++-based implementation the SSL APIs emulate Berkeley sockets and in Java they emulate they Java socket class. As a result it is a simple matter to convert a nonsecure application into a secure application using SSL or TLS.

Disadvantages

In e-commerce the application of SSL and TLS has several disadvantages. Both protocols are able to solve the problem of transmitting a credit card number securely, but they are not designed to help with other aspects of that type of transaction. In particular, they are not designed to verify the credit card number, communicate and request authorization for the transaction from the consumer's bank, and ultimately process the transaction. In addition, they are not designed to carry out additional credit card services (e.g., refunds, back order processing, debit card transactions).

An additional disadvantage of SSL/TLS is security of a credit card information on the server. In particular, if the credit card number is cached on the server it will be stored in plaintext. If the server was compromised then that number would become available in plaintext.

Finally, SSL/TLS is not a global solution. In the U.S., systems that use strong encryption cannot be exported.

Alternatives to SSL/TLS

In the area of e-commerce an alternative to SSL which does not have the disadvantages cited above is SET (secure electronic transaction). SET is a cryptographic protocol developed by Visa, Mastercard, Netscape, and Microsoft. It is used for credit card transactions on the Web. It provides

Authentication: all parties to a transaction are identified;

Confidentiality: a transaction is encrypted to foil eavesdroppers;

Message integrity: it is not possible to alter an account number or transaction amount; and

Linkage: attachments can only be read by a third party if necessary.

In addition, the SET protocol supports all features of a credit card system: cardholder registration, merchant registration, purchase requests, payment authorizations, funds transfer (payment capture), chargebacks (refunds), credits, credit reversals, and debit card transactions. Further, SET can manage real-time and batch transactions and installment payments. In addition, because SET is used for financial transactions only, it can be exported and hence can be a global solution for e-commerce. The details of SET are discussed in another chapter.

In the area of providing a secure channel for messages there are alternatives to SSL/TLS.

One is IPSec (IP Security), which is a set of open standards designed by IETF and specified in RFC 2401 (2002). IPSec provides for end-to-end encryption and authentication at the IP layer. IPSec is supported in Ipv4 and mandatory in Ipv6.

Another alternative to SSL/TLS is SSH (secure shell). SSH is an application and protocol suite that allows a secure connection to be established between two computers that are using a public network. The SSH protocol architecture has three components:

Transport Layer Protocol, which provides server authentication, confidentiality, and data integrity

Authentication Protocol, which provides user authentication

Connection Protocol, which provide multiple data channels in a single encrypted tunnel.

These protocols run on top of the TCP layer in the TCP/IP protocol suite. This is similar to SSL and TLS.

GLOSSARY

Asymmetric encryption A cryptographic algorithm that uses separate but related keys for encryption and decryption. If one key of the pair is used for encryption then the other key of the pair must be used for decryption. This is sometime referred to as a public-key algorithm.

Authentication The process of verifying that a particular client or server is who it claims to be.

Block cipher A cipher that encrypts blocks of data of a fixed size.

Certificate, public key A specified formatted block of data that contains the name of the owner of a public key as well as the public key. In addition, the certificate contains the digital signature of a CA. This digital signature authenticates the CA.

Certification authority (CA) A trusted entity that signs public key certificates.

Ciphertext The result of encrypting plaintext.

Confidentiality A condition in which information exchanged between a client and server is disclosed only to those intended to receive it.

Data encryption standard (DES) A widely commercially used block cipher.

Diffie–Hellman (DH) An asymmetric algorithm that generates a secret shared between a client and server on the basis of some shared, public and randomly generated data.

Digital signature A data value computed using a public key algorithm. A data block is encrypted with the sender's private key. This ciphertext is not confidential but the message cannot be altered without using the sender's private key.

Digital signature standard (DSS) A digital signature algorithm developed by the National Security Agency (NSA) and endorsed by the National Institute of Standards and Technology.

Hash function A function that maps a variable-length message into a value of a specified bit length. This value is the hash code. There is no known method that will produce the original message using the hash value of the message. There is no known way of creating two different messages that hash to the same value.

Integrity Being able to ensure that data are transmitted from source to destination without unauthorized modification.

Internet protocol A protocol that allows packets of data to be sent between hosts in a network or hosts in connected networks.

Message digest #5 (MD5) A one-way hash algorithm.

Nonrepudiation Being able to assure the receiver that the sender of a message did indeed send that message even if the sender denies sending the message.

Rivest cipher #2 (RC2) A block cipher sold by RSA data security. This is a 40-bit key cipher.

Rivest cipher #4 (RC4) A stream cipher used in commercial products

Rivest, Shamir, Adelman (RSA) An asymmetric cipher (public-key cipher) that can encrypt/decrypt. It is also used in creating digital signatures.

Secret key A cryptographic key that is used with a symmetric algorithm.

Session key A secret key that is used for a limited period of time. This time period covers the length of time there is communication between a client and a server.

Symmetric algorithm A cipher that requires one shared key for both encryption and decryption. This shared key a is secret key and the strength of the ciphertext depends on keeping the shared key secret.

Transmission control protocol (TCP) The Internet protocol that provides reliable communication between client and a server.

Triple DES (3DES) A cipher that uses DES three times with either two or three different DES keys.

X.509 A public-key certificate.

Securities Trading on the Internet

E-FINANCE AND SECURITIES TRADING

> I don't know how the first spider in the early days of the world happened to think up this fancy idea of spinning a web, but she did, and it was clever of her, too. . . . It's not a bad pitch, on the whole. (*Charlotte's Web* [White, 1980], pp. 39–40)

Participants and observers in Wall Street's online financial web have used the term "e-finance" to name a variety of digital network technology applications—primarily using the Internet—that have transformed the personal and institutional financial markets. It has been applied to the banking, insurance, and securities industries and even to processes such as risk management in corporate finance. This chapter concentrates on online security trading and online financial services, and in this chapter, "e-finance" will refer "only" to Internet-enabled activities involved in the buying and selling of stocks, bonds, financial derivatives, and mutual funds. These activities include online investment planning, management, and trading; computerized securities exchanges; online registration of new equity offerings; and the explosion of information newly available to investors—both from commercial sources and from other investors in message boards and chat rooms. Other chapters in the *Encyclopedia* discuss online banking, electronic funds transfer, and electronic payment systems. (See Figure 1.)

With the "New Economy bubble" spinning a supportive web of capital from 1995 to 2000, the field of financial securities was transformed from one that relied on person-to-person direct communication to one that exploited the potential size, speed, and collaboration of computer networks. Technology enhanced and expedited traditional investment processes and bred new capabilities that would have been unthinkable before the World Wide Web was built.

WHY E-FINANCE?

The Industry's Perspective

> I have to get my own living, I live by my wits. I have to be sharp and clever, lest I go hungry. I have to think things out, catch what I can, take what comes . . ." (*Charlotte's Web*, p. 40)

"What comes" was more than the flies and insects Charlotte caught in her web. Three factors led businesses and governments to adopt the Internet as a distribution channel for financial services. The first two were unalloyed advantages, the third a mixed blessing:

A rapidly expanding potential market of predominantly affluent Internet users

An extremely efficient supply model for distributing information digitally

Potentially risky investments in technology infrastructures and common standards.

Potential Market

The population of Internet users has grown exponentially since the United States government released constraints on commercial applications in 1991 and user-friendly Web browsers become available in 1994. Although early users were few, they formed an attractive market segment for the financial community: comparatively affluent and innovative, and concentrated in developed and technology-rich economies such as the U.S., Canada, Northern Europe, and Australia. As the 1990s passed, the online population grew more mainstream in North America and spread to inhabitants of the developing and non-English-speaking world. According to *The UCLA Internet Report 2002—"Surveying the Digital Future"* (UCLA Center for Communication Policy, 2003), 71.1% of Americans used the Internet in 2002, whereas 47.0% of those who did not go online anticipated doing so within 12 months (pp. 18, 30). The racial and educational "digital divide" in Internet access that existed throughout the 1990s has largely disappeared; an income divide remains, both within developed economies and between affluent nations and their less affluent counterparts.

For those with access to the Net, time spent online has grown as additional products and services enhanced the utility of the Web and as surfers' experience of it deepened and matured. Years of online experience have proven to be a significant predictor of online commerce in all forms, and e-finance is no exception. *The UCLA Internet Report—Year Three* found that the average Internet user spent 11.1 hours a week online in 2002. For those with 5 years or more experience of the Web, 3.9% of that time was devoted to trading stocks, whereas those with less than a year of experience spent 2.8% of their online sessions on

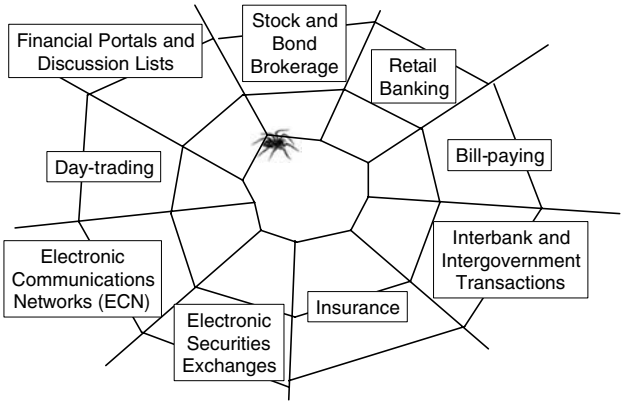

Figure 1: Wall Street's web of online financial services.

investing (p. 19). (This compares to online banking rates of 3.3% and 0.3% of online time, respectively.)

Other sources cite even greater volumes of online investing. As early as May, 1997, NetSmart announced that 42% of Internet users surveyed researched financial services online, and that 30% of them had made online investments (*Research Alert*, p. 8). The Direct Marketing Association's *Statistical Fact Book 2001* includes a Netsmart America.com study reporting that 13% of Internet users invested online in 2000 (Netsmart.America.com, 2001), and Jupiter Media Metrix forecasts 3.6 million online trades by 2006 (out of 32.5 million Internet users), up from 1.5 million in 2001 (Guglielmo, 2001). In a 2001 study, IDC estimated that there were 7 million online brokerage accounts in Europe in 2000 and forecast growth to 17 million accounts by 2004—approximately 10 million less than comparable U.S. volumes. In fact, providing online trading has become a securities industry imperative; Accenture reports that "traditional retail brokers lost $2 billion of their $54 billion in 1999 revenues to online trading companies such as E*Trade, eSchwab, and Ameritrade" (Tsien & Dumaine, 2001, p. 2).

The business-to-business financial sectors have not been left out of this revolution. ActiveMedia Research expects that "finance, insurance, and real estate" will be among the four top "Internet-based commerce leaders" in business-to-business markets by 2004, with e-commerce penetration in "transportation, trade and finance" growing from 1% in 1999 to 34% in 2004 (Karr, 2000).

Digital Distribution

Digital distribution is an extremely efficient supply model. Purely digital "products" can be sent over computer networks cheaply. It is no coincidence that the most profitable e-commerce efforts to date have not had to deal with physical goods. They were able to automate operational processes and to avoid significant warehousing, shipping, and handling expenses. Additionally, the Internet offers opportunities to automate critical procedures and to transfer many customer service activities from venders' employees to the customers themselves. In 2000, Forrester Research documented the precipitous drop in the price of information, from encyclopedias to stock prices, as the transmission medium evolved from paper and ink to bits and bytes. Online financial services were able to take full advantage of these factors. For example, after launching a revised Internet trading product in 1998—one that was low-priced but offered full access to the firm's customer services—Charles Schwab reported that it saved over $100 million annually due to "net efficiencies" (McFarlan and Tempest, 1999). (See Figure 2.)

The Investor's Perspective

> "Where do you think I'd better go?"
>
> "Anywhere you like, anywhere you like," said the goose.
>
> (*Charlotte's Web,* p. 17)

From the investor's perspective, e-finance offers opportunities unavailable in the pre-Web world. It lets individual

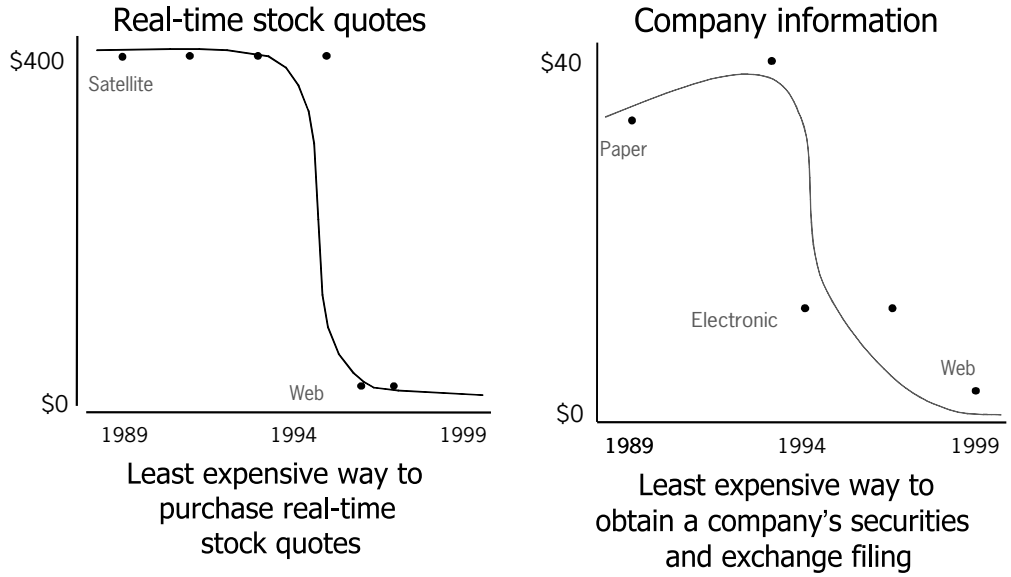

Figure 2: The cost of distributing "digital" products is minimal.

investors go almost "anywhere they like." These opportunities include:

Real-time information, which facilitates greater investment agility
Information sources beyond a human broker who may be biased by commission-driven self-interest
Low-priced trading
Membership in investor "communities" developed by specialized message boards and chat rooms.

The mass media's ubiquitous attention to finance in the late 1990s added to investors' sense of belonging, and conversely, to nonparticipants' sense of missing out on a pervasive cultural phenomenon. Only three negative factors lessened the attractiveness of online investing:

The relatively impersonal nature of online trading
Potential concerns over the security of data from both external and internal piracy—better known as "hacking"
Worries over the use or misuse of sensitive personal and financial data—the critical "privacy issue" that challenges all of e-commerce.

Real-Time, Unbiased Information

Information—voluminous and timely—is the siren call of the Internet. A variety of publishers and vendors have made financial information available online that used to be inaccessible to the individual investor, from industry and company research to real-time stock prices. Of those polled by the *The UCLA Internet Report—Year Three,* 21% cited information as their reason for starting to use the Net in the first place, making it the #1 motivator reported; 90.6% of those respondents said they considered the Internet a "moderately, very or extremely" important source of information. Their trust in the veracity of online information is not unquestioning, but it is surprisingly strong: 39.9% of Internet users considered "half" of online information "reliable and accurate" and 50.6% regarded "most" online information as reliable and accurate. Merely 7.2% endorsed only a "small portion" of online information and 0.2% believed that "none" was reliable and accurate. (Note that this question referred to all information, not financial data exclusively.)

Low-Priced Trading

From the very beginning, online stockbrokers leveraged the low cost of digital distribution into low-priced service offerings. Pioneer brokers such as E*Trade and Ameritrade passed technology-driven savings along to customers and undercut the commissions of even discount "bricks and mortar" brokers such as Charles Schwab.

Community

In addition to commercial research and professional analysis, the Internet offers virtual collaboration for gathering and evaluating information. Investors are now able to share financial news, opinions, and preferences on a variety of Web sites that offer message boards and chat rooms. It has often been said that e-commerce empowers the consumer. Online investing, by "disintermediating" the traditional broker, shifts the power—and the responsibility—for investment strategy and tactics to the individual investor. The sense of community derived from bulletin boards and chat rooms provides the personal touch that is missing from this relationship. Peer-to-peer consultations—especially when not face-to-face—allow the investor both anonymity and reinforcement. The best peer-to-peer financial sites offer basic tutorials to bring novices up to speed so that they may comfortably take part in discussions. For the knowledgeable participants, online debate and commentary can point out new opportunities or risks and can fine-tune their investment choices. Furthermore, the social value of sharing information and developing communities online has been well documented as enhancing the attractiveness and "stickiness" of a Web site by building social relationships in virtual space (Hagel & Armstrong, 1997; Martin, 2002). Many have speculated that, in a climate of escalating terrorism around the world, the need for human contact increasingly will be met though distance communications rather than through physical proximity.

Security and Privacy

Other threats, however, mitigate the physical safety of online investing. Worries about security from theft or misuse of sensitive personal information have long been barriers to Internet and e-commerce adoption. Year after year, marketing research has shown that "security" and "privacy"—often undistinguished in respondents' minds—were the primary reasons given for not exploiting the Web's shopping convenience, and they remain salient even among online shoppers and investors. The *The UCLA Internet Report—Year Three* indicated that security and privacy concerns still exist among "very experienced" (more than 5 years online) and "new" (less than a year online) Internet users alike. Of very experienced users, for example, 48.2% reported that they were "very" or "extremely" concerned about the security of their credit card data—a clear parallel to other financial information—whereas 78.6% of new users expressed that high level of concern (p. 50). (It is interesting to note that overall concern about credit card security had dropped from 2001 to 2002, with 71.3% saying they were "very or extremely concerned" about the issue in the former year and 63.3% in the latter.) Moreover, 81.6% of those already purchasing on the Internet were "somewhat," "very," or "extremely concerned" about the safety of that personal information, a privacy issue. Because most people consider personal income and wealth among the most sensitive of information categories, security and privacy must remain critical issues for e-finance providers and their customers. Disturbingly, Forrester Research found that only 70.9% of online investors were "somewhat or very satisfied" with the clarity of their primary brokerage firm's privacy policy (Table 1).

The "thin, delicate strands" that make up the web of online financial services range from retail and institutional investors—entities such as financial portals, message boards, and day traders—to organizations that see the transactions to fruition. Participants who execute the trades include online stock brokerages, securities exchanges, newly emerged electronic communications networks (ECNs), and regulatory bodies (such as the U.S. Securities and Exchange Commission) that set the markets' rules. In a relatively short time, 10 years or less, all of these participants either have been born or have transformed their operations from a system of personal contacts (often face to face) to computerized transmission and resolution.

Day Traders

Day trading is an inherently risky, extremely short-term investment activity, with investors often buying and selling stocks within minutes in order to take advantage of rapid price changes. Professional investors had sole access to this strategy before the Internet opened it up to retail investors. Some of the purely online brokerages—such as Datek.com—specialized in serving the day trading market and developed direct trading processes that spun off as ECNs such as Island, formerly a subsidiary of Datek. Day trading reached its peak popularity from 1998 to 2000, when the bull market gave traders the illusion of invincibility. With the bursting of the dot-com bubble, however, investment activity slowed across the board as investors became more cautious. Although day trading certainly exists in 2003, it is much less prevalent than in its heyday.

Financial Portals and Message Boards

According to the comScore Media Metrix online ratings service, the top five Web properties as of July 2002 were AOL–Time Warner, Microsoft, Yahoo!, Google, and Terra Lycos. Whereas a "property" is defined as all sites owned by a given corporation, each of these domains features a gateway to financial news, and all but Google include financialdata, links, and tools as well as general-interest home pages (respectively http://www.aol.com or the ISP's welcome page, http://www.msn.com, http://www.yahoo.com, http://news.google.com/news/gnbusinessleftnav.html, and http://www.lycos.com). In addition to these sites, major news organizations such as CNN and CBS, as well as software firms such as Intuit, have created their own gateways to financial content. CNN offers

Money.CNN.com, CBS runs CBS.Marketwatch.com, and Intuit offers www.Quicken.com.

Several financial Web sites were founded with community forums at their hearts. The role of these sites is to form a convenient virtual meeting place where investors can share information and opinions with others about the economy, specific industries, and particular companies. Message boards, chat rooms, and educational content constitute the backbone of these Web sites. As media vehicles, portals and message board forums have generally partnered with online brokerages and banks in order to offer a wide range of transactional services while remaining focused on their core competencies. Two of the most consistently popular investment communities have been The Motley Fool (www.MotleyFool.com) and Raging Bull (RagingBull.Lycos.com).

Raging Bull was one of those Internet start-ups that experienced skyrocketing growth during the dot-com boom. Like Michael Dell before him, Bill Martin, founding partner of Raging Bull, turned a personal interest into a multimillion-dollar company while still in college. Having been fascinated by the stock market since age 9 and with the Internet since high school, Mr. Martin discovered early financial message board forums as a summer intern at Goldman Sachs in 1995–1996.

> As an investor I spent a ton of time that summer in the message boards. I thought, "Wow!" because I remember in high school driving 25 minutes to go to my public library to look up stocks that I owned in ValueLine. . . . And of course ValueLine only updates every couple months, . . . but I can check every day [on the Internet] and it's even cooler for these little companies you're following. A guy reads in his local paper an article and he puts it online—a little news here and there and you [put together] these tidbits and [and produce a phenomenal] amount of information. That just shows you how dramatically things have changed. It truly unleashed the amount of data and information available.
>
> I started talking to my best friend from high school—"Let's start a business together." So we started messing around at the end of '97—launched a small site. In early '98 we were kinda playing around, and then along with another guy decided that the following summer we were going to go full time with this. We took $20,000 between the three of us . . . and we launched it in June of '98 (Martin, 2002 [personal interview]).

Mr. Martin never went back to college. Within a year, Raging Bull was one of the five largest finance Web sites. Its revenue rose to almost $10 million (annualized) in 18 months. In January, 2000, it attracted 3 million unique visitors and 300 million page views. CMGI@Ventures and CNET invested $22 million. The company's management eventually decided not to go public as a stand-alone firm: "Raging Bull's community was nifty and neat, but it would be better as part of something bigger that had a whole suite of services." Instead, they sold the firm to Terra Lycos in 2000 for almost $200 million, and it become the centerpiece of Lycos' financial service offerings.

An article by Tumarkin and Whitelaw (2001) studied the applicability of message board postings as predictors of stock price and volatility. Investigating the

popular belief that such community activity impacted the securities markets, the authors theorized that their influence might be due to the disclosure of new information, the reflection of market sentiment, investors' susceptibility to influence by posted messages, day traders' usage of the discussions to plumb market momentum, and consciously fraudulent efforts to manipulate the market. They found that message board discussions could be associated with short-term movement of the stocks under discussion, at least for companies in the fast-moving Internet sector, where investors could be expected to be especially vigilant. The scholars analyzed 181,633 messages taken from RagingBull.com. The 10,723 unique ticker–day combinations represented 24.1% short-term opinions and 20.8% long-term opinions. "Abnormal" stock returns for the securities discussed were defined as deviations from the Philadelphia Stock Exchange (PSE) Internet Index, and short-term abnormal returns were found to be correlated with—but not necessarily caused by—high levels of message board activity.

Online Stock Brokers

With the rise of the commercial Internet and the World Wide Web, technologically oriented entrepreneurs saw the potential benefits of online trading and launched an industry that was estimated to have captured 25% of all U.S. stock trades in 1999. Working on either a "discount" or a "deep discount" model, the earliest online brokers were "pure plays"—that is, they used the Web as their only channel of distribution to retail customers. As the 1990s ended and the dot-com bubble collapsed, the benefits of consolidation, multichannel distribution, and enriched client service became evident. Table 2 lists the top brokerage houses, in terms of their *online* revenues (i.e., excluding all other revenue) as of November 2001 and trading fees and services as of 2002. Table 3 ranks the top U.S. brokerages houses in terms of the "effectiveness" of their online offerings. The rise and stumble of online brokerage services will be detailed below.

Electronic Communications Networks (ECNs) and Stock Exchanges

Instinet, the earliest ECN, was founded in 1969 to enable institutional investors to match their large blocks of stocks directly and bypass "market makers" such as the specialists on the New York Stock Exchange (NYSE) or the dealers of Nasdaq. In 1997, the SEC imposed new regulations, called order handling rules, that required exchanges to display investors' limit orders, opening up opportunities for individual retail investors to use ECNs via their brokers. Whereas the NYSE's Rule 390 (since rescinded) limited stocks listed on the "Big Board" to trading on organized exchanges, Nasdaq imposed no such requirement. Nasdaq investors and broker/dealers were free to exploit the advantages of ECNs: low transaction fees (as low as $0.00035 per share), narrower price spreads (leading to lower purchase prices and higher sales prices), quicker execution than floor-based or screen-based systems (a fraction of a second versus half a minute or more), anonymity that offers the retail buyer the same alternatives as a large institution, and—by 1999—after-hours trading. ECNs, therefore, thrived on Nasdaq and by the first quarter of 2002 processed over 50% of Nasdaq trades (see Figure 3). Of nine ECNs founded in the past 5 years, Island was the first and remains the largest; it agreed to merge with Instinet on September 20, 2002, making their combined share of Nasdaq stock trading 22%.

ECNs are not without their disadvantages, however. Early criticism focused on their role in fragmenting the market, reducing its liquidity by shrinking the pool of potential buyers or sellers to which a given order was exposed. The larger the pool, the argument went, the greater the chance of finding an interested buyer/seller and getting/paying the best price—in Charlotte's words: the larger the web, the more likely it is to catch flies. order to enhance the liquidity they provided, the ECNs established mutual alliances throughout 1999 and 2000 to link their order lists and offer access to a broader market to their customers. In recent years, moreover, the field has consolidated—partially in response to increased competition from exchanges and partially due to the bear market of 2001–2003 and its lower trade volumes.

In an effort to reduce fragmentation and to defend its competitive position, Nasdaq has developed a voluntary central limit order book, known as SuperMontage, which was approved by the SEC in August 2002 and was rolled out from October 14 to December 2, 2002. Many ECNs balked at the fees Nasdaq charged as well as the competitive advantage it might have gained with the system, in which investor subscribers are notified of the best orders placed by the exchange's market-makers and any participating ECNs. Postings include both bid or asked price and the size of the offer, a piece of information that may hint at market movement. As part of its implementation, however, participants in SuperMontage give up anonymity, so users are able to infer what the big securities firms think of given stocks.

The ECNs have had a profound effect on traditional stock markets in the United States, forcing them to examine their marketing strategies and increase the value they add for customers. This has included upgrading technology significantly so that they can provide quicker order execution, enhancing the information provided to customers, and—due to competitive pressures—compressing the price spreads on securities trades. "Decimalization"—quoting prices in hundredths of a dollar instead of eighths—is one aspect of the efforts to narrow the increments among potential prices cited. In addition, exchanges that were formed as nonprofit associations have found that they cannot respond with enough flexibility to counter new competitive threats and are moving to "demutualize" and reconstitute themselves as for-profit corporations. Much of the recent revision is concentrated to the U.S.; European markets went through radical innovations that included computerization, demutualization. and collaboration in the 1980s in preparation for the economic unification that culminated with the adoption of a common currency (the euro).

Regulatory Bodies

Governments played a vital role in the growth of e-finance; they established the rules by which participants spun the web and defined the kinds of strands that would be allowed. The U.S. government was an early participant in applying technology to the securities industry by creating the initial EDGAR (Electronic Data, Gathering, Analysis and Retrieval System) registry in 1984, allowing firms to submit financial disclosure documents on computer disks. EDGAR was taken online in 1995, making detailed financial documents readily available on the Web. Moreover, the SEC's order handling rules of 1997 laid the foundation for the growth of ECNs, and later regulations opened the door for ECNs to apply for exchange status, established registration requirements for securities traded online (that is, how non-U.S. firms can qualify their Web-based offering to be exempted from registration with the SEC), and developed procedures that allowed companies to register and sell stock offerings online while bypassing underwriters (and their costs).

How the Web Was Spun

The First Strands: Discount Brokers and "Pure-Plays"

> "Well," said Mr. Zuckerman, "it seems to me you're a little off. It seems to me we have no ordinary *spider*." (*Charlotte's Web*, 80)

Early entries into the field of online stock brokerage were the discount brokerages and deep-discount brokerages that emerged from industry deregulation in the 1970s. Charles Schwab launched its first computer-based product in 1985, enabling customers to dial directly into Schwab's computer system via PC modem. E.Schwab, which was launched in 1995, was very similar to this service, still employing a proprietary telephone line to access the Schwab computer system.

Ameritrade, a pioneer in brick and mortar deep discount brokerage, was the first firm to automate consumers' trading in 1988 when it offered a touch-tone phone interface—Schwab followed in 1989—and a firm that Ameritrade later acquired (K. Aufhauser & Company) was the first to offer true Internet trading in 1994.

The first "pure-play" online brokerage—employing only the Internet for consumer trading—was E*Trade. The firm became a retail brokerage when it redirected its services from back-office online processing for discount brokers (begun in 1992) to direct-to-consumer marketing under its own brand. By 1995, commissions on consumer trades made up over 80% of E*Trade's revenue. Its long-term goal was to "become America's dominant deep-discount brokerage firm by fully automating the front and back-office trade processing function and maintaining its position as the low-cost provider" (Lal, 1996, p. 2). From 1995 to 1996, E*Trade gradually but steadily dropped its per-trade commission from $24.95 to $14.95 by exploiting its technological efficiencies. In January, 1996, it invested heavily in advertising to launch a redesigned Web site, gain brand awareness, and attract customers by positioning itself as a market innovator and technology leader with a cut-rate price. The next month, the company's advertising message evolved to differentiate itself from other deep-discounters by stressing newly added products and services: 24-hour access, free quotes, online portfolio management, free checking, and margin and I.R.A. accounts. As a result of this aggressive promotion, E*Trade was able to position itself among investors as the leading Internet broker.

In response to incursions by E*Trade and its ilk on its market share, Charles Schwab enhanced its still-limited e.Schwab service and reduced its commission to $29.95. It also increased the commission discount for its top-tier product from 10 to 20% off full-service retail. Customers and prospective customers responded positively, but as 1997 advanced, the price war among E*Trade, Ameritrade, and other deep-discounters escalated with no floor price in sight. (By 2000, some firms even experimented with free trading services.) Discussing the 2002 move by full-service brokerage houses to reject "small" clients with "only" $300,000–$400,000 to invest,

Cramer (2002) notes the changed "economics of the business":

> In the old days, as your broker, I could execute buy and sell orders for you and charge you a rate per share that could amount to as much as 25 cents on small dollar shares and as much as $1 or even $2 per share on larger amounts. If I courted you on, say, Kimberly–Clark and provided you with research and guidance about why I thought it was an appropriate time to buy the stock, and I enticed you to buy 5,000 shares at $65, I might be able to charge as much as $2,500 or $5,000 in commission. . . . But that game's dead now, slaughtered by the Net and all of those folks who charge $6 a trade!

Comparing the brokerage market to the book market, where Barnes & Noble and Borders were being cornered by an online start-up from Seattle, wits prophesied that the "brick and mortar" securities firms soon would be "Amazon'd."

Snagging the World and His Brother in the Web

> "Charlotte is fierce, brutal, scheming, bloodthirsty—everything I don't like. How can I learn to like her, even though she is pretty and, of course, clever?" (*Charlotte's Web*, 41)

As private investors achieved revolutionary access to the financial markets, their interest was reinforced by a media frenzy about the "long boom" of the 1990s and the growth of the "new economy." Market indicators and stock prices were reported and followed as enthusiastically as football scores in the final months before the Super Bowl. Even people who had never invested before began to participate in this sport.

Grass-roots participation in the equities market, combined with increased speed of execution, has been cited as causing greater volatility in stock prices and reduced holding periods during the late 1990s. In an analysis of online investor data in 2000, Roper Starch Worldwide found that the average online investor traded 12.7 times a year, with Ameritrade customers averaging 14.5 trades a year. Ameritrade itself, after examining its customer files purged of data from day-trading accounts, concluded that its customers tended to respond to short-term changes in the market.

In early 1998, Charles Schwab addressed the newly massive demand for online trading and defended its own historic positioning of value-added services at a discount by consolidating its online products into one. This product, www.CharlesSchwab.com, provided full access to Schwab research, customer service, and all communications channels for $29.95 a trade. The company also invested heavily in technology to be able to handle heavier traffic and to ensure speedy, accurate, and secure order-processing. Although the firm initially lost money and its stock price declined with the new strategy, it more than made up the difference in new customers acquired, increased trading volume among existing customers, and Internet operating efficiencies. Over the next two years, Schwab's growth, results, and market value justified the risks it took. By the end of 1999, wits were no longer talking about Barnes & Noble being "Amazon'd," but of E*Trade being "Schwabbed."

Meanwhile, traditional full-service brokers did not necessarily respond well to the challenge, fearing cannibalization of their high-fee services. Although some, such as Morgan Stanley Dean Witter, were relatively early to adopt the new distribution channel by investing in or partnering with online pure-plays and ECNs, some full-service brokers saw only the threat e-finance offered to their traditional ways of doing business. As Internet discount brokers increasingly took market share from the full-service firms, the greatest Luddite was the retail leader, Merrill Lynch. John L. Steffens, Merrill's head of retail brokerage, notoriously said in June of 1998, "The do-it-yourself model of investing, centered on Internet trading, should be regarded as a serious threat to Americans' financial lives." By the following winter, however, Merrill had spun its first tentative strands of "do-it-yourself investing" by offering a 4-month trial of free access to its global stock research on www.askmerrill.com. On June 1, 1999, it unveiled a totally redesigned strategy and announced a new multichannel vision for the firm. As Mr. Steffens himself characterized the firm's new position, "We have moved forward like a bullet train and it is our competitors that are scrambling not to get run over." Online trading had become mainstream.

Crash and Burn?

> "You lack two things needed for spinning a web . . .
>
> "You lack a set of spinnerets, and you lack know-how."
>
> (*Charlotte's Web*, pp. 58, 60)

Securities markets became increasingly shaky in the winter of 2000, and the instability culminated with a plunge in Nasdaq on April 14 that heralded the bursting of the Internet bubble. Suddenly, after the Nasdaq plunge, "do-it-yourself" investing did not appear as attractive as it had previously, especially to the relatively novice investors who had gotten into the market in the late 1990s. Issues of trust arose that undermined confidence in the quality of information provided by professionals and fellow amateurs alike. The widely quoted stock analysts of the dot-com boom were found to have had conflicts of interest after all, originating in their firms' desires to attract investment banking business from the same corporations whose potential the analysts were evaluating. "Community members" in finance forums were equally suspect: information derived from these sources could turn out to be anything from shared ignorance to outright fraud. In one notorious case, a 15-year-old New Jersey boy was caught artificially inflating the value of stocks he had purchased by posing as a knowledgeable adult and praising them in online chat rooms—a vivid demonstration of how easy it was to run a such a scam on the anonymous Web (Lewis, 2001).

Securities trading volume dropped by about 30% in 2000–2001, with the discount and deep discount

brokerages hit hardest. Newly insecure investors felt the need for reliable advice. Owing to shaky financials and an increased requirement to offer added value, the e-finance web has consolidated. There have been shakeouts, mergers, and alliances among the online discount and full-service brokerages and ECNs, providing new financial strength and access to research, recommendations, and tools that discounters had not offered in the past. Marketing strategies are evolving from a strictly low-price basis to one of convenience and personalization that leverages the nonprice strengths of the Internet.

Successful e-finance business models to date and into the future exploit multiplicity. Three business models promise a thriving potential:

Multichannel model ("clicks and mortar"): Charles Schwab successfully defended its premier industry position against online start-ups by offering its customers a variety of access points that let clients use whatever communications methods, in any combination, they chose: branch offices, telephone, e-mail, World Wide Web, and postal mail.

Multiproduct model: Financial services firms have found it far more attractive to customers, and less expensive for the firm, to offer existing clients products that span the investment, banking, and insurance industries. "Account aggregation" become the buzz phrase of 2001 as companies strove for greater "share-of-wallet" rather than more "share-of-market." E*Trade, for example, moved into the banking arena several years ago by acquiring an online bank and then established a physical footprint by buying into an ATM network.

Multiple technologies: Investors' desire for multiple touch points includes the expectation of timely information flow wherever they happen to be. Wireless reception devices—from Web-enabled cell phones to Internet-enabled PDAs (personal data assistants, hand-held computing devices)—have proliferated and become necessary accessories. Financial data are one of the services most in demand by wireless users, as seen from the list of top 10 channels in AvantGo's mobile network (Table 4).

Wall Street's web of online securities trading has been built strong but flexible. Its shape is evident, but it is equally evident that new strands are being added constantly, creating a richer and more complex net for the future. Charlotte's children may still need to struggle, but they are building an infrastructure that will last.

> Life is always a rich and steady time when you are waiting for something to happen or to hatch. (*Charlotte's Web*, p. 176)

Abnormal returns If an investment yield return on investment higher (or lower) than would be predicted by an efficient market model, it is said to have earned "abnormal" returns.

Bear market A bear market is sometimes described as a period of falling securities prices and sometimes, more specifically, as the point at which prices have fallen 20% or more from a high.

Bid and ask Bid and ask is better known as a quotation or quote. Bid is the price a market maker or broker offers to pay for a security, and ask is the price at which a market maker or dealer offers to sell. The difference between the two prices is called the bid–ask spread, or simply the spread.

Bond Bonds are debt securities issued by corporations and governments. Because most bonds pay interest on a regular basis, they are also described as fixed-income investments.

Bull market A prolonged period when stock prices as a whole are moving upward is called a bull market, although the rate at which those increases occur can vary widely from bull market to bull market. So can the length of time a bull market lasts.

Chat room This rather generic term has come to describe one of the more popular activities on the

Internet. Using special software, Internet users can enter chat areas or "virtual spaces," where they can communicate in real time (live).

Churning If a broker buys and sells securities in an investment account at an excessive rate, it's known as churning. One indication that an account is being churned is that paymentsin commissions exceed earnings on investments. Churning is illegal but is often hard to prove.

Day trader When investors buy and sell investments within a very short time, sometimes as short as a few minutes or perhaps a few hours, they are considered day traders. The strategy is to take advantage of rapid price changes to make money quickly. In the past, professional investors did most of the day trading, but as online trading has gained popularity, many more individuals, usually referred to as electronic day traders, do it as well.

Decimalization The term decimalization denotes the move by United States securities markets to quote stock prices in hundredths (pennies) rather than eighths of a dollar.

Demutualize In an effort to become more flexible and better able to compete with ECNs and adapt to the demands of globalization, traditional stock exchanges—formed as mutual, not-for-profit associations—are switching to a corporate, for-profit structure. European exchanges, facing competition fueled by market and currency unification for two decades, were quicker to adopt this transformation than American exchanges.

Digital divide The disparity in computer and Internet access between rich and poor, ethnic minorities and majority citizens, and developed and developing countries has been called the "digital divide." It portends an increasing gap between "haves" and "have-nots," as the latter are locked out of the benefits of access to online information and services.

Discount broker Brokerages that offer securities trading at per trade commissions ($25–$35) moderately lower than traditional, full-service brokers' current fees, which were originally charged per share traded. Pioneered by the Charles Schwab Corporation in 1975, they offer independent financial products and services rather than actively managing clients' investment portfolios, and offering proprietary products and research. "Deep discount brokers" generally charge $6–$15 per trade.

Disintermediation In the early days of the commercialization of the Internet, it was widely believed that e-commerce would ultimately eliminate "middlemen" from channels of distribution by offering more desirable and more efficient direct distribution between manufacturer or service provider and end user (consumer).

Dot-com bubble The long bull market of the 1990s led to theories of a "new economy." Stock valuation for start-up, usually unprofitable, Internet firms ("dot-coms") often exceeded that of long-established and profitable "old economy" businesses in a classic investment "bubble." By the first quarter of 2000, investors' patience with red ink had worn thin and technology and Internet-sector stocks fell dramatically, most famously on April 14.

EDGAR EDGAR stands for "Electronic Data, Gathering, Analysis and Retrieval System," and was launched by the Securities & Exchange Commission (SEC) in 1984 to automate the submission and processing of financial data filings. EDGAR Online offers clients Web-based access to business, financial, and competitive information disclosed in SEC filings throughout the year by over 15,000 U.S. public companies.

Electronic Communications Network (ECN) An ECN is an alternative securities trading system that collects, displays, and executes orders electronically without a middleman (such as a specialist or market maker).

Financial portal Financial portals are Web sites that provide a single point of access to information, databases, tools, and related Web pages that help consumers manage their personal finances. Most now offer both investing and banking content.

Floor broker Floor brokers are members of a stock or commodities exchange who handle client orders that are sent to the floor of the exchange from the trading department or order room of the brokerage firms they work for.

Full service broker A full-service brokerage participates in all aspects of the investment process, from recommending investment choices to executing the transaction, measuring results, and formulating follow-up strategies. Discount brokers contend that there is an inherent conflict of interest in the full-service brokers' recommendations, as they derive revenue from trading commissions.

Individual retirement account (I.R.A.) These tax-deferred retirement accounts allow anyone who earns income from work, or is married to someone who does, to put up to $2,000 per year in an account and postpone paying tax on any earnings.

Limit order When an investor gives a broker an order to buy or sell a stock when it reaches a certain price or better, it is called a limit order. For example, if an investor places a limit order to buy a certain stock at $25 a share when its current market price is $28, the broker will not buy the stock until its share price is at $25 or lower.

Liquidity If an investment can be converted easily and quickly to cash, with little or no loss of value, it has liquidity.

Margin Buying on margin is borrowing from a broker to buy stocks. The margin is the value of the cash or securities that the buyer must deposit as collateral in a margin account. If the value of the margin account drops below the maintenance requirement, the buyer must, in most cases, add cash or securities to the account to bring its value back to the minimum.

Market maker A dealer in an electronic market, such as the Nasdaq Stock Market (Nasdaq), who is prepared to buy or sell a specific security—such as a bond or at least one round lot of a stock—at its publicly quoted price is called a market maker. Typically, there are several market makers for each security. On the floor of an exchange, such as the New York Stock Exchange (NYSE), however, the dealer who handles buying and selling a

particular stock is called a *specialist*, and there is only one specialist in each stock. Brokerage firms that maintain an inventory of a particular security to sell to their own clients, or to brokers at other firms for resale, are also called market makers.

Message board Also referred to as "discussion lists" and "bulletin boards." Web-based message boards allow users to publish questions, responses, and announcements for others to see and respond to at a later time. Unlike chat rooms, the communication is not necessarily live.

Mutual fund A mutual fund is a professionally managed investment that pools the capital of thousands of investors to trade in stocks, bonds, options, futures, currencies, or money market securities, depending on the investment objectives of the fund.

Nasdaq National Market (Nasdaq) The Nasdaq national market is part of the electronic Nasdaq stock market administered by the National Association of Securities Dealers (NASD). Stocks traded on this market must meet specific listing criteria for market capitalization and trading activity.

New York Stock Exchange (NYSE) The NYSE is the largest equity exchange in the world. Founded in 1789, it has a global market capitalization of over $15 trillion. Common and preferred stock, bonds, warrants, and rights are all traded on the NYSE, which is also known as the Big Board.

Option Buying an option gives an investor the right to buy or sell a specific investment at a specific price, called the strike price, during a preset period of time. An American-style option is an option that the holder may exercise at any time up to and including the option's expiration date. A European-style option is one that can only be exercised on its expiration date.

Over the counter (OTC) The majority of stocks in the U.S. (as well as government and municipal bonds) are traded over the counter, rather than on the floor of an organized stock exchange. That number includes more than 5,000 stocks that are listed on the Nasdaq Stock Market (Nasdaq) and are part of the National Market System (NMS), as well as stock in companies too small to meet stock market listing requirements.

Pure-play A firm is a pure-play if its only distribution channel is the Internet or the wireless Web. In the 1990s, many Internet start-ups were pure-plays.

Securities and Exchange Commission (SEC) The SEC is an independent federal agency that oversees and regulates the securities industry in the U.S. and enforces securities laws. It requires registration of all securities offered in interstate commerce and of all individuals and firms who sell those securities.

Share of market Share of market is a traditional measure of marketing success, calculated as a given company's sales divided by the sales of all competitors (including that company) in a given product market. In contrast, *share of wallet* concentrates on the individual customer. It is calculated as the percentage of an individual's purchases in a given product category that are accounted for by a given seller.

Stickiness Stickiness refers to Website content that induces visitors to spend lots of time at the site, thereby increasing their chances of responding to an advertisement or making a purchase.

Stock A stock is an investment that represents part ownership in a corporation and entitles an investor to part of that corporation's earnings and assets. Common stocks provide voting rights to shareholders but no guarantee of dividend payments. Preferred stocks provide no voting rights but guarantee a dividend payment. (Under certain circumstances and for special purposes, "restricted" nonvoting common stock may be issued by a corporation.)

Yield Yield is the rate of return on an investment, paid in dividends or interest and expressed as a percent. In the case of stocks, the yield on an investment is the dividend per share divided by the stock's price per share. With bonds, it is the interest divided by the price.

Software Design and Implementation in the Web Environment

Jeff Offutt, *George Mason University*

INTRODUCTION

The original Web sites used hyperlinks to connect text documents. Modern Web applications run large-scale software applications that support e-business, information distribution, entertainment, collaborative working, surveys, and numerous other activities. They run on distributed hardware platforms and heterogeneous computer systems. The software is distributed, is implemented in multiple languages and styles, incorporates reuse and third-party components, is built with cutting-edge technologies, and must interface with users, other Web sites, and databases. The software components are often distributed geographically both during development and deployment and communicate in numerous distinct and sometimes novel ways. Web applications consist of heterogeneous components including traditional and nontraditional software, interpreted scripting languages, plain HTML (hypertext markup language) files, mixtures of HTML and programs, databases, graphical images, and complex user interfaces. This heterogeneity has led to the notion of Web site engineering (Powell, 1998).

The tremendous reach of Web applications into all areas of communication and commerce makes this one of the largest and most important parts of the software industry. Yet studies (President's Information Technology Advisory Committee [PITAC] 1999; Schneider, 1999) have found that the current base of science and technology is inadequate for building systems to control critical software infrastructure. Web software development uses cutting-edge, diverse technologies, and we are just beginning to learn how to design and develop high-quality Web software, making this problem particularly severe.

FIRST-GENERATION WEB SITES

The original Web sites were static HTML files, so-called soft brochures, usually created by a single webmaster who used technologies such as HTML and simple CGI scripts to present information to visitors and occasionally obtain information from them with forms (Powell, 1998). Figure 1 illustrates this scenario. A client was a Web browser that people used to visit Web sites. The Web sites were on separate computers, the servers, which delivered HTML files to the client. HTML forms generated data that were sent back to the server to be processed by CGI programs. This is a simple execution model that supports relatively small Web sites. The software involved is by necessity small in scale; such Web sites usually cannot support much load and offer limited functionality. The software also has few provisions for security, and the TCP (transmission control protocol) and HTTP (hypertext transfer protocol) by themselves are not designed to support secure interactions.

SECOND-, THIRD-, AND FOURTH-GENERATION WEB SITES

This situation drastically changed through the late 1990s, with strong impact on and motivation from engineering principles and processes. Second-generation Web sites featured significantly more layout and presentation abilities, graphics, and more robust backend software support, including session management with cookies.

Third-generation Web sites added improved interaction, including client-side execution such as JavaScripts and Java applets. Third-generation Web sites also became fully functional software systems and provide business-to-customer and business-to-business e-business, and a large variety of services to a large variety of users.

Developers of third-generation Web sites found several problems with the software support for the increased level of uses. It was difficult to achieve the reliability needed for e-business, security became a problem, maintenance was difficult, and the software designs did not scale well. Fourth-generation Web sites currently rely on multitiered hardware and software architectures, improved software technologies such as the J2EE platform, communication

among software components with XML (extensible markup language), and a number of design architectures for large-scale Web software applications. Figure 2 illustrates a typical configuration for a fourth-generation Web application.

Most of the software has been moved to a separate computer, the application server. Large Web sites implement the application server as a collection of application servers that operate in parallel. Likewise, Web servers are often clusters of computers that work together to server requests from large numbers of users. Application servers typically interact with one or more database servers, often running a commercial database. The client–server interaction, as before, uses the Internet. The Web servers and application servers are connected by middleware, which are packages obtained from software vendors to handle functions such as communication, data translation, and process distribution. Middleware is sometimes as simple as Java Data Base Connectivity (JDBC), whereas other middleware packages are large and solve complicated problems. Likewise, the application-database servers often interact through middleware.

WEB SOFTWARE ENGINEERING QUALITY FACTORS

Although software engineering researchers, educators, and practitioners have spent years focusing on developing processes and technologies to improve software quality attributes, much of the software industry has had little motivation to improve the quality of their software. Software is often sold with relatively low-quality requirements; the combination of user expectations and market realities has been such that increasing quality usually has not increased profits. A combination of time-to-market and marketing strategies has almost always determined whether traditional software products succeed competitively. As an example, software contractors for government agencies are often paid the same regardless of the quality of the delivered software. Despite the positive impacts of the capability maturity model (Carnegie Mellon Software Engineering Institute, 2002), many contractors are still given additional resources to correct problems of their own making (Tassey, 2002). Commercial software companies (so-called shrink-wrap vendors) are usually

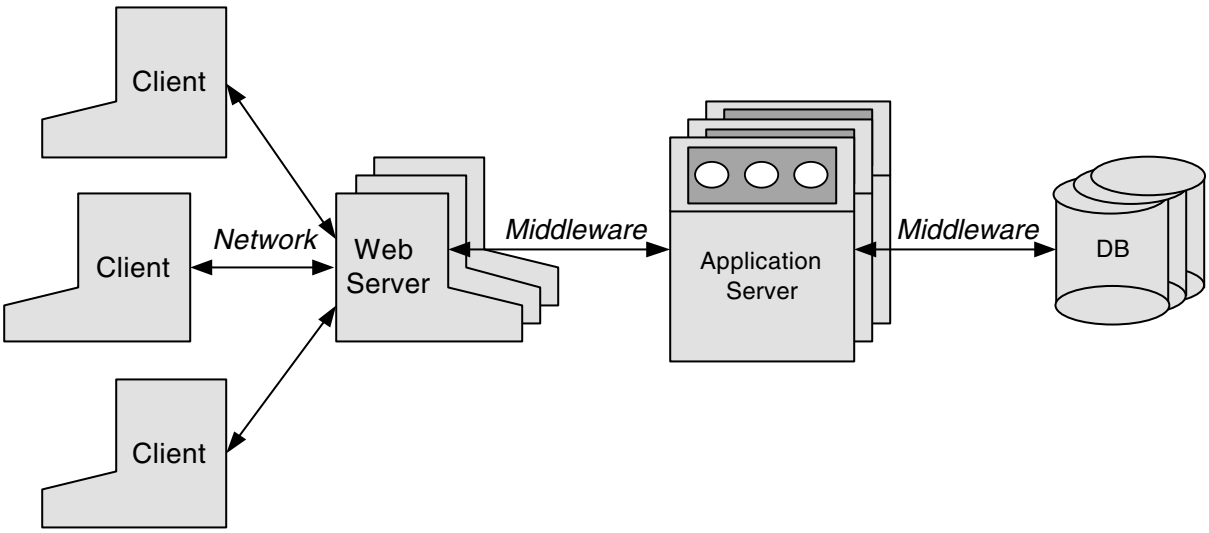

Figure 2: Multitier Web sites.

driven almost entirely by time-to-market; it is almost invariably more lucrative to deliver poor-quality products sooner than high-quality products later. It is a well-known truism that companies can often sell poor-quality first versions of software applications and then make more money by charging for upgrades that contain more bug fixes than new features. For most applications, there has traditionally been little economic motivation for producing high-quality software. In fact, there have often been economic disincentives for creating high-quality software products.

Web-based software is in a completely different situation, one more akin to critical software such as aerospace, telecommunications, and medical devices. One of the interesting challenges is that Web software has extremely high-quality requirements (Offutt 2002; Powell 1998). However, there appears to be little or no brand-name loyalty (that is, "site loyalty") for Web applications. Many companies that sell through the Web depend on customers using their sites, and most important, returning to their sites. Others offer more traditional software services that are available through the Web; these services will not be used if the quality is too low because it is relatively easy for users to switch to other services. Thus, unlike many contractors, Web site developers will only see a return on their investment if their Web sites exhibit sufficient quality (that is, if the Web sites satisfy users' needs). Unlike many software vendors, if a new company puts up a competitive site that customers perceive to have higher quality, customers will almost immediately shift their business to the new site. Thus, it is often advantageous to be "later than and better" instead of "sooner but worse." Although the idea of "sticky Web sites" has been discussed and mechanisms to encourage customers to come back have been developed (Menascé, 2000), thus far the key mechanism to bring repeat customers to Web sites is high quality. It seems likely that this will continue to be true for the foreseeable future.

In software development, a process-driver is a factor that has a strong influence on the process used to develop the software. Thus, if software is required to have high reliability, the development process must be adapted to ensure that the software works well. When I have surveyed the important quality process drivers for traditional software, developers always give a single answer that stands alone far above the rest: time-to-market. But when I recently made the same survey of Web software development managers and practitioners, they claim that time-to-market, although still important, is no longer the dominant process driver. Instead, the three most important quality criteria for success of Web applications (and thus, the underlying software) were given as

Reliability
Usability
Security

An additional four important criteria that were listed are

Availability
Scalability
Maintainability
Performance

Of course, it would be foolish to claim that this is a complete list of important or even relevant quality attributes. Quality attributes such as customer service, quality of products, price, and delivery are also important but not related to the software and thus beyond the scope of this chapter. Nevertheless, these quality attributes track closely with what is said in other books and articles (Constantine & Lockwood, 2000; Dustin, Rashka, & McDarmid, 2001; Kassem et al., 2000; Murugesan & Deshpande, 2001; Powell, 1998; Scharl, 2000). Thus, there is wide agreement that satisfying quality attributes is essential to Web software, and these seven provide a solid basis for evaluating Web software. These quality attributes are used as a basis for suggesting specific ways to engineer Web site software, using the available technologies.

Before proceeding with the technology aspects of this chapter, let's explore the reasons these quality attributes are so important. These quality factors will have a much stronger impact on the profits of Web-based companies than for most traditional software. The reasons for the first three quality requirements—reliability, usability, and security—may become obvious by analyzing some of the new uses of this software. The most obvious is that of direct selling to customers, that is, "B2C." This includes companies that sell books and other small items such as Amazon, plane tickets such as Yahoo and Expedia, and rental companies such as Netflix. Customers who buy books from a Web site expect the same quality of service that they would get from going to a bookstore at the mall, but without the overhead of actually driving to the mall. We expect to be able to find the books we want in a convenient way (usability), we expect to be able to make the purchase without difficulty (usability), we expect the correct books to arrive at our house in the specified number of days (reliability), and we expect the correct amount to be billed to our credit card (reliability).

The issue of security of Web applications is getting more important. One of the major concerns of security for e-business, of course, has to do with security of data. Customers expect their credit card and personal information to be held in confidence. Identity theft, where a criminal takes the entire credit history and assumes the name of another person, is becoming more common and can be done by taking advantage holes in Web software. The security also works in the opposite direction. Improper use of cookies has opened up holes for users. One example is that of Web software storing price information in a cookie on the client-side, which allowed customers to change the price of items they bought on the Web. As a field, we are continuing to evolve our expectations of security and our ability to support security.

The additional quality requirements are less obvious. Whereas a bookstore on the corner ("brick and mortar") might expect to have customers form the neighborhood Monday through Saturday, 8:00 a.m. to 7:00 p.m., a Web-based company can expect customers from all over the world. It might be 3:00 in the morning in Virginia, but it's the middle of the afternoon in Beijing! It might be Thanksgiving holiday in the United States, but it's just another spring day in South Africa. Thus, Web sites must have extremely high availability, not just 24/7, but 24/7/365.

Another key difference is that, unlike shrink-wrap software applications, Web-based applications do not have to be sold or distributed when updates are made. Consider maintenance updates to a commercial word processing program. Immediately after releasing one version, the company starts collecting problems and making a list of needed changes. The first change might be simple and easy, completed within a week or a few days after the version is released. That change is not made available to the customers immediately, however, but held for months or years until the company is able to release the next version. With Web software, on the other hand, that small change can be installed live immediately; moreover, customers expect it to be. These factors, together with the rapid evolution of technology, means that maintainability is crucial for Web software. Instead of an update rate of months or years, Web software must be able to support an update rate of days or even hours.

Unlike traditional businesses whose potential customer base is typically limited by physical concerns such as geography and traffic, growth in Web-based businesses has unlimited potential: There are currently hundreds of millions of users on the Web, each of whom is only a click away and therefore "in the neighborhood" of the store. This means that Web software must be highly scalable and ready to grow in terms of servers, services, and customers very quickly.

Finally, customers expect Web sites to respond quickly to their requests. Nielsen (2000) claimed that users perceive a response that occurs within 1 second to be immediate, but will lose concentration and thus interest after five seconds. After thirty seconds without a response, they will almost certainly give up. Although network speeds usually dominate response times, a bad software design can seriously disrupt performance.

These quality requirements are not new, and certain segments of the software industry have faced some of these problems in various contexts. The novel aspect is that Web software has all of these quality requirements at once. Many of the technological innovations of the past 5 years have been either in response to these requirements or to support the fundamental distributed nature of Web software.

TECHNOLOGIES FOR BUILDING WEB SITE SOFTWARE

The changes in technology for building Web software through the late 1990s and early 2000s have been continuous, fast-paced, fundamental, and dramatic in scope. These changes continue, thus this chapter can only provide a snapshot of the current technologies that are being used. Several varieties of plug-in enabling technologies are currently used to support Web software. An enabling technology is generally any mechanism that is used to make Web pages dynamic and respond to user input. Web browsers use plug-in modules to handle specific enabling technologies on the client. Web servers use server-modules to handle enabling technologies on the server.

Two common varieties of plug-ins to support server-side processing are compiled modules and scripted pages. Compiled modules are executable programs that the server uses to support server-side processing. Compiled modules currently in common use are Java servlets, Apache Modules, Microsoft's Internet server application program interface (ISAPI), and Netscape's server API (NSAPI). Scripted pages are HTML pages that also have the ability to process business logic. Scripted pages are executed server-side, not client-side (as JavaScripts are), but they are HTML pages that can access software on the server to get and process data. Scripted pages currently in common use are Java Server Pages (JSP), Macromedia's Cold Fusion, Microsoft's Active Server Pages (ASP), and the open source PHP platform.

The rest of this section describes some of the technologies in common use for developing Web software. This is a rapidly evolving field, thus any such description is automatically out of date. The first discussion is an overview of some of the client-side software technologies, then a variety of server-side technologies. The original Web server-side technology, CGI, is discussed first, followed by the relatively established J2EE platform, then the newer .NET platform. The section closes with some discussions of data handling, including XML and access to databases.

This chapter does not address Web services, which are built on top of the technologies described here. Web services (sometimes called application services) are services (usually including some combination of programming and data but possibly including human resources as well) that are made available from a business's Web server for Web users or other Web-connected programs (TechTarget, 2003). Providers of Web services are generally known as application service providers. Web services range from such major services as storage management and customer relationship management (CRM) down to much more limited services such as the furnishing of a stock quote and the checking of bids for an auction item. The accelerating creation and availability of these services is a major Web trend.

Client-Side Technologies

There are many plug-ins that Web browsers can contain to support dynamic execution. The browser is the host that supports the technology, and the plug-ins have the ability to execute certain languages and support non-textual media applications such as images, Flash, video, and sound. This is generally associated with dynamic HTML. Dynamic HTML allows client-side processing to be done by using scripting languages. Scripting languages include JavaScript, VBScript, and Jscript, all of which have similar functionalities. When used on the client-side, they can access information about the client's browser, operating environment, and hardware configuration, and access and modify information in the current Web page, and respond to user events. They cannot access server-side data when used as a client-side plug-in (although some of these scripts are also used on the server-side).

Common Gateway Interface (CGI)

One of the first technologies to perform processing on the Web server was the common gateway interface (CGI) protocol. CGI allows data to be sent from HTML form fields on the client to the server and provides a mechanism for

processing that data (server-side processing) and then returning information, usually in the form of a Web page, to the client. CGI programming allows the server to access files and other resources on the server. Although CGI is general enough to allow any programming language to be used, the most common language has been the interpretive language Perl, a very flexible scripting language that is strong in text-handling and accessing system functions.

Developers quickly found a number of limitations of CGI. Each execution of traditional CGI modules requires a new process to be created on the Web server, which severely affects performance. It has no built-in session management services, which makes it difficult to develop e-business applications. Most CGI applications have traditionally used interpretive languages such as Perl, which suffer from a number of software engineering disadvantages; in particular, most do not have capabilities such as type checking and exception handling and offer limited or no support for information hiding and inheritance. Although not a serious limitation for small applications, this makes it hard to write large Web applications that satisfy quality requirements such as reliability, usability, security, and scalability. The Apache server now includes "mod-perl" and "mod.php," which use threads to ameliorate the performance problem, but the other issues remain. One common strategy is to build an initial version of the application in CGI, either a prototype or Version 1 application, then to rewrite the application in compiled modules and scripted pages.

The J2EE Platform

Although many applications are built using CGI, the current trend is toward integrated technologies that avoid some of the disadvantages of CGI. Many of the heavy transactional-based Web sites, particularly those supporting e-business, are building new Web sites with the J2EE platform. The J2EE platform is not a product but a standard that defines the behavior of various pieces of technologies, and there are several implementations of the standard (Patzer, 2000). The standard is defined by one company (Sun), but products are available from dozens of companies, including open-source solutions. The J2EE platform, often in conjunction with Web service platforms, is currently used by many major Web-based companies and services, including well-known sites such as Netflix, eBay, Siemens, Amazon, the National Science Foundation, Major League Baseball (mlb.com), and MovieFone. This chapter discusses the individual technologies.

The J2EE platform is centered around one language, Java. Java program components are compiled to an intermediate form called "bytecode," which is executed by a Java Virtual Machine (JVM). Java bytecode is intended to be independent of hardware, operating system, and browser, and thus can be moved between computers. Java has simple built-in support for interfacing with other languages, thus providing support for connecting with legacy systems.

The primary mechanism for server-side processing in the J2EE standard is the Java servlet. Java servlets are compiled-modules that collect data from the client's Web browser into an object (the request object) with a simple API that can be accessed by servlets, and output from servlets can be returned to the client (through the response object). Servlets are Java classes that inherit from the servlet base class, and execute as lightweight threads within a plug-in called a servlet container. The container cooperates with the Web server and takes care of issues such as instantiating and destroying servlet objects, putting data from the client into the request object and returning data from the response object to the data.

The J2EE scripted page technology is Java Server Pages. A simplistic view of JSPs is as an "inside-out" version of servlets. Instead of Java classes that produce HTML, a JSP is an HTML page that includes Java statements. JSPs are first translated into Java servlet classes then compiled and run as servlets. This makes JSP execution clean and efficient; the Web server does not need a completely new plug-in module to support JSPs. In addition to the HTML, JSPs contain declarations, which are translated to Java class level variables and methods, Java scriptlets, which are translated to blocks of Java statements and that can make external method calls, and expressions, which are values printed inside the HTML.

Integral parts of the J2EE environment are Java Beans and Enterprise Java Beans. A Java bean is a design convention rather than a language feature or plug-in technology and is intended to be used to produce reusable software components. A bean is a Java class that has three characteristics: (a) it is a public class, (b) it has a public constructor that has no arguments, and (c) it has public get() and set() methods. Beans are based on the concept of a property, which is a simple data object (such as a variable) that defines some attribute of the software application. Properties should be associated with only two types of methods, getters, which return the property's value, and setters, which changes the property's value. The usual convention is that a property with name propName is accessed through the methods getPropName() and setPropName().

Despite the name, Enterprise Java Beans (EJBs) differ significantly from Java Beans. EJBs are intended to implement all of the required business logic for Web applications. They are Java classes that follow a well-defined set of rules and conventions that allow them to be installed into and executed within the confines of an EJB container. EJB containers are plug-ins that provide critical services to their EJBs. Specifically, they handle life-cycle and resource management, transaction management, data persistence, and security.

The final crucial element of the J2EE platform is the ability to conveniently interact with databases. The Java Database Connectivity (JDBC) API allows Java programs to store data into sequential databases using commands that are independent of database vendor and hardware–software platform. This allows a program to be moved from, for example, a Unix platform using Oracle's database to a Windows computer using MS Access with only a minimal number of changes. The runtime execution environment (JVM) translates the generic database statements in the program to the vendor-specific database access calls.

The .NET Platform

The Windows .NET platform collection of technologies was introduced by Microsoft as an alternative platform for building Web software applications. Its goals and much of the details of the technologies are similar to the J2EE platform, and comparatively speaking, it is conceptually easy for developers to move between the two platforms (although there are large differences in the syntax and terminology that describes the concepts) (Vawter, 2001). Microsoft .NET is partially based on the older Windows DNA, a previous Microsoft platform for developing Web applications. Windows .NET includes many technologies that were already being used, including Microsoft Transaction Server (MTS) and COM+, Microsoft Message Queue (MSMQ), and the Microsoft SQL Server database. The .NET platform includes these technologies as is or in modified forms and adds a Web services layer on top.

Whereas the J2EE platform is based on the Java programming language, .NET is intended to be language-independent and is designed to allow components in multiple languages to interoperate. Software components within .NET can be written in languages such as VB .NET (Visual Basic for .NET) or C#. C# is Microsoft's new object-oriented programming language and is very similar to Java. C# programs are first translated into Microsoft Intermediate Language (MSIL or IL). The IL code independent of platform and is analogous to Java bytecode. One key (only partially realized as of this writing) is for the IL to be independent of language, thus multiple languages can be translated into IL. If a translator is available to translate a specific language to IL, the language is called .NET enabled. The IL code is how .NET allows integration with legacy software.

The .NET platform handles server-side processing in a variety of languages, although the dominant language is currently ASP .NET. Compiled modules are translated into the IL and processed efficiently with a .NET server. Traditional ASP was a scripted page technology and is still the technology used within the .NET platform. The .NET platform includes specialized components written at the middle-tier layer, called managed components. The managed components are supported by COM+, C#, or another .NET enabled language and are used to implement business logic. Database interaction is through the ADO .NET interface.

A number of articles have compared J2EE with .NET (Farley, 2000; Middleware, 2002; Sessions, 2001; Vawter, 2001). They are all informative but the perceptive reader must take care to check the publisher, underwriter, or author for bias. Although the referenced articles should help the interested reader see more details, the differences can be summed up succinctly. As reported by Farley (2000), the cliché is that "J2EE is language-specific and platform-independent, and .NET is language-independent and platform-specific." This cliché is only half true because J2EE applications can and do include multiple languages (although most J2EE developers try to avoid multiple languages for sound engineering reasons) and many J2EE applications are restricted to single platforms. Additionally, most .NET applications use C# and the other built-in technologies so the language-independence has not, as yet, been widely taken advantage of. Being newer, .NET has also improved on some of the technical weaknesses of J2EE, including better XML support and simpler deployment.

XML as the Glue

A problem that software engineers have faced for many years is that of passing data among software components. The two components must agree on format, types, and organization. Web software applications have two unique requirements for data passing, loose coupling and dynamic integration. The fact that the components are very loosely coupled makes it more difficult for developers to establish a priori standards. The developers may be separated by time and geography and be in separate, even competing, companies. Web software applications also use dynamic integration, which means that the software engineers may not know which components will interact when the software is written.

In the 1970s, data were usually stored as records in files and the file formats were often not documented. If a new program needed to read a file, the software engineer had to deduce the file format by reading the source of the original program if it was available. If not, the engineer would usually induce the file format by trial and error—writing programs to read and print strings from the file. In the 1980s, data were usually stored in memory as abstract data types. They were saved in long-term storage in files, and both the file input–output and access to the abstract data type was managed by wrapper modules. Although much improved over previous methods, this method was usually slow, the developers of the programs had to agree on the data format, types and organization, and maintenance was often challenging because it was not clear who owned the wrapper module. These problems are exacerbated with Web software because of the extremely loose coupling, dynamic integration, and heavy reuse and use of third-party software components.

A solution from the World Wide Web Consortium (2000) is XML, or extensible markup language. XML allows data to be transferred between software components in a way that is independent of type, self-documenting, has an easy-to-understand format, and that can be parsed in simple ways. XML stores data as plain text (UNICODE) strings. Each string value is stored in between tags that are meant to imply some semantics for the contents. For example, the title for an encyclopedia article might be encoded as `<Title>Software Design and Implementation in the Web Environment</Title>`. This allows XML to be used as the primary way to pass data back and forth between Web-based software components. The principal syntax rules (Sall, 2002) are as follows:

- The document must have a consistent, well-defined structure,
- All attribute values must be quoted (single or double quotes `<Title Type = "article">`, not `<Title Type = article>`),
- White space in content, including line breaks, is significant,

- All start tags must have corresponding end tags (`"</Title>"`),
- There must be a single root element, which must contain all other elements,
- Elements may be nested, but they must not cross (`<Title>...<Name>...</Title>...</Name>` is not allowed),
- Each element, except the root element, must be contained by exactly one parent element,
- Element and attribute names are case-sensitive (`<TITLE> is different from <Title>`),
- Keywords and document type definition (DTD) elements must be all uppercase (`DOCTYPE, ENTITY, ELEMENT, and ATTLIST`), and
- Empty element tags must end in `"/>" (<editor/>)`.

Database Connectivity

A natural desire for Web software designers is to store data in general database engines. This offers a general solution to the problem of storing data and allows developers to rely on the many advantages offered by a database, including general access, efficiency of storage and retrieval, and security. Both the J2EE and .NET platforms provide general cross-vendor connectivity and data access across relational databases from different vendors. The platforms' API support mechanisms provide a convenient way to make generalized database calls from within software. The calls are made by embedding structured query language (SQL) statements into programming statements. Within J2EE, the Java Virtual Machine (JVM) uses a special JDBC driver to translate generalized JDBC calls into vendor-specific database calls. With .NET, programs connect to databases using services that Microsoft Host Integration Server 2000 provides, such as the Component Object Model (COM) Transaction Integrator (COM TI). In both platforms, programs can connect to external databases using Web services technologies such as Component Object Model (SOAP); Universal Description, Discovery, and Integration (UDDI); and Web services description language (WSDL).

The typical procedure for Web application programs to connect to databases is to start by loading the database driver. This generally has some database vendor-specific aspects and includes information about where the database is located. The second step is usually to obtain a connection to the database. Again, this requires some vendor-specific information, including security protocols (user IDs and passwords). Subsequent steps are generally completely independent of the database vendor or platform. The program should be able to create and execute database statements and then use the results (called "result sets") from statements to access data returned from the database. An obvious advantage of this approach is that the programmers do not need to know much about databases. Another advantage is that the database does not have to be local but can be anywhere on the Web (although in practice, the database is usually connected to the Web or applications servers through a secure intranet).

DESIGNING WEB SITE SOFTWARE

As a field, we are still learning how to design Web software applications. Some companies rely on prebuilt Web application servers (sometimes called "Web service platforms") such as IBM's WebSphere, BEA's WebLogic, and the open source Java Struts. Other companies buy general-purpose Web sites from vendors, which are then customized to their needs. Still others build their own Web sites completely, because they cannot afford the expensive Web service packages, because their Web sites are small enough not to need that much support, or because their needs are specialized enough so that the Web services do not support them. A complete description of how to define Web site software is certainly beyond the scope of this chapter, and, at present time, probably impossible. Nevertheless, a few hints and design strategies have emerged as being useful.

As with any software product, a crucial step is to establish a strong software requirements baseline, which should be followed by a carefully considered information architecture specification. This should include a site map, navigation among Web pages, compositions, labeling, and data element mappings. The navigation is one of the key components of usability and the literature does not contain much help for how to do this part of the design. A careful Web application design will include a high-level software design, software architecture and system architecture diagrams, class diagrams, sequence diagrams, and class specifications.

One of the most commonly used design structures is the model-view controller (MVC) architecture (Kassem et al., 2000). It provides a way to divide the responsibilities of objects. The intent is to decrease coupling between objects and layers, which supports maintenance. An MVC Web application contains three components, the model, the view, and the controller. The model encapsulates the application state, responds to state queries, presents application functionality to the user, and notifies the view of changes. The view renders the models on screen, requests updates from models, sends user inputs to the controller, and allows the controller to select a view. The controller defines application behavior, maps user actions to model updates, and selects a view to show to the user. Many other architecture styles are currently being developed.

We are also beginning to see techniques for formal modeling of Web site software applications. Sun, Song, Liu, and Wang (2001) presented an XML/XSL approach for developing Web software applications using the formal specification language Object-Z. XSL Transformations (XSLTs) are used to develop projection techniques and tools from Object-Z (in XML) and UML (in XMI). This provides a formal approach to modeling Web applications, which is not only helpful for standard e-business Web applications, but may be necessary for the Semantic Web (Berners-Lee, 1999).

Sound Software Design and Implementation Practice for Web Software

Most software in use today only has had to satisfy modest reliability requirements. The user base for Web software

is large, and users expect the Web applications to work as reliably as purchases at a grocery store or phone orders from a catalog. Moreover, if a Web application does not work well, the users do not have to drive farther to reach another store; they simply have to point their browser to a different Web site. Thus, if Web software is unreliable, Web sites that depend on the software will lose customers and the businesses may lose money. Careful use of sound development processes, full-strength languages such as Java and C#, debugging and testing tools, and well-validated third-party software components have dramatically improved reliability for some Web applications. At this point in time, however, there are many unanswered questions, including what processes succeed, how best to design the software, and how best to test the software.

Several general principles must be followed to ensure quality design of Web software. The software has to work well every time, and it must be easy to maintain, thus the design specifications must be well documented and the program must be well commented. Because the work environments tend to be dynamic and diverse, software components must be integrated, the development team must collaborate heavily, and everybody on the team should have a clear understanding of the design. Web applications need to be scalable and will change often and frequently, so many engineers believe the software must also be written to allow for future requirements. Other engineers have the opposite idea, believing that when requirements change the systems should be rebuilt from the beginning. Although this view has attracted some attention, it runs directly counter to more than 30 years of software engineering wisdom.

Web sites must be usable, so a successful development team must include one or more usability experts (Nielsen, 2000). In addition, actual users of the application must be involved with the user interface portion of the design from the beginning of the project.

CURRENT ISSUES WITH DESIGNING WEB SOFTWARE

The high-quality requirements that Web software must exhibit bring new and interesting challenges to Web software developers. This section identifies a few of these challenges; as of this writing, research is underway to develop ways to ensure the quality of software that is used for Web applications.

Design Challenges

Tremendous effort has been expended to ensure the quality of traditional programs, resulting in testing techniques for both stand-alone and distributed systems. Although some of these techniques can be used to help ensure the quality of Web applications, some of the special features and requirements of Web applications prevent them from being directly adopted. These challenges are summarized in the following paragraphs.

The overall architecture of Web applications is similar to client–server systems in many aspects, but there is a key difference. In traditional client–server systems, the respective roles of the clients and servers and their interactions are predefined and static. In Web applications, however, client-side programs and contents may be generated dynamically. For example, a server may return a dynamically generated HTML file that contains dynamically generated JavaScripts, links and contents. This means that which subsequent interactions between the client and server are available depend on the previous inputs.

For traditional programs, correctness and efficiency are usually the most important quality factors. For Web applications, other quality features can often be more important, and yet we have few techniques for supporting them. For example, compatibility and interoperability are urgent and cause problems that are more serious than with traditional programs. Traditional programs are usually developed for a certain predefined, well-understood environment, with few conflicts and changes. Web applications are often affected by factors that may cause incompatibility and interoperability issues. For example, server components can be distributed to different operating systems, such as UNIX, Linux, Windows, MacOS, and AIX, each of which has multiple versions, and run with different Web server packages, including IIS from Microsoft, Apache from the Apache software foundation, WebLogic from BEA, WebSphere from IBM, and others. The situation is even more complex on the client side, with different versions of Web browsers running under a variety of operating systems. Clients may also use different connection approaches, such as dial-up modems, direct Internet access, or wireless, and they may also use different Internet service providers. All of this heterogeneity makes it more difficult to produce Web application components that are compatible with one another and that interoperate easily and correctly.

Another difference between Web applications and other types of programs is the variance in the control of execution of the application. For traditional programs, the control flow is fully managed by the program, so the user cannot affect it. When executing Web applications, users can break the normal control flow without alerting the program controller. For example, users can press the back or refresh button in the Web browser, which changes the execution context, causing unexpected results. Furthermore, changes in the client-side configuration may affect the behavior of Web applications in ways that are difficult for Web software designers to anticipate. For example, users can turn off cookies, causing subsequent operations to malfunction.

Web applications also have much faster maintenance requirements than most traditional software. Web technologies evolve more rapidly than traditional software technologies, and the changes in Web application requirements can be more dramatic—maintenance not only needs to be done more frequently, but more efficiently.

Web applications also have features that are not present in client–server and distributed systems. These include session control, cookies, the stateless aspect of HTTP, and new security issues (related to the use of public networks). Therefore, new solutions are necessary to implement these features correctly.

GLOSSARY

Many of the definitions in this glossary are derived in whole or part from TechTarget's definitions, including "whatis.com" (TechTarget, 2003). More details can be found on their Web site for some of these terms.

Active Server Pages (ASPs) A scripted page technology that uses HTML templates that can include programming statements. ASPs predated Microsoft's .NET but have been folded into the platform.

Application program interface (API) The specific method prescribed by a computer operating system or by an application program by which a programmer writing an application program can make requests of the operating system or another application.

Application server A server program in a computer in a distributed network that provides the business logic for an application program. The term is sometimes used to refer to the software, sometimes the hardware, and sometimes both.

Browser extensions A compiled program that is written to a browser API, usually for extending the capability of a client browser to play new media forms such as audio or video. For Netscape browsers, such programs are dubbed plug-ins. Internet Explorer browsers use ActiveX controls and other kinds of plug-ins. For the J2EE platform, the equivalent is a Java applet.

Bytecode An intermediate language, similar to computer object code but usually at a higher level of abstraction. It is interpreted by a program, usually referred to as a virtual machine, rather than by the actual hardware. Java is translated to a bytecode that is optimized for fast interpretation that can be executed on a number of platforms by the Java virtual machine.

C# (pronounced "C-sharp") An object-oriented programming language from Microsoft that combines elements of C++ with Visual Basic. C# is has many features in common with Java.

Common gateway interface (CGI) A protocol that defines how data is sent back and forth between Web clients and external server-side programs. Input in CGI comes from HTML form data and HTTP headers (termed environment variables) and output set by HTTP headers indicating multi-purpose Internet mail extensions (MIME) type and common Web formats such as HTML.

Client–server computing A model of computing in which one computer or software component (the server) manages and provides access to resources to another (the client) by responding to requests.

COM+ The .NET middle-tier infrastructure designed to support business components.

Compiled (Web-server) modules A compiled program that that is built into a Web server API such as Apache Modules or Microsoft IIS Internet server application program interface filters or modules. Input and output with server modules is similar to CGI programs but generally is much faster and happens at a much lower level. For the J2EE platform, such modules are dubbed servlets.

Cookies A text string that a Web application stores on a client through the client's Web browser. The intent is to use the string as an index to retrieve information about the user who is associated with the cookie, thereby keeping track of state information that is passed between a server and the user.

Dynamic HTML A collective term for HTML tags and options that support animation user interaction. The tags and options include the ability to respond to user events client-side using BOM–DOM (browser object model–document object model) and scripting languages such as JavaScript.

E-business A company that does all or an important part of its business over the Internet.

Enterprise Java Beans (EJB) Java classes that follow a well-defined set of rules and conventions that allow them to be installed into and executed within an EJB container, which provides services such as life-cycle and resource management, transaction management, data persistence, and security.

Hypertext markup language (HTML) The most common language used to create Web pages.

Hypertext transfer protocol The fundamental network protocol that Web browsers and servers use to communicate. It is a lightweight, connectionless protocol.

Intermediary language (IL) The intermediate language used by the.NET platform.

The Java 2 Enterprise Edition (J2EEE) platform A collection of conventions, plug-ins, and library packages that support Web software. It includes Java servlets, JSPs, Java beans, and EJBs.

Java A general purpose object-oriented programming language. Java is extended by libraries that contain packages and code that support Web software.

Java Server Pages A scripted page technology that uses HTML templates that can include Java statements. Java Server Pages are first translated into Java servlet classes and then compiled and run as servlets.

Java Applets A Java class that can be included in an HTML page. The Java bytecode is transferred to the client's computer and then executed by the browser's Java Virtual Machine (JVM). One common use of applets is to produce high functionality GUIs.

Java Beans A Java class that is used to create reusable software components. A Java Bean is expected to have three characteristics: (1) it is a public class, (b) it has a public constructor that has no arguments, and (c) it has public methods to assign and retrieve values of objects called properties. By convention, the methods are called get() and set().

Java Data Base Connectivity (JDBC) An application program interface (API) specification for connecting Java programs to common databases. Database commands in SQL are embedded in Java programming statements and the API handles most of the interaction invisibly.

Java Servlets A compiled module technology; a Java class that inherits from the servlet base class and executes as lightweight threads within a plug-in called a servlet container. Servlets run on the server, accept requests from the Web server, and generate responses for the client, usually in the form of HTML pages.

JavaScript The common name of a Web scripting language based on ECMAScript, which is unrelated to Java in all but name. JavaScript is traditionally used within Web browsers for validation of form data and other basic tasks but with the rise of complex document object modules, JavaScript is increasingly being used to perform complex client-side manipulations. The use of JavaScript in such a fashion is a major part of dynamic HTML or DHTML.

Middleware Layers of software between client, server, and other N-tier levels that provide services such as communication. Often bought from a third party vendor.

N-tier architecture A software architectural design with components that are broken up into two or more (N) layers, where each layer only communicates with its two adjacent layers.

.NET A collection of conventions, plug-ins, and library packages that support Web software on Microsoft platforms.

Plug-ins Programs that are installed and used in the context of a Web browser; used to process particular types of files from the Web server such as PDF, Flash, and Java.

Scripted pages HTML templates that process business logic by executing on the server side, not client side, and that can access software on the server to get and process data. Common server-side scripting environments include Active Server Pages (ASP), ASP.NET, ColdFusion, Java Server Pages (JSP), and the PHP platform.

World Wide Web Consortium An organization with the responsibility of leading the development of the Web, its technologies, and its standards.

Web site engineering The application of well-documented principles, techniques, and technologies to develop software for the Web that is of high quality, where the quality must satisfy goals in terms of measurable criteria such as reliability, usability, security, availability, scalability, maintainability, and performance.

Web server A program that supplies Web pages and other Web services to clients, or a computer that makes software available through Web protocols.

XML (extensible markup language) A flexible way to create common information formats and share both the format and the data among programs.

Software Piracy

Robert K. Moniot, *Fordham University*

INTRODUCTION

"Don't copy that floppy!" is the rallying cry of the software publishers' organizations. Perhaps nowadays the slogan needs to be updated to "Don't copy those warez!" as the focus of activity shifts to the Internet. But whatever form it takes, there is no question that piracy is a major problem facing the software industry. In the year 2001, an estimated 40% of all copies of business software applications installed worldwide were pirated, having a retail value of some $11 billion. This lost revenue deprives software companies of the remuneration to which they are entitled for their efforts in developing and distributing software. It potentially may increase prices for software and inhibit innovation of new products and may also cause some companies to go out of business.

MODES OF SOFTWARE PIRACY

Software piracy is any copying of software in contravention of its license. One of the biggest obstacles to reducing piracy is the widespread ignorance of what actions constitute piracy. Here are some ways that piracy can occur:

Downloading proprietary software from an unauthorized Internet bulletin board or Web site, or directly from another user via a peer-to-peer file sharing program.

Purchasing counterfeit software in a store or at an Internet Web site or auction.

Borrowing the medium containing an application purchased by an employer for use at one's place of work and installing it on a personal computer at home.

Borrowing a program from a friend, a co-worker, or a library, and installing it on one's own computer.

Selling or giving away an old version of a program after receiving an upgrade.

Leaving an installed program on an old computer after installing it on a new computer without purchasing a new copy of the program.

Installing more copies of a program on the computers in an enterprise than the license allows, or installing it on a server for use over a local area network if this is not permitted by the license.

Note that it is always permissible to make a copy of software for backup or archival purposes, but any such copy must be destroyed if the user no longer can legitimately use the program. Also, users may sell or give away programs they legitimately own to someone else, provided they do not retain their copies. For instance, users can leave installed software on old machines that they sell or give away if they purchase new computers with new software preinstalled.

The term "piracy" has long been used to mean acts of infringement of copyright. Thus in recent times it was natural to adopt the term to include the illicit copying of software, even before the application of copyright law to software was fully clarified. However, piracy is a broad term encompassing many diverse forms of infringement, only some of which are listed above. Each of these forms has its own legal and ethical ramifications, as well as distinct perceptions by its practitioners. One important distinction is between copying for private use only, or end-user piracy, and copying for sale. Many people consider copying for personal use as either acceptable or having only minor ethical significance, whereas most recognize copying for sale as both unethical and illegal. Another distinction is between small-scale and large-scale piracy. Although each act of small-scale piracy is relatively minor, the aggregate effect is quite large. In fact, small-scale copying for personal or corporate use is said to be the most widespread form in practice and to account for over half the total value of pirated software (Software and Information Industry Association, 2000). The growth of the Internet as a medium for exchange of software has greatly facilitated this form of piracy.

End-User Piracy

Small-scale piracy mainly takes the form of "softlifting," which means copying by individuals for their own personal use. Softlifting can be done in a wide variety of ways. Probably the most common method is to borrow the installation media from a friend or co-worker. Or instead of

borrowing the original media, one might obtain an unauthorized, or "bootleg," copy. Bootlegging by sharing of software over the Internet is also frequent. Before the advent of the World Wide Web, individuals often posted software on Usenet newsgroups or on bulletin boards. Nowadays there are thousands of Web sites that post "warez," or contraband software, for download. More recently, peer-to-peer systems have been developed that allow individuals to share software with each other directly.

Renting software and not uninstalling it after use was once a fairly common mode of softlifting. For this reason, the unauthorized renting of software was made illegal in the United States in 1990. Web sites offering software rental can be found on the Internet, but it does not seem that this is a prevalent mode of softlifting nowadays. The law permits libraries to lend software, provided that the package contains a clear copyright notice. Quite likely these loans are often used for softlifting.

Closely related to softlifting is "softloading," or the installation of a legitimately purchased program onto more machines than the software is licensed for. It can also involve the installation of the software onto a server for use by multiple client machines in a local area network. Softloading usually occurs in a corporate setting, which can be a business, a nonprofit institution such as a university or hospital, or a government agency. It can occur inadvertently, if the information technology staff does not keep proper records of licenses and the number of installed copies of each software application.

Commercial Piracy

Industrial piracy can take two very different forms: counterfeiting and cloning. Counterfeiting is the reproduction of packaged software for sale. Sometimes the counterfeiting is done in such a way as to make it appear to be authentic, so that it can be sold for a price that is comparable to the normal retail price. These counterfeiters take care to duplicate the appearance of the media, the packaging, and even the documentation as closely as possible. The purchaser may be unaware that the item is not genuine and will be unpleasantly surprised to find it is not entitled to support such as upgrades from the manufacturer. There may be telltale indications of piracy, such as poorly reproduced artwork, misplaced logos, misspellings, or a missing authenticity hologram. In other cases, the counterfeiters make no attempt to conceal the pirated status of the product, and it is sold for an extremely low price. This practice is also called bootlegging. Often a number of bootleg applications with a market value of hundreds of dollars are bundled together on a single CD that may sell for $20 or less.

Cloning is the independent creation of a functional duplicate of an existing program, which is typically marketed as an independent product. An example was the case of Paperback Software's VP-Planner, which closely imitated the functionality and user interface of Lotus Development's popular spreadsheet program 1-2-3. Cloning takes considerable programming effort, but avoids the laborious prototyping and design effort involved in the creation of a totally new program.

Counterfeiting and cloning are the easiest forms of piracy for software producers to combat, provided there is support from the authorities in the host country. This is because they most closely resemble traditional forms of copyright or patent infringement, for which legal remedies are well established. Furthermore, the offender is often readily identified, and a lawsuit is likely to yield a substantial return in the form of damages and penalties.

Original equipment manufacturers (OEMs) produce personal computers that are typically sold fully loaded with an operating system and a suite of applications. The OEMs typically enter into licensing agreements with the software producers to authorize the installation of this software. OEMs or hardware dealers sometimes illegally load software onto more machines than authorized, or they may load software that was not included in the license agreement, as a way of making the computers more attractive for sale. This practice is called "hard-disk loading." "Unbundling" is the sale of OEM-version software items separately from the computer system for which they are authorized. "Mischanneling" is the diversion of specially discounted software, intended for academic institutions, government agencies, and other high-volume customers, for sale to others who do not qualify for these discounts.

MOTIVATIONS FOR SOFTWARE THEFT

Why does an individual choose to steal software? On the other hand, if obtaining an illicit copy of a software application is so easy and cheap, why does anyone purchase the legitimate article? Probably the reader can think of several likely motivations on either side, but a number of studies have been done in an effort to provide well-founded answers to these questions. (See, for instance, Cheng, Sims, & Teegen, 1997; Simpson, Banerjee, & Simpson, 1994; Taylor & Shim, 1993.) Most of these studies have been based on surveys of students and business executives. These studies are not always directly comparable, because they take different approaches and use different models of softlifting attitudes and intentions. They also vary in the way they validate the measures used and control for various biases. Furthermore, it is possible that some of the reasons given may be rationalizations rather than true motives. Despite these limitations, some consistent patterns emerge from these studies.

Probably the most important conclusion is that the primary reasons for softlifting are economic: the software is seen as overpriced, or the individuals cannot afford it. Another common reason is the desire to try out the software before buying it, or to use it for only a short time. On the other hand, individuals are more likely to purchase the software if they feel that it will be useful for schoolwork or on the job and if it will be frequently used. Another motive for purchasing is the availability of user manuals and technical support. A significant finding of the studies is that the perception of softlifting as unethical, illegal, or against school or company policy has little effect on the decision to softlift. However, a perception that softlifting is acceptable and prevalent among one's peers increases the likelihood of softlifting.

Other studies have tried to identify cultural and socioeconomic indicators that are predictors of software piracy rates. These studies have the advantage of using software industry estimates of piracy rates rather than relying on self-reporting in surveys, which is an unreliable indicator of actual behavior. On the other hand, these studies perforce use data at the level of whole nations and so necessarily average out the differences between individuals or between regions within a given country. It should be noted that the piracy data on which these studies are based include only business software. There is probably a strong correlation between business and personal copying of software in each country, and so the results should be applicable to rates of individual softlifting as well. Marron and Steel (2000) and Husted (2000) found that lower piracy rates are associated with higher levels of economic development (per capita GDP or income), with greater disparities in income within a country (implying a smaller middle class), and with stronger institutions to enforce contracts and protect property from expropriation. They also found that individualist cultures, i.e., those that value individual rights and ownership, have lower piracy rates than more collectivist ones that put greater value on mutual help and sharing. They did not find a significant correlation with the average level of education.

These results are reasonable. Higher levels of economic development mean that individuals and businesses are more able to pay for software. In countries with greater income inequalities, the lower classes are unable or barely able to afford computers at all, and so most technology purchasing is done by the wealthy who can easily afford to pay. It is the middle classes, often struggling to make ends meet, that are the most likely to seek to cut costs by pirating software. Individualist cultures, and those with strong institutional protection of property and contract rights, are characterized by attitudes that will be less likely to view softlifting as legitimate. Collectivist cultures, in contrast, tend to deemphasize rights of individual ownership in favor of the duties of cooperation and sharing of the fruits of one's creativity for the benefit of society. Therefore those countries (which include many in southern and eastern Asia) have been reluctant to grant Western-style copyright protection to software, and even where such protection is provided by law, it must compete in the moral sphere with strongly held traditional values of community and solidarity.

Implications of the Studies

The findings of all the studies cited above carry some implications for software publishers' efforts to reduce the rates of software piracy. First, it appears that educational programs aimed at increasing individuals' awareness of the illegal and unethical nature of softlifting will be of limited effectiveness. The studies show that simple awareness of the illicitness of softlifting has little effect on behavior. Technical copy protection mechanisms (discussed in a later section) are also unlikely to be effective. They are inevitably defeated and may actually encourage piracy due to the challenge they present. On the other hand, perceived consequences, in terms of benefits as well as penalties, are important factors in most individuals' decisions whether or not to softlift. The studies indicate that increasing the likelihood of being caught and punished would deter softlifters. However, it is impractical to prosecute individual softlifters, and besides, an overly aggressive enforcement program could backfire by creating an adverse public reaction.

It appears that the most practical and effective means available to the software publishers for reducing softlifting is to lower prices (perhaps charging different categories of customers different prices) while enhancing the perceived value of products by providing user manuals, technical support, and inexpensive upgrades. The studies show that if individuals value the software for its usefulness, and value the support provided by the vendor, they will be more willing to pay for it. The validity of these reasons is confirmed by the observation that the Linux operating system and its accompanying application software from the GNU organization and elsewhere are successfully sold by a number of vendors, even though the software is all legally obtainable for free over the Internet. These vendors succeed in charging money for the software because they provide valuable support services, including documentation and help lines. Firms that depend on computer systems for their daily operations willingly pay for such support because they want to have someone to turn to for help when something fails.

Organizations That Combat Software Piracy

There are two main trade organizations that represent the software industry in its efforts to counter the illicit traffic in software. The Business Software Alliance (BSA, http://www.bsa.org) is an international organization representing major software and e-commerce developers. Its membership includes such flagship companies as Microsoft, Apple, and Adobe. Founded in 1988, its mission is to educate computer users about copyrights, to lobby for intellectual property legislation, and to combat software piracy. The Software and Information Industry Association (SIIA, htp://www.siia.net) is a coalition of software and electronic content producers. It was formed in 1999 from the merger of the Software Publishers Association (SPA, founded in 1984) and the Information Industry Association (IIA). Its membership includes some members of BSA, but also includes many smaller software and information technology companies. Its mission is to promote the interests of the software and digital information industry, to provide knowledge resources to member companies, and to fight software piracy. SIIA still uses the name SPA for its antipiracy arm.

SCOPE AND IMPACT OF PIRACY

Estimated Piracy Rates

Estimating the extent of software piracy is not a simple task. Obviously, many of the transactions whereby people obtain illicit copies of software are conducted in secrecy, and Internet warez sites do not usually keep careful records of downloads. Consequently any estimates of piracy rates must be indirect. One of the most widely cited estimates of piracy rates and of the economic impact of

piracy is produced by the International Planning and Research Corporation (IPR), a specialized consulting firm. This study has been commissioned annually since 1994 by the BSA and SIIA.

The basic quantity estimated in the IPR study is the piracy rate, defined as the number of illicit copies of software applications in use, divided by the total number of copies in use. Thus a piracy rate of zero would mean that all software was acquired legitimately, whereas a piracy rate of 100% would mean that all software was pirated. The IPR study estimates the piracy rate globally, as well as on a regional and country-by-country basis (Business Software Alliance, 2002). The IPR study considers only business software applications. Not included in the estimates are operating systems, custom software, and typical home-use applications such as recreational, educational, or personal finance software. Piracy rates for these excluded categories are probably different from the rates for business software.

The piracy rates calculated by IPR for the years 1994 to 2001 are shown in Figure 1. This chart shows a steady decline in global piracy rate from 49% in 1994 to 36% in 1999, followed by an upturn to 40% in 2001. The IPR report attributes the decline in piracy rates seen in the first part of this period to a number of factors, including the efforts made by the software industry and national governments to educate the public about copyright laws and to enforce those laws. Also, during that time, U.S. software companies made efforts to increase their presence in overseas markets, including providing better user support, while at the same time software prices generally declined. These developments made the option of purchasing software legitimately more attractive in those countries. It is too soon to tell whether the recent increases in piracy rates represent a reversal of the previous declining trend or merely a temporary fluctuation. The IPR report attributes these increases to the increased competitive pressures during a period of slower economic growth, which led businesses to be more willing to pirate software in order to cut costs. If this explanation is correct, then we may expect to see piracy rates resume their decline once worldwide economic conditions improve.

Figures 2 and 3 show the estimated dollar losses and piracy rates, respectively, by region for 2000 and 2001. Comparing Figure 2 with Figure 3, we see that North America and Western Europe, which have the lowest piracy rates, have some of the highest dollar losses. This seeming paradox is explained by the fact that these two regions are the largest consumers of software. A low percentage of a very large figure can be larger than a high percentage of a small figure. The data also show that the increase in the global piracy rate from 2000 to 2001 results mainly from changes in the Asia/Pacific region, where the increased piracy rate was coupled with a substantial increase in the already large amounts of software used.

Country-by-country piracy data from the IPR study are not shown here for reasons of space. Here we summarize the results in terms of a few broad patterns. First, with

the exception of Eastern Europe, all of the countries with piracy rates over 70% are Third World countries. In most of these countries there is little indigenous software production, and so for them piracy has a net economic benefit without adversely impacting their own local industry. In this regard it is noteworthy that India, which has become a major player in the software industry, reduced its piracy rate significantly, to a low of 61% in 1999 from 79% in 1994 (although the rate has climbed again since then, to 70% in 2001). China's piracy rate, on the other hand, declined only slightly, to 92% in 2001 from 97% in 1994. China was seeking World Trade Organization membership during this period and was consequently under pressure to improve its protection of intellectual property rights, but its efforts in this direction evidently had little effect.

Eastern Europe has consistently had the highest piracy rate of the six regions of the IPR study for each of the years shown in Figure 1. However, if we exclude Russia and most other countries of the former Soviet Union, the rest of the Eastern European countries (including the Baltic States) have made substantial progress recently, reducing their software piracy rates by at least 15 percentage points over the period 1994–2001. Their current piracy rates still have room for improvement, ranging from a high of 75% (Bulgaria and Romania) to a low of 43% (the Czech Republic), and averaging about 54%. The large reductions in piracy rates in these countries probably reflect the emergence of free-market economies, a process that is normally accompanied by improvements in protection of intellectual property (Software and Information Industry Association, 2000). This transition has apparently not happened in the countries of the former Soviet Union, which had a combined piracy rate of 87% in 2001, only a modest decline from 95% in 1994.

Methodology of the Study

In order to calculate the piracy rate for a given country or region, the IPR needs to determine the number of pirated copies and the number of legitimately purchased copies of software applications in use in that region. The IPR has access to proprietary sales information from the BSA member companies, and so the figures for legitimate software sales are readily obtained. The number of pirated copies is inferred as the difference between this number and the "demand" for software, i.e., the number of application programs that one would expect to be loaded onto the computers in use. The IPR uses hardware sales data to determine the number of new machines sold each year. A correction is applied for turnover as older machines are taken out of service and replaced by new ones, to obtain an estimate of the number of machines currently in use. From this figure the demand is calculated based on the average number of application programs that would normally be installed on each computer. The IPR calculation of demand takes into account differences between home and business computers and different levels of technological development in different regions, as well as differences among the various categories of software.

It is important to keep in mind that much software is excluded from the IPR estimates. Only packaged (as opposed to custom or in-house developed) software is analyzed, and only packaged business software applications are included in the final piracy figures. According to PricewaterhouseCoopers (1999), packaged business software currently represents less than 20% of all software revenue. Freeware and shareware also escape the analysis because there are no sales records for them, so they will be counted among the pirated applications. Freeware is software that its producer makes available free of charge, and shareware is software that is distributed for free with a request that users who like it should send the author a contribution. At present freeware and shareware represent an insignificant fraction of the market.

Despite all of the uncertainties involved, the IPR piracy estimates are probably the best obtainable under the circumstances. Marron and Steel (2000) performed a regression of the IPR estimated piracy rates on an independently estimated measure of patent protection in various countries and found a strong correlation, as would be expected. This test gives some confidence in the basic validity of the IPR data.

Financial Impact of Piracy

The estimates of the dollar value of the revenue losses to piracy shown in Figure 2 were obtained simply by multiplying the number of pirated copies by the average market price of a copy. The software categories not included in the IPR figures probably have different piracy rates from those for packaged business software. For instance, the study by Cheng et al. (1997) suggests that piracy rates for game software are probably much higher than those for productivity applications such as word processors. In any case it is likely that piracy in the excluded categories represents a large additional amount of lost revenue. Thus, the calculated losses are probably a considerable underestimate of the total revenue lost to piracy by the software industry. At any rate, it is reasonable to assume that the ratios of the revenue losses in Figure 2 represent the relative financial impacts of piracy in different regions.

Of course, calling the revenues in Figure 2 "losses" implicitly assumes that all software now pirated would be purchased through legitimate channels at current prices if all piracy were stopped. But it is likely that some users who currently pirate software would choose not to purchase the software at all, if piracy were somehow made impossible. Also, very probably prices would change in such an altered market. Thus it would be more precise to refer to this quantity as the "market value" of the pirated software.

Economic models have been developed to consider the overall effect of illicit copying on software producers' revenues. Slive and Bernhardt (1998), among others, describe how, in some situations, piracy of a software product can actually increase the total profits of its manufacturer, through what economists call "network externalities." In essence, the value of a particular software product is increased by having a large community of users. For instance, the users enjoy the convenience of being able to interchange files in the format used by the application. Also, they may invest considerable time in learning to use the application, and can then move more easily to a new employer where the same software is in use than to one

that uses some other product. In this context, piracy can be viewed as a form of price discrimination (the practice of charging different prices to different customers) in which the software is effectively sold at zero price to some customers. The resulting increase in the size of the user community enhances the value of the software, leading to increased sales and possibly also allowing the vendor to charge higher prices for it to those customers that pay. A key element of this effect is the existence of two distinct populations of users. Home users generally place less value on software than businesses do and are less likely to be willing pay for it. Businesses value the software more, and are also likely to pay for it for the sake of reliability and support. Businesses and other organizations are also more easily targeted by antipiracy campaigns. Hence the software companies may find it in their best interest to turn a blind eye to home-use softlifting, knowing that it is helping them to build market share that pays dividends in the more lucrative business market.

For small firms attempting to enter the software market, it is unlikely that the positive network effects of piracy will be sufficiently strong to compensate for the revenue losses. This is especially the case for non-U.S. software producers. They have an inherent advantage in their home countries for producing certain types of applications such as manufacturing, banking, and financial software, areas that are the most dependent on local laws and business practices. But this advantage is defeated if they are forced to compete against extremely low-cost pirated copies of software produced in the U.S. (PricewaterhouseCoopers, 1999).

MECHANISMS FOR PROTECTION OF SOFTWARE

Introduction

Softlifting has been going on ever since there was anything to softlift. The very first consumer application produced by Microsoft was a Basic language interpreter for the Altair microcomputer that appeared in 1975. A paper tape containing a demo version of the interpreter was stolen and soon the demo was circulating widely among the Altair user community. Subsequent software products have fared no better. Industry efforts at education and persuasion have met with only limited success. Therefore the industry soon turned to legal and technical measures to protect its interests.

Legal Protection Mechanisms

Goals of Legal Protection Mechanisms

The laws protecting intellectual property rights generally have as their primary goal the fostering of a healthy creative industry for the benefit of society as a whole. For instance, Article I, Section 8 of the United States Constitution states, "The Congress shall have Power to . . . promote the Progress of Science and useful Arts, by securing for limited Times to Authors and Inventors the exclusive Right to their respective Writings and Discoveries." The notion expressed in this phrase is that individuals will be encouraged to create new inventions, writings, and other creative works if they are assured of reasonable remuneration for their efforts. Therefore the creator of a work must be granted a temporary monopoly on the production and sale of the work. Patent and copyright legislation is carefully crafted to limit the property owner's control of the creation, because a healthy creative industry also depends critically on the interchange of new ideas. The monopoly protection is made contingent on the publication of the idea or its expression, so that others can build on the idea in further creative works. Thus the goal of intellectual property protection laws is not the enrichment of the owners of the property. This is a means, not an end. The end is the provision to society of an abundant supply of high-quality inventions, writings, music, and other creative works.

Some have argued that existing legal conceptions of intellectual property are not adequate for dealing with software (Davis, Samuelson, Kapor, & Reichman, 1996). Copyright laws have traditionally been applied only to writings and other forms of expression, whereas patents were applied only to discoveries and useful inventions. But software is precisely a useful object that happens to be expressed as a writing. Notwithstanding these objections, the existing legal framework has been adapted to deal with software by a process of relatively narrowly focused changes to existing legislation accompanied by court decisions to establish precedents, just as happened with earlier technological innovations such as audio and video recorders.

Still, it should be kept in mind that this legal framework is only one of a number of possible solutions to the problem of ensuring for society an abundant supply of creative works. It is a solution that is situated within the Western tradition of protection for intellectual property. Other solutions, such as state support for software producers, or a system of shared royalty payments funded by hardware or media sales, can be imagined. The "open source" software movement promotes an alternative mode of software production in which widely dispersed programmers contribute to development of an application. However, to date none of these alternatives has found a viable mechanism for funding the work at the levels that would be required to support the current software establishment.

In what follows, the discussion will be mainly in terms of the U.S. legal situation. This is reasonable because most software is produced in the U.S. Also, various international treaties have established a legal climate that is substantially the same in most countries. These treaties include the Berne Convention for the Protection of Literary and Artistic Works, the Universal Copyright Convention, and the General Agreement on Tariffs and Trade (GATT) accord on Trade-Related Aspects of Intellectual Property Rights (TRIPs).

Software Copyright

Because a program must be copied from a distribution medium to a computer's hard drive in order to be installed, and copied again from the hard drive to the working memory (RAM) in order to run, copyright in principle gives the software maker complete control over the use of its product. On this view, the customer does not purchase the software, but only pays for a license to use it, under whatever terms the maker chooses to dictate. In practice,

the strictness of this view is tempered by market pressures and the recognition by the courts that the customer is entitled to certain basic rights. As one example, most packaged software carries a notice on the outside of the package saying that the purchaser indicates acceptance of the license by the act of opening the package. However, because the license is inside the shrink-wrapped package, there is no way the customer can read it first in order to decide whether or not to accept it, and so the legal enforceability of these "shrink-wrap" licenses is doubtful.

Fair Use

One legal question that should be addressed is whether individual copying of software for personal use might fit within the parameters of the fair use doctrine, which permits the duplication of copyrighted material under some conditions. A determination of fair use must consider four factors: (1) the purpose or character of the use (whether commercial or productive); (2) the nature of the use (whether one is primarily availing oneself of the uncopyrightable factual content of the work or of its expression); (3) the substantiality of the use (whether the work is copied in its entirety or only in part); and (4) the effect of the action on the market for the work. Hornik (1994) argues persuasively that softlifting fails to meet the criteria for fair use. (1) Although the software is not being copied for sale, and even though it may be used in ways that benefit the rest of society (the main aim of fair use), it is also likely to be used indirectly for financial gain. (2) What the softlifter is primarily interested in is the "expression" of the software, that is, its embodiment in code. (3) In softlifting, the entire work is duplicated. Finally, (4) although some softlifters would choose not to buy the software if the choice were to pay or to do without, the practice probably decreases sales at least to some extent. Hence, a fair use defense of softlifting as it is typically practiced would probably not stand up in court.

Software Patents

In many cases, protection of the source code by copyright is insufficient to protect the innovations embodied in the software. These innovations, although representing considerable investment in research and development effort, are often quite easy to reproduce, or "clone." Court cases have upheld the use of copyright protection in some cases in which the "look and feel" of a software product was copied. However, copyright cannot protect against copying of the fundamental ideas and algorithms used in its design. Software makers have therefore turned to patents for this type of protection. Initially, the U.S. Patent Office was reluctant to issue patents for computer software, but a series of court decisions in the 1980s clarified the situation, so that in the 1990s there was a surge in the granting of software patents (Hunt, 2001).

Enforcement Efforts

One area in which the software industry has had some success in improving compliance with licensing and copyright laws has been in pressing its case against corporate softloaders. On behalf of its member companies, SIIA has undertaken a program of voluntary audits of large firms, inspecting their computers to determine whether software has been loaded onto them in violation of license agreements. When SIIA receives a reliable report (usually from an employee of the firm) that softloading is occurring, the firm is sent a letter giving it a choice of permitting the audit or being sued for infringement. Most firms choose the audit in order to avoid the adverse publicity that a lawsuit would entail. They may also have favorable software licensing arrangements that would be at risk if they fail to cooperate. If the audit turns up violations, the firm must destroy the infringing software, purchase replacements for it, and pay a fine. In return, SIIA releases the firm from all further legal claims for prior acts of infringement.

Internet piracy presents greater obstacles to legal enforcement. Suppose someone downloads a software package that has been illicitly placed on a Web site. If the software producer wishes to bring suit to redress this action, it faces a number of practical difficulties (Christensen, 1997). First it must decide whom to sue: the downloader, the intermediary (the service provider hosting the Web site), or the person who uploaded the software in the first place. Next it must decide where to sue: because each of the three parties involved in the action could be located in a different country, the choice of an appropriate venue can be complicated. Finally, assuming the prosecution is successful, it must attempt to recover damages.

Prosecution of an individual downloader is difficult in all of these respects. Web sites usually do not maintain logs of download activity for very long. Even with access to these logs, it can be difficult to identify the downloader, and savvy pirates can masquerade as different users. The downloader may be located in a foreign country that may have weaker intellectual property laws than those in the U.S. Although suit may be brought against foreign nationals in a U.S. court, enforcement of the judgment can be difficult. Finally, the amount of damages that can be assessed for a single count of softlifting may not cover the costs of litigation, and the guilty party may not have the means to pay it anyway. The 1997 U.S. No Electronic Theft (NET) Act addressed this last issue by increasing the civil penalties and for the first time providing for criminal penalties for copyright infringement that is not for financial gain, provided the value of the stolen works is at least $1000. These measures have made it more likely that an action against an individual softlifter could result in significant penalties, including jail time. Recently some high-profile actions have been brought against particularly flagrant softlifters, in hopes of making examples of a few in order to deter others. However, because of the difficulties, as well as for reasons of public relations, software companies have historically tended to avoid legal action against individual softlifters.

A more suitable target for legal action may be the uploader. A single upload can be responsible for thousands of downloads, so the damages that can be assessed can be quite large. Furthermore, if the uploader acted for profit, the penalties are even greater. However, many uploaders post software on warez sites simply for the enjoyment of sharing with others and thumbing their noses at powerful software companies. Identification of the uploader can also be difficult, for the same reasons as with

downloaders. Finally, even if the legal action is successful, an individual uploader may not have the means to pay the penalties, and the software company would have to be satisfied with a moral victory.

Prosecution of the online service provider (OSP) used as an intermediary for software piracy may be a viable option. OSPs operate the computers on which reside bulletin board systems (BBSs), Web pages, newsgroups, and chat rooms, all of which can be used to exchange pirated software. U.S. courts have held OSPs responsible for the copyright infringement activities of their customers under the notions of contributory or vicarious liability. Contributory liability is applicable if the OSP knew about the infringing activity and took no action to prevent it. Vicarious liability can apply if the OSP knowingly made available the means to commit infringements, even if it did not monitor or encourage the infringing activity itself. In response to the threat of legal action, many OSPs now enforce strict policies against infringing activities by their users, although undoubtedly much pirating activity still goes undetected.

Prosecution of the OSP has several practical advantages from the point of view of the software maker: the OSP is an established firm that is easily identified, the amount of damages that can be sought is large, and in the event of a successful suit the OSP is likely to have the resources to pay the judgment.

A recent development that makes prosecution of the intermediary harder is peer-to-peer (P2P) file sharing. The novel idea behind a P2P service is that the files to be downloaded do not reside on a central server, but on the computers belonging to the users of the service. The central server, if there is one, only acts as a go-between by maintaining lists of what files the users have made available for download by others. Once a user has located a particular file on another user's machine, the file is exchanged directly from the one machine to the other without any further involvement on the part of the server. P2P file sharing was pioneered by Napster, which was originally designed to allow users to share music files in MP3 format. However, the P2P protocol can be used equally well to share any sort of digital content and many of the newer P2P services support the sharing of software. Some have also adopted an even more decentralized structure that is much less susceptible to legal action.

Technical Protection Mechanisms

Because legal protections alone have not sufficed, software makers have devised various technical mechanisms to prevent the unauthorized copying of their products. The most commonly used protection mechanisms rely on a special key code that must be entered by the user during the installation process. Typically this key code is provided along with the installation medium in each software package. Key codes do not prevent softloading, because there is nothing to prevent the user from installing the same software on multiple machines. The user can at least be limited to using the software on one machine at a time by means of a key disk or a dongle. A key disk is a special diskette or CD, provided along with the software, that must be inserted into the disk drive during operation of the application program. The program queries the key disk from time to time to continually verify the user's authorization. For the key disk to be effective, of course, it must be difficult to copy by the means at a typical user's disposal. A drawback of key disks is that they prevent the disk drive from being used for other purposes while the application is in use. A related alternative is the dongle, a device that attaches to the parallel, serial, or USB port of the computer. As with a key disk, the application queries the dongle as it runs. Dongles are relatively expensive, typically adding $20 to $30 to the cost of an application, so they are only practical for high-end software.

Media-limited installations are a way to prevent softloading. In these schemes, the installation program counts how many times the application has been installed and refuses to exceed the limit. This method requires the installation medium, or at least a component of it, to be writeable. Also, in order for the protection to be effective, the medium must be difficult to copy by standard means.

Mechanisms such as key disks and media-limited installations were suitable during the 1980s when most software was distributed on floppy disks. As applications grew in size and distribution on CD became the norm, these methods were less appropriate. Also, any copy protection scheme that would prevent legitimate uses such as making archival backup copies or reinstalling the software after a hardware failure irritated customers. The result of the consumer backlash against copy protection was that by the early 1990s, relatively few packaged software applications that were being sold included any protection other than an installation key code.

Protection measures that rely on special hardware, whether key disk, uncopyable medium, or dongle, are not well suited to the present time when much software is distributed via the Internet. Often, the software can be downloaded freely, but contains a "time bomb" that will deactivate it after a trial period such as 30 days. Before that period expires, the customer must register and pay for the software, obtaining a key code that renders the installation permanent.

Unfortunately for the software producers, all of the methods that they have invented to deter the unauthorized use of their products can be "cracked," or circumvented. Copy protection schemes suffice to keep the average user, who has no knowledge of the inner workings of software, honest. It is virtually impossible to devise a scheme that a skilled and dedicated cracker cannot defeat. There is a whole underground society of crackers, individuals who vie to be the first to defeat the copy protection of a newly released program. They are very knowledgeable about computers and programming and are often as skilled as the programmers who produce the software. Some crack programs as a hobby, others do it for profit.

Cracking a program typically involves reverse engineering the binary code, taking it apart to find where the key code is checked or the dongle is interrogated, and bypassing or disabling these sections. If the protection scheme involves cryptography, this only adds to the challenge. Cryptography is the science of scrambling the contents of a file in such a way that it can be unscrambled only by using a secret, randomly chosen key. It is a practical impossibility to crack a well-designed modern cryptographic system by sheer guesswork, even using the fastest available computers. However, a fundamental problem facing

any cryptographic copy-protection method is that the software itself must contain a decryption routine including the key, which a clever cracker can in principle discover no matter how well it is hidden.

Recent Developments

The battle against online piracy is no longer the province of the software producers alone. The entertainment media industry is getting involved, due to the increasingly digital nature of their products. Under strong lobbying from Hollywood, proposed new legislation has been introduced in the U.S. Congress that would require copy-protection mechanisms to be embedded in every digital device and in all software that will be produced in the future. The new measures being advocated go even farther than the software industry wishes. Some of the proposed protection mechanisms will interfere with the legitimate duplication of software by OEMs and may prevent computer users from performing legitimate tasks. It is not clear at this time where these efforts will lead, but it is unlikely that they will be any more successful than previous measures in completely stopping piracy.

CONCLUSION

Piracy costs the software industry billions of dollars annually in lost revenues. The precise cost cannot be ascertained, because there are many economic factors that would change if the illicit copying could be stopped entirely. Softlifting and softloading probably account for the largest proportion of the activity, and the Internet is an increasingly important medium for exchange of "warez."

Technical means of enforcing copy protection can always be defeated. Veterans of the struggle against crackers recognize that, at best, copy protection will only slow pirates down and put some obstacles in the softlifters' path, so that enough people will purchase the product for it to be profitable. Furthermore, copy protection, if it is too intrusive, annoys customers and can even backfire by spurring more circumvention efforts. Consequently, most software producers have decided not to rely solely on technical means but to undertake a campaign of user education, coupled with high-profile legal action, to try to persuade customers to obey the laws protecting software. These efforts have borne fruit, reflected in a slow but steady decline in piracy rates in most countries. The biggest reductions in piracy rates have occurred in countries that have been making the transition to free-market economies and developing their own indigenous software industries. Although software piracy will never be completely eliminated, there are good reasons to hope that in coming years it will decline to levels that the software industry can live with.

GLOSSARY

Crack As a verb, to circumvent technical measures intended to prevent the unlicensed operation of a program. As a noun, a program that has been cracked so that it can be used by unauthorized users.

Dongle A specialized hardware device that attaches to a computer's parallel, serial, or USB port and that is queried by a program during operation in order to verify the user's authorization to use the program.

Hard-disk loading The installation of unauthorized software on computers being prepared for sale by original-equipment manufacturers or other computer vendors.

Mischanneling The selling of software intended for academic, government, or other special categories of customers to those who do not belong to the intended group.

Softlifting The unauthorized copying of software by an end user for his or her own use, rather than for sale.

Softloading The copying of software by an end user onto more machines than permitted by the license, or the unauthorized loading of software onto a server for use by client machines in a local-area network.

Unbundling The selling of software that is licensed only to be sold as part of a package as a separate item.

Warez Slang term for pirated software, usually referring to items made available on the Internet.

Speech and Audio Compression

Peter Kroon, *Agere Systems*

INTRODUCTION

Audible signals such as speech and music are acoustic analog waveforms, pressure changes that propagate through a medium such as air or water. The waveforms are created by a vibrating source such as a loudspeaker or musical instrument and detected by a receptor such as a microphone diaphragm or eardrum. An example of a simple waveform is a pure tone, a periodic signal that repeats many times per second. The number of repetitions per second is its *frequency* and is measured in Hertz (Hz). Audible tones are typically in a range from 20 to 20,000 Hz, which is referred to as the *bandwidth* of audible signals. The tone will create a sound pressure displacement that is related to its amplitude. Signals with high amplitude will sound louder than signals with low amplitude, and the range from soft to loud is called the *dynamic range*. Complex sounds (e.g., the sound of a piano, or speech) consist of combinations of many tones of different frequencies and amplitudes that vary over time.

Using a microphone one can capture an acoustic waveform and convert it into an electric signal or waveform. This signal can be converted back to an acoustic signal by using a loudspeaker. To represent this analog waveform as a digital signal, it is necessary to find a numerical representation that preserves its characteristics. The process of converting an analog signal to a digital signal is usually referred to as *digitization*. Digital representation of audio and speech signals has many advantages. It is easier to combine with other media such as video and text, and it is easier to make the information secure by applying encryption. Digital representations also allow procedures to protect against impairments when transmitting the signals over error-prone communication links. The main disadvantage is that straightforward digitization of analog signals results in data rates that require much more capacity of the physical channel than the original analog signal.

Before we provide some examples of this dilemma, let us first take a look at the principles of digitization. To digitize an analog audio signal it is necessary to sample the signal at discrete instants of time at a rate equivalent to twice the highest bandwidth that exists in the signal (this is the *sampling* or *Nyquist theorem*). The frequency that the signal is sampled with is referred to as the *sampling frequency*. Typical sampling frequencies for speech signals are between 8 and 16 kHz, whereas for music signals ranges between 16 and 48 kHz are more common. To get a digital representation, the sample values need to be a discrete set of numbers represented by a binary code. This process is referred to as *quantization*. In contrast to sampling, which allows one to perfectly reconstruct the original analog waveform, quantization will introduce errors that will remain after the analog signal is reconstructed. The quantization error (defined as the difference between the analog sample value and the discrete value) can be made smaller by using more bits per sample. For example, an 8-bit number allows 2 to the power of $8 = 256$ different values, whereas a16-bit number allows 65,536 different values. For speech signals between 8 and 16 bits per sample are adequate, whereas for high-quality music signals between 16 and 24 bits per sample are commonly used.

The process of sampling and quantization described above is referred to as pulse coded modulation (PCM). The total bit rate per second for a PCM signal is given by (sampling rate) $\times$ (number of bits per sample) $\times$ (number of audio channels).

For a stereo signal on a compact disc this means $44{,}100 \times 16 \times 2 = 1{,}411{,}200$ bits per second (1,411 Mb/s). As is illustrated in Figure 1, the typical bit rates needed for various signals can be quite high. For storage and transmission purposes these rates quickly become prohibitive. Although disc-based storage has become cheaper and high-speed Internet connections are more commonplace, it is still difficult to stream compact disc data directly at about 1.4 Mb/s or to store hundreds of uncompressed CD's on a hard disk.

The main goal of *audio and speech compression* is to find a more efficient digital representation of these signals. Because most signals start as simple sampled PCM signals, it is useful to use the resulting relative reduction in bit rate as a measure of efficiency. It should be pointed out that a reduction in bit rate is not always the main objective. For example, one could increase the bit rate to make the signal more robust against transmission errors. In that case the generic term *coding* is more appropriate. In this chapter we will use both terms interchangeably. Figure 2 shows the generic compression operation. The *encoder* takes the PCM input signal and generates the compressed *bit stream*. The bit stream is either transmitted to the

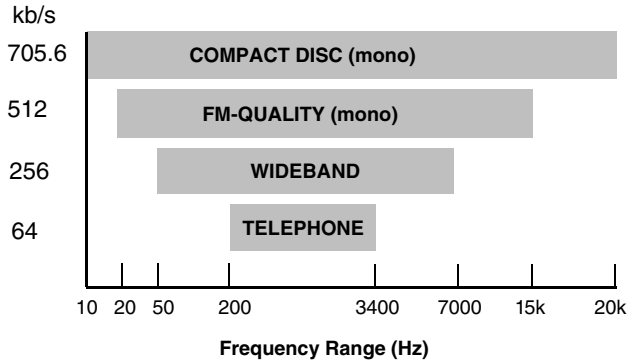

Figure 1: Relationship between bandwidth and bit rate.

decoder or stored for later retrieval. The decoder takes the bit stream and generates the corresponding decoded PCM signal, which is a rendering of the original input PCM signal.

In the remainder of this chapter we will focus on reducing the bit rates of speech and audio signals while providing the best possible signal quality. At this point it is good to point out that quality is a difficult attribute to quantify because it has many dimensions. Most of these are associated with specific applications, and it is important to set proper objectives when designing or choosing a particular compression algorithm. For example, for speech communications it could be important to have consistent performance for various input conditions, such as clean speech, noisy speech, and input level variations. For compression of music signals it could be important to have consistent performance for various types of music, or to preserve audio bandwidth and stereo image as much as possible. As will be clear later, this quality objective will be constrained by other factors such as *delay* (the time needed to encode and decode a signal) and the *complexity* (the number of arithmetic operations) of the methods used.

Speech and audio compression applications can be divided into two classes. The first is *broadcasting* (e.g., streaming); the other is *communication* (e.g., Internet telephony). Each application has different requirements, as can be seen from Table 1.

There are two principal approaches to the compression of digital signals: *lossless* and *lossy* compression. Lossless compression techniques take advantage of redundancies in the numerical representation. For example, instead of using 16 bits per sample uniformly, one could use a new mapping that assigns symbols of shorter length to the most frequent values. Or if the signal values change slowly between sample values, one could encode the differences instead, using fewer bits. Lossless compression is a reversible operation and the input and output signal samples of Figure 2 will be identical. Lossy compression techniques, on the other hand, assume that the signal has

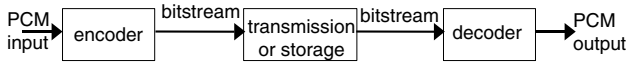

Figure 2: Block diagram of a generic coding or compression operation.

a human destination, which means that signal distortions can be introduced as long as the listener either is not able to hear them, or has no serious objections. Lossy compression is not reversible and the input and output signal samples of Figure 2 will be different. For many signals this difference would be unacceptable, but for audio signals, one only worries about audible differences. If the differences are inaudible the lossy coding techniques used are often referred to as *perceptually lossless* coding techniques. But even if the differences were clearly audible it still would be acceptable for many applications. A good example is the difference between telephone speech and natural speech, where the telephone signal is significantly limited in bandwidth (typically less than 4 kHz).

In practice, the use of lossless coding for audio and speech signals results in limited compression efficiency and its use is restricted to high-quality applications such as the audio DVD. The compression efficiency for lossy coding can be significantly higher and consequently perceptually lossless and lossy coding are the main approaches used in most audio and speech compression applications. Speech compression takes this approach one step further by also assuming that humans generate the source signal, which gives it certain properties that can be taken advantage of by the compression algorithms. As a result, speech compression can achieve very high compression efficiency. Figure 3 gives a summary of the typical bit rates and applications.

Compression for Packet Networks

The compression algorithms described in this chapter are used for communication and broadcasting over wired and

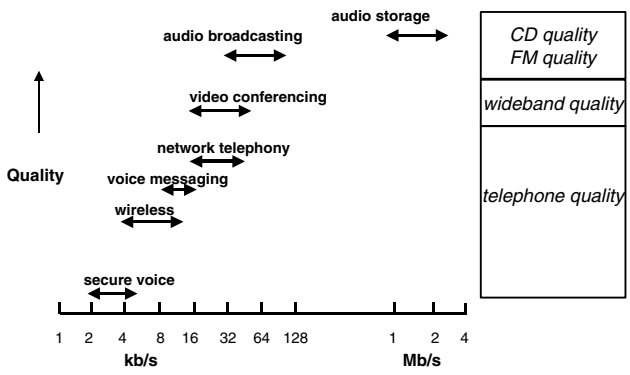

Figure 3: Typical bit rates and applications for speech and audio compression.

wireless networks. Errors that get introduced into the bit stream during transmission can introduce serious degradations in the decoded signal. In contrast to analog signals, where transmission impairments mainly introduce additional noise into the audio signal, digital signals subjected to bit stream errors will produce pops, clicks, and other annoying artifacts. Especially in wireless applications, one is likely to encounter transmissions errors, and it is common to add additional information for *error correction and detection*. However, even with the use of error correction techniques, it is still possible that bit errors remain in the bit stream.

The sensitivity of a decoder to random bit errors (in other words, their relative impact on the decoded signal quality) should be taken into account in such an application. For wired networks the transmissions channels are usually good, and transmission errors are unlikely. However, in packet networks (e.g., the Internet), it is possible that packets will not arrive on time. Due to the real-time nature of the connection, the decoder cannot request retransmission and this information is considered to be lost. To avoids gaps in the signal it is necessary to fill in the missing information. This technique is referred to as *error mitigation*. Sophisticated error mitigation techniques work quite well for segments up to 40–50 ms. For longer error bursts it is necessary to mute the signal. Is it important to realize that for applications where transmission errors can occur, the overall quality of a coder (including the use of error correction and mitigation) may be dominated by its robustness to channel impairments.

Traditional compression applications are optimized for the underlying application (e.g., a cellular system). These systems are homogeneous, in the sense that all terminals and links meet certain minimum requirements in throughput and capabilities. The Internet is a much more heterogeneous network, where endpoints can be quite different in capabilities (e.g., low-end vs. high-end, PC vs. laptop, wired vs. wireless) and connection throughput (dial-up vs. broadband). One solution would be to use scalable coders in which the same coding structure can be used for operation at different bit rates. This requires a handshaking process between transmitter and receiver to agree on the rate to be used. Moreover, if a throughput issue came up somewhere in the middle of a link, it would require decoding at the higher rate first, and then subsequent encoding at the lower rate. The resulting *transcoding* operation introduces additional delay and a significant degradation in quality, because coding distortions are compounded. A better approach is the use of *embedded* coders. In embedded coders there is a core bit stream that each decoder needs to decode the signal with a certain basic quality. One or more enhancement layers enhance this core layer. Each enhancement layer will increase the average bit rate and the quality of the decoded signal. The encoder generates the core layer and enhancement layers, but the decoder can decode any version of the signal as long as it contains the core layer.

This is illustrated in Figure 4. Apart from adjusting for various throughput rates, embedded coders can also be used for temporary alleviation of congestion. If too many packets arrive at a given switch (e.g., switch 2 in Figure 4), the switch can decide to temporarily drop some enhancement packets to avoid congestion. Depending on the size of the enhancement layer bit streams and the coder design, this can be done with only a minor impact on the audio quality. The embedded coding approach will alleviate packet loss problems but will not avoid them. Because we always need the core information, the packet loss problem will remain. A solution to this problem is the use of multidescriptive coders. Multidescriptive coders can be seen as a superset of embedded coders. In this the encoder creates two or more descriptions of the signal, each of which can be decoded independently. When all descriptions are received the best possible quality is received; when only one of the descriptions is received the quality will be lower. In practice, it is difficult to design efficient scalable coders and multidescriptive coders, and this topic is still an active area of research.

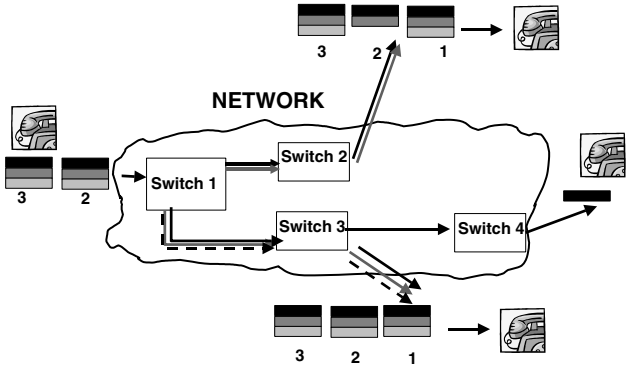

Figure 4: Use of embedded coders in a heterogeneous network.

Speech and Audio Quality Assessment

The quality assessment of lossy speech and audio compression algorithms is a complicated issue. Quite often we want to assess not only the quality of the compression algorithms, but also the quality delivered by these algorithms in a typical operating scenario, which means including other aspects of the delivery chain as well, such as the quality of the network, or the quality and type of playback equipment. Because the coders use perceptual techniques, it is important to use human listeners. Even in this case care has to be taken to get reliable and reproducible results. Choices of test material, number of listeners, training of listeners, test format (e.g., order of playback, inclusion of original), and playback scenario (e.g., headphones vs. loudspeakers) all affect the outcome of the test, and it is necessary to design the test so that the impact of these factors can be minimized. Testing perceptually lossless coders (no audible differences when compared to original) will be different from assessing the performance of lossy coders. The latter will be complicated because tradeoffs have been made in many dimensions, which will produce different listener responses. For example, some people prefer large audio bandwidth to reduced signal distortion. Some stereo audio coders trade off more subtle issues such as stability of the reproduced stereo image. A well-designed test will try to eliminate all these biases and should produce a reproducible result.

Assessment of speech is even more involved, because it involves two-way communication and most material is context-sensitive. Mean opinion scores (MOS) testing in which panels of listeners rate the quality of short sentences on a 5-point scale is the most common. Besides speech quality one can also test speech intelligibility, although this is usually not an issue for telephony bandwidth speech at bit rates of 4 kb/s and higher.

It should be appreciated that none of the testing methods described above can fully predict how people will experience the quality in a real-world scenario, which involves talking to people whose voices they know or listening to music they like.

Tests with human subjects are expensive and time-consuming, and one would like to use objective measures that could predict subjective quality based on a comparison between the original and the processed version. For lossy compression simple objective measures such as segmental signal-to-noise (SNR) measurements are meaningless. A more effective approach is to include models that mimic our auditory system and use the resulting model output to predict subjective quality. Two standards based on such an approach have recently been recommended: ITU-R PEAQ for the assessment of audio compression techniques and ITU-T P.862 for the assessment of telephony-quality speech compression techniques. Although these methods have shown to be quite accurate for some scenarios, they should always be used with caution and with a clear understanding of their shortcomings.

SPEECH CODING TECHNIQUES

Efficient digital presentations of speech signals have been a topic of research since the 1940s, but only since the early 1990s have many applications become technically and economically feasible. Digital cellular telephony has been one of the main applications for speech coding, and many digitization choices were made to be compatible with wired digital networks. For example, the speech signals are sampled at 8 kHz (thereby limiting the signal bandwidth to 4 kHz), single channel (mono), and 8 to 16 bits/sample. The communication application puts a constraint on the *delay* introduced by the compression operation. Not only is it is difficult to have a natural two-way conversation with delays exceeding 250 ms, but it is also more noticeable to hear echoes introduced, for example, by the acoustic coupling between loudspeaker and microphone (e.g., a speakerphone) at either end of the communication link. For conferencing applications, which involve more than two parties, each party will hear the combination signal for all other participants. Because this combining of the signals needs to be done in the PCM domain it is necessary to decompress the signals, digitally combine them, and compress them again. The delay introduced by compression will now be compounded, thereby reinforcing the problems mentioned above. Most compression algorithms introduce delay because they analyze the signal in blocks or frames with a duration of 10 to 30 ms. Analysis in frames is necessary to better characterize the signal behavior and its variations.

For communication applications it is also important to put constraints on the *complexity* of the compression operation because each end-point needs both an encoder and a decoder. This is even more relevant for wireless applications where the end-point is battery-powered and high complexity will reduce battery life. Complexity is defined in terms of computational load (MIPS) and memory usage (RAM and ROM). For most speech and audio coding algorithms there is an asymmetry in complexity, and the encoder can be several more times complex than the decoder.

Most speech coders are based on the lossy compression paradigm, taking advantage of the properties of the auditory system and the properties of the speech production mechanism. The latter can be taken advantage of by using so-called *parametric coders*. With these coders the speech signal is modeled by a limited number of parameters, which are usually related to the physical speech production mechanism. The parameters are obtained by analyzing the speech signal and quantized before transmission. The decoder will use these parameters to reconstruct a rendering of the original signal. When the input and output waveforms are compared, the resemblance may be weak but the signals may sound very similar. Using parametric approaches, it is feasible to achieve reasonable quality with very low bit rates (2 to 4 kb/s). The quality is limited by the accuracy of the model. This is illustrated in Figure 5. To avoid this limit on quality, a more common approach is to use waveform-approximating coders. These coders maintain the waveform of the original signal as much as possible while taking advantage of the properties of both the speech production and auditory mechanisms. The resulting quality is better at the expense of higher bit rates, and at lower bit rates the quality of a waveform coder will be less than that of a parametric coder operating at the same low rate (see Figure 5).

Speech as produced by humans has certain properties that can be taken advantage of for compression. It has limited energy above 8 kHz, and it has a limited dynamic range. This allows sampling with frequencies between 8 and 16 kHz and PCM quantization with 12–16 bits/sample. Using nonuniform quantization (e.g., the quantizer step sizes are small for small input values and large for large input values), it is possible to quantize telephone speech with 8 bits per sample. Figure 6 shows a waveform and its corresponding spectrogram. From looking at this figure one can see that the envelope of the amplitudes change slowly as a function of time. The spectrogram shows that certain frequencies are stronger than others. These emphasized frequencies are called *formants*

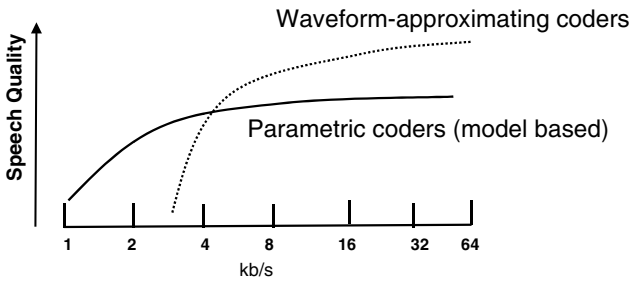

Figure 5: Quality vs. bit rate curves for waveform and parametric coders.

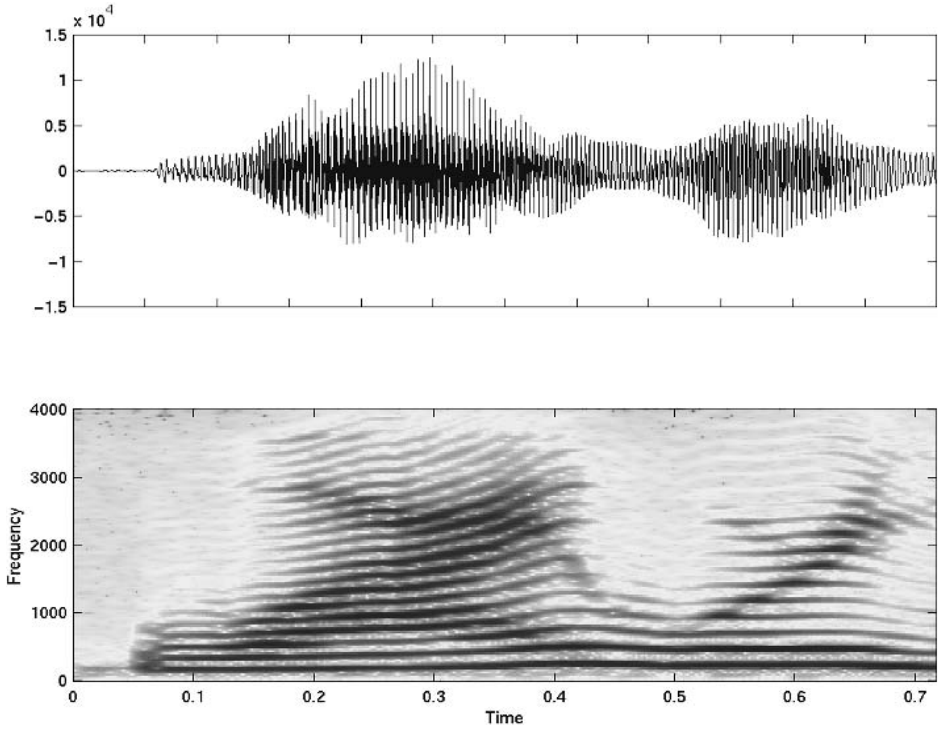

Figure 6: Time waveform of the utterance "Why were you away a year, Roy?" spoken by a female talker (top) and corresponding spectrogram (bottom). The spectrogram shows the power spectrum as a function of time, where the gray level indicates the power level, from low (white) to high (black).

and are caused by resonant frequencies in the vocal tract in response to the glottal excitation signal. Changing the shape of the mouth cavity over time changes the resonant frequencies. The relative position of these formants defines the consonants and vowels that we perceive. One can also see a more harmonic component, which is due to the periodic excitation provided by the vocal cords. This is referred to as the *pitch* of a sound and varies between 100 and 250 Hz for males and 200 and 400 Hz for females.

All these features are produced by the human articulatory system, which changes slowly in time, because it is a biological system driven by slowly moving muscles. As a result it was found very effective to represent the formants by a slowly varying adaptive digital filter, the so-called *linear or short-term prediction* filter. With only 10 predictor coefficients updated once every 20 ms it is possible to accurately reproduce the evolution of speech formants.

Figure 7 shows a short segment of a speech signal and the corresponding signal after filtering with an adaptive linear prediction filter, called the *residual* signal. Because this signal is better behaved it usually easier to quantize with fewer bits per sample. The predictor coefficients have to be quantized before transmission, and numerous methods are available. The most effective methods require only 1,500 to 2,000 bits/s to transmit 10 coefficients every 10 to 20 ms. By recognizing the periodicity in the signal for voiced sounds (e.g., vowels) it is possible to further improve predictor efficiency. A so-called *long-term or pitch predictor* is able to predict the periodic component, resulting in an even more noiselike residual signal. The long-term predictor consists of a variable delay line with a few filter coefficients. The delay and coefficients are updated once every 5 to 10 ms. The most typical configuration is forward adaptive, which means that about 1,500 to 2,000 bits per second are needed for transmitting the long-term predictor parameters. Figure 8 shows the signals after short-term and long-term prediction, respectively.

The signal shown at the bottom of Figure 8 resembles a noiselike signal, with a reduced correlation and reduced dynamic range. As a result it can be quantized more efficiently.

At this point we have all the components needed for a linear predictive coder. A block diagram is shown in Figure 9. The signal is filtered with the short-term filter $A(z)$ and long-term filter $P(z)$ and the remaining residual signal is quantized. The predictor parameters and quantized residual signal are transmitted or stored. The decoder, after decoding the quantized residual signal, filters it through the inverse long-term and short-term prediction filters. Note that without quantization of the residual signal the decoder can exactly reproduce the original signal. For quantization of the residual signal many techniques exist. The simplest quantizers are scalar uniform or nonuniform PCM quantizers. For acceptable results at least 4 to 5 bits per sample are needed. Even refinements such as adaptive quantization, in which the quantizer step sizes are adjusted over time, will not reduce the number of bits per sample significantly. More efficient quantization can be obtained through the use of *vector quantization* (VQ), in which multiple samples are quantized simultaneously.

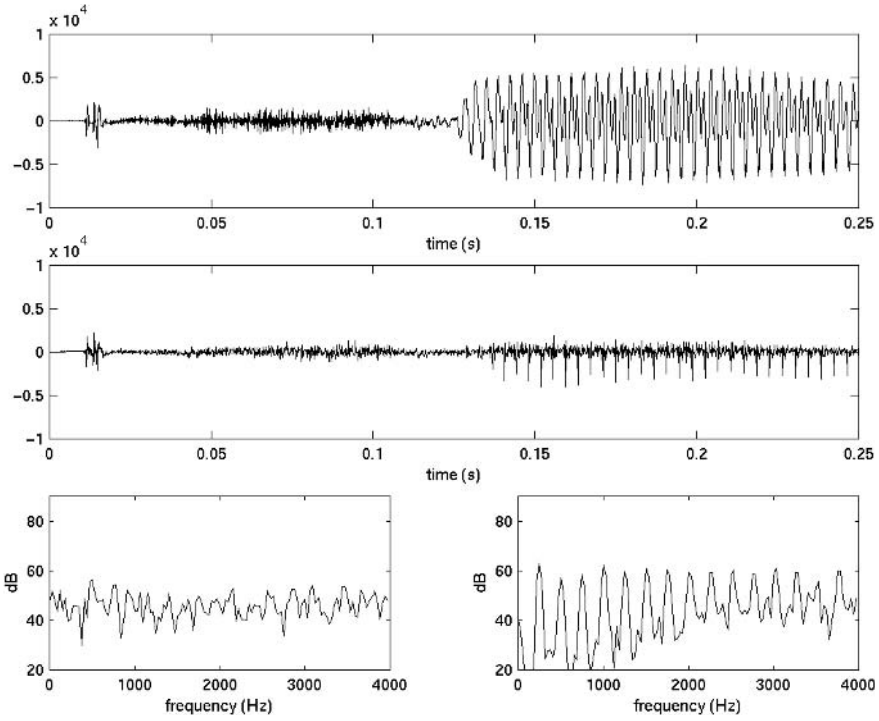

Figure 7: Time waveform (top), corresponding residual signal (middle), and spectra of the residual signal (bottom) for the first part of the sentence (left) and second part of the sentence (right).

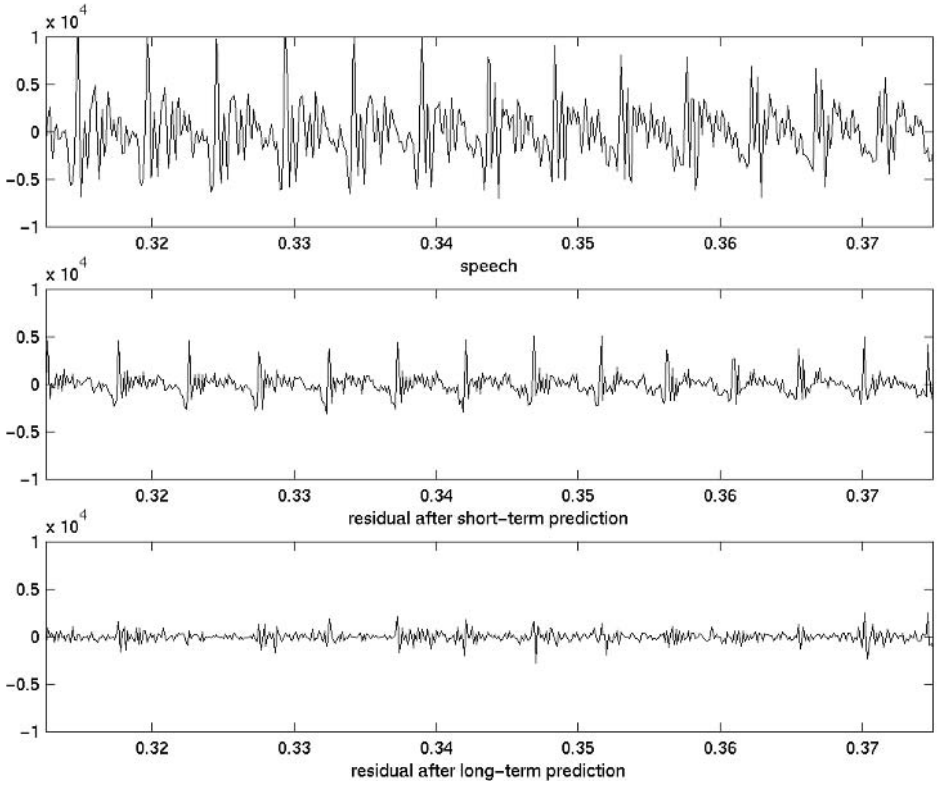

Figure 8: Time waveform (top), short-term residual signal (middle), and long-term residual signal (bottom).

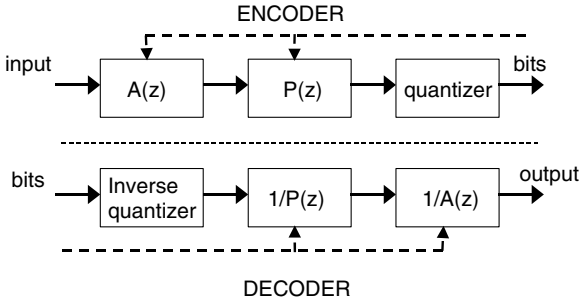

Figure 9: Block diagram of a linear predictive coder with short-term and long-term prediction.

This is achieved by having a number of possible representative sample sets or *codebooks*. Quantization is achieved by selecting the codebook entry (each entry containing multiple samples) that is the best representation of the signal to be quantized. The codebook index corresponding to this entry is transmitted and the decoder, which has a similar codebook, uses this index to look up the corresponding values. Whereas the lowest quantization rate for scalar quantization is 1 bit per sample, VQ allows fractional bit rates. For example, quantizing 2 samples simultaneously using a 1-bit codebook will result in 0.5 bits per sample. More typical values are a 10-bit codebook with codebook vectors of dimension 40, resulting in 0.25 bits/sample. Both scalar and vector quantization attempt to find the quantized value that is the closest to the original unquantized input. In the block diagram of Figure 9 one can argue that the overall goal is not to find the best quantized residual values, but the best quantized speech signal. Especially for coarse quantization (very few bits per sample), this becomes an issue. A powerful technique used in speech coding is *analysis-by-synthesis*, in which the effect of quantization is determined by examining the effect on the decoded output. This is accomplished by operating the diagram of Figure 9 in the configuration shown in Figure 10 .

In this figure the encoder of Figure 9 is enhanced with a local decoder. In most practical coders the predictors are still computed as usual. The quantization of the residual signal is done in an analysis-by-synthesis fashion. If we assume that we use a codebook, then the essence of this approach requires that for each codebook vector we perform local decoding and compare the resulting prototype output with the original input signal. The codebook vector that gives the best approximation is selected. Note that with this paradigm we are indirectly creating a quantized residual signal, and this signal is often referred

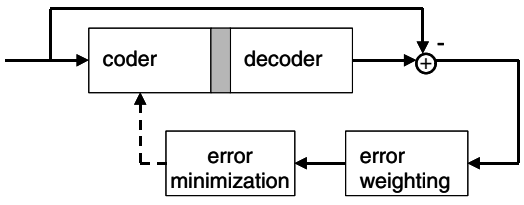

Figure 10: Analysis-by-synthesis encoder with error weighting.

to as an *excitation* signal. Instead of directly comparing the original input signal and the quantized and decoded rendering of this signal, an error-weighting filter is introduced, which better reflects the way our auditory system perceives distortions. It should be noted that this weighting is much simpler than the complex auditory models used in audio coding. The block diagram of Figure 10 forms the basis for a family of coders generically referred to as code-excited linear predictive (CELP) coders. Most modern speech-coding standards are based on this principle. A large amount of research has been done on efficient codebook structures, which not only give the best performance, but are also manageable in terms of search. A commonly used structure is the so-called *algebraic* codebook, which consists of a few nonzero pulses with deterministic positions.

For all coders several techniques can be used to further improve their performance. Some of these techniques can be done independent of the coder, although in practice it makes sense to take advantage of the parameters already computed by the coder. Preprocessing techniques that are useful are gain control and noise suppression. The latter can be quite sophisticated but very effective, especially for the lower rate speech coders, which typically do not handle background noise well. A widely used form of postprocessing is *postfiltering*. In this process the decoded speech signal is slightly distorted in such a way that the coding noise gets suppressed and the signal gets enhanced. If done with care it can clean up a signal, resulting in perceived quality improvement.

Another technique that has found some popularity is taking advantage of the fact that conversational speech comes in bursts, due to the speakers talking at alternate times. Sometimes there can be large pauses in between words. This can be taken advantage of by only transmitting when active speech is present. When speech is not active no signal is transmitted. Because on the average people speak half of the time, this technique has the potential to reduce the bit rate by half. To make this *discontinuous transmission* approach work, a *voice activity detector* (VAD) is needed. For speech without background noise, this approach can work quite well. When background noise is present (e.g., a car), it is more difficult to get reliable decisions from the VAD. Moreover, when no talker is active, and no signal is transmitted, the receiver side needs to substitute a replacement signal. This is referred to as *comfort noise*. For high levels of background noise it is difficult to have this comfort noise match its characteristics. Hence more sophisticated systems transmit low-rate information about the background noise, such as energy and spectral characteristics, at average rates of about 1 to 2 kb/s.

Speech Coding Standards

For communication purposes it is important to establish standards to guarantee interoperability between equipment from different vendors, or between telecommunication services in different geographic areas. Telecommunication standards are set by different standard bodies, which typically govern different fields of use.

The International Telecommunications Union, ITU-T, establishes worldwide telephony and communication standards, whereas regional standards bodies such as ETSI and TIA define standards that are more regional in character (e.g., wireless standards). For Internet applications there is a proliferation of ITU-T standards and protocols. Table 2 summarizes the most relevant ITU-T speech coding standards.

G.729 is one of the more commonly used coders in VoIP applications. Besides the main standard there are many extensions to this standard, which in ITU-T terms are referred to as annexes. Annex A, for example, is a low-complexity version of G.729, which generates bit-compatible output. It requires only about half the complexity, at the expense of minor degradation in speech quality. Other annexes of G.729 define a low-bit-rate version and a high-bit-rate version and integration with Voice Activity Detection.

Most of the discussion has focused on coders for an 8-kHz sampling rate, which limits the audio bandwidth to 4 kHz. With the availability of new endpoints, it is now more feasible to provide higher quality output, specifically increased audio bandwidths. A commonly used sampling rate is 16 kHz, which supports audio bandwidths up to 8 kHz. Table 3 summarizes several ITU-T standards that have been defined for encoding these so-called wide band signals.

Most of these ITU-T standards not only come with detailed technical descriptions of their underlying algorithms but also are accompanied by reference source code and test vectors. The source code is provided as floating point C code or fixed point C code or both. Fixed-point code reflects implementation on signal processor and VLSI chips, which are typically used in most portable devices.

Although standards make the technology readily available, they are not license-free. In most cases proper royalty agreements must have been obtained before one can use the coder in a commercial application.

AUDIO CODING TECHNIQUES

The most common high-quality audio distribution format is based on the compact disc format introduced in the early 1980s. The signal is encoded using PCM with 16 bits/sample using a 44.1-kHz sampling rate. For stereo signals this means a data rate of $44{,}100 \times 16 \times 2 = 1.41$ Mb/s. More recent formats such as DVD-audio support up to 24 bits/sample, multichannel formats (e.g., 5.1), and sampling rates up to 192 kHz, resulting in even higher data rates. For most practical purposes these signals will be used as digitized source signals. For Internet streaming and computer storage applications, it is necessary to reduce these rates significantly and to bring them into the 32 to 128 kb/s range. As discussed earlier, this can be accomplished by the use of perceptually lossless coders, which take advantage of the limitations of our auditory system. For CD quality it is possible to make signals sound perceptually indistinguishable from the original at 64 kb/s per channel (128 kb/s for stereo). At lower rates we lose some of the information, but if this is done by proper combinations of bandwidth reduction, reduced dynamic range, and the use of mono instead of stereo, the resulting signal will still be acceptable for many applications. Perceptually lossy and lossless compression uses two main techniques. First we have *irrelevancy* removal, which removes parts of the signal that we cannot hear. The second technique, *redundancy* removal, finds the most compact signal representation.

Irrelevancy removal exploits the properties of the human auditory system. The human auditory system is a highly sophisticated system with tremendous capabilities. It acts as a converter of acoustic waves to auditory nerve firings, while performing a spectral analysis as part

of this process. The auditory system has been shown to have masking properties. Masking describes the process in which one signal becomes inaudible in the presence of another signal. In other words, under certain circumstances it is possible to make quantization noise inaudible while the decoded audio signal is present. Masking can happen both in time and in frequency. Understanding the principles of masking has taken many decades of research using both physiological and physical measurements. Masking data are obtained through psychoacoustical studies, in which subjects are exposed to test signals and asked about their ability to detect changes (increase in frequency, audibility, etc). Most of the understanding of masking is based on simple tones and noise. Because complex signals can be viewed as composites of time-varying tones, a common approach has been to derive the masked threshold by analyzing the signal tone by tone in specific frequency bands, related to the frequency bands used by the human auditory system to analyze sounds. These bands, called critical bands, are spaced nonuniformly with increasing bandwidth for higher frequencies. In each critical band, the signal and its corresponding masking function are calculated, and the masked threshold is derived as a superposition over the complete frequency band. It should be noted that the actual procedure is much more complicated, taking into account several interactions and characteristics of the signals (e.g., if the signal is noiselike or tonelike). Figure 11 gives an example of the power spectrum of a signal and its corresponding masked threshold. In this figure, as long as the quantization noise remains below the solid line, it will be inaudible.

In general the model that is used to derive the masked thresholds is referred to as the *psychoacoustic* or *perceptual model*. Building a good perceptual model and matching it properly to a given coder structure is a very complex task. It also should be noted that for a given coder structure (or coder standard such as MPEG 1, Layer 3), it is possible to improve the perceptual model while still being compliant to the standard. This also explains the quality differences in various encoders that all support the same standard.

To achieve redundancy removal, and at the same time take advantage of the frequency-domain masking properties, it is beneficial to perform a spectral decomposition of the signal by means of a filter bank or transform. Most modern audio coders are based on some form of lapped transform, which not only provides computational efficiency, but also allows perfect reconstruction. In other words the transform and its inverse will produce a delayed version of the original time signal. The transform sizes and overlaps will be chosen in such a way that the signal is critically sampled (i.e., the number of frequency components is the same as the number of time samples). The size of the transform will determine the spectral resolution. A larger transform will provide better spectral resolution at the expense of decreased time resolution. A common solution is to make the transform size adapt to the signal. For stationary signals, a large transform size is chosen, whereas for nonstationary signals or onset's a smaller transform size is chosen. Typically sizes vary from 256 to 2,048 samples for sampling rates in the range 20 to 40 kHz. This process is called window switching, and care is taken to make sure that the whole process is invertible. A commonly used transform is the modified discrete cosine transform (MDCT). It uses a transform of length 2M samples, which advances M samples between adjacent transforms. It is critically sampled and only M coefficients are generated for each 2M set of input samples. Computationally efficient implementations have contributed to the widespread use of the MDCT in many audio coding standards.

Figure 12 shows a generic block diagram of an audio encoder incorporating the filter bank and the perceptual model. The resulting spectral components (MDCT coefficients) are quantized in such a way that the resulting quantization noise is inaudible. This is accomplished by using the masking level obtained from the *perceptual model*. The amount of noise is controlled by the resolution of the quantizer. By choosing a different quantizer step size the amount of noise can be quantized. Typically the same quantizer is used for a set of coefficients, and the corresponding step size for that set is transmitted to the decoder. It should be noted that at this point, due to quantization, the decoded signal will be different from the original (i.e., lossy coding). To accomplish perceptually lossless coding, we need to make sure that the quantization noise remains below the masked threshold. The redundancy removal is accomplished by encoding the quantizer indices with lossless coding techniques (e.g., Huffman coding). To avoid confusion it should be clear that this is a lossless coding technique on quantizer indices; hence the overall operation is still a lossy coding

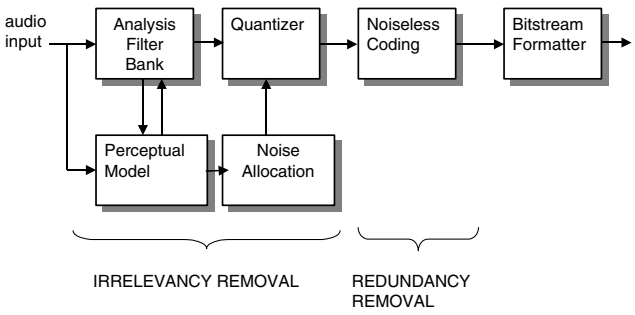

Figure 12: Block diagram of generic audio encoder.

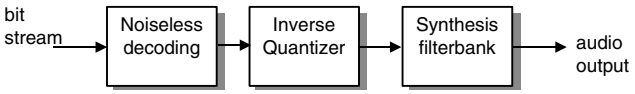

Figure 13: Block diagram of generic audio decoder.

operation. The resulting bit rate will be variable and will be signal-dependent. In many implementations an iterative procedure is used to find the optimum quantizer step sizes that result in coding noise below the masked threshold that will result in the lowest possible bit rate.

The decoder operation performs the operation in reverse, without the need for a perceptual model. A generic block diagram of an audio decoder is shown in Figure 13 . After the coefficients are reconstructed, the signal is transformed back to the time domain and ready for playback.

The block diagrams of Figures 12 and 13 are the principle for coding a single audio channel. For encoding multiple channels (N channels) once could in principle use N of these encoder/decoder pairs. However, in practice one would like to take advantage of the possible correlations that exist between the various channels. Also, for transparent coding, one would take into account that masking levels will differ for signals that are spatial in nature. Some distortions that are inaudible in each individual channel will become audible when listening to its multichannel version (e.g., in stereo).

Most state-of-the-art audio coders will produce a variable bit rate. In most communication scenarios a fixed bit rate is more desirable. This is accomplished by a buffering scheme that interacts with the coder quantization decisions. Designing buffering schemes that minimize buffer size (and its corresponding delay) and minimize impact on audio quality turns out to be a challenge, and various solutions exist, each with advantages and disadvantages.

Audio Coding Standards

Two types of standards exist. The first type is based on sanctioning by a standard organization (e.g., ISO and its MPEG standards). The second type is based on a proliferated proprietary *de facto* standard (Windows Media Player, RealPlayer, Dolby AC-3, etc). In both cases proper licensing is needed to use these standards in commercial applications. The MPEG coding standards are widely used for audio and video. The well-known MP3 standard is actually MPEG-1, Layer 3. Table 4 summarizes the MPEG standards.

The MPEG standards are defined in a different way than most ITU-T speech coding standards. They consist of a normative part defining the bit stream syntax and the decoder description (sometimes accompanied by reference C code). As a result anyone should be able to implement proper decoders. The encoder is described in the informative part and just describes the algorithmic concepts and operating modes. However, to build good encoders it is necessary to understand the algorithms, and the standard document will not provide details on how to build a good encoder. As a result standard compliant encoders can be quite different in performance.

Besides coders based on the traditional coding paradigm described above, other paradigms exist as well. These alternative paradigms play a role in very-low-rate coding. Two paradigms that have become part of the MPEG-4 standards are structured audio and parametric audio coding. Structured audio consists of a set of tools that can be used to generate music in a way similar to a music synthesizer. It also contains a structured way of describing musical scores and their subsequent conversion to sound using synthesizers. A structured audio bit stream describes how to build the synthesizers and provides the musical score and information on how to play this on the synthesizer. The resulting description can be very compact and low-bit-rate (only several kb/s). The resulting audio signal can be of very high quality, and because many modern music productions use synthesizers extensively, it can be very close to some originals. Parametric audio coding uses ideas similar to those used in speech compression by modeling some of the production mechanisms of the music sounds. Although it will work well for some sounds, it is difficult to make this technique work in a consistent way for a wide variety of input signals.

APPLICATIONS

Two popular Internet applications of speech and audio compression are telephony and streaming. In both cases the IP data network is used to transport digitized (and compressed) audio signals. The basic protocol is the IP (Internet protocol), which is used to set up connections between machines and sessions between applications. For most data applications the next protocol layer would be TCP (transmission control protocol), which guarantees a reliable connection. Because this is accomplished by acknowledgment of receipt and possible retransmission it cannot guarantee continuous throughput and is therefore not suitable for telephony applications. Instead the UDP (user datagram protocol) is used (see Figure 14) . UDP is a simple protocol that does not support retransmission. As a result the data transmission is based on a best effort. For voice communications the use of UDP alone is usually not sufficient. For example, all packets could arrive but the order could have changed. Another protocol layer that is usually used on top of UDP is real-time transport protocol (RTP). This protocol is used to provide delivery services for real-time data such as time stamping, source identification, and sequence numbering. The sequence count is used to determine the playback order of packets and to identify if packets are missing. The time stamp is used to determine the amount of delay variation and could be used, for example, to adjust a jitter buffer. The source identifier is used to allow different calls to be combined into bigger packets. The RTP protocol is often used together with the real-time transport control protocol (RTCP). This defines a mechanism for hosts conducting a RTP session to exchange information for monitoring and control of packet counts, and number of packets lost. The RTCP packets use the same header as RTP packets, but its payload contains the control information. The RTCP packets are transmitted only several times per second to reduce overhead, but at least once every 5 s. RTCP can be used to monitor network performance, for example by reducing the load introduced by non-real-time traffic that is part of the same session (e.g., graphics) if too many packets are lost. It could also control the compression algorithm by increasing or decreasing its bit rate.

The use of the various protocols significantly increases the overhead (i.e., the extra information beyond the useable (payload) information). The currently common standard IPv4 has a 20- to 24-byte header, whereas the new proposed IPv6 header has a 40-byte header. UDP and RTP add another 20 bytes, resulting in a significant packet overhead. One way to minimize this overhead is by increasing the packet size. For audio signals this is not always desirable, because a large packet size corresponds to a large delay, or in case of packet losses, the removal of a large time segment of audio information.

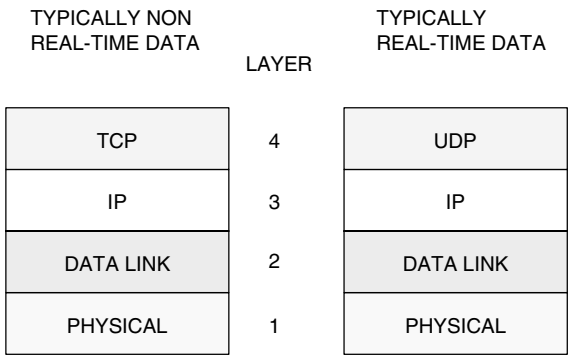

Figure 14: Protocol stacks for non-real-time and real-time sensitive data.

Another challenge in transmitting real-time sensitive data over a packet data network is the fact that the Internet is a best effort network. This means that one cannot guarantee the on-time arrival of the audio data, resulting in interruptions in the audio, or introducing unacceptable delays. In other words, *quality of service* (QoS) cannot be guaranteed for real-time communications. Many recent efforts have focused on improving this situation. For example, new protocols support differentiation of packets in terms of being real-time critical or not and improved routing schemes reduce the overhead needed for traffic flow management. To give real-time sensitive data a better guarantee on arrival it is necessary to prioritize these packets. It is important to keep in mind that prioritization can only work if other packets can get a lower priority and if routers can handle these priority requests. The resource reservations protocol (RSVP) tries to address this problem by negotiating priorities with routers. Another approach is based on the use of the differentiated services protocol (DiffServ), which sets priorities in the header bits and assumes multiple priority queues in the router. DiffServ is considered to be a more manageable protocol when used on a large scale, because it does not require routers to keep track of all requests and streams. Both protocols assume that the desired QoS result is achieved, but they will not guarantee it.

Internet Telephony

The use of the Internet for voice communications is now commonly referred to as *Internet telephony* or *voice over IP* (VoIP). Vocal Tech introduced the first consumer implementation in 1985 and it was widely hailed as a way to make free phone calls both domestically and internationally. As a result the concept of Internet telephony has become a reality, especially when used over managed networks such as found in enterprise networks. It not only will replace traditional circuit-switched phone systems in terms of functionality but also will open up many new opportunities. Examples are multimedia conferencing, integration of productivity tools on a PC with phone functionality, and Internet call centers. Economically, it makes sense to integrate voice and data services, not only from the end-user's perspective but also from the enterprise or service provider perspective.

To transport voice data over the IP network the signals are digitized and compressed with any of the coders described in the previous sections. The most commonly used ones are 64 kb/s ITU-T G.711 or lower rate coders such as the 8 kb/s ITU-T G.729 and G.729A. The media streams are transported using the IP/UDP/RTP protocol layering described before. To provide a complete phone service it is necessary to support numbering schemes, billing and call setup protocols, and servers that can acts

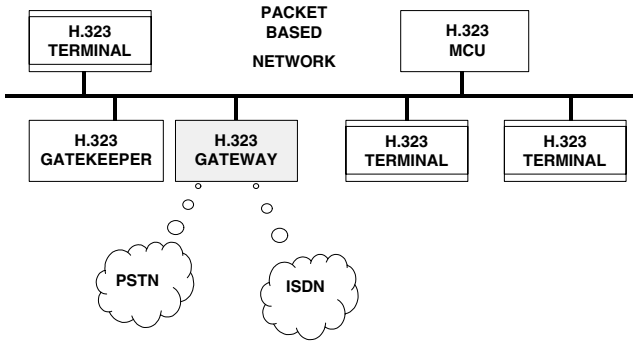

Figure 15: An example network topology using the H.323 protocol.

as intermediaries between end points. Two protocols that are widely used are H.323 and SIP. Both of these protocols build on existing protocols. The H.323 protocol suite was defined by ITU-T to support multimedia communications over IP independent of network topology. It contains four endpoints: (1) the terminal, which serves as the interface to the user, (2) the gatekeeper, which supports services such as billing and authentication, (3) the gateway, which supports connection to other networks, and (4) a multipoint control unit (MCU), which supports teleconferencing. Figure 15 shows an H.323 network topology. A simple end-to end call can be accomplished with two H.323 terminals, without the need for the functional modules.

Although we can build a telephony network independently of the traditional PSTN (public switched telephony network), in most cases we need to be able to interface with the legacy networks, for example when making a call from an IP phone to a traditional PSTN phone. The interface function between the Internet-based telephony and PSTN telephony is served by a so-called gateway. This gateway will facilitate the protocol translation and will also convert the audio data into a format suitable for the PSTN network.

The session initiation protocol (SIP) was proposed by IETF. It is modeled after the simple mail transfer protocol (SMPT). It is independent of the underlying packet protocol, and it leverages the Internet and Web structure. Although most existing IP phones use H.323, SIP is gaining momentum due to its simplicity. It is expected that both protocols will coexist for a long time and that most equipment will support both protocols.

Despite the use of RTP, there are still no guarantees that all packets will arrive on time, or will arrive at all. Buffering the incoming packets can compensate for late arrival, at the expense of an increase in delay. Hence it is common to make this buffer, the so-called jitter buffer, adaptive and to have it increase in size if the throughput becomes less reliable. Proper error mitigation is also important, and some coders have this built in, whereas others such as G.711 need external concealment. Due to buffering and other transport delay mechanisms, quite often there is a need for echo cancellation, especially if a speakerphone is used (or the speakers on a PC).

Although it is hard to believe that Internet telephony over the public Internet will replace PSTN services soon, it is a very likely to become a dominant application in corporate networks. Besides the economical advantage of only needing one network structure, these networks are also more carefully managed, thereby making it possible to guarantee a minimum quality of service.

Audio Streaming

There are two popular ways of distributing music over the Internet. *Downloading* is a copying operation from some server containing the original or compressed version of the material. The downloading will typically use the IP/TCP protocol, and one has to wait till all the material has been downloaded before being able to play the music. Once downloaded, the same material can be played repeatedly. The other common form of music distribution is *streaming*, which is very much like radio broadcasting. The material is transmitted to the end user, but the signal is played out almost instantaneously without local storage. Similarly to the VoIP scenario, it is necessary to buffer the packets to compensate for late arrival. Because this is a broadcast or one-way communication scenario, the amount of buffering can be large (a few to 30 s). Although in principle the buffers could be made even larger, this would create large delays before a player produced an audible signal. From a user interface perspective this is undesirable. Hence, sophisticated buffer control has been developed to make sure that continuous throughput is maintained, while maintaining a relatively small buffer. Some streaming services accomplish this by reducing the coder rate temporarily if the average available connection rate cannot support the initial streaming rate.

The compression techniques used are typically based on audio coding algorithms, because most material that is being streamed will be music. For lower rates it is possible that speech-coding algorithms are used instead. A commonly used format is the MP3 (MPEG-1 Layer III) format running at bit rates varying from 64 to 128 kb/s. For streaming applications, it is possible to use proprietary coders, as long as the decoders are available as downloads. However, most content providers will only support one or two formats, and as a result a couple of proprietary standards have become de facto standards. Examples are Apple's Quicktime, Microsoft's Windows Media Player, and RealNetworks' RealPlayer. All of these proprietary coders have a reasonable quality vs. bit rate performance, while trading off other parameters such as delay, complexity, and audio bandwidth. As should be clear from the previous sections, the best quality is obtained at higher bit rates (e.g., 96 to128 kb/s), whereas at lower rates (e.g., 24 to 64 kb/s) tradeoffs will be made by reducing the audio bandwidth, or even switching to mono. It should also be noted that even at the same bit rate and using the same format, differences in quality could exist due to the quality of the source material and the encoder used. For most streaming applications it is important that a variety of rates can be accommodated to support the various connection speeds. It is also important that the decoder have a relative low complexity to allow it to run on the host processor. With the advances in computing speed, this has become less of an issue. However, if these formats are used for downloading in portable players, complexity becomes an issue because it is connected to battery life and cost.

CONCLUSION

This chapter has explained the basics of speech and audio coding and its applications to Internet telephony and Internet streaming. It should be clear that especially for the lower bit rates, there is no single coder that is good for all applications, and that careful tailoring toward the application is important. Speech and audio coding is a mature field, with many available solutions. Based on our current knowledge and the various constraints that exist, it is expected that future developments in this field will focus less on compression efficiency and more on application-specific issues, such as scalability, error robustness, delay, and complexity.

GLOSSARY

Audio compression Reducing the amount of digital information to describe audio and speech signals, while maintaining audio quality as much as possible.

Digitization Creating a digital version of an analog signal by sampling and quantization.

Error mitigation Techniques used to reduce the perceivable impact of transmission errors of a compressed audio signal.

ITU International Telecommunications Union, which sets standards for global communications.

Linear prediction A technique commonly used to remove redundancies in a speech signal.

Lossless compression A compression technique that uses statistical properties of a digital representation to create a compressed version. After decompression the output signal will be equivalent to the input signal.

Lossy compression A compression technique that creates a compressed version of the input signal by taking into account that the decoded audio signal may sound different.

MPEG Motion Picture Experts Group, which sets worldwide standards for media compression.

Perceptually lossless compression A particular subset of lossy compression techniques, in which the differences between input and out signals are not audible.

Quantization Converting an analog value into a discrete digital value.

Quality of service A term commonly used in the context of Internet communications and broadcasting to describe consistency in delivering a particular signal quality.

Sampling frequency The rate at which analog signal samples are digitized. The value of the sampling frequency will be twice the highest possible frequency that can be contained in the signal.

Streaming Delivering audio signals over a packet network for continued broadcasting.

Transcoding Converting from one compressed format to another by decoding and encoding. If the coders used are lossy coders, the transcoding process typically introduces additional degradation.

Standards and Protocols in Data Communications

David E. Cook, *University of Derby, United Kingdom*

INTRODUCTION

This chapter focuses on the importance of open standards in the development of today's interoperable and global Internet. Many definitions are possible but this from the ISO meets our needs:

> Standards are documented agreements containing technical specifications or other precise criteria to be used consistently as rules, guidelines, or definitions of characteristics, to ensure that materials, products, processes and services are fit for their purpose. (ISO, 2002)

Global standards protect users from incompatibility problems between competing suppliers and government-sponsored systems.

While providing an introduction to the most important standards bodies and their historical background in the world of data communications it also discusses the new and emerging multimedia-dominated applications. Several standard protocols for file interchange, in particular those associated with the Internet and electronic commerce (e-commerce), are covered in detail. A variety of applications have been spawned specifically for the Internet as it has matured; these vary from the functionality required for good management to the World Wide Web (WWW). The chapter covers the new and emerging standards associated with e- and m-commerce (mobile commerce). Currently the demand for wireless applications is creating a considerable number of variations on existing protocols and several emerging new ones. These later applications are dependent upon a variety of multimedia approaches to file interchange that have become increasingly popular as Web services. Originally the standards were driven by forces requiring data exchange as a consequence of their businesses; today businesses solely dependent on the presence of exchangeable data have emerged, and it is these that now demand new standards for interoperability. These businesses are those that we now collectively know as e-commerce (Aaron, 1997). They in turn are attempting to accommodate and assimilate into their structures new technologies of a wireless nature under the banner of m-commerce. Therefore, the future of e-commerce on the Internet requires the development of more efficient standards in five areas: security, multimedia, document control standards, banking (e-money), and associated enabling technologies.

Security is still the single most formidable block to the growth of e-commerce. Consumer fears in this area are well founded. Most of these fears are due to Internet fraud and not the inability of technology to provide standards for secure transactions. The use of the secure socket layer (SSL) standard is commonplace and its details are covered elsewhere in this book; however, we briefly consider the major security standards.

Multimedia applications are the key to many online sales and, given increasing availability of bandwidth for mobile devices, this area will grow rapidly. This chapter examines the modifications necessary to the older standards as well as the current developments, particularly MHEG, driven by the Working Group 12 (WG12).

Inevitably the increasing use of mobile applications is forcing the introduction of specific protocols and standards to cope with the rapid growth in this area.

Document control standards are now increasingly needed to cope with the potential for microtransactions across the Web. One of the related problems is how to recognize content providers contributions to multimedia content. This area is being tackled by the Joint Photographic Expert Group (JPEG) and Motion Picture

Expert Group (MPEG) groups. Independently subsets of the standard generalized markup language (SGML) are being developed for electronic document and data-mining purposes.

Electronic banking is not just about the ability to access an account but the need to automatically and securely record transactions, which are increasingly becoming smaller in size and more numerous. The problem here is one of cost efficiency per transaction and the protocols and standards used cannot themselves be allowed to make the transaction prohibitive.

Enabling technologies for the future of the Internet are those concerned with the explosive growth in mobile and wireless applications and subsequently the use of personal networks. Without adequate standards growth will continue to be sporadic.

It is with these emerging technologies that we look to the future and bring the chapter to a close.

The evolution of standards has historically been ad hoc and in the field of communications is known to date back to the Greeks; however, we are not concerned with these early signaling systems but with the advent of electronic communications in the past century. Initially developed as internal mechanisms for developing the owners marketplace the standards have grown in influence from the recognition of the global need to cooperate as corporate bodies outgrew their national boundaries and were forced to allow standards bodies to grow and act independently.

In order to understand the need for standards and the consequent proliferation of standards bodies it is instructive to look at the nature of telecommunications traffic in general. There are fundamentally two contexts, voice and data, with multimedia being a mix of the two. Each of these is carried on a network that may be of two types, circuit switched, e.g., telephone, or packet switched, e.g., the Internet. The consumer end may be fixed, mobile or wireless. This is further complicated by the capabilities of the technologies available at a given time. This was understood by the ITU, who classified into three "generations" the technological advances (IMT-2000, 2000). First generation (1G) is the traditional analog systems, second generation (2G) systems are digital and cellular, and third generation (3G) systems are digital and cellular with higher data transfer rates. At each stage and for each type suitable recognized standards must be available to the service providers so that they can be assured of the structure of their marketplace.

STANDARDS BODIES

No standard will survive for long if there is no organization to support and promote its use. Some of these are supported by government funding but a surprisingly important sector is not. These are voluntary and unpaid collections, not only of companies but also scientists, researchers, and other interested parties. There are several of primary importance to the data communications world and particularly the future of the Internet; this section discusses these key organizations. Perhaps the most important are the ITU and the International Organization for Standardization (ISO).

International Organization for Standardization (ISO)

Established in 1947, the ISO is a collection of national standards bodies from around the world. Each country is allowed one representative standards body as a member and shares in the running costs of the organization. The agreements reached within the ISO are published as agreed international standards (the initials ISO are not an acronym but come from the Greek word "isos," or equal). All technical fields are covered (there are approximately 2850 committees) by ISO except electrical and electronic engineering, which is the responsibility of the International Electrotechnical Commission (IEC). Joint committees formed with the IEC produce standards in the information technology fields.

The Internet

The Internet is extraordinary in the sense that it began (and mainly continues) as a collection of voluntary and, in the main, open bodies collectively determining the current direction and future of the most important networked system in the world today. The Internet Society (ISOC), which was established in 1992 as the need for some control was appreciated, consists of professional Internet experts that concern themselves with policies and oversee a variety of boards and task forces dealing with Internet issues (ISOC, 2002).

Several key associated groupings exist such as the Internet Engineering Task Force (IETF), the Internet Engineering Steering Group (IESG), the Internet Architecture Board (IAB), and the Internet Assigned Numbers Authority (IANA). The IETF is the protocol engineering and development arm of the Internet Society. Although it had existed for some time, the group was formally established by the IAB in 1986. It is this group that proposes protocols for consideration as standards, although it is possible for any organization to do so. This is due to the use of the requests for comments (RFC) process. The technical management of IETF activities is conducted by the IESG, which also has responsibility for the Internet standards process. It guides the standards process according to the procedures that have been published by the ISOC. The IAB, originally known as the Internet Activities Board, first came into being in 1983. It was the guiding force behind the organized approach to the Internet. Under the IAB both the IETF and the IRTF (Internet Research Task Force) were formed in 1986. It was reconstituted in 1992 as the Internet Architecture Board and now serves as the technology advisory group to the Internet Society and as such is responsible for defining the architecture of the Internet. IANA is in charge of all IP (Internet protocol) addresses and any other parameters defined for the Internet. A major part of its task is to ensure the uniqueness of such parameters.

In order to ensure that network research and development was conducted in an open manner the RFC process was formulated in 1969 as a result of the ARPANET development commissioned by the DoD (Department of Defense, USA) for research into networking. Each RFC is assigned a unique identifier no matter what its content. Some were just for fun, e.g., RFC 527 and RFC 968;

however, most are of a serious nature so that the system exists to this day. Of special interest here are those RFCs concerned with standards and codes of practice. The standards process begins with a specification, which undergoes several review phases within the Internet community. These reviews are usually conducted via mailing lists. Each version of the specification is published as an RFC. When the specification becomes a standard it keeps the same RFC but additionally has a label of the form STDxxx. A similar process applies to codes of practice where the label is BCPxxx (best current practice). Each standard must pass through a set of three maturity levels known as the "standards track." They begin life as a "proposed standard," at which level it is assumed they have no known problems or omissions. The second stage requires the specification to have two implementations from two different code bases. Once sufficient successful operational experience has been gained, the level is raised to that of "Internet standard."

Once approved, the RFC editor is informed and it is the editor's responsibility to ensure publication and currency.

The World Wide Web Consortium (W3C)

The World Wide Web is without doubt the most popular application ever to be placed upon the Internet. It consists of multitudes of files scattered across the globe on millions of computers. The Web began life at the European Particle Physics laboratory in 1989 when Tim Berners-Lee wished to exchange data with fellow scientists (Berners-Lee et al., 1994). In 1994 he made agreements between MIT and CERN to develop the Web with support from the European Commission and DARPA. The W3C collects ideas from around the world to form a view of future directions for the WWW. It then designs appropriate Web technologies and contributes to standardization through specifications (recommendations). All of this is offered freely as part of the WC3 stated philosophy. This raises ethical questions when companies attempt to commercialize areas of the Web or its infrastructure. W3C has over 30 working groups working on what it terms as "activities." Their results form the basis for recommendations, some of which are PNG (1996), CSS (1996), XML (1998), DOM (1998), SVG (2001), XHTML (2001), and XML-Signature (2002). For a complete list the reader is referred to the W3C Web site (W3C, 2002).

ATM Forum

Although standards for ATM have been in place since 1984 under the auspices of the ITU-T it was not until 1991 that the ATM forum was established to promote this broadband technology as the packet-switching technology for high-speed data exchange. (ATM is particularly suited to multimedia applications because it allows different data rate streams to operate concurrently.) Like so many of its counterparts the Forum is an international voluntary organization that makes "recommendations."

International Telecommunication Union (ITU)

The ITU is the world's oldest international organization, being first established on 17th May 1865 to manage the early international telegraph networks in Europe. Initially there were 20 European founding states in the International Telegraph Union (ITU); its current name came into effect on 1 January 1934. In 1947 under an agreement with the United Nations, it became a UN specialized agency with headquarters in Geneva. In 1992 the organization was divided into three sectors: Telecommunication Standardization (ITU-T), Radiocommunication (ITU-R), and Telecommunication Development (ITU-D).

The work relevant to the Internet is carried out by study groups that develop new and revised ITU-T recommendations. The ITU-T currently produces some 210 of these recommendations each year.

Commitée Consultatif International Téléphonique et Télégraphique (CCITT)

The CCITT was a separate organization that set international communications standards; it is now part of the ITU. Amongst its more well-known standards are those for fax transmissions, e.g., Group 3 and Group 4, and the V series for communication at lower modem speeds. With respect to the Internet, the CCITT provided X.25, a packet-switching protocol for WANs; X.400, the protocol for e-mail; X.500, an extension to X.400 that defines addressing formats so that e-mail systems can be linked up; and the I xxx series for user interfaces.

INTERNETWORKING MODELS AND LAYERING PROTOCOLS

Standards are necessary to provide interoperability between two network-connected hosts. For this to occur, both hosts must agree on their approach to issues such as call establishment, error correction, and data transfer. This agreement then forms a set of rules that defines a protocol that each peer layer must follow. These rules are formalized as standards, and in order to provide a common framework for these standards a reference model is defined. This section examines the common reference models.

OSI (7-Layer) and TCP/IP Models

The most widely known reference model is that of the Open Systems Interconnections (OSI), referred to commonly as the 7-layer model. It is most often compared directly to the transmission control protocol/Internet protocol (TCP/IP) model and we shall follow the same pattern in this section. For any model the concept of a service provider and receiver is used. Each standard divides the reference model into a number of layers, each of which acts as a service receiver or provider, depending upon the logical state it is in. The OSI reference model was produced by an ISO working group and is occasionally referred to as the ISO model. It is the generic model for all networked systems although other protocol standards use a different number of layers.

In the OSI 7-layer model the following layers are present: physical layer, data link layer, network layer, transport layer, session layer, presentation layer, and the application layer. It is common practice to use the numbers associated with these layers rather than their names;

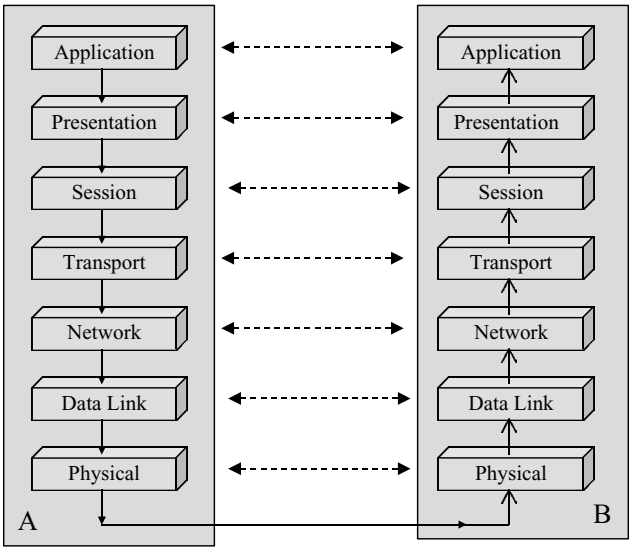

Figure 1: The OSI 7-layer model as applied to two networked hosts, A and B.

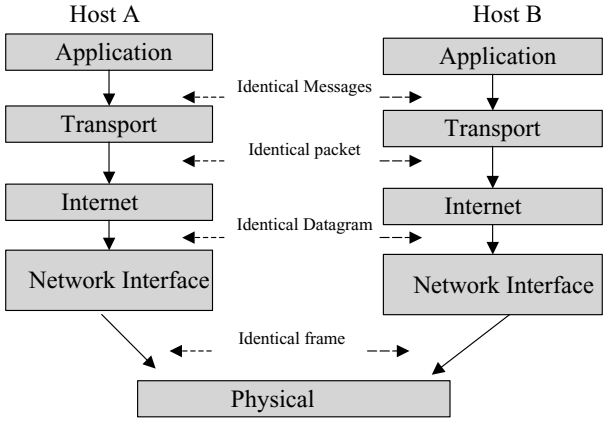

Figure 2: The reference model for TCP/IP. Note the lack of the session and presentation layers.

therefore the physical layer is known as layer 1 and so on. These interact with their corresponding layers across the network on a peer-to-peer basis so that each believes it has direct contact with its own peer layer. This is shown in Figure 1 for a single connection. The fact that each layer conceptually responds to its neighboring layer at the same level allows network connections to operate without the upper layers.

The physical layer (layer 1) defines the physical and electrical characteristics of a network interconnection. These are implemented in the wiring, the connectors, and the network interface cards of the hosts. The data link layer (layer 2) determines how the physical medium is accessed. HDLC, SLIP, and PPP protocols operate in part at this level. For the Ethernet MAC addresses are located at level 2 and this allows a LAN to become aware of its constituent members by their unique hardware addresses. The network layer (layer 3) allows systems using the same protocol to establish, maintain, and terminate connections. The IP protocol operates at the network layer, as do local hardware components such as routers. The transport layer (layer 4) ensures data reliability and integrity (TCP is usually considered to operate at this layer); retransmission requests and packet duplication problems are also resolved. The session layer (layer 5) has responsibility for ensuring sessions are completed without interference when necessary. This is important to e-commerce where the transaction cannot be disturbed by load sharing during its processing. The presentation layer (layer 6) deals with decryption, protocol conversion, and graphics expansion prior to presenting the information to the application layer. Layer 7, the application layer, is the part the user sees and uses. At this layer are applications such as FTP and other packages that require network access.

The TCP/IP structure is similar and due to its earlier commercial support (and support from the DoD in the USA) is the de facto applied standard. (It should be noted that the DoD did eventually formally move to the OSI model.) The structure is shown in Figure 2. See Figure 3 for the TCP/IP version of a network connection via a router (the OSI version is similar).

Each layer provides a recognizable service to the preceding and succeeding layers, which implies structural changes to the message stream if it is to be recognizable by peer layers. At any given layer we require transparency; e.g., each layer believes it alone is involved in the communications process with a peer layer elsewhere.

For the data link layer this requires it to know the physical address of the next destination or source, for the network layer it must know the network address, and for the user a pseudonym for the file is sufficient. This is achieved by a process known as encapsulation. See Figure 4. The original data packet from the TCP has been encapsulated within a datagram by IP, which in turn is enclosed within a frame. Depending upon the final protocol used for transmission at the data link and physical layers the structure may be further modified. The reader is referred to the appropriate chapter for the details.

It is evident that having a common network infrastructure provided by third parties will lead to further protocols and standards that apply to the physical layer of a real system. These parties operate their lines at a variety of speeds that determine the pricing for user access. Since

more than one user may access the same line a variety of multiplexing techniques are used. The following sections discuss some common protocols associated with delivery across nonproprietary networks.

Asynchronous Transfer Mode (ATM)

The ATM design was a response from the integrated services digital network (ISDN) design for a broadband mode to offer packet services to service providers across the digital subscriber networks. As such it is the delivery mechanism for B-ISDN services. It uses small packets or cells of 53 bytes for delivery: 48 bytes for data, 5 bytes for the header. This allows faster routers to be implemented but in order to reduce overhead a virtual connection approach is used.

The ATM reference model defined in CCITT I.321 introduces the concept of planes for different types of functionality, e.g., user, control, and management. Each plane is divided into layers where higher layers follow the OSI model but the lower layers, data link and physical, are replaced by the ATM adaptation layer (AAL), the ATM layer, and the physical layer.

The physical layer converts the ATM cell stream into bits for transfer across the chosen medium. Since ATM was aimed at broadband delivery it is usual to operate at 155.52 Mbps or the higher 622.08-Mbps rates delivered across fiber-optic cable.

The ATM layer provides multiplexing and demultiplexing of cells from different connections into a single stream, implementation of flow control, and management functions.

The ATM adaptation layer segments higher layer data into ATM size cells and vice versa. Several types of AAL have been defined to support different levels of service.

Fibre Distributed Data Interface (FDDI)

The fibre distributed data interface was designed as a very reliable high bandwidth fiber optic LAN. It is configured as a dual ring, thus ensuring continuity of service should one cable fail. Based on the original token ring protocol, IEEE 802.5, it was originally developed by the American Standards Institute (ANSI) working group X3T9.5 in 1982. It was not until 1988 that implementations first appeared. The FDDI reference model replaces the data link and physical link layers of the ISO model and connects to the IEEE 802.2 model logical link layer (LLC). Figure 5 shows the four layers peculiar to the FDDI, e.g.,the medium access control (MAC), the Physical, the Physical Layer Medium Dependent, and the Station Management layer.

The following is a brief description of the relevant layers:

The MAC layer controls network access and is defined in ISO 9314-2 "Information Processing Systems: Fiber Distributed Data Interface Part 2: Token Ring MAC."

The physical layer determines encoding and decoding and the clocking of the data stream to the line. Simply, it is responsible for the moving of the actual stream of 1's and 0's from host to host. It is defined by ISO 9314-1 "Information Processing Systems: Fiber Distributed Data Interface Part 1: Token Ring Physical Layer."

The physical layer medium dependent layer provides the actual connection to the ring and is defined in ISO 9314-3 "Information Processing Systems: Fiber Distributed Data Interface Part 3: Token Ring Physical layer Medium Dependent."

The station management layer functions are necessary for the control, supervision, and management of the connected stations. Its purpose at the network level is addressing and configuration.

Integrated Services Digital Network (ISDN)

The ISDN services were introduced in the 1980s to provide PSTN users with the opportunity to access services other than telephony. Initially converting analog service to digital it soon became apparent that a broadband service would be required (ISDN originally provided up to 2 Mbps, or 30 × 64 kbps channels). This was introduced as B-ISDN and initially used synchronous transfer mode due to technology limitations; in 1988 ATM was chosen as the carrier (see Asynchronous Transfer Mode (ATM)). It is the responsibility of the ITU CCITT group XV111.

TCP/IP PROTOCOL SUITES

The TCP/IP protocol is covered in detail elsewhere within this chapter. Also see Black (1995). Here we will briefly look at its origins and pay particular attention to its use and that of associated protocols on the Internet and in e-commerce. Although now universally known as two separate entities, TCP/IP began life in 1974 when Vint Cerf and Bob Kahn published "A Protocol for Packet Network Interconnection," which specified the design of a transmission control program (TCP) (Cerf & Kahn, 1974).

TCP/IP were split in 1978 and recognized as separate entities in 1982 when formally established as the ARPANET protocol. The IP has become the de facto standard for packet-switched transport across the Internet.

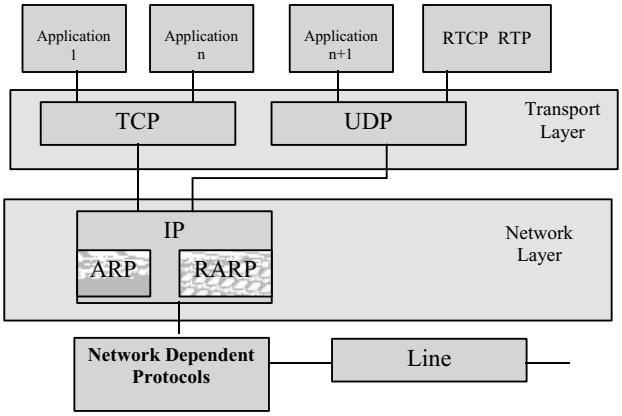

Figure 6: Relative levels of common Internet protocols.

Functionally, it is a connectionless protocol and relies on best-effort service. Although this provides a simple solution to a short message system over very reliable networks, it has problems when operating over public services.

Associated with the IP are several well-known service-providing protocols that operate at and above the network layer as defined by the ISO 7-layer model. They are the transmission control protocol (TCP), user datagram protocol (UDP), real-time transport protocol (RTP), and the real-time transport control protocol (RTCP). See Figure 6 for their relative positions in the reference model.

Transmission control protocol is offered as a connection-orientated service to the user at the transport layer. The user believes they have a permanent connection to the desired endpoint. The purpose of TCP is to provide application protocols with network-independent information exchange services.

User datagram protocol provides a connectionless service to application protocols. It is particularly useful for short message reporting.

The advent of the Web and multimedia content has provided a demand for real-time services across the Internet and hence via IP. The real-time transport protocol is able to transfer data types such as audio and video where real-time characteristics are required; however, it does not guarantee sequence delivery, error correction, or quality of service (QoS).

The real-time transport control protocol was designed for control of processes involved in conference calls. It can provide synchronization, framing, error detection, and source identification. It can also monitor the QoS. Both the RTP and RTCP protocols may be considered complementary and use separate ports; hence, they may be used together.

The Internet has grown as a collection of cooperative networks, each initially with its own addressing scheme. These became unified and where necessary correspondences between hardware addresses and Internet addresses are resolved and stored using the address resolution protocols (ARP) and the reverse address resolution protocols (RARP). Ultimately these addresses must be communicated to other networks so that data can be transferred. Thus devices known as routers are required. The routers calculate the most efficient path to a given address using the interior gateway protocol (IGP) within local groups. In order to check the availability of other routers outside the local group an exterior gateway protocol (EGP) is used.

Multicast and Unicast Control Protocols

It is often a requirement that more than one recipient receive a message or that more than one user are involved in a connection, e.g., conference calls. One such protocol is the Internet group management protocol (IGMP). IGMP is defined in RFC 1112. It is used to allow joining and leaving of multicast groups. Routers involved in multicasts periodically send membership queries to determine who is on the Net for that group. If a response is received, in the form of a report from a host detailing membership of groups, this is recorded for the forwarding of group messages.

IPv6 and the Future

It is only in the past ten years that the home user has become a major source of traffic on the Internet. This has led to an explosive growth in Internet address requests. The IETF has defined in RFCs 1883–7 a new version of the Internet protocol, IPv6, to replace the current version, IPv4. This has increased the address space to 128 bits from 32 bits. This new version addresses several other areas of concern. Amongst these are the introduction of improved security and data integrity, the ability of a host to acquire automatically an IP address without human assistance (this is particularly important to mobile applications), and better quality of service guarantees for multimedia applications.

INTERNET APPLICATIONS AND THEIR PROTOCOLS

The Internet is often seen as synonymous with the TCP/IP protocol suite and closely related protocols; however, many other protocols exist at various layers for specific purposes. This section looks at a few not covered elsewhere. It is interesting to note that DARPA in 1973 put the number of networks at over 7500. Currently according to figures obtained from the May 2002 Netcraft surveys (Netcraft, 2002) the number of active server sites now stands at 15.5 million. This level of use would not have occurred without the many applications that became available, the most famous of which is the WWW.

File Access (FTP, Telnet, NFS)

The Internet could not be the success it is without the early file access and transfer utilities and a supporting file structure standard known as the network file structure (NFS). Details of these application and support protocols may be found in RFCs 1122 and 1123. The file transfer protocol (FTP) is still considered the primary standard for file transfers on the Internet (as opposed to Web page delivery, which does not provide a local copy explicitly).

Remote access of files presupposes the ability to log onto the remote machine. This is catered for by Telnet, which is specified in RFC 854.Other log-in protocols such

as rlogin are available, and command shells such as rsh simplify access. More recently a secure shell known as SSH has become available. This ensures encryption is used to protect networks from hackers when logging on.

The World Wide Web (HTTP, HTML)

The original data transfer method for network use was FTP; however, with the advent of the WWW and the hypertext transfer protocol (HTTP), a different approach was possible. Now users could specify content for provision via a Web server as pages rather than files of material. HTTP therefore only needs to transfer the content of the page into the local Web browser for viewing. In this sense it is a one-way device, whereas FTP allows the file to be transferred, modified, and returned. Hypertext markup language (HTML) is the document-structuring language used by content creators on the WWW to create Web pages. It is a tag-structured language; although not strictly compliant as a subset of SGML, it is similar in concept.

The Next Generation (XML, SOAP, .NET)

The W3C is actively developing new features and services for the WWW, several of which are subsets of the SGML standard. Using HTML the content provider has restrictions on how they control their pages, which are set by HTML itself. Using the extensible markup language (XML) users can create their own tags. XML allows the definition, transmission, and interpretation of these data between applications. The proposed standard simple object access protocol (SOAP) was developed by Microsoft in conjunction with other software vendors as a way of adding document object models (DOMs) to standard HTTP streams. This effectively violates the purpose and intent of firewalls. Currently Microsoft is offering an OS known as .NET, which is specifically designed to operate as a distributed Web-based operating system. This will lead to the concept of paying for use of software as required since it will be downloaded from the relevant Web site on demand.

Emerging Multimedia Protocol Standards

Multimedia is now a common application format across all Internet-enabled devices; however, the needs of such data combinations of graphics, text, audio, and video are different from those historically associated with the Net. For an excellent introduction to the subject the reader is referred to Halsall (2001). Some of these needs are the following:

The audio and video must meet deadlines or defined time intervals or the user will experience indeterminate delays.

Variation in timings (jitter) must be bounded to avoid large buffers being needed to smooth the flow of data.

Multicast is a requirement for cooperative work and video conferencing.

Mechanisms are needed for synchronizing different data streams.

A current standard that addresses the needs of audio is known as MIDI.

The MHEG (Multimedia and Hypermedia Information Coding Expert Group) are one of several working groups of the ISO currently looking at standards for multimedia application use. The ISO/IEC JTC1/SC29 committee (Coding of Audio, Picture, Multimedia, and Hypermedia Information) carries overall responsibility for three working groups: WG1 Coding of Still Pictures (JBIG/JPEG), WG11 Coding of Moving Pictures and Associated Audio (MPEG), and WG12 Coding of Multimedia and Hypermedia Information (MHEG). Both the MPEG (Motion Picture Expert Group) and the JPEG (Joint Photographic Expert Group) are of particular importance to the multimedia world and the future of automated content costing for e-commerce use.

E-COMMERCE ENABLING PROTOCOLS

SSL/TLS and HTTP

Transactions over the Web for e-commerce require complete security if customer confidence is to be maintained. Without the assurance that others will not be able to access account details no potential e-commerce transaction will take place. Little can be done to stop certain types of fraud such as the nonexistence of goods for sale but the network transaction itself must be seen as secure. Several schemes exist but the secure socket layer (SSL) protocol, which lies in the session layer of the OSI model, provides authentication services for the client or the server. Full details of these services can be found in another chapter.

All e-commerce transactions require the transfer of documents of some kind. This implies that not only the content but also the structure should be exchanged. It is reasonable to require these structures, or document architectures, be the same at both ends of the network connection, hence the need for standards. The two current popular standards are the SGML and the open document architecture (ODA). A well-known application standard from typesetting is postscript. These document control systems have become increasingly important with the advent of the WWW and multimedia applications, and have coined the terms hypermedia and hypertext due to their abstract manner of access. The exchange format for multimedia is MHEG. Different task forces are working on the standards for hypermedia; amongst these are ISO/IEC JTC1 SC2/WG12 MHEG for coded representations of multimedia and hypermedia, the ANSI X2V1.8M for the Music Information Processing Committee, and the Standard Music Description Language (SMDL).

SGML (ISO 887) is a tag-based system, which means the standard specifies the form of the tags but user groups determine their position and meaning. The most famous application is HTML, which is understood across the WWW.

Emerging Mobile E-commerce Protocols

The ubiquitous use of mobile phones has provided the opportunity for Internet-based e-commerce applications to grow as an independent market area. Traditionally the main content for the telephone companies was voice; however, this has changed to data. A similar change is occurring with mobile traffic. Initially almost entirely voice,

the channels are now providing mixed voice and data channels. The Web has provided a mountain of content, which is a ready source for use in wireless communications. Many organizations now have Internet sites capable of supporting mobile applications, and wireless intranets are becoming more common. A typical use for these is in the reuse of historic buildings where new wiring is problematic or may not be allowed. A wireless intranet provides a cost-effective solution. This particular approach is currently being implemented in the University of Derby, England, at its Royal Devonshire Hospital campus in Buxton, which is governed by the specifications of the English Heritage Society. Efficient and common protocol standards are important if continued development is to be possible.

Currently the mobile phone services rely on the short message service (SMS) or WAP; however, the availability of wider bandwidth is encouraging the use of standards such as I-Mode from Japan, which is finding increasing favor in Europe. This is possible because national governments have made certain frequency allocations available for commercial use. Radio-frequency band usage varies from country to country due to historical reasons; however, they are sufficiently similar for standards to be set across national boundaries, for example, in the United States 2.4000–2.4835 GHz, in Europe 2.4000–2.4835 GHz (some variation), and in Japan 2.471–2.497 GHz.

The Institute of Electrical and Electronics Engineers (IEEE) instituted a working group known as IEEE 802.11 to create the current wireless LAN standards. The original standard had a signaling rate of 1–2 Mbps. Two variants rapidly followed, 802.11a and b. Surprisingly 802.11a operates at the higher frequency 5–6 GHz and has the greatest potential for supporting higher bandwidths (54 Mbps). 802.11b operates at 2.4 GHz and 11 Mbps. Each has their own supporters; however, 802.11b is rapidly becoming the accepted commercial standard.

802.11a products are currently expensive, and have high-power consumption. They are not compatible with 802.11b devices due to their different radio frequencies. 802.11b was named as Wi-Fi by the Wireless Ethernet Compatibility Alliance (WECA), an organization founded by commercial interests (3Com, Aironet (acquired by Cisco), Intersil, Lucent, Nokia, and Symbol) to promote Wi-Fi as a wireless standard. 802.11b products are generally backward compatible with 802.11 products. Several improvements have been made to security (802.11i), for use for multimedia (802.11e), and for higher bandwidths at the lower frequency range (802.11g). This latter works with the older wireless networking technology, 802.11b, allowing users to keep existing equipment and aimed at increasing the number of wireless connections in homes and businesses.

CONCLUSION

This chapter has tried to introduce the reader to the great variety of protocols and standards that have impacted the growth of the Internet. It is not possible to cover them all in the space provided; therefore, I have focused on those that have or will have the greatest impact on the development of the Internet. This chapter discussed the new and emerging standards associated with e- and m-commerce. This is an area where standards will continue to develop as the concepts of electronic shopping malls become more popular and e-banking becomes the norm. Wireless applications are in their Internet infancy and awaiting broader bandwidths. As this becomes available the scope for applications on a cost-per-view basis will increase. Of particular interest for the future are the attempts to commercialize WWW by offering software, which relies on the WWW's free infrastructure to be viable, on a pay-per-use basis. These in turn will need new protocols and standards to deal with transaction processing. These later applications are dependent upon a variety of multimedia approaches to file interchange, which is still an area of protocol research and development. Standards by their nature develop, mature, and die, to be replaced with versions more appropriate to their age.

Storage Area Networks (SANs)

Vladimir V. Riabov, *Rivier College*

INTRODUCTION

The volume and value of enterprise data have been growing faster than the speed at which traditional backup company utilities have been increasing. Enterprises have become more dependent on their online systems and cannot ensure the availability of these data by relying only on traditional, network-bottlenecked, server-attached storage systems. Solutions to this problem have been offered by SAN technology, which provides enterprises with serverless zero-time-windows backup. In this new backup approach, backed-up data are removed to a secondary remote storage device, and the enterprise server becomes off-loaded, permitting high-performance continuous access to both applications and data. A SAN fabric is usually based on fibre channel technology that allows up to 10-km long-distance connections. This feature has a significant advantage in a campus environment where reliable backup resources can be shared among several divisions. For example, fibre channel SANs for the Healthcare Enterprise allow 24 × 7 continuous operation, patient record backup, and medical image archiving (Farley, 2001).

The SAN becomes a key element of the enterprise environment where data availability, serviceability, and reliability are critical for a company's business. Many enterprise solutions (e.g., ATTO FibreBridge products, rack mount solutions, ATTO FibreCenter3400R/D, host bus adapters, the ATTO Diamond array, Compaq StorageWorks products, EMC Connectrix solutions, LSI Logic E4600 Storage System) are available today. They can be effectively used in multiple platform storage-infrastructure solutions for data-intensive applications such as e-commerce, online transaction processing, electronic vaulting, data warehousing, data mining, Internet/intranet browsing, multimedia audio/video editing, HDTV streaming, and enterprise database managing applications.

This chapter describes fundamentals of storage area networks (SANs), their architectural elements (interfaces, interconnects, and fabrics), technologies (fibre channel-arbitrated loop transport protocol, Brocade's configurations, InfiniBand switched-fabric architecture, crossroad systems with a storage router, virtual interface architecture, direct access file system, IP storage technologies, SANs over IP, fibre channel over IP, Internet fibre channel protocol, Internet SCSI, storage over IP, fabric shortest path first protocol, storage resource management, and adaptive network storage architecture), solutions, standards, associations, initiatives, forums, coalitions, vendors, and service providers.

SAN FUNDAMENTALS

What Is a SAN?

A SAN (*storage area network*) is a networked high-speed infrastructure (subnetwork) that establishes direct access by servers to an interconnected group of heterogeneous storage devices such as optical disks, RAID arrays, and tape backups, which are effective for storing large amounts of information and backing up data online in e-commerce, online transaction processing, electronic

vaulting, data warehousing, data mining, multimedia Internet/intranet browsing, and enterprise database managing applications. SANs provide additional capabilities (fault tolerance, remote management, clustering, and topological flexibility) to mission-critical, data-intensive applications. A SAN is typically a part of an enterprise network of computing resources (Sachdev & Arunkundram, 2002). A simple model of the storage area network as a networked high-speed infrastructure is shown in Figure 1.

A SAN can be considered as an extended and shared storage bus within a data center, consisting of various storage devices and specific interfaces (e.g., fibre channel, ESCON, HIPPI, SCSI, or SSA) rather than the Ethernet (Peterson, 1998). In order to be connected to the enterprise network, the SAN utilizes technologies similar to those of LANs and WANs: switches, routers, gateways, and hubs (see Figure 1). Wide area network carrier technologies, such as asynchronous transfer mode (ATM) or synchronous optical networks, can be used for remote archival data storing and backup. As an important element of modern distributed networking architectures of storage-centric enterprise information processing, SAN technology represents a significant step toward a fully networked secure data storage infrastructure that is radically different from traditional server-attached storage (Clark, 1999). In addition, SANs provide improved options for network storages, such as a creation of remote or local, dedicated or shared data storage networks with access capability faster than *network attached storage* (NAS).

SANs are based on the storage-centric information-processing paradigm, which enables any-to-any connectivity of computers (servers) and storage devices over a high-speed enterprise network of interconnected fibre channel switches that form the SAN fabric. The incidence of unconnected clusters of information is eliminated or significantly reduced by SANs. According to this concept, a SAN resides behind the server and provides any users or devices on the enterprise network ("clients") with fast access to an array of data storage devices. It can be viewed as multihost connected-and-shared enterprise storage. Adding new storage devices and server elements resolves traditional network-bottlenecks and small-scale problems of interfaces, such as the small computer systems interface (SCSI) and network attached storage (NAS), and

can easily expand the scale of the SAN (Thornburgh & Schoenborn, 2001). Another advantage of SAN technology is that backups can be made over the SAN fibre channel subnet, and, in this case, backup traffic is totally removed from the enterprise network.

The SAN represents a new segment of the information services industry called storage solution providers (SSP). However, isolated SANs cannot realize SSPs' services, such as real-time data replication, failover, storage hosting, and remote vaulting.

Benefits of SANs

A SAN makes physical storage capacity a single, scalable resource and allows the flexible allocation of virtualized storage volumes (e.g., RAIDs, JBODs, and EMC, SUN, and DELL storage devices). The SAN can manage backup tasks that were a huge administrative and computer-resource burden under old storage architectures. The storage management cost savings can be higher than 80%. A cost-effective, scalable SAN enhances overall system performance. It can integrate legacy SCSI devices, which allows increasing their system-wide effective usable capacity by up to 30% (InfraStor, 2002).

SANs are an integral part of a large financial services enterprise, ISP, government organization, research laboratory, electronic publisher, digital video production group, TV-broadcasting station moving to digital services, or educational institution, or any organization with increasing data storage needs.

There are several key reasons for implementing a SAN (InfraStor, 2002). The first three concern business issues of return on the investment in data storage, as well as the protection of existing investments:

SANs are cost-effective (reduced cost of storage management, including backup and recovery; increased user productivity; cost-effective implementations of high availability disaster protection, using remote clusters and remote mirrored arrays);

SANs reduce business risk (faster disaster recovery; reduced revenue loss from down-time; reduced lost-opportunity costs);

Legacy investments are protected (SANs can be implemented without abandoning existing storage infrastructures such as devices using SCSI connections).

The next four address critical technical issues that face data-center managers at a time when the volume of data to be managed and made available in many organizations is increasing at a 60% annual rate (InfraStor, 2002):

SANs provide scalability (add servers and storage independently);

SANs allow flexibility (reconfigure storage and servers dynamically without interrupting their services; load sharing and redistribution);

SANs enhance overall system performance (more effective use of existing server compute cycles; real-time backup without impacting LAN/WAN; multiple server-to-storage paths; networked storage arrays that can outperform bus-attached storage; compatibility with parallelized database applications);

SANs are an integral part of any high-availability plan (facilitation of shared on-line spares and remote backup or mirroring; reduced down-time requirements; storage independent of the application and accessible through alternate data paths such as found in clustered systems).

The implementation of a SAN can realize significant overall cost savings in data-center operations and can increase user productivity. The opportunity to avoid escalating costs depends on decentralization of data and applications. A key element in the consolidation of data storage must include the implementation of a basic SAN infrastructure in order to provide (InfraStor, 2002) the following:

Bandwidth to service clients;

Maintenance of data availability without impacting LAN bandwidth;

Scalability for long term, rapid growth with protection of legacy investments;

Flexibility to provide optimum balance of server and storage capacity;

Manageability for ease of installation and maintainability;

Shared access to data resources for real-time backup and recovery.

Distributed environments require high-cost maintenance in terms of staff resources. The consolidation of distributed NT-based storages to a virtualized SAN-based resource can save 80% or more of the costs of management (InfraStor, 2002).

SAN Applications

SAN applications cover the following areas of data transfer (Peterson, 1998): (1) the externalization of data storage out of the server-SAN-attached-storage (SAS) and NAS-with-SAN-interconnects network architectures; (2) clustering, a redundant process that provides failover, high availability, performance, and scalability through the use of multiple servers as a data pipe and allows data storage resources to be shared; (3) data protection solutions for backup, remote clustering, file mirroring, and replicating and journaling file systems by creating data storage redundancy on a dynamic basis; (4) data vaulting, which is the process of transferring archived data to less expensive media; (5) data interchange from one storage system to another or between different environments; and (6) disaster recovery, which is similar to data interchange, moving copies of data offsite, and is built on remote vaulting (backup) processes or on remote array mirroring or clustering. Several new applications benefit from 2 Gb/s fiber channel SANs (Hammond-Doel, 2001): multimedia audio/video servers that provide the ability to stream higher resolution files, medical imaging, prepress that speeds up design and file preparation, and video editing of uncompressed HDTV data.

The first effective application of SANs has been serverless backup, which provides enterprises with full-time

information availability. All backup-related tasks have been relegated to the SAN. Large enterprises can store and manage huge amounts of information (several terabytes or more) in the SAN high-performance environment. Enterprise servers are connected to storage devices (e.g., RAID arrays) via a high-speed interconnection, such as fibre channel. The SAN any-to-any communication principle provides the ability to share storage resources and alternative paths from server to data storage device. A SAN is also able to share the resources among several consolidated servers.

A cluster of interconnected servers may be connected to common storage devices in the SAN environment and be accessible to all clients. Modern enterprises employ this clustering technology to resolve several challenging application problems (Barker & Massiglia, 2001, p. 244), i.e., providing customers, partners, and employees with *continuous* application service, even if the enterprise systems fail, and supporting application performance growth as demand grows, without service disruption to customers. Clusters provide load balancing, high availability, and fault tolerance and support application scaling. In some implementations, the clustered servers can be managed from a single console. Clustering methodology is effectively used in e-commerce, online transaction processing, and other Web applications, which handle a high volume of requests.

SAN methodology has its roots in two low-cost technologies: SCSI-based storage and the NAS-based concept. They both successfully implement storage-network links, but are limited to a low volume of data flows and rates. SCSI still remains the most popular "bus-attached" server–storage connection in SAN-attached storage (SAS) systems, especially at the stage of transition from SCSI bus devices to fibre–channel switches using the SCSI-fibre protocol converter in a new enterprise storage ("data center") environment. In the network attached storage (NAS) system, storage elements (i.e., a disk array) are attached directly to any type of network via a LAN interface (e.g., Ethernet) and provide file access services to computer systems. If the NAS elements are connected to SANs, they can be considered as members of the SAN-attached storage (SAS) system. The stored data may be accessed by a host computer system using file access protocols such as *NFS* or *CIFS*.

SANs provide high-bandwidth block storage access over long distance via extended fiber channel links. However, such links are generally restricted to connections between data centers. NAS access is less restricted by physical distance because communications are via TCP/IP (InfraStor, 2001). NAS controls simple access to files via a standard TCP/IP link. A SAN provides storage access to client devices, but does not impose any inherent restrictions on the operating system or file system that may be used. For this reason, SANs are well suited to high-bandwidth storage access by transaction-processing and DBMS applications that manage storage access by themselves. NAS, which has the inherent ability to provide shared file-level access to multiple OS environments, is well suited for such requirements as Web file services, CAD file access by combined WinNT/2000, UNIX, and LINUX devices, and wide-area streaming video distribution (InfraStor, 2001). A balanced combination of these approaches will dominate in the future.

SAN Architecture

The SANs architectures have been changed evolutionarily, adapting to new application demands and expanding capacities. The original fibre-channel-based SANs were simple loop configurations based on the fibre channel arbitrated loop (FC-AP) standard. Requirements of scalability and new functionality had transformed SANs into fabric-based switching systems. Numerous vendors offered different solutions of problems based on fabric switching. As a result, immature standards created various interoperability problems. Homogeneous high-cost SANs were developed. Ottem (Ottem, 2001) refers to this phase as the legacy proprietary fabric switch phase. The latest architectural approach is associated with a standards-based "Open" 2Gb fabric switch that provides all the benefits of fabric switching, but based on new industry standards (FC-SW-2) and interoperability architecture that runs at twice the speed of legacy fabric. The standards-based switches provide heterogeneous capability. The latest feature reduces prices of the SAN's components and management costs of running a SAN. Characteristics of three generations of SANs are summarized in Table 1.

The Open 2Gb fibre channel allows doubled SAN speeds, enables greater flexibility in configuring SANs for a wide range of applications, and is especially useful for managing 1.5-Gb high-definition video data. In the HDTV applications, a single fibre can carry a full high-definition video stream without having to cache, buffer, or compress the data. Other examples (Ottem, 2001) include storage service providers that must deliver block data from to users at the highest possible speeds and e-commerce companies that have to minimize transaction times. The 2-Gb fibre channel provides the high-speed backbone capability for fibre channel networks, which can be used to interconnect two SAN switches. This configuration increase overall data throughput across the SAN even if servers and disk subsystems continue to operate via 1-Gb channels.

A SAN system consists of software and hardware components that establish logical and physical paths between stored data and applications that request them (Sheldon, 2001). The data transforms, which are located on the paths from storage device to application, are the four main abstract components (Barker & Massiglia, 2001, p. 128): the *disks* (viewed through ESCON, FCP, HIPPI, SCSI, and SSA interfaces as abstract entities), *volumes* (logical/virtual disk-like storage entities that provide their clients with identified storage blocks of persistent/retrieved data), *file systems*, and application-independent *database management systems*. In a system with a storage area network, five different combinations (Barker & Massiglia, 2001) of these data transforms and corresponding transformation paths serve different applications and system architectures by various physical system elements. The disk abstraction is actually the physical disk drive. The abstract volume entity is realized as an external or embedded RAID controller, as an out-of-band or in-band SAN appliance, or as a volume manager

serving a database or an application. Storage servers (such as NAS devices), database servers, and application servers may contain the abstract file systems. These devices and servers can be clustered to increase scaling and application availability. In that case, their volume file and management systems should be cluster-aware (Barker & Massiglia, 2001).

Any SAN-based client–server system consists of three architectural components: *interfaces*, *interconnects* or *network infrastructure components* (switches, hubs, routers bridges, gateways, multiplexors, extenders, and directors), and *fabrics*. The SAN interfaces are fibre channel, ESCON, HIPPI, SCSI, and SSA. The SAN interconnects link these storage interfaces together, making various network configurations. Routers and bridges perform protocol transformation in SANs. Switches increase the overall SAN bandwidth by connecting system elements for data transmission and allow advantages of the centralized storage repositories with the shared applications and central management. The most common SAN fabrics are switched fibre channel, switched SCSI, and switched SSA, all of which physically link the interconnects and determine the SAN's performance and scalability. Some fabrics embed operating systems that provide for SAN security, monitoring, and management. Hosts are connected to the fibre channel SAN through host bus adapters (HBAs), which consist of hardware and interface drivers. Fibre channel HBAs support negotiation with network-attached devices and switches and allow the host to minimize its CPU overhead.

SAN Operating System Software Components

The SAN software plays an important role in providing an environment for various business and management applications, called *system applications* (Barker & Massiglia, 2001, p. 13), such as clustering, data replication, and data copying. The *management applications* (zoning, device discovery, allocation, RAID subsystems, and others) manage the complex environment of distributed systems. These applications can significantly reduce the cost and improve the quality of enterprise information services.

SAN TECHNOLOGIES AND SOLUTIONS

The SAN infrastructures support multiple protocols, such as SCSI, SNMP, VI, ESCON/FICON, TCP/IP, and SSAIP, over a single physical connection. This unique capability provides the SAN system with a coupled functionality of an interface to storage devices and a server interconnect.

In the early 1990s, fibre channel was developed by the Fibre Channel Systems Initiative (FCSI) and adopted later by the ANSI X3T11 Committee as a high-speed interface for connecting storage devices to servers and other network configurations. These interconnect standards provide SANs with the vital properties of connectivity, bandwidth, interconnectivity, protocol efficiency, distance range, recoverability, failure tolerance, and cost options. The fibre channel standards specify electrical and optical transmission media, as well as conventions for signaling and transmission/functional protocols. Optical medium (with SC, LC, and MT-RJ connectors) supports reliable signaling over long distances. Fibre channel provides data rates in the range from 133 Mbit/s to 4 Gbit/s over low-cost copper cabling (shielded twisted-pair wire or coaxial cable with DB-9 and HSSDC connectors) or higher-cost multimode fiber-optic cable. Fibre channel fabrics have transceivers, called gigabit interface converters (GBICs), which convert optical to electrical signals to cable connectors. The fibre channel technology supports distances up to 10 km.

Fibre-Channel-Arbitrated Loop Transport Protocol (FC-AL)

The fibre channel methodology has means to implement three topologies: point-to-point links, arbitrated loops (shared bandwidth loop circuits), and bandwidth-switched fabrics that provide SANs with the ability to do

bandwidth multiplexing by supporting simultaneous data transmission between various pairs of devices. Any storage device on the loop can be accessed through a fibre channel switch (FCSW) or hub. The fibre channel switch can support entry-level (8–16 ports) to enterprise-level (64–128 ports) systems. Under the ANSI X3T11 standards regulation, up to 126 storage devices (nodes) can be linked in the fiber channel arbitrated loop (FC-AL) configuration, with the storage interface bandwidth about 100 Mbits/s for transferring large files. More than 70 companies, including industry-leading vendors of disk arrays and computer and networking systems, support the FC-AL voluntary standards. The FC-AL topology is used primarily to connect disk arrays and FC devices. Originally developed as the high-speed serial technology of choice for server–storage connectivity, the FC-AL methodology is extended to the FC-SL standard that supports isochronous and time-deterministic services, including methods of managing loop operational parameters and QoS definitions, as well as control. The FC-VI regulation establishes a fibre channel-virtual interface architecture (FC-VIA) mapping standard. See the chapter on fibre channels for more information about various implementations of the technology in various network configurations, including SANs.

Because of the high cost of the FC interconnect components and separation of storage and servers at the wide area network scale (resulting in slow capabilities of WAN–SANs with fibre channel), alternatives to FC technologies have been developed. The *ipStorage* technology (Barker & Massiglia, 2001, p. 187) employs TCP/IP as a storage interconnect. The Internet Engineering Task Force (IETF) has proposed the iSCSI (*Internet SCSI*) standards that address the issues of long distances (WAN-scale), reducing the interconnect cost, high security, and complex storage network topologies. The iSCSI is layered on top of the TCP/IP protocol hierarchy and can instantly access all modern transmission media and topologies. TCP/IP and related protocols have been implemented in the server-based systems that allow the most general storage networks to be constructed with the iSCSI methodology. The main challenge is a reduction of the iSCSI processor overhead of operating iSCSI packets below the Fibre Channel overhead level.

InfiniBand Solutions

InfiniBand is a new emerging interconnect technology, developed by the standards of the InfiniBand Trade Association (founded by Compaq, Dell, Hewlett-Packard, IBM, Intel, Microsoft, and Sun Microsystems) that offers the most general low-cost server system topologies (InfiniBand Trade Association, 2003). It is expected that InfiniBand interfaces will be embedded into all Intel-based servers (Barker & Massiglia, 2001, pp. 188–192; Intel InfiniBand Architecture, 2003) and will allow Windows and Linux servers to be available for resolving complex problems of data centers by adopting clusters and multihost enterprise RAID subsystems. The InfiniBand technology implements a switched-fabric architecture with the packet-switching communication protocol (PSCP) that relates to the virtual interface (VI) architecture methodology. SANs, parallel processing systems, and systems area networks can effectively use InfiniBand as a high-performance/low-latency interconnect.

Crossroads Systems With a Storage Router

InfiniBand technology has been successfully implemented by Crossroads Systems, Inc., which promotes storage solutions based on protocol-independent connectivity at Gigabit/s speeds and unparalleled manageability for various storage devices. The Crossroads' storage routers (e.g., Crossroads™ 10000) support peer operations between storage devices and multiprotocol servers on fibre channel storage networks.

Brocade's Configurations

Brocade Communication Systems, Inc., has developed an intelligent fabric services architecture that creates a scalable and secure environment for enterprise mission-critical storage applications such as data backup and business continuity. The Brocade SANs (SilkWorm™ family of fabric switches and software) provide enterprises with any-server-to-any-storage-device connectivity and consolidate storage resources and servers, as well as sharing backup resources (Beauchamp, Judd, & Kuo, 2002).

OTHER STORAGE NETWORKING TECHNOLOGIES

The following emerging technologies introduce new system architectural approaches in storage networking. SAN developers and users are trying to adapt them to a new enterprise environment that is characterized by host-level heterogeneous complexity, management flexibility, new TCP/IP network communication services, file-access-protocol developments, and the repartitioning of the functionality of the file management systems.

VI (Virtual Interface) Architecture

The virtual interface (VI) architecture is a midlayer protocol specification that regulates virtual intercommunication between applications running on different remote servers (i.e., in a cluster). This methodology significantly reduces the latency and the volume of the system I/O operations by using message and data buffer pools that are insensitive to heterogeneous operating environment or other applications. The reduction of the I/O-related interrupts increases the CPUs' time for processing various other system tasks. Developers of the VIA technology (Compaq, Intel, Microsoft, etc.) utilize this architecture as an efficient way of message communication between the SAN nodes at the application level, creating only a small overhead of intercommunication between the remote applications. This methodology has been successfully implemented in database managers and NAS devices (Barker & Massiglia, 2001, pp. 189–190). Several efforts (i.e., the Direct Access File System and Network File System initiatives) have been made to improve file system performance by utilizing VIA-type advanced transport protocol features. The Emulex Corporation promotes the GN9000/VI™ 1 Gb/s VI/IP PCI host bus adapter, which

is based on the virtual interface (version 1.0) architecture, supports standard TCP/IP-reliable data delivery, IP routing, and the direct access file system (DAFS) standard, and speeds data access over standard Gigabit Ethernet networks.

Direct Access File System (DAFS)

The direct access file system is a new file access/transfer protocol that is based on CIFS/NFS characteristics and VIA-type transport protocol features. DAFS/VIA technology supports direct file transferring between the storage system and clients. In the SAN environment, data can be directly transferred among a number of servers.

IP Storage Technologies

Another *block-mode data* mechanism has been used by the IETF IP Storage Working Group in developing standards for a new IP-based transport-through-network technology that encapsulates fibre channel and SCSI high-speed interfaces and provides direct access to data on disks, tapes, and optical storage devices. IP storage technology allows embedding low-cost SANs into IP-based enterprise infrastructures over existing Gigabit Ethernet networks.

SANs Over IP

To avoid the distance limitation of the fibre channel interconnects, enterprises build remote SANs that can be interconnected by means of the SAN-over-IP technology originally developed by the Computer Network Technology Corp. The distant SANs appear as local storage entities. This technology improves enterprise management and data access, disaster recovery, business continuity, disk mirroring, electronic tape vaulting, and wide area clustering. The Storage Networking Industry Association (SNIA) offers three technologies for integrating fibre channel SANs into the IP backbone. These methodologies include fibre channel over IP (FCIP), iFCP, and Internet SCSI (iSCSI). The FCIP, iFCP, and iSCSI transport protocol descriptions are presented in (Clark, 2002) and on the CNT Web site (CNT, 2002).

Fibre Channel Over IP (FCIP)

FCIP is the simplest point-to-point IP tunneling solution for intercommunicating remote SANs with fibre channel fabrics. The FCIP gateways establish TCP/IP connections over a WAN path to transport the fibre channel encapsulated frames. A typical discrepancy in data communication rates between an FCIP-attached WAN link and fibre channel fabric generates various flow control issues that can be resolved by TCP sliding-window algorithms. Several FC-FCIP management issues cannot be properly determined for the FCIP pipes because the TCP/IP transport component ends at the external nodes of the fibre channel network. These problems have been addressed and successfully resolved in the iFCP and iSCSI approaches.

Internet Fibre Channel Protocol (iFCP)

The gateway-to-gateway Internet fibre channel protocol (iFCP) supports a means of integrating fibre channel end devices into a single IP SAN. By using iFCP, the fibre channel fabric services can be provided to the remote FC devices over a TCP/IP network. The iFCP IP storage switches can directly connect fibre channel storage arrays, HBAs, hubs, switches, and routes. The iFCP is a protocol stack, which can be implemented in an IP storage controller interface or integrated into Gigabit Ethernet IP storage NIC (known as ANSI X3T10 and X3T11 Standards) (Clark, 2002, pp. 126–139). It supports any-to-any IP routing of storage data. A mismatch in data communication rates between an iFCP-attached WAN link and fibre channel fabric generates various flow control issues that can be resolved by TCP sliding-window algorithms. The IPSec, public or private keys, and zoning methods can provide security across the Internet. One of the important applications of the iFCP technology is the support of multiple TCP/IP connections for concurrent storage transactions.

Internet SCSI (iSCSI)

In contrast to the FCIP concept, the iSCSI methodology, which follows the SCSI client/server model, is based on the implementation of a light switch technology in IP storage networking (Clark, 2002, pp. 139–149) and excludes fibre channel elements. The iSCSI servers (*targets*) are present in disk arrays and client nodes (*initiators*) that occupy host platforms. The iSCSI protocol over the TCP/IP layer is used for block data transport between these entities over the IP network. Data can be directly written into application memory through a steering and data synchronization layer located below the iSCSI sublayer. IPSec, Keyberos, public key, and other methods can provide security across the Internet. SANs use the iSCSI adapters with TOEs to minimize processing overhead and realize high-performance features of the iSCSI technology. The enterprise solutions with IP SANs can also support the Gigabit and faster Ethernet on iSCSI-switch infrastructures.

Storage Over IP (SoIP)

Based on the SoIP remote storage technology, the Nishan Systems Corporation developed IP Storage switches of the IPS 4000 Series™and a suite of storage management software that allow configuration and monitoring of large-scale storage networks.

Fabric Shortest Path First (FSPF)

Fabric shortest path first (FSPF) is the OSPF-based standard routing protocol for fibre channel that determines the next shortest route for data traffic, updates the routing table, and detects the failed routes (Vacca, 2002, p. 152). The optical, link, or switch failures can be effectively handled by FSPF with minimal impact on the interconnected devices in the FC/SAN environment.

Adaptive Network Storage Architecture (ANSA)

The Procom Technology Corporation has developed the adaptive network storage architecture (ASNA) approach, which delivers both block level and file access to data.

Procom's NetFORCE3000™Series provide filer functionality (together with advanced features of security, high stability, backup, and recovery) to an enterprise storage that can result in high-performance information management systems. The ASNA technology has been successfully applied to database management, data warehousing, e-mail delivering, and 24 × 7 rich media applications.

Storage Resource Management (SRM)

The SRM technology provides applications for managing logical and physical storage-system resources (virtual devices, disk volumes, file resources, storage devices and elements, and appliances). SRM tools allow storage-system administrators to configure and monitor SANs and other storage resources. During the administrative monitoring, the transport or storage data remain unchanged. Vendors of the SRM tools, products, and services include SUN Microsystems (*Sun StorEdge*™), HighGround Systems, Inc. (*Storage Resource Manager*, *Media Mirror*), and Storage Computer Corp. (*Storage Administrator*) (Toigo, 2001).

STANDARDS

American National Standards Institute (ANSI)

The American National Standards Institute (ANSI) coordinates SAN voluntary standards (ANSI, 2003). The ANSI X3T10 and X3T11 working committees are associated with storage networking issues including SCSI I/O interface standards (X3T10) and fibre channel interface standards (X3T11). The first set of fibre channel standards (ANSI X.3230–1994) (Vacca, 2002, pp. 75–78) describes standards for a switch fabric (FC-SW2), the interconnect that supports high volumes of throughput and bandwidth for disk output and input, as well as a management information base (MIB) management standard that permits fibre channel devices (switches) to be managed by any vendor's software, which includes an implementation of the simple network management protocol (SNMP). SAN users can find a brief description of other X3T11 Fibre Channel standards in (Barker & Massiglia, 2001, pp. 384–386).

Several FC SAN equipment vendors, including Brocade Communications Systems, have refined SAN standards in the areas of management, discovery, data transport, and WAN connectivity. This allows the fibre channel SAN to become an integral part of the enterprise framework (Vacca, 2002, pp. 78–79).

Distributed Management Task Force (DMTF)

The Distributed Management Task Force (DMTF) has introduced management standards for computer systems and enterprise environment (DMTF, 2003). The SAN-related management standards (Barker & Massiglia, 2001, pp. 386–387) cover a set of the Web-Based Enterprise Management (WBEM) XML-based technologies. They support an object-oriented approach in developing a business's management environment, using the Common Information Model; architectures and frameworks for desktop, laptop, and server management (desktop management interface); standard data models for a network, its elements, policies, and rules (directory enable networks); and functional calls for transaction monitoring (known as the application response measurement [ARM] standard).

Storage Systems Standards Working Group (SSSWG)

As a division of the Institute of Electrical and Electronics Engineers (IEEE), the Storage Systems Standards Working Group (SSSWG) develops models and architectures of storage systems, including SANs (SSSWG, 2003). The SSSWG project authorization requests (Barker & Massiglia, 2001, pp. 387–388) include the Guide to Storage System Design; Media Management System (MMS) Architecture; Session Security, Authentication, Initialization Protocol (SSAIP) of the MMS; Media Management Protocol (MMP) for both client and administrative applications; Drive Management Protocol (DMP) of the MMS; Library Management Protocol (LMP) of the MMS; the Media Manager Interchange Protocol (MMIP) for information exchange between autonomous Media Managers; the Media Manager Control Interface Protocol (MMCIP); the C Language Procedural Interface for implementation of the MMS's components; MMS User Mount Commands for establishing "command line interfaces" (CLI); MMS standard administrative and operational commands for administering and operating an MMS; and "MOVER" specifications of a storage system data mover architecture and its interfaces.

Internet Engineering Task Force (IETF)

The Internet Engineering Task Force (IETF) organization defines a variety of the transmission control protocol/Internet protocol (TCP/IP) standards that are widely used in the enterprise environment with SANs (IEFT, 2003). The IETF standards related to storage networking (Barker & Massiglia, 2001, pp. 388) include the simple network management protocol (SNMP) for managing and monitoring devices and systems in a network; the Internet protocol over fibre channel (IPoFC); and policy for quality of services (QoS).

STORAGE NETWORKING ASSOCIATIONS, INITIATIVES, FORUMS, AND COALITIONS

The following organizations promote storage networking technologies and products, develop standards, undertake marketing activities in information technology industry, educate, train, and create the knowledge base for implementing SAN technology:

SNIA (Storage Networking Industry Association)

The SNIA, an international association of developers of storage and networking products, is focusing on the creation of a forum of IT companies, system integrators, and application vendors for delivering architectures,

education, and services in storage networking, as well as defining the specifications and infrastructures, and proposing standards for storage networking systems, including SANs, SAN attached storage (SAS), and network attached storage (NAS) (SNIA, 2003).

Fibre Channel Industry Association (FCIA)

The FCIA is an international organization of manufacturers, systems integrators, developers, systems vendors, industry professionals, and end users. In June 2002, this organization included more than 190 members and affiliates in the United States, Europe, and Japan. The FCIA is committed to delivering a broad base of fibre channel infrastructure to support a wide array of industry applications within the mass storage and IT-based arenas. FCIA working groups focus on specific aspects of the technology that target markets, which include data storage networking and SAN management. The overview of fibre channel's SAN and networking applications and examples of fibre channel solutions for high-performance networks of heterogeneous storage, server, and workstation resources can be found on the technology section of the FCIA Web site (FCIA, 2003).

Fibre Alliance (FA)

The Fibre Alliance is the networking industry consortium originally founded by a group of storage networking companies, including EMC Corporation, to develop and implement standards for managing heterogeneous fibre-channel-based SANs. In collaboration with the Internet Engineering Task Force (IETF), this group develops the definition of simple network management protocol management information bases (SNMP MIB) for storage network and device management (Fibre Alliance, 2003).

Jiro

Jiro is a Sun Microsystems technology that delivers intelligent management services for networked devices. Using the principles of Java and Jini platform-independent application development interfaces (Jini, 2003), Jiro technology provides the architecture for connecting and managing complex distributed environments such as storage area networks. The Jiro technology brings higher levels of interoperability, adaptability, and manageability to enterprise networks with storage resources (Jiro, 2002).

National Storage Industry Consortium (NSIC)

Since April 1991, the National Storage Industry Consortium has consolidated the efforts of over 50 corporations, universities, and national labs in the field of digital information storage. The corporate members are major information storage manufacturers and companies from the storage industry infrastructure, including SANs. As a nonprofit organization, NSIC supports precompetitive joint research projects, involving collaboration among users and integrators of storage systems, storage system and device manufacturers, storage component and media manufacturers, suppliers, universities and national laboratories (National Storage Industry Consortium, 2003).

SANS' MARKET, VENDORS, AND SERVICE PROVIDERS

Evolution of SANs' Market

SAN technologies allow existing enterprises to effectively manage more transactions, customers, suppliers, and services. Company operations are significantly improved by providing continuous high availability through uninterruptible access to data, increasing scalability through multiple-channel data transmission, and reducing the network and server's CPU overhead. Additional opportunities for the IT enterprises are also associated with the Internet, which allows them to increase the volume of data and rates of their transmission. According to the International Data Corporation (IDC), since the mid-1990s, the number of users of e-commerce services has increased exponentially up to several hundred millions. SANs have revolutionized the IT enterprise's infrastructure and improved its e-business applications including e-commerce, e-mail, online transaction processing, data replication, and enterprise database management. Global continuous delivery of multimedia secured information has become the main service of modern e-business enterprises.

By adding networking and intelligence features to data storage, fibre channel SAN switches enable the solution of several challenging e-business storage problems, such as linking high-performance workstation clusters, connecting high-performance tape storage on disk farms, giving server farms a high-speed data-transmission pipe, clustering disk farms, and linking Ethernet, FDDI, ATM, and token ring LANs to the backbone. Intelligent SAN systems allow improving enterprise performance significantly, decreasing latency, supporting direct access to the storage shared by multiple servers, reducing network traffic on the front-end network, and removing storage management tasks from servers.

In December 2000, the IDC Corp. estimated that worldwide disk storage systems sales were about $31.7 billion in 2000. Networked-based systems with SAN installations represented 20% of the 2000 revenues. Trends indicate that both SAN and NAS implementations are accelerating, as SANs have grown 70% year over year. This trend is expected to continue during the next 5 years. Networked storage on the whole experienced a 43% capital asset growth rate during the same period, with SANs growing at 33%.

SAN Vendors and Service Providers

Table 2 represents a list of SAN vendors, storage-networking service providers, and their products. The complete list of SAN deployment companies can be fount in (Vacca, 2002, pp. 495–497) and on the Network Buyers Guide Web site (Network Buyers Guide, 2003).

The main providers of SAN solutions are EMC Corporation (about 40% of the market), Compaq Computer Corporation (13%), Sun Systems, Inc. (11%), IBM Corporation (10%), Hewlett-Packard Company (7%), Dell Computer (3%), Hitachi Data Systems (2%), Brocade Communication Systems, Inc., SANgate, TrueSAN Networks, Inc., and XIOTech Corp.

CONCLUSION

SANs, networked high-speed infrastructures, enable e-business enterprises to improve significantly their 24×7 continuous scalable services. They have become a critical part of the enterprise network infrastructure. The above-considered technologies and effective SAN solutions allow companies to shift their focus from numerous IT infrastructure problems to the successful performance of their businesses and services.

GLOSSARY

CIFS Common Internet file system, also known as the Microsoft server message block protocol; a network file system access protocol that is primarily used by Windows clients to communicate file access requests to Windows servers.

CIM Common information model; an object-oriented description of entities and relationships in the enterprise management environment.

DWDM Dense wavelength division multiplexing; a method that allows more wavelengths to use the same fiber.

FC-AL Fibre channel-arbitrated loop transport protocol.

FCSW Fibre channel switch.

FC-VIA Fibre channel–virtual interface architecture.

FSPF Fabric shortest path first; a routing protocol used by fibre channel switches.

IPoFC Internet protocol over fibre channel.

iSCSI Internet small computer systems interface.

JBOD Just a bunch of disks; a term for a collection of disks configured as an arbitrated loop segment in a single chassis.

NAS Network attached storage.

RAID Redundant arrays of inexpensive disks; a technology for managing multiple disks.

SAN Storage area network.

SAS SAN attached storage.

SoIP Storage over IP; a storage technology developed by the Nishan Systems Corporation.

SSA Serial storage architecture.

VI Virtual interface architecture; a midlayer protocol specification.

STRATEGIC ALLIANCES IN E-COMMERCE

Strategic alliances are separating competition. The winners are creating "best of the best" branding by forming teams of people and "completing" companies from past "competing" companies. Today, more than ever, most businesses don't have the desire, capacity, or resources to grow without the help of other aligned partners. Former paradigms of business development are being challenged daily as new ideas, new companies, and innovation provide the leadership for others to follow.

STRATEGIC ALLIANCES—THE WAY TO SUCCESS IN BUSINESS

Trading Partner Relationships

A "win/lose" mindset that exists in many trading partner relationships is a dynamic that has kept value chains from achieving a desirable performance. As stated in the Voluntary Interindustry Commerce Standards (VICS) Association for the Collaborative Planning, Forecasting, and Replenishment (CPFR) Committee, a VICS committee made up of retailers, manufacturers, and solution providers, "Under the CPFR approach, companies have to look across value-chain processes to see where their information or competencies can help the value chain and thus benefit the end consumer and the value-chain partners. This outlook acknowledges that nobody wins until the *consumer is satisfied*. One of the keys to the success of CPFR, in other words, is a changeover from 'win/lose' to 'win/win' value-chain relationships" (*Corporate Values*, n.d.).

On the CPFR Web site, http://www.cpfr.org/GuidingPrinciples.html, are the guiding principles developed for CPFR out of the JMI and VMI best practices: "In the course of this discussion, we examine traditional aggregate forecasting and replenishment as well as vendor-managed inventory (VMI), and jointly managed inventory (JMI)" (*Current Process State*, n.d.).

The trading partner framework and operating process focus on consumers and are oriented toward the value chain success.

Trading partners manage the development of a single shared forecast of consumer demand that drives planning across the value chain.

Trading partners jointly commit to the shared forecast through risk sharing in the removal of supply process constraints.

Various trading partnerships exist today for unique enhancements to the relationship. A vendor exists to sell something, a subcontractor to work for someone, a tactical partner, possibly to oversee the partnership, and a strategic partner, possibly integrated for several reasons of interdependence that could also include a joint venture partner, developed through an acquisition or a merger.

Partnerships vs. Strategic Alliances

A "partnership" in business typically suggests a legal agreement of participating in a venture of some sort for a very specific outcome. Real estate partnerships, for instance, might be formed to accumulate funds to buy real estate for the partnership. In *Webster's New Collegiate Dictionary,* partnership is defined as a legal relationship existing between two or more persons contractually associated as joint principals in a business. A partnership may or may not be represented by a written contract but could still be formed legally. "Strategic" in the same dictionary is defined as "of great importance within an integrated whole or to a planned effect." "Alliance" is defined as "an association to further the common interests of the members."

Strategic alliances is a term that has been used most recently as it has related to commerce through the use of the Internet. On Cisco's corporate Web site page is an explanation of their philosophy: "Our strategic alliances form a customer-centric, total solution approach to solving problems, exploiting business opportunity, and creating sustainable competitive advantage for our customers" (Cisco Systems, 2002a).

At Cisco, **strategic alliances** engage in **impact partnering** that is differentiated by eight **unique but integrated** characteristics:

- Industry Leaders,
- Multiple Touch Points Across Both Companies,
- Cross Value Chain Impact,
- Joint Solution and/or Technology to Address Customer Needs,
- Long Term Investment of Resources and IP,
- Anticipate Competitive Threats,
- Create New Global Markets and IP, and
- Weave Multiple Partners Together to Target New Markets (Cisco Systems, 2002b).

Although partnership and strategic alliance can be used interchangeably in some circumstances, the formation of a strategic alliance seems to insinuate a relationship of interdependence, so important that the entity cannot exist without the sum of all of those involved. As stated in the *ASCI Journal of Management* in 1992, strategic alliances have brought about a new dimension to a globalizing economy. They have led as well as are being led by various shifts in the global markets (Asma, 1992).

Partnerships as Strategic Alliances Development Prior to E-commerce

Creating partnerships, legal or otherwise, is not a new concept in business. In ancient history, bartering was a common form of existence because it provided a way to obtain products or services through an exchange. Typically, merchants focusing on developing a certain skill to create a product or service depended on others for products or services that they had no skill or abilities to produce. This type of business arrangement provided a certain amount of stability and peace to a village.

Franchising concepts have been another form of creating partnerships. Franchising is at least 150 years old. One early example resulted in the characteristic look of historic hotels (bars) in New South Wales, with franchising agreements between hotels and breweries. An American example was the telegraph system operated by various railroad companies but controlled by Western Union.

Multilevel marketing (or network marketing), such as used in the Amway business, is another partnering business model. Typically, independent business owners are associated with the company in a contractor-like relationship. A percentage of the profits from the sale of goods is distributed between the relationships.

Strategic Alliances in E-commerce

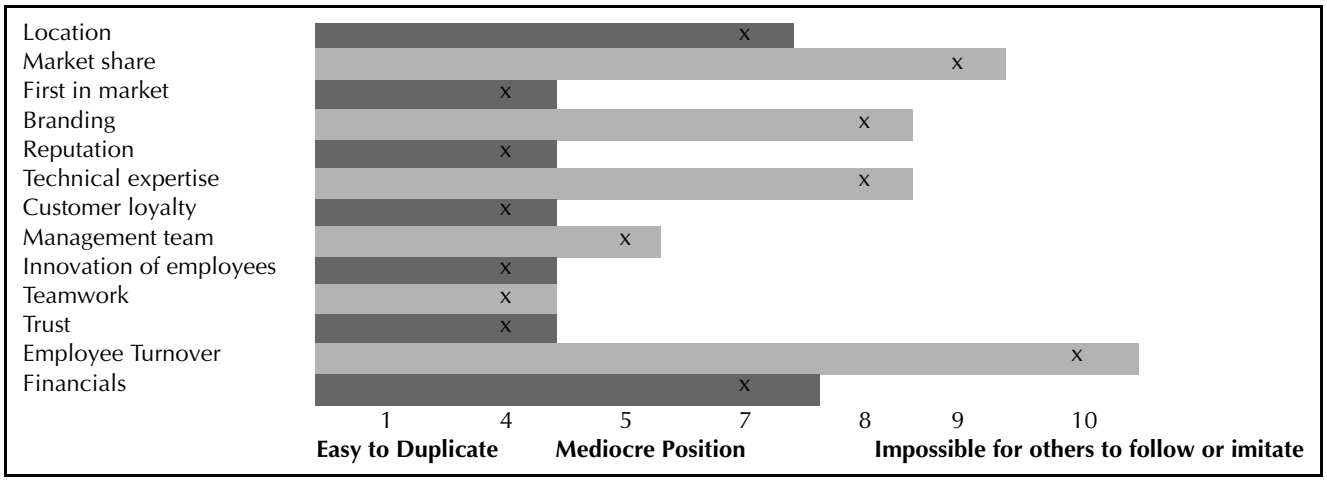
As the Internet has grown so exponentially in use, so has commerce activity over the Web. Businesses have been forced to create specific partnerships as a means of working through the complexities of producing, selling, and distributing products over the Web. At the same time, they have been required to create a strategy for a totally new way of connecting to the customer. The broadened exposure to the market and the speed requirement induced by that exposure coupled with the speed expectations of the customers has furthered the need to find and develop appropriate strategies. In contrast to earlier times when skills were limited, the use of the Internet has added so much complexity that it has once again forced business owners to focus on doing one thing really well.

The speeding up of finding, ordering, paying, and demanding for delivery has caused a need for companies to focus on their strengths, and at the same time, eliminate the processes within their company that others can do better. As downsizing and financial burdens have increased in recent years, businesses are more focused on "outsourcing" their needs as a means of balancing the budget. Focusing on the highest and best use of company resources has required development of synergism with other companies.

Identifying and Developing Core Competency

The processes identified to develop a clear understanding of a firm's core competency must begin with the simple question: What do we do better than anyone else? Some of the most important core competencies are listed in Table 1. As a company begins a process to consider the advantage they have over competitors, they also need to assess how important, or not, those characteristics might be to the overall strategies. Table 1, for instance, gives the opinion that while a company might be the first company to come into the market with a particular invention, they might not be the company that ultimately makes a success of that invention. The table estimates a value of 3 out of a possible 10 for how the importance of being first to market might be compared to other indications of a company's ability to be successful. The intent of the graph is to show the likelihood of a competitor being able to surpass a firm's particular competency. This graph, obviously, values employee stability as one of the most important factors in

Table 1 Core Competency Indicators Grid



the success of a company. One might conclude that it is more important to spend time and dollars on employee development and general satisfaction than in branding if budget is at issue.

Comparing Strategic Alliances for Different Businesses

As companies have focused on their core business mission and have looked to others to complete their desired business model, interesting relationships have begun to emerge. As computer manufacturers searched for ways to differentiate themselves from other similar firms, they looked for software other companies had developed for use as operating systems many years prior to the Internet.

As Gateway Computers strived for a market share greater than that held by Dell Computers and others during the 1990s, they looked for new ways to expand. They began to create strategic alliances with software companies to develop and produce programs that Gateway could include on their computer desktops. They created hundreds of these strategic alliances as a means of outperforming their competition. During the same time, several small businesses beginning to establish an Internet presence were trying to identify potential partners that might provide additional market exposure. Many of these smaller companies did not have the resources to develop marketing and human resource services "in-house." The blending of these companies' strengths created opportunities previously unattainable.

In another example, during 1999, CollegeCapital, an Internet college preparatory and scholarship database company developed a strategic alliance with American Express. They provided resources to American Express families as American Express provided exposure to their enormous market. Both companies benefited from each other's third-party recommendation as they both had developed reputations in their specific markets of strength and integrity.

Strategic alliances usually provide several equitable benefits to each party in addition to revenue sharing, including the use of each other's sales forces, executive leadership, and marketing ideas. Careful consideration should be focused toward an identifiable, specific outcome before the formation of any type of partnering association.

STRATEGIC ALLIANCE APPROACH TO ENHANCEMENT OF DEPARTMENTS WITHIN A COMPANY

Through corporate reorganization and downsizing, many executives have been left without jobs or reengineered to jobs that pay less. At the same time, small companies have been unable to afford human resource departments or assistants that at one time seemed imperative. As executives became proficient with the use of computers and technology, the need for many support jobs once considered necessary was lessened or eliminated. Circumstances like these have drastically changed the market in general and have also lead to a boom of support-related services and small business growth. Previously, where one secretary worked within a corporation for one executive, many former secretaries have now started secretarial companies, supporting several companies with secretarial outsourcing. Through using these types of strategic alliances, companies are able to downsize or add support almost overnight with very little disruption to ongoing business. Professional corporations previously were most known to be attorneys, accountants, and physicians. Since the Internet boom, with the complexity and speed of technology, small businesses as professional corporations have formed to provide outsourcing for housekeepers, personal chefs, Web site developers, software developers, secretaries, human resource directors, creative designers, and consultants of all types. The list includes companies focused on creating strategic alliances.

Enhancing Executive Management through the Use of Strategic Partners

Accounting scandals over compensation of senior executives, corporate bankruptcy, and misuse of company

assets uncovered during 2002 created an unprecedented economic turmoil. Executives, accustomed to comfortable corporate salaries, suddenly found themselves without jobs. Lack of corporate opportunities caused several senior executives to develop creativity in marketing themselves as strategic partnering consultants. This arrangement as the newest form of a management team has lead to an attractive alternative and creation of a win/win circumstance for companies and individuals. Talented executives have been able to work for several companies at once, using the best of their own resources and have been able to choose their schedules, work habits, and companies for whom they want to work. For executives who chose to work through consulting companies, many were able to make more money and experienced greater flexibility in how and when they worked. Larger companies have benefited by being able to hire extremely talented individuals, at a fraction of the cost of a full-time executive employee, participating in a sort of "executive" time-share with other companies. Companies can bring in the best people as a brain "tank" for less money and the consultants are glad to be there. Establishing an environment surrounded by excited and appreciative new individuals creates enthusiasm as well, throughout the organization and for long-time employees. Charrettes can be formed in a short amount of time using the most cutting-edge information and executives, and can lead a company out of a tremendous upheaval toward new successes. This paradigm shift being experienced by many companies today seems to be creating the new ideal business model. Although this type of business arrangement is a fairly recent one, these partnerships seem to be established for the long-term gain.

Enhancing Marketing through the Use of Strategic Partners

Marketing, branding, advertising, and public relations have followed the rest of the business world in becoming increasingly more complex and competitive. Most large corporations previously created marketing solutions through their own employees, sometimes as a human resources department function or within their marketing group. The Internet and sophisticated systems of marketing have created a need for a focused understanding and knowledge of marketing as a complete system of tools and branding that will constantly update and change according to rapid changes in market conditions. Public relations firms have had to reorganize drastically in recent years to be able to handle the complexity of maintaining market share in a global market, using the Internet as well as all other forms of media. The statistics and effects of certain marketing techniques seem to reinvent themselves daily. The interests and desires of customers tire easily as massive groups use the Internet. Web sites experiencing a great amount of traffic will many times change their look once a day to keep customer interest, and several companies change the front page of their Web site upon each computer visit.

Creating strategic alliance partnerships between marketing companies and businesses as a means of revenue sharing has been a boost for many marketing companies as well as for their host businesses. Traditionally, marketing companies billed for work performed and were left out of the windfall of financial success that came from growing start-up companies. As companies develop best of the best branding, some have decided to form a revenue-sharing process with marketing companies as an incentive to help build market share. The company needing marketing benefits from an alignment with a great marketing company at an early discounted rate while it is small and trying to build growth. As market share increases, the marketing company's revenue sharing increases exponentially, a benefit that previously was not an option for payment. This type of arrangement could build residual future incomes as well for the marketing company, depending on the particular contract agreement.

Enhancing Supply Chains through the Use of Strategic Partners

In a news release of October 1997 on Boeing's Corporate Web site, Boeing created a revolutionary partnership to obtain a large U.S. Army contract. By forming a partnership with Apache, Lockheed Martin, and Army Depot, a repair work company, they were able to combine cost saving "support costs while bolstering the Apache's readiness capabilities" (Boeing, 1997).

In 2000, Gateway Computers and CollegeCapital created a partnership that would expand the market of each company while providing resources to each of their customers. Gateway, as a means of creating distinction from competitors, wanted to create software solutions as an added incentive to purchase Gateway Computers. By adding CollegeCapital's membership to the sale of a computer to a student's family, Gateway was able to add greater value to the computer purchase. CollegeCapital developed mass purchase discounts for individual student memberships in exchange. The exposure for CollegeCapital in Gateway Country Stores created a dynamic growth to their market. By combining marketing campaigns, both companies benefited from each other's endorsements to their perspective customers. CollegeCapital was able to provide computer discounts to students through special pricing incentives from Gateway, and the customers were able to obtain better pricing, a better overall product, and ease of delivery. Both companies benefited from obtaining a greater percentage of sales and market share and were able to create cost savings in many support areas where only one company's resources were needed. Teams of employees from each company were shared and excellent ideas formed by the diversity that was created in bringing the expertise of employees together from completely separate companies and corporate cultures.

Enhancing Delivery through the Use of Strategic Partners

There was a time when the doctor would come to the home of an ill patient, prescribe medication, and then deliver it to the patient. Of course, the doctor had a limited choice of medications contained in the little black bag, the downside of a simple solution.

Today with the introduction of the Internet and e-commerce, delivery has become one of the most demanding and difficult management problems. As customers simultaneously connect to a merchant's site, the computer takes the order, captures the payment, and sends notice to have the order filled. There is almost an endless capacity for the number of orders that can be obtained at the same time. The need for human interaction becomes an essential element to the automated ordering procedure in many cases. If an order was created inaccurately, a customer most likely desires to call someone. The order then needs to be fulfilled and shipped. This slowing of the overall procedure has created new businesses that focus on specific aspects of these processes. Huge call centers having 24-hour access have formed almost overnight. Fulfillment houses, warehouses full of several different products from several different companies, have been created. Product delivery is a system that has become so competitive, complicated, and focused that there are companies specializing solely in overnight delivering. In some cities, like New York, delivery of office products to waiting businesses involves bicycle delivery because of traffic congestion. It seems in many circumstances that there has been a simplicity reversion, of sort, to the "old days" in order to deliver and obtain desired goods immediately.

Creating strategic alliances from necessary delivery partners has demanded unique approaches. If a company's service is to guarantee a specific delivery, they must have a dependable partner. Revenue sharing has been developed in some cases, to create a specific strategy to ensure dependable delivery. Delivery companies benefit by creating a built-in customer base and are able to advertise that they are partnered with a company known for excellent customer service. An example of this type of an alliance was referenced in the book *Getting Partnering Right*. The authors wrote, "FedEx has partnered with Intel to take over part of Intel's logistics. As a result, guaranteed delivery time has improved from four business days to three—and delivery errors have been substantially reduced" (Rackham, Friedman, & Ruff, 1996 p.13).

During the summer of 2002, one physician in Los Angeles, CA, decided to take his office to his patients. An improvement over the "black bag," by using today's technology and several partner teams, patients are able to have access to very sophisticated procedures while at home.

STEPS TO FINDING THE RIGHT STRATEGIC ALLIANCE PARTNERS

It is obvious in the complexity of e-commerce that one company cannot "do it all." Processes, regulations, ideas, and human potential have grown to require an enormous amount of expertise and information. Daily, the news carries stories of large corporations, past "do it all" companies, now in trouble or already bankrupt. They missed the mark. The larger some companies have become, the more difficult it has become to readjust to competition at the speed required to stay on top of the market.

How do companies create partnerships that will be mutually beneficial? How do companies even know that they need partners? What steps can be taken for older, established companies needing to be retooled? How can partnerships be established when a company is just beginning to form as a new e-commerce venture? Table 2 provides a checklist for determining strategic alliances.

CASE STUDY

During the past several decades of business, as a company grew, it usually expanded the various departments needed to fulfill its business model. During the 1970s, for example, a developer in Arizona started a home-building company by obtaining land and partnering with a contractor who built houses. Several subcontractors were hired to perform specific tasks: a large equipment operator, a cement contractor, a framer, a roofer, and so on. The profits of the development were split between the company owning the land and the general home-building contractor. As the company grew during a 20-year period, it began to form various departments within its own organization, eventually buying out the original home-building contracting partner. The development company grew to over 1,200 employees in more than 100 intercompany departments. The developer owned the water company, the landscaping company, the large equipment operations, the cable television, and even the mortgage company. As e-commerce began, customers were able to see home-building options and several home developments advertised on the Web. They compared building plans with other developers across the country, simultaneously. Mortgage rates were compared against Web-enabled mortgage loan applications, rates, and funding. Buyers could shop for trees and landscaping packages advertised on the Internet that once were sold as part of the package with the house. Cable television was being compared to other sources for television reception delivery. This explosive change caused the developer to reengineer the entire company. Layoffs occurred in many departments as the developer had to refocus on exactly the things that his company could do better than the competition. After the company was restructured, the obvious competitive advantage was their ability to build beautiful homes on unique land lots. Using years of accumulated customer information, knowledge as to what the buyers wanted and how decisions were made, they began to focus their marketing efforts through the use of strategic alliance marketing partners, instead of through additional employees. Partnered marketing companies focused on staying ahead of marketing trends, not only as related to home building but also other trends that might effect a home purchase. The development company downsized, and closed many departments, replacing them with consultants and strategic alliance partners.

The development company was able to view the enormous change in the market and react quickly. Unfortunately, many large companies have been lost because of the inability of key executives to see the big picture driven by e-commerce changes. If embracing innovation was not a key ingredient of a company during the past 20 years, the company has probably failed during the past 5.

The steps taken during the reorganization of the development company began with a focus on their core competencies. All key executive and management personnel

Table 2 Checklist for Determining Strategic Alliances

Internal
Assess the willingness to change by each employee.
Is management crisis orientated or proactive?
Are all processes and employees documented for accountability?
Is customer service a priority and does it start with internal customers, employees, vendors, etc.?
What current systems need to be revamped?
What is the result of the analysis of the firm's core competency indicators?
Current market conditions
What are the priorities to the current market?
What are the top core competencies of the firm in relation to the market?
Does the market demand growth?
Can the present company culture handle rapid growth/change?
Growth potential
Identify any examples of possible growth/expansion.
Identify positives/negatives to growth including cost vs/profit, using 80/20 rules.
Identify unknowns regarding results of possible expansion.
Next step: Think tanks
Develop several think tank and focus groups of trusted advisors, including good and difficult customers, employees, and potential partners to further discuss outcome of this checklist.
Implementation
Begin to identify a list of potential partners or strategic alliances that could see value in the present company's core competencies and develop a process to explore the likelihood of the partnership.
Specific desired outcome
As potential partnerships are identified, develop clear specific desired outcomes compelling to each entity.

were sequestered for several days to come up with ideas that would create a path for long-term survival, using an outside consulting group. A "think tank" approach was used to inspire innovation and creativity within the group. Through a series of questions and answers over several days, the company was able to bring into focus the things that they could do better than others and the things that they must do if they were to stay competitive. Recommendations for immediate and long-term planning were created. Hiring and partnering outside of the company was the new "norm" and getting rid of partially productive departments saved the company's core assets.

Timelines were developed according to the seriousness of the impact of the change. Cost savings and the ability to compete within the new e-commerce environment were of primary importance.

Let us review the steps taken by the development company in reengineering corporate structure to compete in an e-commerce environment:

Market changes were noticed and calibrated.

Key decision-makers met in a sequestered environment to participate in a "think tank" to formulate plans for changes.

"Highest and best use" was developed for all departments and key executives.

The company mission was changed to give better focus.

Weaknesses of the company were identified as possible areas for strategic partnering needs and as a means of identifying unnecessary use of company assets.

A new business plan to establish the new mission was developed.

Restructuring occurred to eliminate waste and unnecessary departments and employees.

Goals were established for "If we had strategic partners, what could be accomplished?"

Assignments were made with appropriate personnel to set meetings with potential partners.

Compatibility in key areas were thoroughly discussed between stakeholders of the companies involved, which included

- Corporate missions;
- Corporate culture: attitudes, dress, work structure philosophies;
- Time in business;
- Customer service attitudes and procedures;
- Marketing budget, present and future;
- Reputation with vendors, subcontractors, employees and customers; and
- Employee pay and benefits;
- Government and legal compliance.

Procedures to establish appropriate strategic alliance with long-term contracts as the goal were developed.

CREATING A LARGER COMPANY MISSION

There have been many articles and books written on how to create a company mission, but with the introduction of e-commerce, new questions that once were not important have had to be considered. Because the Web introduces

the possibility of worldwide exposure, a larger look at potential should be assessed from the very beginning. Any company mission should create a long-term focus with a broad use of the mission.

It is obvious, more than ever, that individuals and companies must know exactly what they are best at, or their highest and best use. Once an individual or company understands their truly unique talents and abilities, they can begin to encourage and grow those talents, through more specific education and experience. Once the core competencies are recognized and defined, focus and direction to develop those competencies can occur. Money is not wasted trying to grow something that at best will be mediocre in the competitive arena. Today, because competition is a global concern, there is no need to encourage a business, a department, or an individual to be or do something that cannot be maintained in excellence. With the added complexities and extreme competition in today's business environment, a company must do what it does better than anyone else. To do otherwise is a prelude to failure.

IDENTIFYING THE PART YOUR BUSINESS PLAYS

As a business answers, "What do we do better than anyone else?" the list becomes shorter and shorter. The next question then becomes "What are we doing now that we could get someone else to do better?" More often than not, it is a perceived direct competitor that has an ability that could be very beneficial if resources were combined. Competitors, when partnered, typically can become complimentary, each company focusing on what they do best and sharing in the support teams of employees. This thinking, although seeming common sense, requires individuals, as well as companies, to look at what drives them. If individuals are untrusting and in control of a company, they will be unable to develop a company based on respectful relationships and open communication. These attributes are imperative when creating strategic alliance partnerships. Unfortunately, many CEOs tend to hire persons with similar traits, and when they are of a suspicious nature, they unknowingly tend to surround themselves with similar individuals. This practice within a company, large or small, is one to avoid. Ultimately, strategic alliances will only work if integrity is woven throughout the organizations involved. So the rules for building strategic alliances are

Rule 1: Find partners that your company wants to be around, those your company can respect and work with, as a strategic alliance partner, whatever reputation they have, will be attributed to your company.

Rule 2: Find partners who have an established reputation of market strength, stability, and history in their focus.

As the mission is being developed and focus is identified, the mission will be expanded to encompass growth of that core competency and greater market share of that focus. The focus may change to becoming more of a business-to-business partner with strategic alliances than marketing directly to the public.

As CollegeCapital's business model continued to evolve from its inception, it became obvious that its best use of developing and providing the largest secured database of scholarships would facilitate schools helping students. In the original formation of its business plan, CollegeCapital was to help students directly, one at a time through connecting with them over the Internet. The model had to expand in order for CollegeCapital to stay focused on its core business, which was to maintain and sell information contained in their database of scholarships. Schools were in the business of connecting to and providing service for students. CollegeCapital decided to find partners with those companies that needed what they had. It had not developed a business based on understanding how students connect to information regarding college preparatory and scholarships. Schools typically provided that connection. One of the largest partnerships occurred for CollegeCapital from forming a strategic alliance with Cox Communication and Learning Station, companies connecting schools through an ASP design, delivering curriculum and information directly to the classroom. The strategic alliance brought CollegeCapital back to focus on its core business, that of developing the scholarship and college information, bringing value to those able to deliver it. The companies were able to share in revenue, marketing, and expertise using each other's employees and partners. Mutual trust and communication became the necessary component of the relationship. Cox Communication and Learning Station trusted that CollegeCapital would stay focused on the creation of the information that they needed to deliver. CollegeCapital trusted that Cox Communication and Learning Station would continue to focus on ensuring that the schools had a connection to the information. As the alliance grew, just as in most relationships, so did other opportunities. The project for Arizona schools was the largest technology project with the most partnerships ever attempted.

Change is usually upsetting and although most companies and individuals have felt greater stress, aggravation, and complication with the many changes of recent years, the formation of strategic alliance partners can actually simplify an organization into a more focused effort. Instead of trying to be good at many different businesses within one corporate structure, a business has an opportunity to use very focused efforts to expand what it does best. This focused effort filters throughout a corporation to individual effort. When individuals focus on developing their own core competencies, usually what they enjoy doing and are uniquely good at, they add much greater value to their company. Companies are able to benefit from employees who master and use their greatest talents instead of trying to create a mediocre mix of abilities of several talents.

Identifying Strengths and Weaknesses

In 1994, Larry Wilson in his book, *Stop Selling Start Partnering*, quoted Alvin Toffler from his revolutionary best-seller, *Future Shock*, "No generation has witnessed so many simultaneous changes that are interrelated and of

a global nature.... On many, many fronts, we're in for a couple of decades of rattling, shaking and reorganization" (Wilson, 1994). In 1994, the author did not realize the complexities of the changes that were about to occur and the speed at which the market would continue to do so.

Just as a person takes tests to help identify their talents and personality type, and then embarks on a lifelong journey of self-improvement, businesses must conduct a checkup a minimum of at least once a year, especially now with market changes occurring so rapidly. There are experts in the field of organization identity and branding that all businesses should involve from time to time, at least to gain a different perspective from outside of the organization. Key decision-makers should meet to look at reorganizing or restructuring in order to meet the needs and changes of the current market. The need to constantly look at what you do, how you do it, and on what are you spending money and resources cannot be overemphasized. In the days of large corporate structures and jobs that lasted 20 or 30 years, there may have been an atmosphere that condoned complacency and waste. In today's market, however, "If you snooze, you lose." If one is not prepared to embrace change and constantly seek to become better, one will almost immediately begin to lose market share and marketability.

Who could have predicted that in one action American Express, a huge corporate structure, would be taken to its very core? The tragedy of September 11, 2001, and subsequent closure of airports left American Express travel customers stranded, trying to find a way home. Destroyed corporate headquarters and a damaged technology infrastructure was a catastrophe American Express and other companies could not have planned for. For weeks the travel business nearly stood still. Although American Express had grown considerably over many years of success, having been founded in 1850 and having added companies and complexities to their organization, they had maintained the core mission of what they felt that they did better than anyone else, to "provide world class customer service." When employees were unable to reach their managers and customers were not able to connect with travel guides, the essence of the company began to shine through the chaos. Employees from other departments, unrelated to travel customers, began to take frantic calls to help in rerouting. Employees throughout the organization began to pitch in to continue as much uninterrupted customer service as possible, even though facilities destruction was prolific. Phones were rerouted, technology was rerouted, and customer service continued even with the absence of strategic managers. The company was able to create change immediately to address extreme circumstances because individuals within the company had been trained to know and understand that at the core, American Express focused on maintaining outstanding customer service. The turnaround from losses caused by that fateful day was extraordinary. Stories of heroic efforts made by employees striving to continue to provide world-class service to their customers abounded.

In the fast-moving business of e-commerce, every individual within a company must internalize a company's mission. The simple truth of the Golden Rule becomes the dependable element particularly during a crisis. The story of American Express and its ability to recover from the catastrophe of 2001 is further evidence of the importance of being conservative and cautious when seeking like-minded, strategic alliance partnerships.

Create Compelling Reasons for Others to Seek Your Company as a Strategic Partner

Just as American Express continued to evolve its reputation of always maintaining outstanding customer service, so did those companies wanting to partner with them. While CollegeCapital knew that it had the best databases and information regarding college preparatory, no one else did. As they were reviewing the companies that might be willing to partner with them, American Express seemed to be a possible match. Identifying with a company that demanded outstanding customer service could have its challenges but would give an immense amount of credibility for a young company. CollegeCapital had developed information that could be used as an added benefit to the customers American Express already serviced. The student loan division of American Express, at that time, was a natural fit.

In order to create partnerships, individuals or corporations must obviously be desirable partners and others need to be able to recognize it. In forming a relationship with a well-known partner, a smaller company will have to establish evidence that they can bring a noticeable benefit to them. When a corporation is great at producing a certain product but is known for taking ruthless or less than ethical business advantage over other businesses, partnerships will be nearly impossible to maintain even if an initial agreement is reached. People should seek personal associations with those who provide strength rather than those who extract it and it is the same with strategic alliance partners. The best e-commerce partners are those that reflect positively on one another, creating greater substance, market share, and dynamic impact. The result, hopefully, is a partnership that is greater than the sum of each partner.

DEVELOPING AND MAINTAINING A STRONG RELATIONSHIP WITH STRATEGIC ALLIANCES

Comparing Benefits

Partnerships are born from a leader's vision of what can be achieved with the right circumstances and assets. A close look at competitors will typically reveal aspects of companies that if joined together could create a stronger market share for both companies or solve problems that are occurring. In e-commerce, for instance, it makes little sense to reinvent a software shopping cart system, even if the exact nature of what is desired is not readily available. A close evaluation needs to reveal whether it would be better to partner and share revenue with an existing shopping cart developer to create a new one, which would decrease future ongoing revenue, or to hire the work done and continue to support it.

A similar figure used in Rackham et al.'s *Getting Partnering Right* (1996, p. 12) represents the intersections

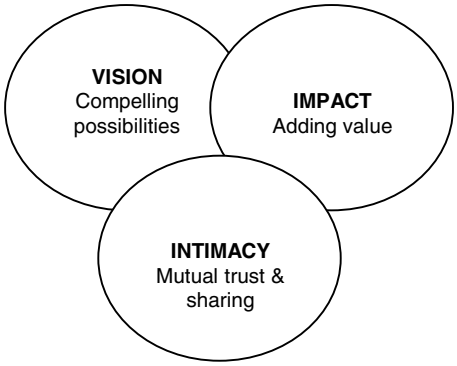


Figure 1: Spirit of partnering: trust, enthusiasm, and opportunities grow as the relationship intertwines. Source: Rackham et al. (1996). Reprinted with permission.

necessary for partnering to work and the level to which it can. As the amount of trust and sharing increases, so does the partnering effort and the mutual benefit. Attorneys usually develop necessary contracts but there is a degree of partnering that cannot be contracted for or ensured: it either is or is not a partnership based on mutual trust and benefit. Much like a marriage, it either works or it doesn't, depending on the attitudes behind the commitment. Partnering has a subtle ingredient that is nearly impossible to identify but supersedes all but intention. It could be called the "spirit" of the partnership, or the "spirit" behind it. As the components grow, dependency on the relationship also grows.

In order for a strategic alliance to work, everyone must have a stake, appreciation and respect for the proposed partnership. To the degree that greed, intolerance, difficult personalities, lack of sharing, and feelings of inequity enter the partnership, the relationship may erode. In a strategic alliance, there must be a compelling axiom: "We exist better because of the partnership." There is no reason to force a relationship or enter into a relationship that seems to be too difficult. Mutual respect for the various teams and employees must be shared by all of the employees involved in the alliance. Just as one negative employee can destroy the efforts, attitudes, and work of several within a company, one disgruntled employee can cause exponential damage to a more complicated structure of maintaining a strategic alliance. During the initial partnering effort, if it hasn't already occurred, it's time for a good "house cleaning," a cautious review of all employees' value, and values within the company. Anyone not adding specific, intrinsic value should be reevaluated with respect to his or her association with the organization.

Negotiations

In the world of creating strategic alliances for e-commerce, it is more important than ever to approach it from a standpoint of personal relationships. The old standby and still today as important a book, *How to Win Friends and Influence People* (Carnegie, 1936), references a conversation John D. Rockefeller had with Matthew C. Brush. Rockefeller said, "The ability to deal with people is as purchasable a commodity as sugar or coffee. And I will pay more for that ability than for any other under the sun."

The ability to negotiate the best partnership for all will depend largely on whether the principals want to spend time with each other. If they don't, no matter how important the deal, it probably won't work. Things have become so complex with the introduction of technology that we have had to resolve to the most simple of truths, the Golden Rule: "Do unto others that which you would have done unto you" (see http://www.fragrant.demon.co.uk/golden.html).

Before Closing the Deal: Identifying, and Resolving, Potential Problems with the Relationship

If it hasn't happened yet, get rid of the whiners in the company. Find employees willing to embrace change and be excited about working with a new strategic alliance. Communication, or lack of it, is always at the root of any problem in relationships. In developing e-commerce strategic partners, this cannot be overemphasized. A strong communication procedure must be developed to address any potential breakdown. Depending on the complexity of the partnership and the number of people and companies involved, it may make sense to use a Web-based communication or project management system. These systems only work when people use them, so tracking and requiring their use is imperative. The diversity of users and the number of work locations will determine the extent to which a Web-based communication project tracking system would be effective. Even when talks are begun between key executives, getting used to a Web-based system from the beginning can be very productive. Face-to-face contact and communication can never be underestimated, however. From time to time, it makes sense to bring the stakeholders together.

In the late 1990s, the State of Arizona wanted to create a way to provide a statewide connection for all students, teachers, and schools into one common system. In order to begin to address the complexities of such a mammoth project, a series of two-day "think-tanks" was implemented about six months apart. In the beginning, key decision-makers were invited to work at creating the solutions that would be needed. The "think-tank" events continue to be held for all of the partners involved in providing course content software on the system. During the events, they discussed communication problems and resolutions and the use of a Web-enabled project tracking system. The entire project partnered about 50 companies and political entities, some as strategic alliance partners, others as consultants and service providers to the project. The project had many stakeholders and requirements that needed to be addressed:

The State of Arizona would be assured that they had obtained discounted prices on all curriculum software, with an appropriate tracking system.

Statewide administrators would be able to get instant assessments, statistics, and communication throughout their district's schools.

Teachers would be able to have help in creating and augmenting their courses.

Children would have access to the most cutting-edge education content and information in a protective Internet environment, 24 hours a day, from any computer.

Parents would be able to communicate with their children's teachers to monitor their children's progress.

Cox Communications would be the first to develop the largest and most sophisticated ASP in the world through a partnership with Learning Station and others.

The main problem of any project of size is to create and maintain a system that allows and encourages, even demands, constant communication efforts. Communication works to eliminate barriers, crucial to all partnerships. Trust also becomes a critical ingredient in the beginning of any strategic partnership and continues to be an important issue throughout the relationship. As communication breaks down from time to time in all projects and partnerships, success, then, depends on proceeding with a collaborative effort of mutual respect. There must be a spirit of resolve: that one party is not trying to outdo the other and that everyone is important in maintaining a good communication and effort.

In the book *Getting Partnering Right*, the authors say, "In a complex partnership there will be so many uncertainties and unknowns that the path can't be charted with any precision . . . . The target that a shared vision is trying to hit is constantly moving" (Rackham et al., 1996 p. 118).

In the previously sited case of American Express and its disaster recovery, the spirit of the company ingrained in the employees ultimately solved the severe problems. A resolution projection for the issues created or for the possibilities of such a tragic event had never been designed. However, American Express as a company was able to weather the storm by the perseverance of employees and their commitment to the company mission.

The Contract

Once the expectation and vision for a partnership has been established, how does that evolve to a contract? In *Getting Partnering Right*, reference is made to a partnership document used by British contract specialist McGregor Cory, in which the opening simply states that it specifically disclaims any legal intent:

> This document is not written nor entered into as a formal or legal agreement but is only a definite expression and record of the purpose and intention of the parties, to which they each honorably pledge themselves. The document covers performance criteria and sets up agreed-upon communications channels. (Rackham et al., 1996 p. 20)

Perhaps business development is changing to be first dependent upon an honor system of what is right and just, and then building on character strengths for creating profits. Businesses and partnerships are recognizing that profit is a result of taking the necessary, honorable approaches.

There have been many articles written on how to create partnerships that avoid any antitrust issues. It should be stressed that all agreements avoid any potential conflict with regard to antitrust laws. It is important to obtain adequate counsel and information regarding the subject, and to make certain of all regulatory compliance issues. The U.S. judicial branch of the U.S. government's Web site has helpful suggestions and recommendations regarding this serious consideration.

The Internet, while giving greater control to the consumer, has eliminated many older traditional sales processes. The decision to buy today is based, as in the past, on price, integrity, dependability, service, and desire. The use of e-commerce brings instantaneous information and cross-referencing, giving consumers, instantly, an unparalleled amount of information and statistics they need in order to make decisions. The slightest issue, the smallest critical element, can make the difference in the sale. Dynamic, growth-oriented strategic alliance partnerships seem to be able to focus and deliver on details that customers search for and are demanding. These details should be part of the contract.

The contract should discuss all key talking points and consideration. The best contracts also require some resolution points for possible conflict that might arise into the future. Typically, the more complicated, longer contracts seem to be those that create the greatest aggravation to the forward purpose of the relationship. It is always advisable to obtain help from a contract attorney to finalize the document.

Win/Win? Or Not?

Is there any other way? In the past, several win/lose philosophies were invoked, perhaps not win/lose but at least win/more win. The philosophy of winning by causing others to lose has been rampant throughout corporate America. Employees were taught in many instances not to support each other and some felt that the only way to obtain recognition or a promotion was to undermine or eliminate another's opinion or position. Corporate executives, unsure of their own standing, have removed valuable employees from their teams as employees appeared to have talents not held by the executive. Instead of practicing teamwork and encouraging value for contributions, many employees have been taught to divide and conquer within their own departments and, ultimately, within the company. Secretive meetings, positioning, and last-minute layoffs have been common during the past decade.

Win/lose attitudes, common in many large and small corporations, created unhealthy models for competition or for partnering. Less than ethical personal and corporate behavior has had an enormous backlash. Employees laid off or rearranged in new positions many times coincidentally end up working together again. Former managers have become employees of individuals the manager once fired. Competitors purchasing formerly competing companies have forced a merging of teams. It seems that in many cases "what goes around, comes around."

Winning through Intimidation (Ringer, 1993) suggested that if one learns how to intimidate first, then one might be able to avoid the pitfalls of being intimidated. It seems

that in this world of global competition and technology, if one is going to use intimidation tactics to negotiate a partnership, they probably are too weak to be considered a partner for anyone. The best partners come from strength, whether it is personal, financial, spiritual, or corporate success. Finding the strongest partner and then identifying strengths that could be brought to complete them is the best way to formulate a long-lasting strategic alliance. The partners that continually help each other to improve and grow are those that last. In the end, the stronger the partners, the greater enjoyment and financial success for all involved.

Parts of the Contract Never to Forget!

The intent of a contract and the payment arrangements and revenue sharing is usually spelled out from the beginning. Most companies and individuals are anxious to establish criteria for cash assets. Other important assets many contracts tend to forget or to neglect have to do with company identities and branding. Will the new entity have its own identity or will the shared companies have permission to use each other's logos, marketing, and branding? What about the intellectual property? Who owns what and will some ownership be shared? Most technology companies are very familiar with the intellectual property that they own. The problem remains that as new specific partnerships are put into place between two or more companies, the new marketing or technology solutions do not take into account how the solutions will be used by each of the involved parties.

CollegeCapital had cobranded with an international firm to market specific blended products and assumed that the cobranded name of the effort had been checked and trademarked by the dozens of attorneys that had been involved in the formation of the products and services. Several months and millions of marketing dollars later, a competitor company was noticed as using the same name in a competitive situation. After several letters, negotiations, etc., the entire program had to be renamed and redesigned by the partners because the proper legal documents and protections had not been put into place and the new company had created a claim to the branding and names that had been created. A seemingly, slight oversight became a very costly mistake.

Remember: Do not assume that because a company has millions of dollars of revenue, a huge market share, and thousands of employees that all of the appropriate measures have been addressed. Sometimes the most obvious issues are overlooked.

As simple as it sounds, a list of all possible mishaps should accompany all contracts, and at the very least, be items for discussion. There is no way to predict the future with perfect accuracy. This is again where the spirit of the individuals involved and their commitment to solidifying a win/win long-standing partnership becomes the most serious of considerations.

Closing the Deal

It sometimes seems that the negotiation processes continues long past the time of the hoped for contract closing. In several cases, the demand and timing for the alliance partnership may have been so great that the partnership started working before the paperwork was complete. This is another caution in ensuring that your partners will uphold their promises. Whenever possible, don't start working on something without the proper agreements and contracts in place. It usually causes fewer problems to wait a few days and do whatever it takes to complete the contracts.

Creating a Process for Maintenance and Growth of the Strategic Alliance

A simple strategy for managing any relationship is to agree on specific needs for communication as early as possible. Simplifying all processes to be easy to duplicate throughout all of the companies will hasten the success of any project but especially the relationships between individuals within several companies. Look at the communication and process designs as if a franchised system was being designed for the least knowledgeable employee.

The following questions should be answered whenever any consideration to design the implementation of creating a strategic alliance occurs:

What is the ultimate long-term goal to be established using this particular procedure?

What is the short-term result that we should be able to quantify?

Is there a simpler way to achieve this outcome?

What are the quantifiable results that should be expected in one week, one month, 1 year, 5 years, and 10 years?

If all goes well, where will the company be in 20 years?

What reassessment strategies will be used and how often?

What are ways to consider now for growing the relationship for more profits into the future?

CONCLUSION: STRATEGIC ALLIANCES ON A LARGER PLATFORM SUCH AS THE NATION OR THE WORLD

If individuals focused on developing the best of their talents and trusted that they could find others—businesses and persons with whom they could form collaborations to create a unique dynamic product or result—would that not eventually create a better, more peaceful world? Wouldn't companies, countries, or persons be less likely to destroy that which they need for their own gain? And if that need, search, and respect for unique talents were the driving force throughout society, wouldn't we be compelled to nurture, educate, and create opportunities to seek out the uniqueness in all persons, companies, governments, schools, and even religions? Could this constant seeking for completion begin to honor our own seeds of greatness? Wouldn't we be perpetual in offering what we are really great at and admitting to others what we seek or need? Every family, society, and company reflects the thoughts and attitudes of its leaders.

In the Current Events section of *Forbes Magazine* of July 8, 2002, p. 43, Ernesto Zedillo, former President of Mexico, wrote about a new round of trade liberalization talks. He said that during the last talks,

> stressing the strategic value that the substance and timing of this new WTO round—beyond the significant potential economic effects—have for international stability and security.... The industrialized countries, and particularly the U.S., told the world that constructive interdependence (rather than isolationism) and concerted multilateralism (rather than aggressive unilateralism) are essential components of the answer to the challenges that became brutally evident on Sept. 11. It seemed to be the beginning of a coalition, broader than the military one that would fight decisively against the dangerous polarization between the haves and have-nots of the world. This position was reinforced at the U.N. Financing for Development conference in March. (Zedillo, 2002)

Scandals and corporate bankruptcy uncovered in 2002 within several corporations have completely disintegrated investors' faith, as the public found misuse of money, information, and accounting and business practices. Lack of integrity and trust abounded in the disclosures that surrounded the companies' downfalls. Within the e-commerce environment, bad news spreads faster and farther than ever. If financial success is the ultimate goal, doing things right and partnering with those who do things right is all that works. In the advertising campaign developed for AEP, American Electric Power, the banner reads, "Strength + Agility = Performance," a perfect explanation of what the right strategic alliance partnerships in the e-commerce are able to create.

GLOSSARY

Alliance An association to further the common interests of the members.

Acquisition The act of contracting, assuming or acquiring possession of something.

Antitrust Opposing or intended to regulate business monopolies; usually a legal action brought against parties charged with limiting free competition in the marketplace.

Application service provider (ASP) A managed application/software hosting, usually on the Internet.

Barter To trade by exchanging one commodity for another.

Call centers Provide (usually) 24-hour telephone (and e-mail) support services providing a company system backup for customers placing orders; usually providing a complete solution that allows companies to generate a presence on the Web to fulfill orders from all over the world, and staffing customer service personnel.

Charrette A final, intensive effort of a group of experts to finish a project before a deadline (from the word "chariot," as in the speed of wheels).

Commodity A mass-produced, unspecialized, useful product.

Core competence A primary area of expertise; narrowly defined fields or tasks at which a company or business excels; primary areas of specialty.

Customer-centric Focused on or revolves around a customer.

E-commerce The business of buying and selling goods and services on the Internet.

Executive time-share To use executives on an as-needed basis, simultaneous to the use of the same executives by other companies or organizations.

Franchise A license granted to an individual or group to market a company's goods or services in a particular territory.

Golden rule "Whatever you wish that men would do to you, do so to them" (Christian Bible, *Matthew:* 7.12).

Joint venture A partnership or conglomerate formed often to share risk or expertise.

Merger The union of two or more commercial interests or corporations.

Multilateralism Involving or participated in by more than two nations or parties.

Paradigm shift A shift of complete transformation from what was to what is and will be. It is a change in thinking, a revolution, or a sort of metamorphosis. It is usually driven by agents of change.

Partnership A legal relationship between two or more persons contractually associated as joint principals in a business.

Strategic Of great importance and emphasized within an integrated whole or to a planned effect.

Strategic partner Person or company you are closely involved with in some way for a planned effect.

Subcontractor A person or company that does part of a job that another person or company is responsible for.

Tactical partner One that is calculated, clever, deliberate, planned, political, prudent, shrewd, strategic, or skillful in planning or maneuvering under pressure to accomplish a purpose.

Think-tank A consortium of stakeholders and idea people who by coming together in a sequestered, specific time-allotted, environment develop ways to formulate new plans or solve issues.

Unilateralism Done or undertaken by one person, nation, or party, or relating to or affecting one side of a subject.

Vendor One that sells.

World Trade Organization (WTO) A rules-based, member-driven organization—all decisions are made by the member governments, and the rules are the outcome of negotiations among members.

Structured Query Language (SQL)

Erick D. Slazinski, *Purdue University*

INTRODUCTION

Applications developed today, including Internet applications, data-mining software, and other general applications, will most likely have database components on the back end. Example applications vary from the online CD database located at CDDB.com to a recipe database, like the one located at FOODTV.COM. The databases used may range from powerful enterprise-scale versions of Oracle, DB2, and Sybase to more personal desktop version like Microsoft Access. This chapter will focus primarily on standard SQL, not any specific implementation. Regardless of the database platform, one accesses the data utilizing the provided query language. Because most popular databases use the relational model, the query language provided is a derivative of SQL. Currently most database systems provide users with languages such as SQL to allow them to retrieve or update stored information (Chan, Tan, & Wei, 1999).

There are several mechanisms for a user to interact with a database. Most database vendors provide users with line-mode interfaces where a user can enter supported statements and receive results. Other, graphical interfaces may be available from a database vendor or a third-party application. These graphical interfaces provide what is known as query-by-example (QBE) facilities. QBE was developed by IBM in the 1970s to help users in their retrieval of data (Connolly & Begg, 2002, p. 197). The QBE facilities provided by database vendors either allow users to graphically depict queries or provide templates for users to fill out. These facilities then generate SQL, which often can be viewed and modified and which then is sent to the database engine for execution.

MATHEMATICAL BEGINNINGS

Although database technology has been around for quite some time and in various forms, the relational model put forth in 1970 by E. F. Codd has enjoyed the greatest success. The relational model is firmly grounded in relational algebra, which has roots in basic set theory. This actually makes the basics of SQL accessible to most people.

Basic Set Theory

In basic set theory, a universe of domain is specified. In the database arena this translates to all of the data included in a database. In our universe, items may be categorized (perhaps multiple times) into set(s) and then relationships between these sets may be explored, using inclusion and exclusion operations. Likewise, in the relational model, data are often retrieved as result sets. These result sets may then be compared either inclusively or exclusively.

Relational Algebra

Relational algebra "is a collection of operations that are used to manipulate entire relations. . . . The result of each operation is a new relation, which can be further manipulated by the relational algebra operations" (Elmasri & Navathe, 1989, p. 148). This is consistent with the mathematical definition of set operators. Relational operators are often separated into two groups. The first "group includes set operations from mathematical set theory . . . . The others consist of operations developed specifically for relational databases . . . ." (Elmasri & Navathe, 1989, pp. 148–149).

The set of relational algebra operators includes the SELECT (σ), PROJECT (π), UNION ($\cup$), DIFFERENCE ($-$), and CROSS-PRODUCT ($\times$) operators. "It has been shown that the set of relational algebra operations $\{\sigma, \pi, \cup, -, \times\}$ is a *complete* set; that is, any of the other relational algebra operations can be expressed as a *sequence of operations from this set"* (Elmasri & Navathe, 1989, p. 159). An example of a complex relational operator (one made from this minimal set) is the intersection operator ($\cap$), which is defined as

$$R \cap S \equiv (R \cup S) - ((R - S) \cup (S - R))$$

(Elmasri & Navathe, 1989, p.159).

"The select operation is used to select a subset of tuples (tuples represent rows in a table) in a relation. These tuples must satisfy a *selection condition*" (Elmasri & Navathe, 1989, p. 149). The general form for the SELECT operation is $\sigma_{<\text{selection\_condition}>}(<\text{relation name}>)$, where the SELECTION_CONDITION is a boolean expression made up of clauses of the form <attribute name> <comparison op> <constant value> or <attribute name> <comparison op> <attribute name>, where ATTRIBUTE NAME is the name of an attribute of the <relation name> (Elmasri & Navathe, 1989, p. 149). For ordered domains, such as integer or date domains, <comparison op> is from the set $\{=, <, >, <=, >=, \neq\}$. For unordered domains, such as color = {red, blue, green}, the only valid <comparison op> is from the set $\{=, \neq\}$. Boolean operators AND, OR, and NOT are used to connect the selection condition clauses together. An example of a table of tuples is as follows:

name	sex	address
Smith	M	Lexington Park
Taylor	M	Detroit
Burr	M	Lusby
Malcolm	M	Akron
Tefft	M	Ridge
Carpenter	M	Lexington Park
Lucas	M	Hollywood

An example of the selection operation is as follows:

```
Give me all candidates who are male.
[select] σ(sex="M") (CANDIDATE)
```

The PROJECT operation is used to select a subset of attributes in a relation. The general form for the projection operator is $\pi_{<\text{attribute\_list}>}(<\text{relation name}>)$. Only attributes that are part of the relation are valid in the attribute list. If duplicate tuples appear in the result relation, all but one instance of the tuple will be removed, enforcing the mathematical set definition, which allows no duplicate items.

An example of the projection operation:

```
Where do the candidates live?
[project]πAddress (CANDIDATE)
```

address
Lexington Park
Washington DC
Detroit
Hollywood
Lusby
Pittsburgh
Cherry Valley
Akron
Ridge

As stated previously, all relational operators may operate on the results of previous relational operators.

Examples involving both select and project operators:

```
Give me all of the names and addresses of
  the candidates that live in Hollywood.
πName, Address (σ(address = "Hollywood") (CANDIDATE))
```

name	address
Rupert	Hollywood
Day	Hollywood
Lucas	Hollywood

The above relational operators are unary, operating on only one relation at a time. The rest of the relational operators are binary, operating on two relations at a time. The UNION and DIFFERENCE operators require that the relations also be union-compatible. The UNION operation returns all tuples (rows) that are either in R or S, or in both R and S. Enforcement of the set definition eliminates duplicate tuples. The difference operation returns all tuples that are in R but not S. The CARTESIAN PRODUCT operation returns all possible tuple combinations between R and S. The resulting relation has all attributes from both relations and the new tuples are of the form $(\text{tuple}_{1_R}, \text{tuple}_{1_S})$, $(\text{tuple}_{1_R}, \text{tuple}_{2_S})$, $(\text{tuple}_{2_R}, \text{tuple}_{1_S})$, $(\text{tuple}_{2_R}, \text{tuple}_{2_S})$, . . . $(\text{tuple}_{m_R}, \text{tuple}_{n_S})$.

The JOIN operator (ξ) is used to combine related tuples from two relations into single tuples (Elmasri & Navathe, 1989, p. 157). The JOIN returns all possible tuple combinations from R and S where the combination satisfies the JOIN CONDITION. An example JOIN is $R\ \xi_{<\text{join condition}>}\ S$. JOIN CONDITIONS are of the form $A_R \theta A_S$, where A_R and

A_S are domain-compatible attributes from relations R and S, respectively, and θ is one of the following comparison operators: $\{=, <, \leq, >, \geq, \neq\}$. JOIN CONDITIONS may be connected with the Boolean AND operator. For example, to retrieve all of the data about a candidate the statement CANDIDATE $\xi_{(\text{candidate.name} = \text{candidate-body.name})}$ CANDIDATE-BODY would yield the following relation:

name	sex	address	name	height (in)	age
Smith	M	Lexington Park	Smith	75	50
Jones	F	Washington DC	Jones	77	26
Taylor	M	Detroit	Taylor	65	36
Rupert	F	Hollywood	Rupert	62	30
Burr	M	Lusby	Burr	71	25
Zimmerman	F	Pittsburgh	Zimmerman	61	38
Roberts	F	Cherry Valley	Roberts	68	40
Malcolm	M	Akron	Malcolm	72	20
Tefft	M	Ridge	Tefft	70	29
Carpenter	M	Lexington Park	Carpenter	74	30
Day	F	Hollywood	Day	64	25
Lucas	M	Hollywood	Lucas	70	19

Null Values and Trivalue Logic

One concept that was added to basic set theory was the concept of null value. An attribute that has a value of null is said to be an attribute that is not applicable, unknown, or undefined for the data row. One must be careful to properly account for the possibility of null values appearing in a database.

Null values, when used in numeric computations, act like infinity; anything we do in conjunction with a null value ends up as null. For example, if we add 3 + null, the result is null. When used in character operations (such as concatenation) the null typically acts like a blank.

The two places where one must handle the null are in the *select* statement and the *where* clause. In the select statement, we must decide what to display to the final recipient of the SQL statement that we are inputting instead of the null, which typically displays as a blank character. In the *where* clause, the results are more profound. In trying to evaluate a *where* clause where portions of the clause may null out (return a value of null), the desired result set may not be returned. This is due to the fact that SQL uses a trivalue logic set as shown in the table below:

p	q	p AND q	p OR q	NOT p
True	True	True	True	False
True	False	False	True	False
True	Null	Null	True	False
False	True	False	True	True
False	False	False	False	True
False	Null	False	Null	True
Null	True	Null	True	Null
Null	False	False	Null	Null
Null	Null	Null	Null	Null

So if one portion of a *where* clause nulls out, depending on the operation, the entire *where* clause may null out, leaving the empty set as our result set. For the "and" operation to return a value of "True" both predicates ("p" and "q" above) must evaluate to "True." Because the value of null is unknown (it could be "True"), the evaluation cannot be complete and therefore returns a null value. For the "or" operation, only one of the predicates must evaluate to "True." The not operation simply changes the predicate's value: a "True" value become a "False" value, and so on.

IBM'S SEQUEL LANGUAGE

Even though Codd proposed relational databases in 1970, it was not until 1974 that Chanberlin and Boyce published an article proposing the form of a structured query language, named SEQUEL (Hursch & Hursch, 1988, pp. 1–2). This name is often used (incorrectly) today to reference the present-day SQL language.

STRUCTURED QUERY LANGUAGE

All of the basic concepts of relational algebra are present in today's relational database management systems (RDBMs). However, the concept of a domain is only implemented for primitive data types, such as integer, float, date, versus any data type, as defined in the model (Date, 1994, p. 66). SQL is the American National Standards Institute (ANSI) standardized version of IBM's SEQUEL "data sublanguage," for use in a relational database (Hursch & Hursch, 1988, p. 1). SQL (pronounced "ess, queue, ell") is more than a language for retrieving information out of tables; it also "includes features for defining the structure of the data, for modifying the data in the database, and specifying security constraints. Each feature has its own set of statements that are expressed in, respectively, Data Definition Language (DDL), Data Manipulation Language (DML), and Data Control Language (DCL)" (Hursch & Hursch, 1988, p. 1). DML implements the relational operators and will be addressed later.

Sets of data, relations, are stored in a RDBMS in the form of tables. Each table consists of rows and columns. Each row of data is a specific and unique instance (entity) of a member of the table (i.e., a tuple). Each column is said to be an attribute of the table. To create the database objects required, SQL's DDL provides the following data definition statements (DDS): CREATE TABLE, CREATE INDEX, ALTER TABLE, DROP TABLE, DROP VIEW, and DROP INDEX. The table names created with these statements are the identifiers used by the DML to resolve SQL statements.

SQL's DML supports the following operations on tables: INSERT, UPDATE, DELETE, SELECT, and CREATE VIEW. INSERT, UPDATE, and DELETE operations are data maintenance functions and will not be addressed. The SQL SELECT is the data retrieval mechanism. The CREATE VIEW statement is an alternative way of looking at the data in one or more tables called a derived table and is based upon the SELECT statement.

SQL's DCL is used to control authorization for data access and auditing database use. DCL statements include the GRANT and REVOKE statements. Database administrators and developers primarily use these operations.

ANSI Standardization

SQL is in its third revision as an ANSI standard. The first revision was released in 1986, the second version (SQL2 or SQL-92) was released in 1992, and the latest release (SQL3 or SQL-99) occurred in 1999. Each release added major functionality to the standard and, in theory, increasing compatibility for those willing to program in "pure" SQL (Eisenberg & Melton, 2002).

> IBM developed SQL in the 1970s for use in System R. It is the de facto standard as well as being an ISO and ANSI standard. It is often embedded in general-purpose programming languages.
>
> The first SQL standard, in 1986, provided basic language constructs for defining and manipulating tables of data; a [minor] revision in 1989 added language extensions for referential integrity and generalized integrity constraints. Another revision in 1992 provided facilities for schema manipulation and data administration, as well as substantial enhancements for data definition and data manipulation.
>
> Development is currently underway to enhance SQL into a computationally complete language for the definition and management of persistent, complex objects. This includes: generalization and specialization hierarchies, multiple inheritance, user defined data types, triggers and assertions, support for knowledge based systems, recursive query expressions, and additional data administration tools. It also includes the specification of abstract data types (ADTs), object identifiers, methods, inheritance, polymorphism, encapsulation, and all of the other facilities normally associated with object data management. (FOLDOC, 2002)

DDL

SQL's DDL provides the following data definition statements (DDS): CREATE TABLE, CREATE INDEX, CREATE VIEW, ALTER TABLE, DROP TABLE, DROP VIEW, and DROP INDEX. The create statements create the named structures within the database (tables, indexes, etc). The drop statements remove the corresponding structures. The create view statement will be handled in a later section.

DML

SQL's DML supports the following operations on tables: INSERT, UPDATE, DELETE, SELECT, and CREATE VIEW. The SQL SELECT is the data retrieval mechanism. The operations are self-explaining; the insert operation adds data into a named table, the update operation modifies data in a named table, and the delete operation removes data from the named table. All of these operations are permanent modifications to the database if and only if they are followed by commit statements—refer to the section on transaction control.

The Select Statement

The select statement is one of the most flexible and often used in SQL. The simplest form of the SELECT statement, "select * from <table name>," returns all of the rows from the indicated table. By specifying a *where* clause, the resultant set is restricted by a set of conditions. The *group by* clause allows data grouping (ordered by the attributes listed). The *having* clause can further restrict the results returned by the *where* clause. The *order by* clause allows a final ordering to occur before results are returned to the requester. The SQL SELECT statement has no restrictions on the number of tables that may be accessed to fulfill the user's request. Besides being the query construct, the select statement can be used in conjunction with every DML statement. The syntax of the select statement is

```
select      * | <attribute list>
from        <table list>
{where      <condition> }
{group by   <grouping attributes> }
{having     <group condition> }
{order by   <attribute list> }
```

SINGLE TABLE ACCESS AND THE RESULT SET

Because SQL was designed using set theory, one important carry-over was the result set. The result of any query is a set, named the result set. This makes for a very powerful and flexible design. Because we have a set, we can then apply another query to this result set (in the case of refining as we go).

The most basic of queries returns the contents of a specified table:

```
select * from TICKET_PRICE;
```

The result set is the entire ticket_price table:

TICKET_TYPE	PRICE
KIDS	4.50
SENIORS	5.00
ADULT MAT	5.00
ADULTS	7.00

The "select *" statement is often used to inspect the data that are stored in a table (that is not too large) and to verify that DML operations were successful (especially inserts and deletes).

Reducing the Size of the Result Set

Often the "select *" statement returns too many rows for useful analysis. To trim down the size of the result set, we can perform some combination of column and row reduction. To reduce the number of columns, we simply replace the "*" with the column names that we want to investigate. To reduce the number of rows, we must include a *where* clause. The *where* clause provides a list of criteria that can be joined using trivalue Boolean logic.

The criteria specified can be very specific, such as returning those rows that have this exact value for an attribute (e.g., returning all movies with a rating of "PG"). The criteria can be less specific (e.g., returning all movies that begin with an "A"). Examples follow:

To return all movie titles with a PG rating (exact match):

```
select MOVIE_TITLE
from MOVIE
where MOVIE_RATING = "PG";
```

The result set would be

MOVIE_TITLE
THE BEST MAN IN GRASS CREEK
CROCODILE DUNDEE IN L.A.
SPY KIDS

To return all movie titles and rating which begin with the letter "A" (inexact match):

```
select MOVIE_TITLE, MOVIE_RATING
from MOVIE
where MOVIE_TITLE like 'A%';
```

The result set would be

MOVIE_TITLE	MOVIE_RATING
A KNIGHT'S TALE	PG-13
AMORES PERROS	R

Note: from this point forward, unless difficult to determine, the results sets will be left as an exercise to the reader.

To return all movie titles with a PG or PG-13 rating (exact match), we can use either exact or inexact matching techniques. If a new movie rating was created, say PG-15, and we only wanted PG or PG-13 movies, the inexact technique would no longer work. The following queries will return the same result set:

```
select MOVIE_TITLE
from MOVIE
where MOVIE_RATING in (
       "PG," "PG-13")
```

```
select MOVIE_TITLE
from MOVIE
where MOVIE_RATING
like 'PG%';
```

```
select MOVIE_TITLE
from MOVIE
where MOVIE_RATING ='PG'or
      MOVIE_RATING ='PG-13';
```

Other queries using string searching techniques are also possible.

If we want to get a range of values, we can use the *between* keyword. For example, we want all movie tickets priced between $5.00–$7.00. The query would look like this:

```
select *
from TICKET_PRICE
where PRICE between 5.00 and 7.00;
```

The following comparison operators are specified for use in a *where* clause: <, >, =, ! =, <>. IN, BETWEEN, and LIKE are used on string data only.

Computations

Perhaps we want to enlarge the result set or perform a computation, such as computing the total for a shopping cart application or performing what-if scenarios relating to the price of a movie ticket. We can perform operations on the attributes listed in the select statement. Note: we cannot perform these operations when we use the "select *" notation. We can either perform a static computation (e.g., what would our pricing structure look like if we raised ticket prices by 15%?) or a dynamic computation (e.g., a calculation involving two or more attributes). An example query would be:

```
select TICKET_TYPE, PRICE, PRICE * 1.15
from TICKET_PRICE;
```

Arranging the Result Set

SQL provides us with a mechanism for sorting the rows of a result set. This mechanism is the *order by* clause. When using the *order by* clause, the query developer specifies which attribute(s) to sort the data on and the direction asc (ascending) or desc (descending). If more than one attribute is specified, then the outer attribute specifies the major ordering and the next attribute(s) indicates the ordering within the primary ordering.

Note: the *order by* clause is the last clause of a select statement. For example, the following query using the *order by* clause generates the result set that follows:

```
select MOVIE_RATING, MOVIE_TITLE
from MOVIE where MOVIE_TITLE like 'A%'
order by MOVIE_RATING desc, MOVIE_TITLE asc;
```

MOVIE_RATING	MOVIE_TITLE
R	ALONG CAME A SPIDER
R	AMORES PERROS
PG-13	A KNIGHT'S TALE

Segregating the Result Set

Often we want to work on a partitioned result set (i.e., for each movie rating in our result set, we want to count the number of movies that have the rating). Or we want to get the most (or least) expensive book in our inventory. To support these types of queries, SQL has defined a number of aggregate functions. Example aggregate functions include COUNT(), MIN(), MAX(), SUM(), and AVG(). All functions take in column expressions (either column names or column computations). The count function can also take in a "*." In order, these functions perform the following computations—counting the number of rows, determining the minimum value, determining the maximum value, totaling the value, and determining the average value. In general, these functions are most useful when we partition the result set (e.g., total

value of inventory by product line) as opposed to running them on an entire result set (such as an entire table's contents).

Examples

How many movies of each rating are there?

```
select count(*), MOVIE_RATING
from MOVIE
group by MOVIE_RATING;
```

Results:

COUNT(*)	MOVIE_RATING
3	PG
6	PG-13
11	R

The various functions can be used without the *group by* clause; however, the value is computed for the entire table. The COUNT(*) function (without the *where* clause) is useful to determine the number of rows that a table contains.

Reducing the Segregated Data

Now that our data are partitioned and we have some calculated information about them, we may want to reduce the number of rows that are output. The proper way to accomplish this is to use the *having* clause. If we continue with the above example, and now only want to view the data associated with the PG and PG-13 grouped values, we could add a *having* clause like this:

```
select count(*), MOVIE_RATING
from MOVIE
group by MOVIE_RATING
having MOVIE_RATING like 'PG%';
```

Note: the *having* clause must be used in conjunction with a *group by* clause, though a *group by* clause can exist without a *having* clause.

Handling Null Values

Remember that null is a special value that can be assigned to an attribute. Most functions, like COUNT(), will ignore a column with a null value. Other calculations, like mathematical operations, treat null as infinity, so that when we add a number to a null value, the result is also a null—that is the result is unknown. There may be times when we want to search out these unknown or not applicable values to fulfill some business query. To search for an attribute with a null value we cannot use the " = " comparison operator; we must use the keyword *is*, yielding an expression of the form "MOVIE_RATING is null." Of course, the converse to "is null" exists: it is "is not null." Many RDBMSs also provide replacement mechanisms for generating reports, so that the null value does not interfere with calculations and the like. Refer to an RDBMS's user guide for the exact syntax.

Joins

So far the various options have been demonstrated against a single table, but if we are using a relational database, then the relationships between tables are equally important. To retrieve result sets with data from multiple tables, we need to use a join. There are several types of joins defined: equi, natural, Cartesian, inner, outer, and self. The equi and natural joins are the most common; the inner, outer, self, and Cartesian are special cases. In all cases, all tables that participate in a join must be listed in the *from* clause.

Equi-joins

An equijoin combines the data from two or more tables based on a match defined in the *where* clause. For example, if we wanted to count the number of tickets sold for a particular movie, we would enter:

```
select count(*)
from TICKETS_SOLD, MOVIE
where TICKETS_SOLD.MOVIE_ID = MOVIE.
  MOVIE_ID and
       MOVIE_TITLE = 'DRIVEN';
```

Natural

A natural join is a specific instance of an equijoin. The join columns must have the same name. The fields must be the same length and data type. When the result set is generated, only one instance of the join column is included.

Cartesian

The product of a Cartesian join is all possible combinations of data combined in one result set. If we have a table A with three rows and a table B with two rows, the Cartesian product result will have six rows:

A
A1
A2
A3

B
B1
B2

select * from A,B
A1 B1
A1 B2
A2 B1
A2 B2
A3 B1
A3 B2

Union

The union operation combines the result sets of two or more queries together into a new result set. This corresponds directly with the union operation in set theory. The only restriction is that the result sets being joined must be union-compatible. That is, the numbers of columns in the result sets to be joined must be the same. Additionally, every corresponding column must be of the same datatype (that is, column 1 of result set 1must be the same datatype as all of the other column 1s from all of the other result sets being so joined). It is up to the developer to ensure that the meaning of the columns is consistent between result sets. Unions are useful when combining related data

that are stored in different tables—such as salaried employee wages and hourly employee wages. It makes no sense to have number of tickets and ticket price joined via a union, but SQL will probably allow it because they are both numeric columns. The syntax is:

```
select statement 1
UNION
select statement 2
```

Minus

The minus operation, also directly ported from set theory, removes matching rows from multiple result sets. This is useful in determine what is different between these results—or "what didn't sell while it was under a promotion." The syntax is:

```
select statement 1
MINUS
select statement 2
```

DDL

Create Table

The *create table* statement allocates storage for data to be stored. This storage has a structure (columns with datatypes) and optional constraints defined. Once the table is created, the table is ready to receive data via the INSERT statement (see below). The syntax is straightforward:

```
create table <TABLE_NAME> (
     <column_element> | <table_constraint> )
```

For example, to create the movie table located in Appendix A, the following syntax was used:

```
CREATE TABLE MOVIE (
       MOVIE_ID         NUMBER        NOT NULL,
       MOVIE_TITLE      VARCHAR2(50)  NOT NULL,
       INVENTORY_ID     NUMBER        NOT NULL,
       MOVIE_RATING     CHAR(5)       NOT NULL,
       PASS_ALLOWED     CHAR(1)       NOT NULL);
```

Keys

When a database is modeled using entity–relationship techniques, identifying attribute(s) are identified for all fundamental entities (tables), along with those attributes that relate two or more tables. The identifying attribute(s) uniquely distinguish one row of data from all others in the table. In SQL these identifying attribute(s) are identified to the database engine as a primary key. Many database engines use this information to enforce the uniqueness property that is inherent in the definition. Attributes that tie relations together are known as foreign keys. Keys can be identified either when a table is created (with the create table command) or after (via the alter table command).

Create Index

The create index statement allows the database engine to create an index structure. An index structure provides a mapping to data in a table based upon the values stored in one or more columns. Indexes are used by the database engine to improve a query's performance by evaluating the *where* clause components and determining if an index is available for use. If an index is not available for use during query processing, each and every row of the table will have to be evaluated against the query's criteria for a match. The syntax is not part of the SQL language specification (Groff & Weinberg, 1999, p. 387) though most DBMSs have a version of the create index statement.

For example, to create an index on the MOVIE_TITLE of the movie table located in the Appendix, the following syntax was used:

```
create index MOVIE_NAME_IDX on MOVIE
  (MOVIE_TITLE);
```

Create View

"According to the SQL-92 standard, views are virtual tables that act as if they are materialized when their name appears" (Celko, 1999, p.55). The term *virtual* is used because the only permanent storage that a view uses is the data dictionary (DD) entries that the RDBMS defines. When the view is accessed (by name) in a SQL *from* clause, the view is materialized. This materialization is simply the naming, and the storing in the RDBMS's temporary space, of the result set of the view's select statement. When the RDBMS evaluates the statement that used the view's name in its *from* clause, the named result set is then referenced in the same fashion as a table object. Once the statement is complete the view is released from the temporary space. This guarantees read consistency of the view. A more permanent form of materialized views is now being offered by RDBMS vendors as a form of replication, but is not germane to this discussion.

The syntax for creating a database view is below:

```
create view <name> [<column list>] as
         <select statement>
```

The power of a view is that the select statement (in the view definition) can be almost *any* select statement, no matter how simple or complex—various vendors may disallow certain functions being used in the select statement portion of a view's definition.

Views have proven to be very useful in implementing security (restricting what rows and/or columns may be seen by a user); storing queries (especially queries that are complex or have specialized formatting, such as a report); and reducing overall query complexity (Slazinski, 2001).

Constraints

Constraints are simple validation fragments of code. They are (from our perspective) either the first or last line of defense against bad data. For example, we could validate that a gender code of "M" or "F" was entered into an employee record. If any other value is entered, the data will not be allowed into the database.

Domains

A domain is a user-created data type that has a constrained value set. For our movie example we could create a movie rating domain that was a 5-character data type that only allowed the following ratings: {G, PG, PG-13, R, NC-17, X, NR}. Once the domain was created, it could be used in any location where a predefined data type could be used, such as table definitions. Not all database vendors support the creation and use of domains; check the user guide for information and syntax specifications.

DCL

SQL's DCL is used to control authorization for data access and auditing database use. As with any application with Internet access, security is a prime concern. Today's RDBMSs provide a host of security mechanisms that the database administrators can use to prevent unauthorized access to the data stored within.

Granting Access to Data

By default, in an enterprise-edition RDBMS, the only user who has access to an object (table, index, etc.) is the user who created that object. This can be problematic when we have to generate a report based on information that is stored in tables that are owned by other users. Fortunately, the solution is the *grant* statement. The syntax is

```
grant <access> on <table> to <user>;
```

One drawback to the grant statement is that it requires a grant statement for every user–object–access level combination—which can be a challenging task in a large enterprise where data security is critical. Accounting departments usually want a high degree of accountability from those individuals who have access to their data. Depending on a database's implementation, there may be mechanisms in place to help ease the burden of security management.

DML

Inserting Data

Syntax:

```
insert into <table> (column {[, column]}))
             values (<value> | <expression>)
```

For A Single Row

For example, inserting a new row of data into the ticket_price table would look like this:

```
insert into TICKET_PRICE values (
                     'MIDNIGHT SHOW', 5.50);
```

For Multiple Rows

If we want to insert multiple rows of data we simply have multiple insert statements; however, if we have data stored in another table that we wish to place in our table (perhaps copying data from a production database into a developer's personal database), we can use an expression.

For instance, if we had ticket price information in a table named master_ticket_price, and we wanted to copy the data into our local ticket_price table, we could issue the following command:

```
insert into TICKET_PRICE
    select * from MASTER_TICKET_PRICE;
```

Now this is assuming that the structure of THE MASTER_TICKET_PRICE table and the TICKET_PRICE table are the same (i.e., the same columns). If we only want a partial set of values from the MASTER_TICKET_PRICE table, we can add a *where* clause to our select statement. Likewise, we can reduce the number of columns by selecting only those columns from the MASTER_TICKET_PRICE table that match our TICKET_PRICE table.

Modifying Data

Syntax:

```
update <table>
set <column> = <value> | <expression>
{where_clause};
```

For a Single Row

To update only one row in a table, we must specify the *where* clause that would return only that row. For example, if we wanted to raise the price of a KIDS movie ticket to $5.00, we would issue the following:

```
update TICKET_PRICE
set PRICE = 5.00
where TICKET_TYPE = 'KIDS';
```

We could perform a calculation or retrieve a value from another database table instead of setting the price equal to a constant (5.00).

For Multiple Rows

For modifying multiple rows there are two options—if we want to modify all of the rows in a given table (say to increase the price of movie tickets by 10% or to change the case of a column), we just leave off the *where* clause as such:

```
update TICKET_PRICE
set PRICE = PRICE * 1.10;
```

If we want to modify selected rows, then we must specify a *where* clause that will return only the desired rows. For example, if we want to raise just the adult prices by 10%, we issue the following:

```
update TICKET_PRICE
set PRICE = PRICE * 1.10
where TICKET_TYPE like 'ADULT%';
```

Removing Data

Syntax:

```
delete <table>
{where_clause};
```

For a Single Row

To delete only one row in a table we must construct a *where* clause that returns only that row. For example, if we wanted to remove the SENIORS movie ticket type, we would issue the following:

```
delete TICKET_PRICE
where TICKET_TYPE = 'SENIORS';
```

For Multiple Rows

For deleting multiple rows there are two options—if we want to delete all of the rows in a given table, we just leave off the *where* clause as such:

```
delete TICKET_PRICE;
```

If we want to delete a set of specific rows from a table, then we must specify a *where* clause that returns only those rows. For example, if we want to delete only the movies that allow passes, we issue the following:

```
delete MOVIE
where PASS_ALLOWED = 'Y';
```

TRANSACTION CONTROL

A database transaction is a unit of work performed. This could be the checkout portion of a shopping cart application—when the user finally hits the purchase button. It could be a data entry person entering time card data or performing an inventory to verify that stock levels match what is on the shelves. In database terms a transaction is a series of DML statements that are logically grouped together. Because there are humans involved, SQL provides us with the ability to recover from mistakes (to a certain degree). We can start a transaction by issuing a "begin transaction" statement. This marks the beginning of our work session. We can then proceed with modifying the data in any way that is required. Once we are sure of our changes—verified via SQL queries, no doubt—we can issue a "commit." The commit statement tells the database engine that we are done with this unit of work and the changes should be made a permanent part of the database. If we are not satisfied with out changes or we made a mistake we can issue a "rollback" statement, which undoes all of the work performed since the "begin transaction" was issued. Note that SQL does not support multiple levels of undo, like many computer applications. Once a commit is issued, we must manually undo any portion of our transaction that we are not satisfied with. The classis example that is often used to illustrate mutual, dependent, or two-phase commits is the use of an ATM machine. When someone uses the ATM machine he or she expects to receive the money requested, and the account will be altered to reflect this withdrawal. Likewise, the bank is willing to give the requesting person his or her money (if sufficient funds are available) and the account is properly adjusted. If both of these actions (dispensing funds and altering account) are successful, then all is well. If either action fails, then all transactions must be rolled back.

MULTIUSER ENVIRONMENTS

One of the reasons for the success of the RDBMS is its ability to handle multiple, simultaneous users. This is a critical feature for many Web sites. Amazon.com would not be around too long if only one person at a time could look up a book's information or check out. However, in order to handle multiple, simultaneous users we must have some locking mechanism in place in order for users not to overwrite each other's information. Likewise, we do not want to delay a user's ability to browse through our dataset while it is being worked on—a common problem for any system (Web site or otherwise) that is in a 24×7 support mode. Various operations cause various types or levels of locks to be placed on the data. For example, in modifying the data, an exclusive lock is entered. This forbids any other user to modify the same data until the first user has completed his or her transaction. A commit or rollback statement will either permanently record or undo the change. This is the why developers should commit often and as early as possible. Too many locks without committing or rolling back the data have profound performance implications. Different RDBMSs lock at different levels—some lock only the data that are modified, others lock certain chunks of data (the affected rows and other rows that are contiguously stored with them). Techniques for dealing with various locks are beyond this chapter.

Concurrency Issues

Concurrency is a big issue in multiuser systems. Every user wants the most current data, yet just because we are entering data into a system does not mean that we entered them correctly—this is why transaction control was invented. All enterprise RDBMSs have a form of locking that permits the querying of data that are in the process of being modified. However, because the data being modified are not yet committed to the database, the query will only be allowed to see the committed data. The impact is this—we can run a query, study the result, and 5 min later, rerun the query and get different results. The only alternative would be to have all queries wait until all of the pieces of information that they are requesting were not being modified by any other users. Another impact, where a user may have to wait until another user has completed a transaction, is when a user wants to modify a piece of information that is in the process of being modified by another user. In this case only one user can modify a piece of information (set of rows in a table) at a time.

Deadlock

Deadlock is a condition where two users are waiting for each other to finish. Because they are waiting on each

other, they can never finish their processing. An example of deadlock would be as follows: User 1 is updating all of the rows in the MOVIE table and at the same time User 2 is updating all of the rows in the TICKET_TYPE table. Now, User 1 decides to update all of the rows in the TICKET_TYPE table. The database will make the user wait (because User 2 currently has the TICKET_TYPE data locked—the transaction has not been committed). Meanwhile, User 2 decides to modify all of the rows in the MOVIE table. Again the database will make User 2 wait (because User 1 has not committed his or her data). At this point deadlock has occurred—both users are in a wait state, which can never be resolved. Many commercial RDBMSs test for deadlock and can perform some corrective measures once it is detected. Corrective measures can range from aborting the SQL statement that caused the deadlock to terminating the session with the least amount of process time that was involved with the deadlock—refer to the RDBMS's user guide for details on a system.

ENHANCED VERSIONS OF SQL

Even though there have been three versions of the SQL language published, there is no vendor that adheres 100% to the standard. All vendors add features to their database engines in an attempt to entice consumers. This is not always a bad feature. This is part of the reason that there have been three standards to date: the database vendors are continuously improving their products and exploring new areas that can be supported by database technologies. Two of the most popular extensions are procedural extensions and specialized derivatives of SQL.

Procedural Extensions to SQL

Although SQL is great at manipulating sets of data, it does have some shortcomings. A few immediately come to mind. It is usually very difficult with standard SQL to produce a top *n* listing, e.g., the top 10 songs on the *Billboard* charts. It is impossible to process a result set, one row at a time. Complex business rules governing data validation cannot be handled by normal constraint processing. Last, performance of SQL queries (from the entire parse, execute, send results perspective) can be very poor when the number of clients is large, such as in a Web environment. Note that a performance gain can be had if every query was stored as a View (see above). The first three of these items are typically handled in stored modules and triggers. The last item can be handled either by using database views or by making use of the database engine's query caching scheme (if it exists)—this is beyond the scope of this chapter.

Stored Modules

A stored module (typically a procedure or function) is a piece of procedurally enhanced SQL code that has been stored in the database for quick retrieval. The benefits of having the code stored are numerous. By storing the code, an end user does not have to type the code in each and every time that it needs to be called upon. This supports the concepts of code reuse and modularity. Performance is increased, because the code has been verified to be correct and security policies can be enforced. For example, if we want to limit access to a given table, we can create an insert stored procedure and grant end users rights to execute the procedure. We can then remove all rights to the table from all users (except the table's owner) and now, if our database is broken into by any username other than the table's owner, the only operation that can be performed is the insert stored procedure.

Triggers

A trigger is a piece of procedurally enhanced SQL code that has been stored in a database, which is automatically called in response to an event that occurs in the database. Triggers are typically considered unavoidable—i.e., if the event for which a trigger has been defined occurs, the trigger fires (is executed). Some RDBMSs do allow bulk load programs to disable the triggering mechanism—refer to the RDBMS's user guide for details.

For example, for security reasons it has been determined that the finance manager will log all modifications to the EMPLOYEE_SALARY table for review. Granted, we could make use of a stored module (refer to the example above) and add the logging code into the stored module. However, we still have the loophole that the database could be broken into using the EMPLOYEE_SALARY table's login ID (or worse yet the database administrator's login!). If this were the case, the stored module would not be the only access point to the EMPLOYEE_SALARY table.

CONCLUSION

This chapter has given a brief introduction to the SQL language, including its historical and mathematical foundations. There are many good resources available online and in books, periodicals, and journals. Even though there is a standard for the SQL language, many vendors have added extensions and alterations that are often used to gain performance enhancements, which are very critical in Web apps. Complications in multiuser environments require that a locking analysis be conducted to detect and correct bottlenecks.

APPENDIX: SAMPLE SCHEMA AND DATA

Figure 1 depicts the tables that are used in this chapter and their relationships. The database supports the operation of a set of movie theaters (named SITES). Each site can run a MOVIE for a given number of weeks (this is stored in MOVIE_RUN). Because a movie can have different showtimes each week that it is being shown, this information is stored in the MOVIE_RUN_TIMES table. Of course, a movie cannot be shown without selling some tickets (TICKETS_SOLD). Because there are various charges for movies, this information is stored in the TICKET_PRICE table.

Supply Chain Management

Gerard J. Burke, *University of Florida*
Asoo J. Vakharia, *University of Florida*

INTRODUCTION

Supply chain management (SCM) is the art and science of creating and accentuating synergistic relationships among the trading members that constitute supply and distribution channels. Supply chain managers strive to deliver desired goods or services to the "right person," in the "right quantity," at the "right time," in the most effective and efficient manner. Usually this is achieved by negotiating or achieving a balance between conflicting objectives of customer satisfaction and cost-efficiencies. Each link in each supply chain represents an intersection where supply meets demand, and directing the product and information flows at these crossroads is at the core of SCM. The integral value proposition of SCM is as follows: Total performance of the entire chain is enhanced when all links in the chain are simultaneously optimized compared with the resulting total performance when each individual link is optimized separately. Obviously, coordination of the individual links in the chain is essential to achieve this objective. The Internet, and information technology in general, facilitate the integration of multitudes of channel enterprises into a seamless "inter"prise, leading to substitution of vertical integration with "virtual integration." Overcoming coordination roadblocks and creating incentives for collaboration among disparate channel members are some of the major current challenges in SCM.

How well the supply chain performs as a whole hinges on achieving fit between the nature of the products it supplies, the competitive strategies of the interacting firms, and the overall supply chain strategy. Planning also plays a key role in the success of supply chains. Decisions regarding facility location, manufacturing schedules, transportation routes and modes, and inventory levels and location are the basics that drive supply chains. These dimensions of tactical effectiveness are the sprockets that guide the chain downstream through its channel to end demand. Accurate and timely integrated information lubricate the chain for smooth operation. Information technologies allow supply chains to achieve better performance by providing visibility of the entire supply chain's status to its members, regardless of their position in the chain. The success of the collaborative forecasting, planning, and replenishment (CPFR) initiative illustrate the value of the internet to SCM (CPFR Committee, n.d.). A few of the most popular information tools or vehicles available to supply chains are enterprise resource planning (ERP) software and related planning applications, application service providers (ASP), online markets and auction mechanisms (business-to-business [B2B] commerce), and electronic customer relationship management (eCRM and business to consumer [B2C]).

A supply chain can be visualized as a network of firms servicing and being serviced by several other businesses, although it is conceptually easier to imagine a chain as a river, originating from a source, moving downstream, and terminating at a sink. The supply chain extends upstream to the sourcing of raw materials (backward integration) and downstream to the afterlife activities of the product, such as disposal, recycling, and remanufacturing (forward integration). Regardless of magnitude, all supply chains can be visualized as consisting of a sourcing stage, a manufacturing stage, and a distribution stage.

The supply chain operations reference model developed by the Supply Chain Council (n.d.) assumes that all processes at each of these stages are integral in all businesses. Each stage plays both a primary (usually physical transformation or service creation) and a dual (market mediator) role. This primary role depends on the strategy of the supply chain, which in turn, is a function of the serviced products' demand pattern (Fisher, 1997). The most strategic link is typically in the manufacturing or service creation stage, because it is positioned between suppliers and consumers. Depending on the structure of the chain (in terms of products and processes employed), power can shift from the supplier (e.g., monopolist supplier of key commodities such as oil), to the manufacturing (e.g., dominant producer of a unique product such as semiconductors), to the distribution (e.g., key distributor

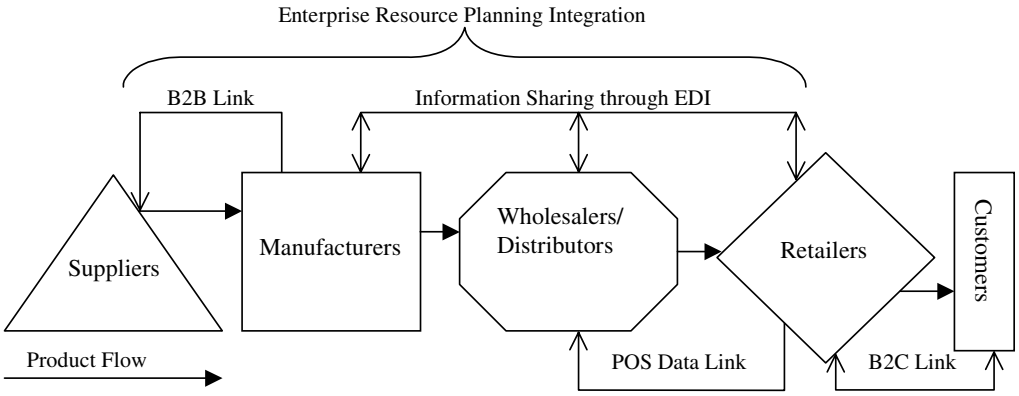

Figure 1: Example of an information-enabled supply chain.

of consumer items) stage in the supply chain. Obviously, power in the supply chain has a key bearing on the strategic positioning of each link in the chain.

The remainder of this chapter is organized as follows. In the next section, we describe the key strategic and tactical issues in SCM. This is followed by a discussion of mechanisms for coordinating stages in the supply chain. The third and final section focuses on describing the significant impact of information technology on SCM practices.

STRATEGIC AND TACTICAL ISSUES IN SCM

A holistic supply chain comprises multiple processes for suppliers, manufacturers, and distributors. Each process employs a distinct focus and a related dimension of excellence. Key issues in managing an entire supply chain relate to (a) analyzing product strategies, (b) network design and the related sourcing strategy employed, and (c) a strategic and tactical analysis of decisions in logistics, manufacturing, distribution, and after-sale service. It is our view that by analyzing product demand characteristics and the supply chain's capabilities, and crafting a fit between them, an individual manager can ensure that the specific process strategy employed does not create dissonance in the entire supply chain.

Product Strategies

SCM has evolved from process reengineering efforts to coordinate and integrate production planning at the factory level to initiatives that expand the scope of strategic fit beyond a single enterprise (Chopra & Meindl, 2001). Positive results from intra-functional efforts extended the SCM philosophy throughout the enterprise. Process improvements at the firm level highlighted the need for suppliers and customers of supply chain managed firms to adopt the SCM philosophy. A supply chain is only as strong as its weakest link. How the chain defines strength is at the core of a supply chain's strategy and, therefore, its design. Is strength anchored in efficiency, responsiveness, or both?

Achieving a tight fit between the competitive strategies of supply chain members and the supply chain itself is gained by evaluating the characteristics of the products serviced by the chain. "The root cause of the problems plaguing many supply chains is a mismatch between the type of product and the type of supply chain" (Fisher, 1997, p.105). Critical product attributes are (a) the demand pattern, (b) the life cycle, (c) the variety of offerings, and (d) the product delivery strategy. Fisher (1997) categorized a product as being either functional (basic, predictable, long-lived, low profit margin) or innovative (differentiated, volatile, short-lived, high profit margin). Furthermore, using the product life-cycle argument, innovative products (if successful) will eventually evolve to become functional products. The types of supply chain needed to service these two categories of products effectively are distinct. An efficient or low-cost supply chain is more appropriate for a functional product, whereas a responsive or customer attuned supply chain fits an innovative product better. Obviously, a spectrum of chain varieties exists between the end points of responsiveness and efficiency, hence most tailored supply chains are hybrids that target responsiveness requirements for each product serviced while exploiting commonalities in servicing all products to gain economies of scope. Thus, the strategic position of a supply chain balances customer satisfaction demands and the firm's need for cost minimization.

Information technologies enable both efficient and responsive supply chains because they have the potential to provide immediate and accurate demand and order status information. Efficiency gains via information technologies are gleaned from decreased transactional costs resulting from order automation and easier access to information needed by chain members. Likewise, responsiveness gains can be obtained by a quicker response to customer orders. Hence, in practice, it seems to have become standard for all supply chains to use some form of information technology to enable not only a more efficient physical flow of their products but also to simultaneously improve their market mediation capability.

Network Design

Network decisions in a supply chain focus on facility function, facility location, capacity, and sourcing and distribution (Chopra & Meindl, 2001). In general, network design

determines the supply chain's tactical structure. The significant capital investments required in building such a structure indicate the relative long run or strategic importance of network decisions.

Facility Function

How will each network investment facilitate the supply chain strategy? Consider a manufacturing plant. If the plant is set up to produce only a specific product type, the chain will be more efficient, but less flexible than it would be if the plant produced multiple product types. A supply chain providing innovative products will likely perform better with flexible manufacturing facilities.

Facility Location

What locations should be chosen for facilities? A good decision in this dimension is essential because the cost ramifications of a suboptimal location could be substantial. Shutting down or moving a facility is significant not only in terms of financial resources but also in terms of the impact on employees and communities. Other factors that should be considered are the available infrastructure for physical and information transportation, flexibility of production technologies employed, external or macroeconomic influences, political stability, location of competitors, availability of required labor and materials, and the logistics costs contingent on site selection.

Capacity

Depending on the expected level of output for a facility, capacity allocations should be made so that idle time is minimal. Underutilization results in lower return on investment and is sure to get the attention of company executives. On the other hand, underallocating capacity (or large utilizations) will create a bottleneck or constricted link in the supply chain. This will result in unsatisfied demand and lost sales or increased costs as a result of satisfying demand from a nonoptimal location. The capacity allocation decision is a relatively long-term commitment, which becomes more significant as sophistication and price of the production technology increases.

Supply and Distribution

Who will serve our needs, and whose needs will we serve? This is a recurring question. Decisions regarding the suppliers to a facility and the demand to be satisfied by a facility determine the costs of material inputs, inventory, and delivery. Therefore, as forces driving supply or demand (or both) change, this decision must be reconsidered. The objective here is typically to match suppliers and markets to facilities to minimize not only the systemwide costs but also the customer responsiveness of the supply chain. In general, these criteria are often orthogonal, implying that the sourcing and distribution decisions require a multiobjective focus with some prioritization of the cost and responsiveness aspects.

Each of these network design decisions are not made in isolation since there is a need to prioritize and coordinate their combined impact on the tactical operations of the supply chain. They jointly determine the structure of the supply chain, and it is within this structure that tactical strategies are implemented to reinforce the overall strategy of the entire chain. Once network design has been finalized, the next key decision within the supply chain focuses on sourcing strategies.

Sourcing Strategies

A primary driver of a firm's SCM success is an effective sourcing strategy. The firm's ability to deliver its goods and services to customers in a timely manner hinges on obtaining the appropriate resources from the firm's suppliers. Because manufacturing firms typically spend more than 50% of earned revenue on purchased materials, the costs of disruptions to production due to supply inadequacies are especially significant. Furthermore, a firm's financial and strategic success is fused to its supply base.

The nature of a firm's connection to its suppliers is evident in its sourcing strategy and is characterized by three key interrelated decisions: (a) how many suppliers to order from, (b) what criteria to use for choosing an appropriate set of suppliers, and (c) the quantity of goods to order from each supplier.

Single sourcing strategies seek to build partnerships between buyers and suppliers to foster cooperation and achieve benefits for both players. With the adoption of just-in-time inventory policies, supplier alliances with varying degrees of coordination have shifted supply relations toward single sourcing to streamline the supply network. At the strategic level, single sourcing contradicts portfolio theory. By not diversifying, a firm is assuming greater risk. Therefore, tactical single sourcing benefits need to justify the riskiness inherent in this relationship. One method of alleviating the risks of single sourcing is to ensure that suppliers develop contingency plans for materials in case of unforeseen circumstances. In fact, suppliers dealing with IBM are required to provide details of such contingency plans before the company will enter into purchasing contracts with them.

The obvious benefits of single sourcing for the firm are quantity discounts from order consolidation, reduced order lead times, and logistical cost reductions as a result of a scaled down supplier base. The ordering costs advantage of single sourcing is diminishing, however, because of the proliferation of Internet procurement tools, which tend to reduce ordering costs and streamline purchasing processes.

In contrast, a larger supply base possesses greater upside volume flexibility through the summation of supplier capacities. Strategically, a manufacturer's leverage is kept intact when the firm diversifies its total requirements among multiple sources. Additionally, alternative sources hedge the risk of creating a monopolistic (sole source) supplier, and the risk of a supplier integrating forward to compete with the buying firm directly. Online exchanges and marketplaces also provide multiple sourcing benefits by automating the cumbersome tasks associated with multiple supplier dealings.

In concert with decisions regarding the number of suppliers for a product, a firm must develop an appropriate set of criteria to determine a given supplier's abilities to satisfy the firm's requirements. In practice, this is evaluated using scoring models which incorporate quantifiable

and qualitative factors related to quality, quantity, delivery, and price. Although the supplier's price may be the most important criteria for generic or commodity-type goods, other dimensions incorporated in these models are probably more or equally important for innovative products. Thus, supplier selection is not simply a matter of satisfying capacity and price requirements, but also needs to integrate supplier capabilities in terms of quality and delivery. It should be obvious that it is the collective suppliers' capabilities that can enable or limit supply chain performance at its inception.

Once an appropriate set of suppliers has been identified, the firm must determine a suitable order quantity for each vendor. Because the overall demand for the firm's goods are typically uncertain, newsboy-type models can be successfully used in this context. Essentially, these models take into account the cost of inventory (overage cost) and the cost of unsatisfied demand (underage cost) to determine an appropriate order quantity. Ultimately, decisions regarding the number of suppliers from which to purchase, supplier selection, and order quantity allocation among selected suppliers should support the supply chain strategy's focal purpose of being efficiently responsive or responsively efficient. Sourcing decisions are one of the primary drivers of transportation and logistics-related issues discussed in the following section.

Transportation and Logistics

Transportation decisions affect product flow not only between supply chain members but also to the market place. In most supply networks, transportation costs account for a significant portion of total supply chain cost. Transportation decisions are mainly tactical, however. In determining the mode(s) and route(s) to employ through the supply chain, transportation decisions seek to strike a balance between efficiency and responsiveness so as to reinforce the strategic position of the supply chain. For example, an innovative product's typically short life cycle may warrant expensive air freight speed for a portion or all of its movement through the chain, whereas a commodity is generally transported by slow but relatively economical water or rail freight. Shipping via truck also is used frequently. Trucking is more responsive and more expensive than rail and less responsive and less expensive than air. Most supply chains employ an intermodal strategy (e.g., raw materials are transported by rail or ship, components by truck, and finished goods by air).

A supply chain's transportation network decisions are inextricably linked to its network design decisions. Transportation network design choices drive routing decisions in the supply network. The major decisions are whether to ship directly to buyers or to a distribution center and whether a routing scheme is needed. A direct shipping network ships products directly from each supplier to each buyer. A "milk run" routed direct shipping network employs a vehicle to ship either from multiple suppliers to a single buyer or from a single supplier to multiple buyers. A network with distribution centers ships from suppliers to a warehouse or distribution facility. From this facility, buyers' orders are picked from the distribution center's inventory and shipped to the buyers. This design can also employ milk runs from suppliers to the distribution center and from the distribution center to the buyers. Through the supply network, combinations and variants of these designs that best suit the nature of the product provide locomotion from supplier to buyer.

B2C transactions enable end consumers to demand home delivery, creating a larger number of smaller orders. This trend has enhanced the role of package carriers such as FedEx, United Parcel Service, and the U.S. Postal Service in transporting consumer goods. Additionally, bar coding and global positioning systems (GPS) provide accurate and timely information of shipments enabling both buyers and suppliers to make better decisions related to goods in transit. Technological advancements of the past decade enable consumers to demand better responsiveness from retailers. The resulting loss of some scale economies in shipping, have been offset by shipping cost decreases due to information-technology-enabled third-party shippers that more efficiently aggregate small shipping orders from several suppliers. As consumers' expectations regarding merchandise availability and delivery become more instantaneous, the role of a supply chain's transportation network in overall performance expands. This provides the link to operations and manufacturing issues because the role of information technology has forced these processes in a supply chain to be more responsive.

Operations and Manufacturing

"A transformation network links production facilities conducting work-in-process inventories through the supply chain" (Erenguc, Simpson, & Vakharia, 1999, p. 224). Suppliers linked to manufacturers linked to distribution systems can be viewed as a transformation network hinging on the manufacturer. Transforming supplies begins at the receiving stations of manufacturers. The configuration of manufacturing facilities and locations of transformation processes are determined by plant-level design decisions. The manufacturing process employed at a specific plant largely drives the decisions. An assemble-to-order plant may have little investment in production but a great deal of investment in storage. A make-to-stock facility may have little or no investment in component inventory but a great deal of investment in holding finished goods inventory. A make-to-order factory may have significant investment in components and production facilities, and no finished goods investment. A product's final form can also take shape closer to the end consumer. To keep finished goods inventory costs as low as possible and to better match end demand, a supply chain may employ postponement to delay customizing end products.

Major design decisions such as facility configuration and transformation processes are considered long-term decisions, which constrain the short- to mid-term decisions addressed in a plant's aggregate plan, a general production plan that encompasses a specific planning horizon. Information required to develop an effective aggregate plan include accurate demand forecasts, reliable supply delivery schedules, and the cost trade-offs between production and inventory. Each supply chain member develops an aggregate plan to guide short-term operational

decisions. To ensure that these individual plans support each other, the planning process must be coordinated. The degree and scope of coordination will depend on the economics of collaborative planning versus the costs of undersupply and oversupply. It is likely unnecessary and impossible to involve every supply chain member in an aggregate plan for the entire supply chain; however, a manufacturer should definitely involve major suppliers and buyers in aggregate planning. Whether this planning information trickles to other supply chain members (a key for the success of integrated supply chain management) will depend on the coordination capabilities of successive layers of members emanating from a collaborative planning center, which is often the major manufacturer.

The strategy employed to execute the aggregate plan is a function of the information inputs into the aggregate plan. It is vital that these inputs be as accurate as possible throughout the entire supply chain. Integrated planning in a supply chain requires its members to share information. The initiator of integrated planning is typically the major manufacturer. To understand why, we must understand the dynamics of distribution.

Distribution Channels

To anticipate the quantity of product to produce, a manufacturer must compile demand forecasts from downstream supply chain members. Forecasting accuracy is paramount because it is the basis for effective and efficient management of supply chains. The root challenge of SCM is to minimize costs and maintain flexibility in the face of uncertain demand. This is accomplished through capacity and inventory management. Similarly, marketers attempt to maximize revenues through demand management practices of pricing and promotion. Therefore, it is vital that marketing and operations departments collaborate on forecasts and share harmonious incentive structures. The degree of coordination among order acquisition, supply acquisition, and production process directly affects how smoothly a firm operates. Likewise, the coordination level of buyers, suppliers, and producers directly affects how smoothly the supply chain operates. More specifically, accurate information flows between channel members are essential to SCM.

A distribution channel is typically composed of a manufacturer, a wholesaler, a distributor, and a retailer. The "bull-whip effect" is a classic illustration of dysfunction in such a channel due to the lack of information sharing. This effect is characterized by increasing variability in orders as the orders are transferred from the retailer upstream to the distributor, then to the wholesaler, and finally to the manufacturer. Distorted demand information induces amplifications in variance as orders flow upstream. Therefore, the manufacturer bears the greatest degree of order variability. It is for this reason that manufacturers often initiate collaborative efforts with downstream channel members.

Lee, Padmanabhan, and Whang (1997) analyze four sources of the bull-whip effect that correspond to respective channel practices or market conditions. The first two causes are a direct consequence of channel practices, whereas the latter two causes are more market-driven. The first source, demand signal processing, is largely due to the use of past demand information to modify demand forecasts. Each channel member modifies her or his forecasts and resulting orders in isolation. These multiple forecasts blur end demand. This problem is exacerbated as lead time lengthens. Current practices employed to remedy this source of information distortion include contractual agreements to provide point of sale data from retailers to manufacturers, vendor managed inventory to centralize ordering decisions, and quick response manufacturing to decrease lead times for order fulfillment. The second source of information distortion, order batching, arises mainly from periodic review ordering practices and processing costs of placing orders. Without specified ordering times, the timing of order placement for several vendors may coincide as a result of fiscal period delineations. Additionally, a buyer may accumulate orders to minimize high costs of ordering and shipping. Measures that can alleviate these causes are automated and fixed-time ordering, electronic data interchange (EDI), and the use of third-party logistics providers to offset less than truckload diseconomies. These first two causes of information distortion generally result from each channel member individually optimizing inventory decisions.

Price fluctuations, the third cause of the bull-whip effect, result from marketing efforts such as trade promotions to generate increases in sales volumes. Wholesale price discounts result in forward buying by retailers. The lower price motivates retailers to stock up on product for not only the current but also future periods. This strategy results in uneven production schedules for manufacturers and excess inventory carrying costs for retailers. The push for everyday low prices is an effort to do away with trade-promotion-induced order variability. The final cause of the bullwhip effect occurs when there exists a perceived shortage of product supply. If the supplier adopts a rationing scheme that is proportional to the quantity ordered, buyers will simply inflate their orders to ensure receipt of their true requirements. This type of gaming can be avoided by rationing based on historical market share of buyers and information sharing between buyers and suppliers to prevent supply shortages.

This concludes our discussion of key strategic and tactical issues in managing supply chains. In general, it is obvious that chain members are motivated to minimize information distortion and resultant order variability. It is also clear that the remedies to these problems are rooted in information sharing upstream through the supply chain. Coordination mechanisms facilitating information sharing in a supply chain are described in the next section.

SUPPLY CHAIN COORDINATION

In a supply chain, coordination occurs when the constituents act in unison for the betterment of the supply chain as a whole rather than their own link. Thus, it is likely that on an individual basis, a chain member may stand to suffer a "loss" associated with a coordinated decision. In economics, this is the classical principal-agent dilemma. Supply chain coordination is fraught with

impediments stemming from human nature and technological limitations. On the other hand, in addition to "bull-whip" remedies, mechanisms do exist to promote coordination within the supply chain, and these are described next.

Incentive Impediments

Lee and Whang (1999) discuss incentive problems that prevent coordination in a supply chain with a decentralized decision structure. In this type of system, each site manager makes decisions to optimize his or her personal benefit. This type of incentive misalignment can exist within and between functional areas of a site (firm) and also between sites (firms) in the supply chain. For instance, a marketing manager's objective may be revenue maximization, and he or she may attempt to generate sales with trade promotions to induce forward buying. Meanwhile, a manufacturing manager may have a conflicting objective, such as minimizing production variability or level utilization. As illustrated through the bull-whip effect, trade promotions generally increase variability in production.

These types of conflicts of interest can be addressed by corporate operating guidelines or rules. For instance, manufacturing representatives should be evaluated over a rolling horizon on average sales of their products by their customers instead of to their customers. This performance measurement scheme removes the incentive to foster forward buying and reduces cycle inventories. Although, this type of approach works well for allaying conflicts within a firm, to mitigate incentive misalignment between firms, contractual relationships are formed. From a supply chain perspective, two obvious conflicts of interest exist between upstream managers and retail managers. The upstream managers covet end demand information that retailers own and which, in isolation, they have no incentive to share. Likewise, if retailers are the only site managers penalized for stock-outs, upstream sites have no incentive to carry safety stock even though they typically incur lower inventory carrying costs than retailers. To reconcile conflicting interests, channel members resort to manipulating performance requirements embedded in contractual agreements.

Fostering Trust between Partners

Contractual agreements can also be used to develop a foundation of trust between trading partners. A simple contractual relationship is far from a collaborative relationship, however. Firms' inability to collaborate has often been blamed on technological limitations of information management. Interestingly, Gallagher (2001) commented that during a spring 2001 Supply Chain Council executive retreat, that attendees cited a "lack of trusted relationships between key supply chain participants" as the main obstacle to effective collaboration. Information sharing is no longer constrained by information technologies; it is held back by the impersonal nature of automation. Collaboration, especially information sharing, is limited by shallow business relationships. It is for this reason that collaborative supply chains seek to identify channel members that add significant value and develop richer relationships with those firms. Higher levels of trust can be achieved through elaborate and exhaustive contingency contracts or by interacting over time in a consistent mutually beneficial manner. These relationships can be sustained if both parties are mutually interdependent and gain mutual benefit from the partnership. Whether the investment in strategic alliances is justified will depend largely on the supply chain's strategy.

Incentives from Terms of Sale

Supply chain coordination can be accomplished through a quantity discount schedule for commodity type products. Because prices for these products are set by the market, a lot size quantity discount scheme can coordinate the supply chain. This holds as long as the increased cycle inventory costs are less than the benefits of the quantity discount scheme. This mechanism is well suited for supply chains with an efficiency driven strategy associated with commodities. A related approach for incentivizing suppliers is to enter into long-term blanket orders with multiple order releases within the planning horizon.

If a seller has market power through a patent, copyright, and so on, channel coordination can be achieved through volume-based quantity discounts. The key difference between this scheme and the lot size quantity discount is that the volume-based discount is based on the rate of purchase instead of the amount purchased per order. An example of a volume-based quantity discount is a two-part tariff. With this arrangement, the seller charges an initial fee to cover his profit, and then unit prices are set to cover production costs.

Another way sellers can induce buyers to purchase greater quantities is to have a returns policy. In offering a buyback contract, a seller stipulates a wholesale price per unit as well as a buyback price. The optimal order quantity for the buyer then rises as a result of a guaranteed salvage value for unsold products. In situations in which the costs of returns are high relative to the salvage value of the product, sellers may coordinate the supply chain through quantity flexibility contracts. This arrangement allows buyers to modify their order quantity after observing their respective demand. Rather than committing in advance of observing demand to a specific order quantity, the buyer commits to a minimum order quantity, and the seller commits to providing a maximum quantity. Total supply chain profits can increase as a result of this contractual agreement. By manipulating the terms of sale, sellers can induce buyers to purchase in greater quantities, which ensures sellers greater profitability. What is somewhat surprising is that buyers, too, can gain increased profits if these terms of sale are appropriately set.

Supply chain coordination can be achieved if incentives are aligned throughout the supply chain via contracts or consistent performance measures, information passes accurately through the supply chain, operations perform optimally, and the requisite level of trust exists within the supply chain. It is therefore understandable that until recently, achieving channel coordination or optimizing total supply chain performance seemed impossible.

With advances in information technologies over the past decade, however, this pipe dream may actually become reality.

INFORMATION TECHNOLOGY AND SCM

At the overall level, the broadest impact of information technology on SCM is by enabling tighter connectivity between supply chain members. The time and distance gaps that previously hampered information flows and supply chain responsiveness are all but eradicated by the Internet's relative immediacy of access to existing information. Keskinocak and Tayur (2001, p. 71) noted that the Internet's rapid communication, innovative trading spaces, accessibility of new distribution channels, and facility for collaboration encourages supply chain managers the rationale for envisioning virtual integration as a reality. Obviously, sharing of accurate information is essential for collaboration. To this end, trading partners must have a means to exchange information. The explosion of ERP implementations in the 1990s "dramatically improved the quantity and quality of data" that could be used for effective SCM (Sodhi, 2001, p. 56). Current information technologies such as enterprise applications, on-line auctions, e-markets, and web-based services provide gears that supply chain managers can shift to tailor the sequence of paths taken by the chain to best move its product(s).

Enabling Collaboration

ERP systems, offered by firms such as SAP and Oracle, provide the basic functionality of visibility and tracking on which tighter connectivity is executed. For example, through Web interfaces, customers and suppliers can place orders to the firm or provide replenishment information for the firm. The ERP system pulls this information from a database and compiles an enterprisewide view that provides order status information for customers, generates shipping orders to suppliers, and inventory positions to APS applications offered by SAP, Oracle, i2 Technologies, Manugistics, and others.

APS provides planning and execution functionality, and these products have become more focused and refined to keep pace with empowered customers seeking efficiencies through collaboration (Harreld, 2001). More specialized SCM applications for supply management generally are execution or planning focused. For example Sears, Roebuck & Company and its major appliance suppliers use a SeeCommerce execution focused application to manage supply chain performance. This application pulls data from transactional purchasing and quality assurance systems to generate real-time performance metrics that are visible to each supplier. This allows Sears and its appliance vendors to address problems proactively before they become unwieldy. Alternatively, a planning focused SCM application by SynQuest is used by Ford Motor Company to optimize auto part delivery costs in a just-in-time environment. This software models Ford's myriad of inbound logistics and evaluates several variables to determine the best movement of inbound parts. As a result of this implementation, missing parts errors have improved 100-fold.

Application service providers (ASP) play a key role in information-enabled supply chain coordination and collaboration by providing Web-based focused solutions for tactical planning. The standardization of data largely due to the adoption of XML (extensible markup language) allows disparate ERP and ASP applications to transact. ASPs provide small supply chain members with small budgets an avenue to tighter connectivity. In additional to B2B portal provision, ASPs provide value to their customers by providing software applications, access to hardware, or consulting services to allow customers to outsource some or all of their IT functions effectively. Standardization efforts through the CPFR Committee strive to foster effective SCM via the internet. Furthermore, interoperability of applications across the supply chain appears more viable with Web services platforms such as Microsoft.NET.

Auctions and Exchanges

Major ERP vendors also provide products that enable firms to create online auctions. The time and financial resources spent developing and organizing an auction are significant overhead expenses. Therefore, industry partnerships or third parties host many auctions and e-markets. B2B (e.g., Covisint) and B2C (e.g., Onsale) exchanges are dramatically changing the manner in which supply chain activities are being structured. The underlying structure of these exchanges is built around an auction mechanism. In general, an auction can be viewed as a way for sellers to obtain information on the reservation prices of potential customers in the market for a particular product. The implementation of auctions on the Web provides a guarantee for consumers in terms of price efficiencies and simultaneously helps to match buyers and sellers.

Electronic End Demand Fulfillment

With ever-increasing consumer demands for customization and competition, and ever-decreasing product life cycles, SCM has gravitated toward a sense and respond approach. Sodhi (2001) provided the following examples of Internet enabled demand fulfillment processes:

Design

The data regarding end-consumer-preferred product attributes can be gathered quickly and efficiently through Web surveys. Designers can also collaborate and plan product launch particulars via the Internet to speed up time to market.

Customer-Relationship Management

Data collected from navigational paths of individual Web site visitors can be used to predict purchasing behavior, which can lead to better forecasts and inventory decisions for e-businesses. For example, collaborative filtering software compiles profiles based on customers browsing or purchasing behavior to fit them into a market segment. Based on this real-time classification, advertisements are displayed to entice initial or further purchases. Collaborative filtering is one method of personalization. Personalization attempts to modify Web site offerings to match

the interests of individuals. Another personalization tool is "clickstream" analysis.

Self-Service

Web-based package tracking provided by United Parcel Service and FedEx is an example of the Internet providing better service to customers at a lower cost per transaction to the seller. Other online applications read e-mail from customers to sort or even respond to e-mail, providing more timely feedback to customers.

Disintermediation

The current state of information technology also expands the options available for distributing products. Manufacturers that were once reliant on wholesalers, distributors, and retailers can more effectively market directly to end customers. The success of Dell's direct model, which leverages Internet technologies, has encouraged other firms to pursue direct selling. Nonetheless, although one can eliminate a link in a supply chain, the functions that link performs cannot be eliminated.

SUMMARY

At the core of SCM is the optimal coordination of activities at and between individual supply chain members. We have outlined how supply chain members individually and collectively must support and enhance the characteristics of the products serviced by the chain. Friction between product type and the type of supply network servicing the product may be the underlying cause of many supply chain problems. Given that product and supply chain strategies are aligned, effective execution of the SC's strategy is built on operational foundations including overall network design, sourcing, logistics, transformation processes, and distribution channels. These basic activities work in concert to balance requirements of quality or service levels with economic realities of cost containment. Supply chain managers invariably rely on information technology to facilitate more efficient physical flow of their products, and foster better market mediation throughout the chain.

Coordinating the activities of the links in the supply chain to act in the best interest of the entire chain is a major challenge. The information technology required to streamline transactional processes and enable integrated decision making throughout the supply chain exists. Therefore, the key to accomplishing coordination is establishing and maintaining trust between trading partners. SCM seeks to elevate the supply network's performance with technology while enhancing business relationships between its constituencies. The science of SCM demonstrates that the supply network's sum is greater than sum of its parts, while persuading decentralized members of the network to act in the best interest of the network overall is probably more of an art than a science.

GLOSSARY

Application service provider (ASP) A remote provider that hosts software and provides access for a periodic rental fee.

Advanced planning and scheduling (APS) Applications employed to optimize production schedules or supply chain activities.

Business-to-business (B2B) Electronic business conducted between two firms.

Business-to-consumer (B2C) Electronic business conducted between a firm and a consumer.

Collaborative planning forecasting and replenishment (CPFR) Efforts to coordinate supply chain members through point-of-sale data sharing and joint planning.

Distribution channel Supply chain members involved in moving end products to consumers.

Electronic customer relationship management (eCRM) Applications designed to automate demand satisfaction.

Enterprise Resource Planning (ERP) Information systems that keep track of transactional data to provide decision makers with better information.

Newsboy model Inventory model to determine the optimal balance between stock-out and inventory holding costs.

Postponement Delaying product customization until closer to the point of sale.

Vendor managed inventory A suppliers' making replenishment decisions based on retailer sales data for products at retail sites.

Extensible markup language (XML) Language designed to describe data that is key to efficient Web-based data transfer and manipulation.

Supply Chain Management and the Internet

Thomas D. Lairson, *Rollins College*

INTRODUCTION

The Internet creates a new environment for exchanging information and conducting business transactions. More than ever possible before, the Internet increases the quantity and expands the richness of information in real time to a much wider set of participants and thereby raises dramatically the value of information in supply chain management. The Internet also increases transparency, which is the ability to "see across the supply chain," through the enhanced capacity to obtain, distribute, and create information across distances, and does so at a cost that has been decreasing by 35% per year.[1] This ability changes the management of supply chains by expanding capabilities and extending the scope of management across the supply chain, and contributes to reductions in cost and improved service. As a consequence, the strategic calculations of firms must now incorporate supply chain operations and new business models that concentrate on reaping the benefits of an Internet-based supply chain. This places a tremendous premium on creating, sharing, and using information throughout the supply chain. Where once firms in a supply chain had little choice but to operate mostly alone in an information vacuum, now they must operate in a collaborative environment with an abundance of information. Trade-offs that once seemed immutable are now significantly modified by new Internet capabilities.

THE GLOBAL BUSINESS REVOLUTION AND SUPPLY CHAINS

The Internet has emerged as a new medium of business at a time of revolutionary changes in global business, and it will reinforce and accelerate these changes. Many traditional business problems and issues will continue into the Internet era, but with new technological options and management challenges. The business environment began to change in the 1970s, as a result of the globalization of production, trade, and capital flows (Nolan, 2001). Making this possible were the familiar forces of falling trade barriers, liberalization of capital movements, and declining transportation, communication, and information processing costs. The result was a transformation of the production of goods, with a focus on cost reduction through lean manufacturing, shortened product cycles and more flexible manufacturing capabilities, and increasing pressure for greater product variety and customization. The new competition made many firms rethink their capabilities and shed secondary operations so as to focus on "core capabilities." The most competitive firms were able to develop a global brand and amass the product technology, R&D, financial strength, information technology, and human resources necessary to develop and manufacture products through globally constructed supply chains. These "core system integrators" were successful in assembling the most globally competitive suppliers—usually those with the ability to invest in the needed R&D and information technology—and this forced second-tier suppliers to make similar investments needed to participate in the system. The consequence was a geographical dispersion of production and a much finer division of labor within supply chains, with ever more differentiated product components located in ever wider geographical areas. This global value chain typically is tied together by the "system integrator," a firm that is especially effective in gathering and distributing information on a global scale.

These global supply networks have restructured the competitive position of firms and the development opportunities of nations. Supply chains have become a central source of competitive strength, operating as the main ingredient for the development of a system of lean, flexible production, customization, and rapid, accurate distribution. Firms have been forced to upgrade the efficiency of their supply chains, and this process raises the value of information dramatically. Many of these changes had occurred by the mid-1990s, when the Internet emerged

[1] This calculation is derived from Moore's Law, which describes the rate of increase in the number of transistors on a fixed size of semiconductor material. Gordon Moore predicted, correctly, that this number would double every 18 months. The consequence is that the processing power of a computer doubles every 18 months, at a constant to falling cost. The result is that the cost of information creation and distribution falls by roughly 35% per year and has done so for more than 30 years (Woodall, 2000).

as a commercial instrument. Building on already developed technologies such as electronic data interchange (EDI) and satellite communication, the Internet has become a central technology for advancing the revolutionary changes occurring in the nature and location of production.

HOW DOES THE INTERNET AFFECT SUPPLY CHAIN MANAGEMENT?

The management of a supply chain in the era of globalization, lean and flexible manufacturing, and mass customization presents managers with a formidable set of tasks. The need for lower costs, greater speed, more flexibility, and increased service generates a series of optimization problems compounded by a complex array of trade-offs. Because the Internet is a cost-effective and near-ubiquitous medium of information exchange, it expands the opportunities for coping with these difficulties. The most direct effect of the Internet is to create new opportunities to improve the efficiency and effectiveness of the operation of the supply chain. This is because of the cost-effective capacity to generate visibility across all aspects of the supply chain, including point-of-sale information, manufacturing schedules, vendor stocks, customer inventories, demand patterns, sales/marketing initiatives, and carrier schedules. However, achieving these gains requires many management decisions and organizational changes, most of which are focused on recognizing the value of collaboration among members of the supply chain and designing a system to facilitate this collaboration. At the same time, barriers to collaboration arise from the different interests and needs of the members of the supply chain, and because the benefits are not equally available to all members. Collaboration is also difficult to achieve because it requires a rethinking of the nature of the business enterprise and the relationships among external suppliers, core business operations, and customers.

The application of the Internet to the management of supply chains is one of the most important forms of e-business. Supply chain management is the organization, design, optimization, and utilization of the business processes and physical and information networks that link raw materials to the delivery of end products to customers. The supply chain is a system of production, assembly, exchange, information flows, financial flows, transactions, physical movement, and coordination. The business processes involved include relationships with customers, fulfillment of orders, payment, management of demand, procurement of materials and supplies, manufacturing coordination, and the logistics of moving materials and products (Lambert, 2001).

However, what is e-business? By one definition, it is the "marketing, buying, selling, delivering, servicing, and paying for products across (nonproprietary) networks to link an enterprise with its prospects, customers, agents, suppliers, competitors, allies, and complementors" (Weill & Vitale, 2001, p. 5). Others have offered a view emphasizing e-business applications to the supply chain: "planning and execution of the front-end and back-end operations in a supply chain using the Internet" (Lee & Whang, 2001a, p. 2).

The application of the Internet to supply chain management involves developing the capacity for greater integration, for new forms of collaboration, and for using the new information systems to redesign business practices.

We will approach the question of e-business from the perspective of the extended, real-time enterprise (Siegele, 2002) and consider not only the internal integration of the supply chain but also how linking the supply chain to customers and strategic partners solves problems and expands opportunities. The extended, real-time enterprise is a core concept for understanding the operation of e-business. It involves the development of an integrated information system linking together customers, the firm and its operations, strategic partners, and the relevant supply chains. Information about orders, operations, suppliers, and logistics is available in real-time and permits new forms of management and relationships with customers and suppliers.

Opportunities for Gains

The greatest barrier to improvement in the operation of supply chains is the segmentation and separation of the various elements of the supply chain. The different units of a supply chain—suppliers, manufacturers, distributors, logistics, and retailers—have typically operated without the information integration, synchronization, and coordination needed to improve operations. Even when firms in a supply chain have wanted to improve integration, because information has traditionally been expensive to generate and distribute, they have been forced to operate in relative isolation. This contributes to higher inventory levels, difficulties in responding to customers in a timely manner, ineffective use of resources, problems in developing new products, limited knowledge of customer demand, and lower profits. Because the Internet generates more and better information in real time and shares that information in a cost-effective way across the supply chain, it offers efficiency gains from speed, cost, flexibility, and expanded service. Put another way, these capabilities result in reduced segmentation and separation and greater integration of the supply chain through information sharing.

The Internet, with the capacity to generate and distribute information at low cost, provides significant opportunities for integration of the elements of the supply chain. As Figure 1 suggests, information flows in an Internet-enabled supply chain are much more complex than in a tradition supply chain. To be the most effective, information flows must be continuous and must link all parties in the chain, so that each firm can see what is happening throughout the system. Thus, the potential benefits from the Internet require much greater collaboration, since information generated at each point of the supply chain must be shared, and decisions regarding this information must be based upon a joint frame of reference. Thus, integration is achieved by a sequence of actions in the development and use of information across the supply chain.

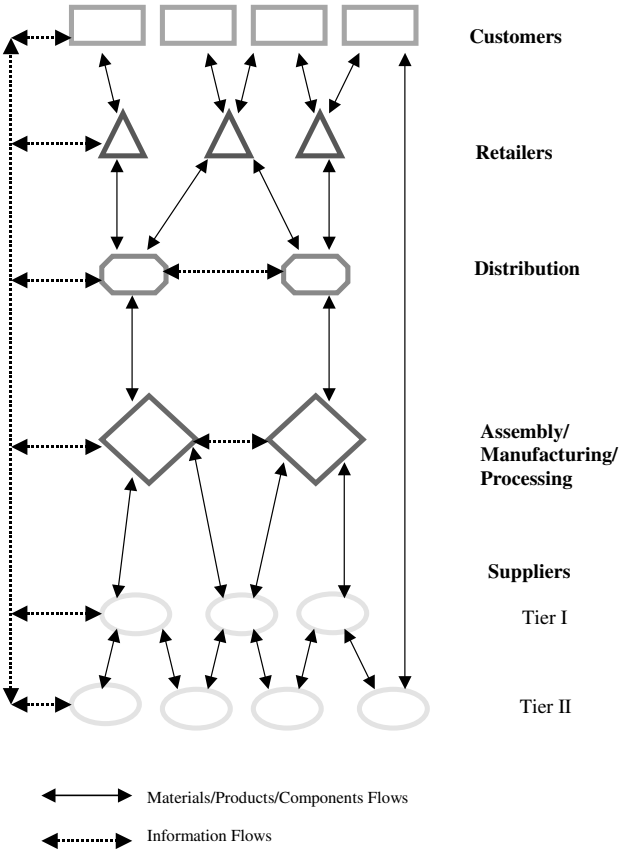

Figure 1: Integrated supply chain for an extended real-time enterprise.

One main approach to integration identifies four stages: information integration, planning synchronization, workflow coordination, and the recognition of new business models (Lee & Whang, 2001a). The first stage, information integration, requires the collection and sharing of a broad range of data regarding the status of operations in the supply chain. This includes data on sales, inventory, production, promotion plans, demand forecasts, and information about the location and delivery schedules of goods in transit. The second stage, planning synchronization, involves identifying how the newly developed and shared information is to be used. This requires not only the joint creation of decision-making standards, including common rules for defining outcomes and making choices, but also the application of this system to production planning, forecasting, replenishment, design, capacity utilization, and service. The third stage, workflow coordination, extends the activities in planning synchronization to the actual coordination of the operation of the supply chain, including production decisions, procurement and ordering, and product development and design. The final stage, recognition of new business models, takes advantage of the opportunities of the creation of an extended, real-time enterprise. This requires bringing customers into the information system and using customer information and involvement for real-time product customization, demand management, dynamic pricing, real-time quality control of manufacturing based on user experiences, reallocating capacity, developing new categories of information available from integrating the extended enterprise, developing new forms of service, and redefining the relationship between products and services.

Table 1 Efficiency Benefits from an Internet-Enabled Supply Chain

Make better forecasts
Reduce inventory risks and costs
Reduce procurement costs
Coordinate production, distribution, and fulfillment more effectively
More easily locate specific items in the supply chain
Monitor and respond more quickly to bottlenecks and other problems in the supply chain
Reduce lead time
Reduce delays and time lags in movement of components through the supply chain
Improve service while lowering costs
More rapid development of products
Faster time-to-market
Moderate bullwhip effect

Table 1 lists some of the most important gains we can expect from the new system of information integration across the supply chain. Perhaps the most significant is the ability to manage and control inventory levels, primarily by moderating the bullwhip effect. This is the term used to describe the tendency for small variations in demand by downstream end customers to result in increasing inventory variation across the various upstream stages of the supply chain (Simchi-Levy, Kaminsky, & Simchi-Levy, 2000).

The bullwhip effect is a consequence of decision-making using incomplete information, which comes from the absence of supply chain integration (Lee, et al., 1997). Typically, production decisions are made using information only from the next level in the supply chain, and this results in the use of hedging decision models to adjust for the uncertainty in this incomplete information. In other words, when individual actors in a supply chain use information known only to them (usually orders from the actors at the next level of the chain) to make forecasts and orders, and then pass only their orders on to the next actor in the chain, the result is that increasing levels of inventory are held at succeeding lower levels of the chain. When this incomplete information is combined with production lead times, use of large batch orders, and use of higher order size to protect against shortages, the end result is considerable overshooting or undershooting of optimum inventory levels. Thus, much of the bullwhip effect and its negative effects on inventory levels is the result of each level of the supply chain making demand forecasts and optimization decisions based on information affecting only a limited part of the entire chain (Simchi-Levy, 2000). When each unit makes independent production decisions based on independently generated forecasts, using incomplete data, the resulting inventory levels for each organization in the supply chain and cumulatively across the supply chain are excessive and inefficient.

By contrast, when each part of the supply chain obtains real-time information about actual end demand, and when inventory management decisions are coordinated, inventory levels are reduced across the supply chain. The key is to provide each unit of the supply chain with more complete information shared by all units. Exactly what kind of information is this? Demand forecasts, point of sale, capacity, production plans, promotion plans, and customer forecasts are some of the many forms this information can take (Lee & Whang, 1998). This more complete information helps reduce distortions and errors and permits better decisions. An important example is shared information about point of sale demand and demand forecasts, which permits development of a single demand forecast, or at least a coordinated series of forecasts based on common data, everywhere in the supply chain.

Different forms of cooperation are created through linking together the information systems of firms using the Internet. For example, we can distinguish between automatic replenishment programs (ARP), where inventory restocking of individual items is triggered by actual needs, and collaborative planning/forecasting/replenishment (CPFR), where firms engage in joint planning to make long-term forecasts that are updated in real time based on actual demand and market changes. CPFR involves a higher level of cooperation and collaboration than ARP does. Efficiency gains in CPFR come from reductions in overall inventory while increasing stock availability (especially during promotions) and achieving better asset utilization (Stank, Daugherty, & Autry, 1999). One reported success story is a CPFR trial at Nabisco and the grocery chain Wegmans Food Markets that resulted in increasing sales while significantly reducing inventory and improving service levels (Oliver, Chung, & Samanich, 2001).

The efficiency gains from the Internet arise from its capacity to quickly transmit large amounts of complex information throughout the supply chain. However, there are important choices about the nature of the Internet links to suppliers. Generally, two broad e-procurement options exist: first, use of broadly based transactional exchanges to aggregate sellers (and sometimes buyers) so as to create a larger market with lower search costs and lower product costs; and second, the use of Internet-based links to create a relationship exchange among established suppliers so as to increase information flow and manage inventory. There are important distinctions between these options relevant to management decisions (Kaplan & Sawhney, 2000). The great benefit of the broad transactional exchange is the ability to consolidate markets, expand access to suppliers, lower search costs, and lower acquisition costs. The online auction is perhaps the best example of such a system, with many buyers and sellers operating much like the stock market. The reverse auction is a variant, in which a buyer places a request for bids for a product and receives competing bids from a collection of suppliers. By contrast, the private trading exchange (PTX) or private hub is a term used to describe a relationship exchange used for exchanging information and automating transactions with a long-term supplier (Dooley, 2002; Gurbaxani, 2002).

The use of a broad transactional exchange for e-procurement has many potential benefits, especially if the product has commodity-like characteristics with many suppliers, many of which have additional capacity (Emiliani, 2000). Where price is the primary consideration, transactional exchanges can generate significant savings. Goods such as those for maintenance, repair, and operations (MRO) meet these criteria (Croom, 2000). However, there are important qualifications to the hoped-for benefits. Many of the public exchanges established to provide such markets failed to generate adequate aggregation of buyers or sellers (*The Economist*, 2001). Additionally, the realized gains from reverse auctions may be much less than expected. Firms using an online reverse auction may achieve significant gross savings, only to find those savings reduced by hidden costs associated with switching suppliers (Emiliani & Stec, 2002). The relationship with suppliers in an arm's length public exchange is generally adversarial, and this is compounded by the fact that use of an exchange for e-procurement sets suppliers against each other in a bidding war. Consequently, many suppliers have avoided these exchanges, thereby holding down liquidity. Attempting to fix these weaknesses, many arm's length transactional exchanges have developed new capabilities for adding value. This includes Free Markets' ability to provide specialized information needed for complex transactions, specialized solution providers like Biztro.com, and sell-side asset exchanges such as transportal network (Wise & Morrison, 2000).

Perhaps more significant, arm's length trading in an exchange is inconsistent with achieving greater collaboration with suppliers. In a mutually beneficial relationship with a supplier, negotiations over price, quantity, replenishment, product development, and variations in product can be used to establish parameters for automating actions over the Internet. The relationship exchange provides benefits beyond price. Savings can be realized through reductions in ordering costs, time saving, lower search costs, and procedures for facilitating the ordering process. These savings can be considerable, such as the reduction in transaction costs by British Telecom from $113 to $8 (Lucking-Reiley & Spulber, 2001). A relationship exchange can also be used to combine a transaction environment for suppliers with a complex interfirm communication system. Exostar is a defense aviation exchange supported by Rolls-Royce, BAe Systems, Boeing, Lockheed Martin, and Raytheon. This exchange is used to coordinate the relationship of suppliers and product design for complex systems, such as fighter aircraft (*Economist Intelligence Unit*, 2002).

The decision to use a B2B exchange (whether a transactional or relational) must link Internet strategy with the nature of the relationships that exist in the supply chain (Jap & Mohr, 2002). The obvious difficulties come when firms previously engaged in an arm's length transaction attempt to shift to a more collaborative environment or when firms in a collaborative environment are moved to a public exchange with more intense conflict.

MANAGEMENT ISSUES IN SUPPLY CHAIN COLLABORATION

The Internet does not create the need for cooperation and collaboration in supply chains; this has always been important. However, the Internet does provide new

opportunities to be won from collaboration and offers some potential ways to overcome barriers to collaboration. Most of the improvements in efficiency from the Internet happen only when the separate parts of a supply chain work closely together. There are considerable gains from collaboration, but there are perhaps as many hurdles to be overcome. Managers of supply chains must be even more aware of the barriers to collaboration and work to use the Internet to overcome these barriers. The demands of information sharing and collaboration in an extended, real-time enterprise are much greater than in traditional supply chains and will require organizational innovations.

Collaboration is difficult to achieve because different firms have different economic interests, goals, and ways of conducting business. Additionally, there are technical barriers, including problems in developing systems based on Internet standards that link legacy systems and provide a communication path between firms in the supply chain; integrating EDI systems to Internet systems; defining standards for content management; establishing XML and ebXML standards; providing common systems for logistics and procurement; and defining datamining standards.

Competing efforts by different firms to control the information system and capture profits from its use create conflicts among the members of a supply chain. The benefits of collaboration and coordination may flow disproportionately to one part of the supply chain, although these benefits can only be achieved through working together. Moreover, different firms have different levels of risk associated with their position in the supply chain, and this invariably affects the measures they use to define the operation of the supply chain and choices on production, resupply, promotions, and product development and innovation. The willing transfer of vital information by parties that could use it to achieve market advantage or improve the strategic position of a supply chain partner is problematic. An end seller will need to devote considerable resources to a complex information gathering system in order to obtain real-time point of sale data, and will share this information only for a fee. Achieving genuine information visibility across several organizations, given the variety of these constraints, is perhaps unattainable.

Simulations of supply chain operations help to identify many of the benefits and barriers to information sharing and coordination (Zhao, Xie, & Zhang, 2002). Several factors can influence the magnitude and distribution of the benefits, including different patterns of demand variation at the retail level (amount of demand fluctuation and whether demand is rising or falling through the period), different levels of capacity tightness (high and low), and different kinds of coordination and information sharing (no sharing, sharing of demand forecasts and order information, and amount of advance time for coordination of orders). Also the benefits themselves can be differentiated by costs for retailers, costs for suppliers, costs for the entire supply chain, service levels for suppliers, and service levels for retailers. The results of repeated simulations suggest a complex pattern of benefits. Information sharing is uniformly beneficial to all parties in the supply chain, with the best performance coming when order information is shared. Coordination of ordering benefits all parties but provides the greatest benefits to suppliers, who are able to improve capacity utilization with more order information and a longer planning horizon. Likewise, information sharing and order coordination under different demand patterns generate much larger gains for suppliers than for retailers, because suppliers are able to use the information to adjust capacity utilization. Although suppliers almost always experienced large gains, when demand is falling and capacity utilization low, retailers find their total costs rise and service declines under information sharing and order coordination. These differential benefits suggest some of the barriers to coordination and information sharing in a supply chain. Despite the large gains to the entire chain, the uneven distribution of the gains means some mechanism for redistribution of the gains is needed to reap these benefits.

Another useful way to highlight some of the barriers to collaboration is to examine the metrics needed to evaluate an Internet-enabled supply chain, and the issues related to reaching agreement about the metrics and trigger points for decisions. Efforts at collaboration engage the different needs, expectations, and interests of different firms in a supply chain. One firm might prefer an exclusive focus on measures such as its inventory turns or capacity utilization, whereas a much better approach for enhancing collaboration would be metrics that provide measures of performance across the chain and identify points where weakness can damage the entire operation. Thus, effective measures need to be multifunctional and cross enterprise. With an Internet-enabled supply chain, these kinds of measures are more easily attained. However, this means shifting the emphasis from the individual enterprise to the supply chain (extended, real-time enterprise) as a whole in its capacity to provide customer satisfaction (Hausmen, 2000). Getting separate firms to accept this kind of interchain thinking can be difficult; these difficulties become obvious when we consider some of the actual metrics.

The Internet creates new opportunities to interact with customers and to provide products more closely customized to individual customer preferences. However, supply chains may be organized so that only the firm facing the customer is focused on this opportunity. In this setting, customer service measures will be based on either "build-to-stock" or "build-to-order" products; different firms in a supply chain with different emphases will find agreement on such measures difficult. The firm building to customer order will want measures of rapid customer response time throughout the chain, but may need to deal with companies having a build-to-stock approach. Similarly, an integrated supply chain will need to provide inventory measures across the entire chain, not just at a single firm, and then use these measures to compete against other supply chains. Such measures must aggregate the inventory of upstream suppliers and downstream end customers. Measures of the speed of flows must also consider the entire system and each of its links to materials.

Obviously, developing this information, sharing it, and agreeing on its meaning for managing the supply chain can encounter many difficulties, primarily because firms are not in the same situation. A firm that centers its value proposition on low cost will need measures different from those of a firm that emphasizes customized products. Just

because the value proposition for the firm nearest the end customer uses an approach for measuring value, this doesn't mean all firms in the supply chain can or should use it.

Are there solutions to these problems? The Internet itself may present some new opportunities. The availability of real-time information providing visibility across the supply chain permits formulation of a wide variety of refined measures of supply chain operation and of the benefits of various choices. This high-quality information can be used to reach agreement where past conflicts were the result of poor information. Another possible solution to intrachain conflict is to recognize that in addition to the different economic interests of firms in a supply chain, there are also significant differences in economic power (Cox, Sanderson, & Watson, 2001). Buyers typically have more power than suppliers and may be in a position to define the terms of the supply chain and terms for information sharing and collaboration. Sometimes, as in the role of Intel or Microsoft as suppliers to the personal computer industry, this relationship can be reversed. This power can mean that buyers (or suppliers) may be able to use their strategic position to determine the division of profits from the information supply chain and extract the greatest profits.

Another possibility is to limit the type and scope of information shared and accept the now limited gains this can bring (Lamming, Caldwell, & Harrison, 2001). This way steps back from the ideal of complete supply chain integration, and is more likely to work in situations involving a long-term relationship where a series of negotiated arrangements through time that reflect the relative distribution of power in the chain and adjust to reflect the different economic interests of the parties emerges. The nature of this negotiated outcome may be some combination of an adversarial and collaborative relationship. One "federated" approach (Oliver et al., 2001) to the process advocates supply chain partners working to align their business objectives, "performance levels, incentives, rules, and boundaries" in conjunction with developing an understanding of the trade-offs relating to cost and service. This approach calls for an ongoing set of negotiations on broad objectives rather than a detailed one-time specification of measures and outcomes. The continuous flow of high-quality information facilitated by the Internet can help firms engage in this continuous negotiation over actions and needs.

This federated, or decentralized, approach is suggestive of the organizational innovations needed to realize the benefits of an Internet-enabled supply chain. The exchange of complex information in real time facilitates precisely this kind of continuous negotiation and adjustment of goals, operations, and measures. The main purpose of cooperation and collaboration is to reap the efficiency gains and the production flexibility inherent in adopting an Internet-based system. The specific meaning of these benefits is likely to be highly differentiated from one supply chain to another and even for different product variations in the same supply chain. Continuous negotiation can make these adjustments and help sustain collaboration. Further, the distributed decision-making environment of an extended, real-time firm may be much more conducive to collaboration than the vertical, centralized model (Tapscott, 2001).

NEW BUSINESS MODELS

Assuming the roadblocks to collaboration presented by technical problems and the differences in economic interests can be overcome, gaining the benefits of collaboration facilitated by the Internet also requires the development of new business models and practices. The application of Internet technologies expands the business options for the firm and the role of the supply chain in achieving its goals. For purposes of illustration, we will emphasize three:

1. The simultaneous development of products, processes, and supply chain design. This requires high-level collaboration but enables the various firms in the supply chain simultaneously to develop new products, configure the production processes, and design the supply chain. When a new product requires both a new set of production processes and changes in the configuration of the supply chain, simultaneous development permits these decisions to be coordinated, thereby reducing conflicting needs (Fine, 1998).
2. Increased ability to use and extract information from the supply chain, which makes possible efforts to integrate demand management and the supply chain, and the integration of supply chain management and customer relationship management (Lee, 2001).
3. The development of pull–push strategies to replace push strategies. This business model allows for reshaping the make/buy decision from the perspective of the extended enterprise and permits improved flexibility in developing the capacity for customization (Simchi-Levy, 2000).

The development of an extended, real-time enterprise through the Internet requires the supply chain be reconceptualized into three chains—organizations, technologies, and capabilities—and used to rework the way products are developed in relation to the production processes across the supply chain (Fine, 1998). This involves understanding the assets that exist across the supply chain: knowledge assets, integration assets, decision system assets, communication assets, information extraction and manipulation assets, and logistics assets. A key element of an extended enterprise strategy is to direct the design and redesign of the supply chain in relation to existing and new products so as to create competitive advantages. Resources for competitive advantage reside across the entire supply chain, and the chain itself must be designed so as to take advantage of these assets. Through the Internet, rich information can be exchanged among various tiers of the supply chain, which permits the identification of emerging assets and their organization into increasing competitive advantage. The most important result of this business model is the ability concurrently to create products, develop production processes, and design supply chains. This capability permits the solution of potential manufacturing problems in the supply chain at the point of its design and in conjunction with design of the product and thereby reduces time to market. In a competitive world

with short product cycles and a high premium on flexibility and customization, this capability provides enormous competitive advantage.

The ability to integrate product development, process, and supply chain design alters the choices to either make or buy an element of the product (Fine, Vardan, Pethick, & El-Hout 2002). As always, firms must decide where the greatest value is generated in the supply chain and distinguish between areas of internal competence and external dependence. The Internet can affect these decisions. Because the value of rich information available in real time rises so dramatically, even as its cost falls dramatically, control over the creation, distribution, and use of information in the supply chain may be where the greatest value lies. Traditionally, decisions about make or buy were defined in terms of the strategic value of the component or process, as in the value added, the importance to the customer, or the knowledge value. In an e-business environment, where rich information is plentiful and easily shared, and where products, processes, and supply chains are codeveloped, the core competency may reside in the ability to orchestrate the organizations, technologies, and capabilities in a supply chain. The ability to anticipate market opportunities and configure or reconfigure a supply chain to respond rapidly and flexibly may replace traditional make/buy decisions. This may mean that what remains consistently in-house are the knowledge assets associated with technology, markets, and supply chain design.

A second illustration as to how an Internet-based supply chain can have a significant impact on strategy and new business model development is in the management of demand (Lee, 2001). The ability to link real-time demand information through the supply chain gives rise to the capacity to manage the relationship between customer needs and supply chain capabilities, so as to increase benefits for both. The key is to recognize actions taken by the firm to influence demand, and to integrate those actions with the capabilities of the supply chain. In the most elementary sense, this means that marketing efforts to boost demand should consider the impact over time on the actual shape of the demand profile and whether this is consonant with an optimized supply chain. The cost of expanding capacity to meet induced demand spikes may exceed the revenues generated in extra sales. The solution is to have a clear and precise sense of supply chain costs associated with different levels of production, and integrate those costs with decisions relating to promotions. Further, promotions need to be coordinated across the supply chain, so that promotions at the retail level are linked to promotions at the wholesale level. Internet-based systems achieve this coordination for individual SKUs and at retail, wholesale, and production sites. The system can take into consideration the impact of decisions on one product as they ripple over other products, production, and logistics.

A final area for new business models that derive from Internet-based supply chains is the ability to substitute a push–pull strategy for a push strategy (Holweg & Pil, 2001; Simchi-Levy et al., 2000). In an era where information about final demand was not available across the supply chain, production decisions were based on demand forecasts supplemented by order information from the next level in the chain. Products of limited differentiation were manufactured based on aggregate long-term forecasts and pushed forward to consumers in the usually unrealized hope that the forecast was correct. By contrast, a pull strategy involves a direct sales and build-to-order capability in which customers order products configured to their specifications (that is the meaning of highly differentiated). This is a very unusual situation; a more realistic option enabled by Internet technology is to redefine the boundary between push and pull. Typically, some production must take place prior to the receipt of actual orders because of lead times and the fact that customers typically want quick delivery. This is true even in a direct sales system with end demand shared across the supply chain. Thus, one part of the supply chain will need to be organized around the push model while the other part will be organized around the pull model. The goal of many firms is to move beyond complete reliance on a push strategy, and define the most efficient point in the supply chain to locate the boundary between production to stock (push) and production to order (pull).

The availability of demand information across the supply chain expands the options for locating this point. Availability of final demand information in real time makes it possible for firms throughout the chain to generate better forecasts and reduce demand uncertainty. Forecasts are still necessary at the push level of the production process, but real-time demand information permits more accurate and more differentiated forecasts. This is because long-term forecasts can be updated and adjusted based on more accurate information, rather than the bullwhip affected information found in the traditional supply chain. Further, firms have long relied on aggregated forecasts because they were more accurate than forecasts of specific products. However, this forces greater reliance on push strategies, with the attendant costs from unsold goods and lack of flexibility.

Use of real-time information about final demand permits more differentiated forecasts, because final demand information is about specific products, and this information can be use to spread pull strategies further down in the supply chain. Differentiated forecasts permit push production strategies using specific product information, and permit the development of pull strategies at points farther upstream in the supply chain. More generally, real-time information about final demand permits the design of the supply chain so as to integrate and optimize considerations associated with both push and pull. Push focuses on production scale, distribution logistics and timing, lead times, inventory, and transportation. Pull focuses on flexibility, customization, service levels, and delivery. The trade-offs between push and pull still exist, but are shifted in such a way that both can be achieved in more effective ways (Holweg & Pil, 2001).

As we have seen, one important goal in adopting an Internet-based supply chain is to shift the push–pull boundary so as to provide a more responsive and even agile supply chain. This is especially important when demand is uncertain as to volume and variety of product and when the supply base is affected by uncertainties related to process and technology of production (Lee, 2002). One

company facing such a situation is Xilinx, which designs high-end and customized semiconductors. The market for application-specific semiconductors is highly variable and the production process is technologically sophisticated and difficult. Xilinx operates without fabrication facilities, using instead close partnerships with fabrication foundries in Asia. The production process is split between a push level and two different opportunities for production based on pull. First, the fabrication of the chip is separated between an initial phase and a final phase, which are carried out by different foundries. The final configuration of the chip is delayed until actual demand is known, which permits Xilinx to respond to shifts in customer needs. Second the Internet is used for customized configuration of products even after customers have received shipment (Lee & Whang, 2001b). The field-programmable logic devices made by Xilinx, and used in products like communication satellites, need continual changes in configuration. In normal circumstances this would require frequent on-site service and replacement. However, Xilinx has developed the ability to use the Internet to modify and upgrade these devices after they have been delivered to customers, in effect extending the pull model to an after delivery capability.

Another example of a firm making extensive use of Internet-based communication and collaboration with its suppliers is Adaptec (Hauseman, 2000; Lee & Whang, 2001b). The "fabless" semiconductor manufacturing business model requires close connections with suppliers, a significant challenge from both a cost and performance perspective, especially given that the elements of the supply chain are dispersed around the globe. Adaptec uses specialized communication software for the Internet to link its customers to the design, production, assembly, and packaging stages of the supply chain. The information includes purchase orders, production forecasts, shipment schedules, prototype specifications, and test results. In a market based on rapid response to custom demand, Adaptec has used this information system to cut in half its cycle time for new product development. The relationship with suppliers has helped to generate trust, which facilitates continuing investment in the technology needed to make the information system work.

CASE STUDIES

Nortel

A number of firms have adopted some or all of the operations of e-business in an extended, real-time enterprise. Nortel is a good example of a firm that rearranged its business model and supply chain using the Internet in order to cope with rapidly changing markets (Fischer, 2001). The anticipated growth of fiber-optic networks offered an opportunity for Nortel, but its realization required much more agility in its production and supply chain system. Nortel sold off production facilities and partnered with its component manufacturers. Because the product required extensive customization, each customer is now assigned to a dedicated, but virtual, supply chain. This means that Nortel's role is to work directly with each customer to design and configure products, and communicate this information in real time to the Nortel supply chain partners. The people at Nortel who design systems also communicate with suppliers, an example of linking product design and the supply chain by customizing each simultaneously. Design of products also includes suppliers in early stages, made possible by the increased communication flows. The benefits include shorter time for suppliers to develop bids, greater willingness by suppliers to commit capacity to Nortel because of visibility into Nortel customers' end demand and Nortel's strategy, better understanding of supply chain capabilities by Nortel and its customers, and more informed decisions about trade-offs, shifting the push–pull boundary to permit delayed configuration of products, and more rapid response to orders. At the same time, however, inventory has not declined, and Nortel is still not as agile as some of its competitors in the fiber-optic market.

Two other firms that have come to define many of the benchmarks for implementing an Internet-based integrated supply chain strategy are Dell Computer and Cisco Systems. These firms provide blueprints for how integrated systems can be constructed, along with the benefits and the perils of such systems. Each firm is an example of a radical outsourcing strategy based on the construction and integration of a global supply chain.

Cisco Systems

Cisco's products are quite complex and include the hardware (large-scale routers, LAN switches, and WAN switches), software, service, and integration capabilities to implement an end-to-end network solution for an enterprise. The extraordinary growth and the rapid technological changes of the networking market present significant challenges for Cisco. In response, it has adopted an aggressive strategy for developing new technology and knowledge assets. In addition, Cisco created a remarkable networking system to link its customers, employees, and the myriad collection of assemblers, suppliers, semiconductor manufacturers, logistics, and service providers who make up the Cisco system. Cisco's acquisitions and the creation of an extended, real-time enterprise have made possible rapid expansion to meet sales growth and technology changes.

A central feature of Cisco's overall business strategy was the creation of an integrated information system from customer to supplier, and selection of strategic partners and suppliers to populate its supply chain. Indeed, Cisco is one of the best examples of the use of the Internet to create a collaborative system designed to benefit all members of the system. The main goal is the performance of the supply chain, not merely obtaining the lowest price from suppliers. Internet-defined protocols are used for all communications across the system and common applications throughout the company. This permits high levels of interoperability of communication capabilities, information systems, decision support systems, collaboration systems, employee access to information, and rapid access to all information concerning a customer.

The implementation of this system at Cisco began in 1993, and the most recent version is the e-Hub (Grosvenor & Austin, 2001). This is a private e-marketplace that

facilitates information flows across the entire supply chain. The e-Hub permits information sharing about demand forecasts, supply status updates, event alerts, and inventory levels for components, and provides the basis for collaborative planning and execution. Additional features include an Internet-based customer service and support system, product testing using the Internet, the use of "dynamic replenishment" software to link customer orders to supply chain producers, and a sophisticated system for data mining of the information system. The benefits of this system are considerable and are outlined in Table 2. By early 2000, Cisco had the largest market capitalization of any firm in the world.

In the wake of a steep decline in spending for networks, however, this remarkable system floundered and then broke down The capacity of the Cisco supply chain to scale up to meet market growth did not work well in reverse; that is, Cisco was unable to scale down as quickly or effectively. The result was an enormous buildup of inventory and a $2.5 billion inventory write down against Cisco's earnings.

The problem, according to one study (Lakenan, Boyd, & Frey, 2001), came from the misalignment of goals and business plans between Cisco and its supply chain partners, who are mostly contract equipment manufacturers. Various units of the supply chain used different standards for making decisions, and the informal communication that could have uncovered these differences did not happen. The formal contractual relationships between Cisco and its suppliers were unable to capture the tacit rules necessary for an effective relationship, and the information flowing through the supply chain was not rich enough to make adjustments to changing market conditions. The source of the differences was a mismatch between Cisco's need for production flexibility and its suppliers' need for predictability, which made it difficult to turn off the push part of the production system fast enough to adjust to deteriorating market conditions. What could have been done differently? According to Lakenan et al., firms like Cisco need to think in terms of a supply web with differentiated production capabilities and greater flexibility of capacity utilization. This involves not only more flexibility in product design but also a greater willingness for strategic supply partners to make adjustments and adaptations to the supply web as conditions warrant.

Dell Computer

Dell is rightfully seen as one of the closest approximations of an extended, real-time enterprise. Dell's business model has always been direct sales to end users, who are primarily enterprises (Mendelson, 2000). Its role is to assemble and rapidly deliver the final product based on customer configuration, with all components outsourced. A large and growing portion of Dell's sales are made over the Internet, which also is the medium for much of Dell's customer support and a key element of the integrated information system linking customers to the supply chain. Except for a brief interlude, Dell has always been a direct sales firm that provided build-to-order machines, which facilitated its adoption of the Internet for sales. Additionally, the initial emphasis on speed of operation and low inventory also contributed to the adoption of the Internet. The direct sales model already contributed valuable information about end demand and market shifts, along with indicators about how service and support could be used to add value to the product. In many ways, Dell's operations were defined in Internet terms before the emergence of the browser-based Web. Dell was already an information-intensive firm that used this information to accelerate the speed and leanness of its operation.

The Internet built on and accentuated Dell's business model and corporate culture. This helps account for Dell's status as the primary example of an Internet-based firm. Dell's position rests on its ability to create and manage an information system that integrated the production and delivery of components, assembly of machines, and direct sales, distribution, and servicing of those machines. One measure of the ease of transition to the Internet was the rapid jump in Internet sales from $1 million per day in early 1997 to $50 million per day in 2000 (Kraemer & Dedrick, 2001). At the same time, the transition brought significant increases in efficiency and customer satisfaction.

Much like Cisco, Dell's Internet capabilities extend from customer to suppliers. The ability to custom configure the machine effectively brings the customer inside Dell. Further, the Internet permitted Dell to provide customers with rich information about the product, including the cost for each variation of the machine. Customers became much better informed about the product and the purchase experience, and felt like they were on the shop floor making choices and understanding those choices. The Internet provided better tracking information to customers at a lower cost to Dell than the telephone. Also service was made easier by using the Internet to provide downloads and even to diagnose problems. The development of a customized Web site for customers provided Dell with asset management capabilities. The Internet-based volume of rich information about customers allowed Dell to seek out and use this customer information to develop products and services. As a result, marketing strategies can be quite differentiated and the Internet can

be used to get instant feedback on the effectiveness of these strategies.

The Internet-based information system extends to the supply chain base in much the same way as it extends out to customers (Kraemer & Dedrick, 2001). The Dell supply chain is composed of a relatively small number of suppliers, each with a very strong relationship with Dell. The supply chain is global, as is the assembly system. Dell receives real-time information from its suppliers about their capacities, inventory, quality measures, and costs, and suppliers receive information from Dell on demand forecasts, sales, quality measures, and customer needs. The assembly plants receive orders every two hours and establish a new production schedule. Suppliers maintain component inventories close to the assembly plants. Typically, Dell is able to assemble an order in one day (Holweg & Pil, 2001).

Dell ties this supply chain together with the information that comes from customers. First-tier suppliers are able to see Dell's demand forecasts (updated through an Internet portal) and are able to gauge their operations accordingly. Providing direct information about sales and demand forecasts in real time to suppliers mitigates the bullwhip effect. Suppliers, aided by real-time information, are in a position to produce for end demand and make adjustments separated only by lead time (Kraemer & Dedrick, 2001; Kraemer, Dedrick, & Yamashiro, 2000). The information system also permits some suppliers to ship parts of the end product directly to the customer, thus avoiding shipment to the Dell plant and reshipment to the customer.

For Dell itself, all inventory is work in progress; there is no finished goods inventory, since products are shipped as soon as they are assembled and tested. This Internet-based information integration has significantly contributed to the remarkable decline in inventory, from an average of about 35 days of component inventory on hand in 1995 to less than 4 days in 2001 (Kraemer & Dedrick, 2001). Dell also provides information about product defects for use at the point of production to improve quality control. Integration of the supply chain is enhanced by suppliers who are in close physical proximity to Dell, holding inventory within a few minutes of the assembly factory. Information is also used to establish very tight integration between delivery and service. The integrated supply chain permits a very simple yet powerful push–pull system. Information about end demand is used to pull the individual product through the supply chain system and to push components to the assembly floor in a flexible and adjustable manner. However, the Dell system does not reach the high standard of a build-to-order system, primarily because suppliers are required to maintain inventory levels and do not have complete access to customer orders and therefore cannot base their production on this information (Holweg & Pil, 2001).

Dell exemplifies a systemic understanding of how supply chain management must operate in an extended real-time firm. The benefits include reduced costs for sales, service, and supply chain operations, plus improved quality, delivery time, and service satisfaction. Dell's performance is better than that of its less Web-enabled competitors, and its broad capabilities have been essential in increasing its market share. Nonetheless, Dell has also experienced some of the same inventory problems as Cisco as a result of a misalignment with suppliers.

NMS Communications

The experience of NMS Communications helps to illustrate many of the issues in developing an Internet-based supply chain strategy. In particular, this case depicts the consequences of integrating the supply chain with near real-time information and the impact of this information on the operation of the firm. NMS produces printed circuit board assemblies for the telecommunications industry to enable transmission of voice over Internet protocol (Arntzen & Schumay, 2002). Manufacturing of its products and new product prototypes is completely outsourced. Similar to Cisco and Dell, this is a business with high rates of technological change and the need for rapid delivery and quick time-to-market for new products. However, NMS operated its supply chain based on a traditional build-to-forecast system. This led to many expectable inventory and product development problems: excess inventory, parts shortages, long customer order cycle times, low delivery predictability, high end-of-quarter peak loads, and slow new product development. Recognizing many of these problems, NMS developed a plan to shift to an Internet-based, build-to-order supply chain and reposition itself as the integrator of the entire supply chain. NMS wanted to become the core of an extended, real-time enterprise. The effort to achieve this led to an understanding of the enormous changes in internal thinking and external relationships required by this plan.

To support these changes, NMS created a "hub-and-portal" IT architecture to integrate its internal systems and connect electronically with key customers and suppliers. The portal is multimode (it operates using XML, EDI, Web-based, and extranet capabilities) and supports the integrations of business processes, along with visibility and collaboration across the supply chain. Customer orders are posted to a Web site available to manufacturers and suppliers. The consequences for NMS and its relationship to customers and suppliers were substantial. These are summarized in Table 3.

NMS found the transition process to be difficult, primarily because of the scope of the changes required. Clearly, operating in near real time as an Internet-based, build-to-order firm requires rethinking much of operations. At the same time, many benefits and competitive advantages are also available.

FUTURE TRENDS

What is the future role of the Internet in supply chain management? Adoption of Internet-based business-to-business systems has been slower than many predicted, perhaps affected by the bursting of the dotcom bubble. What trends can we expect? The projection of one study (Carter, Carter, Monczka, Slaight, & Swan, 2000) is that before 2010 the Internet and World Wide Web will become the "backbone of electronic purchasing," integrating supply chains by providing the medium for all basic and essential transactions and communications, operating as the basis for access to "critical" information and

Table 3 Consequences to NMS Communication of Real-Time Operation

Changes in the process of production
Reduction of inventory levels meant that much greater agility was needed to deal with variations in demand and the uncertainties of the supply chain
Increased agility was accomplished through the following:
1. Greater modularity in components.
2. The time required to shift from producing one product to another was reduced from six hours to a few minutes.
3. The ability to see through to actual demand gave suppliers and manufacturers the ability to adjust production based on real-time data and minimize the use of forecasts.
4. Production shifted from a two-week schedule based on forecasts to a daily schedule based on actual orders.
5. The push–pull boundary was altered significantly. Where once customers pulled products only from finished goods and the forecast governed a large-batch manufacturing system, now customers would pull out of the vendor's raw materials inventories (still partly based on forecasts) into a flexible manufacturing system.
Changes in customer relations
NMS and the contract manufacturer can now use the information about orders and production capabilities and work with customers placing large orders.
Similarly, real-time communication across the supply chain permitted an iterative process of demand management between the NMS sales department and the contract manufacturer.
Demand management strategies based on lead times for production were implemented to reduce the variability of demand.
Virtually all customers were eager to participate in the new system.
Changes in product development
Delays and flaws in new product development not discovered until production had begun. This was caused by poor communication between product design at NMS and the production engineers at the contract manufacturer. The implementation of the Internet-based communication system led to a reduction of six weeks in new product development time.

measures of performance, facilitating complex partnering relationships that will provide the core competencies of many firms, supporting an expanded role for "demand-pull" business models, increasing the global reach for supply chains, and altering the skill set required of managers of supply chains.

Achievement of these predictions will require solutions to a multitude of problems. The integration of information systems is a considerable technical challenge; barriers to cooperation are created by conflicting interests among supply chain partners; goals are misaligned due to poor communication, even though the environment permits rich information flows; and management of a system with constant iterations and improvisations is complex and difficult, especially across multiple enterprises. Nonetheless, there are compelling business reasons for adopting the model of an Internet-based business in supply chain management.

GLOSSARY

Bullwhip effect The tendency for small variations in demand by downstream end customers to result in demand amplification and increasingly larger inventory levels and inventory variation across upstream stages of the supply chain.

Demand-based management Actions taken by a firm to influence the overall level of demand and the mix of products purchased to account for the needs and capabilities of the firm that supplies those goods.

E-business The marketing, buying, selling, delivering, servicing, and paying for products across nonproprietary networks that link an enterprise with its prospects, customers, agents, suppliers, competitors, allies, and complementors.

E-procurement The use of the Internet to purchase supplies through auctions, trading networks, or collaboration with long-term suppliers.

Extended enterprise The operation of a business through use of an integrated information system that aligns the various firms to permit collaboration with customers, strategic partners, and other parties in the supply chain.

Push–pull strategies Different strategies of production: push is production based on a forecast of demand; pull refers to production to fulfill a specific order.

Real-time firm The operation of an extended enterprise so that information about orders, operations, suppliers, and logistics is available in real time and permits new forms of management and relationships with customers and suppliers.
